# COMMITTEE REPORT

## SENATE

1/27/77

2/9/77 Date

Mr. President:

The Committee on RESOURCES has had SB 18  
licensing of pesticide applicators  
under consideration. A majority of the members of the Committee

- recommends it do pass
- recommends it do not pass
- recommends it do pass with attached amendment(s)
- recommends it be replaced with CS for SB 18 and that  
CS for SB 18 do pass
- (and) recommends it be referred to the \_\_\_\_\_  
committee
- reports it back without recommendation
- AND attaches a report of its intent
- (other) \_\_\_\_\_

### MEMBERS SIGNING THE MAJORITY REPORT:

\_\_\_\_\_  
\_\_\_\_\_  
\_\_\_\_\_

### MEMBERS NOT CONCURRING IN THE MAJORITY REPORT:

\_\_\_\_\_ recommends: \_\_\_\_\_  
\_\_\_\_\_ recommends: \_\_\_\_\_  
\_\_\_\_\_ recommends: \_\_\_\_\_

\_\_\_\_\_  
Chairman

# STATE OF ALASKA

JAY S. HAMMOND, GOVERNOR

DEPT. OF ENVIRONMENTAL CONSERVATION

Pouch O  
Juneau 99811

October 15, 1976

*10/23/76  
Sally Hanson  
Legislative Affairs Agency  
Juneau, Alaska*

Ms. Sally Hanson  
Office of Senator Jalmar Kerttula  
c/o Legislative Affairs Agency  
Pouch Y  
Juneau, Alaska 99811

Dear Ms. Hanson:

Thank you for your telephone call relating to the status of the Wasilla water study included by the Legislature in the FY 1977 capital budget for this Department. As you know, the original appropriation was for both a water study and a sewer, \$35,000; this was reduced by the Governor to \$15,000 for a water study only, as there are other Federal and State funding sources available for sewer studies. We are working closely with the City of Wasilla on this project, and hope to be able to release the funds to them soon. As you are aware, there have been some changes in the city's staff, and the new staff had to be made familiar with this project. We will probably have someone from our construction grants staff visit the city soon to finalize plans for this project. We will try to keep you informed as this project goes along.

You will recall we also discussed the impact of the 1972 Amendments to the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA). As I mentioned, FIFRA requires that EPA classify all pesticides and pesticidal products as being for "general" or for "restricted" use. General use pesticides are to be those which are relatively safe for use by the general public. Restricted use pesticides are to be those which are deemed too dangerous for untrained persons to use.

In order to purchase or use restricted pesticides, persons must be trained and certified by the state in which they plan to work. States, of course, would then need the legal authority to require certification, and to establish a training, examination, and certification program. While Alaska has had such legal authority for a number of years for contract, commercial, and custom applicators, we have no such authority over private

"1776-A TRIBUTE FROM OUR STATE TO OUR NATION 1976"

Ms. Sally Hanson

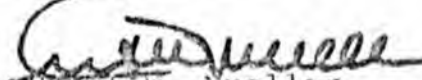

- 2 -

October 15, 1976

applicators. Under EPA's proposed regulations, farmers are "private" applicators if they apply pesticides on their own land. It is proposed that the training and examination requirements for private applicators be significantly less rigorous than those for commercial or contract applicators. If the State does not have sufficient authority to establish this as a private applicator certification program, these persons would not be able to purchase or use restricted pesticides, but would have to contract with a certified commercial applicator. As one of the herbicides commonly used in Alaskan agriculture, Premerge, will probably be a restricted pesticide, our agriculture community could lose a valuable tool, or be forced to pay a much greater price for its use.

Attached is a simple language change proposal that the Attorney General assures us would solve this problem. I would appreciate your views on this proposal, and Senator Kerttula's consideration for introduction.

Sincerely yours,

Ernst W. Mueller  
Commissioner

Pertinent Questions and Answers on Subject of Waste Heat

By  
D. H. Eikel

Q. What is waste heat?

A. Waste heat is the term commonly used for energy that is rejected from various industrial sources. It usually results from the burning or other consumption of fossil fuels; however, it may also result from nuclear power plants or represent the unused heat from geothermal sources. The waste heat rejected from a process using fossil fuel usually exceeds the amount of the energy that is put to useful work such as the production of electricity. For example, most electrical power generation facilities that operate with fossil fuels have only a 30 per cent efficiency and the remainder is rejected as hot water or hot air.

Q. What is the extent of unused heat in Alaska?

A. The quantity is enormous at the present time and it will increase greatly as the pipelines, refinery and other power plants are placed into operation. It is estimated that each pumping station along the Trans-Alaska Pipeline could heat 2000 homes. The estimate for the North Pole Petroleum refinery is that 10,000 homes could be heated. Canadian sources estimate that each pumping station associated with their Mackenzie Valley Pipeline will produce enough clean waste heat to meet the requirements for 15 to 20 acres of greenhouse vegetable production. However, there has not been an inventory made of the present and future status of the waste heat that will be rejected and that could be used in the state.

Q. What are some proposed uses?

A. Agriculture, fisheries and aquaculture, forestry, processing and district heating in commercial and domestic areas. High temperature waste heat also may be useful in some cases for the generation of electricity where uses can be found for the remaining lower temperature heat so that vapor and thermal pollution is not a problem. For example, it would be technically possible to generate electricity from the high temperature waste from the North Pole Petroleum refinery. However, if this is done the reject energy would be in a form that could not be injected into the upper atmosphere and would create a vapor or ice fog problem during winter months. Agriculture and district heating could provide a use for this remaining low temperature reject energy.

Agriculture

The high temperature reject heat could be useful for forage and grain drying and may provide the necessary component that would make potato processing feasible in the state and therefore, expand potato production.

Heat energy consisting of hot air, hot water or steam and at temperatures ranging from 80°F to 800°F would be useful for greenhouse

production and vegetable and plant production in areas that would support horticulture crop production resulting from soil warming. The use of the heat in greenhouses and then during the summer months in the soil for crop production is necessary to all wise proposals that suggest a near total use for the energy. This crop use is probably necessary because it can utilize the low temperature energy and would utilize the heat as less is needed for other uses. It appears to be an important part of every systems approach to utilizing this resource because the near total use of the resource will make the collection and distribution more economical for each use.

#### Aquaculture, Forestry Processing and District Heating

The use of heat to improve production of fisheries through hatchery rearing and in fish production ponds is suggested. The heat requirement for forestry, processing industries and in district heating of homes and businesses is obvious if the heat can be collected and distributed. The more complete use that would result by greenhouse and soil heat use would provide a better economic picture for the above uses.

Q. Is our environment suitable for the types of intensive crop production that is suggested?

A. During the four summer months it is superior to most other areas of the nation. The northern latitudes are recognized to have the highest photosynthetic production rate in the world during these four summer months. If the season can be lengthened and/or the soil warmed, the productive capacity can be further increased, and this photosynthetic advantage further exploited.

Q. Why hasn't the greenhouse industry developed without the waste heat use?

A. It is one of Alaska's major agricultural industries at the present time, but it has been developed through the use of fossil fuels which are even higher in cost than they are in the rest of the nation.

Q. There are indications that hundreds of acres of greenhouse and soil heated vegetable production is possible. Could all of these products be marketed in Alaska?

A. No. Besides providing Alaskans with vegetables and ornamental plants, it would be necessary to market cut flowers such as roses, carnations, chrysanthemums and etc. on national and world markets. It is proposed that this could be done competitively during 5-6 months of the year because of Alaska's superior environment for greenhouse production and through the use of waste energy.

Q. Why do you feel that it is important to examine national and world markets for cutflowers?

A. Because it appears to be necessary at the present time in order to make more complete use of our unused resource. It also would add to the stability of our economy to have a renewable resource such as this contributing to the state's economy. It would also decrease the nation's consumption of fossil fuels now used for this purpose in the present greenhouse growing areas.

Q. What will be the temperature of the Waste Heat?

A. The temperature of the reject heat energy will vary with the type of industry and will range from about 80°F to above 800°F. It will be exhausted as hot air, hot water or steam.

It is expected that not all reject energy could be utilized at this time because of accessibility problems, the lack of adjacent growing areas and the lack of technology. A systems approach with agriculture as a major user appears to give the best potential.

Q. What is the urgency in the legislation now in process?

A. We must promote the use or it will not happen. The potential for use must be designed into the system in the beginning in order to develop the most economical recovery system. For example the oil pipeline pumping stations were not designed with reject heat use in mind, and, therefore, it will cost more to recover the heat.

Although the technology appears to be available at the present time to make economical use of the energy, it is necessary to demonstrate this and to improve this technology.

Research Proposal

The Development of technology necessary to use  
"waste" heat for the enhancement of horticulture in Alaska and  
to reduce thermal pollution problems

University of Alaska  
Agricultural Experiment Station  
Fairbanks, Alaska 99701.

D.H. Dinkel  
Principal Investigator

## Abstract

The purpose of this project is to develop the horticultural technology necessary to use the enormous quantities of excess heat that will be rejected in Alaska from power plants, refineries, pipeline pumping stations and geothermal sources. The use of waste heat for the production of horticultural crops in greenhouses and heated areas of soil outdoors is common to all wise proposals to completely utilize reject heat. The horticulture production part is necessary because the heat can be utilized during summer months and when less is required for space heating or other uses.

It is estimated that the quantity of excess heat that would be available from industry in Alaska could meet the heat energy requirements for hundreds of acres of high value vegetable and flower production.

In this project, both soil heating and "space" heating for greenhouses will be employed in conjunction with proven Northern Agricultural practice, with the dual purpose of improving agricultural production and reducing final output temperature and consequently thermal pollution from power plant cooling water.

The agricultural industry, and particularly the horticultural industry, is probably in the best position of many of the energy consuming activities to use low-grade heat from cooling waters discharged by industry. The Agricultural industry is also in the best position to utilize the high temperature excess heat from the pumping stations of the oil and gas pipelines.

Considering the magnitude and basic importance of agricultural production and the extent of its' energy use, a significant increase in efficiency of production would be obtained through the substitution of waste energy for nonrenewable resource-consuming energy. In addition, the increase in solar energy conversion to food and ornamental plants would be an important Alaskan and national gain.

The principle reason for agriculture's favorable position in Alaska is that growth rates are increased dramatically when soil temperatures are increased slightly or conventional greenhouses and temporary plastic canopies are used to improve air temperatures. These practices make possible in Alaska the use of solar energy that otherwise is not useable for food and other beneficial production. In some instances, lengthened growing seasons may permit additions of another crop, possibly doubling and tripling production of the land. Increasing Alaska's critically low soil temperature and using canopies and greenhouses creates a significantly better plant growth environment than found in most other areas of the U.S. because of the long sunlight days. This advantage should allow us to produce high value intensively cultured crops at world market prices, and more important provide these products to Alaskans.

Much of the basic information needed for the establishment of a horticultural industry using waste heat in Alaska is available in literature and from preliminary research in the state. What is most needed now is applications research, and the engineering and economic design required to demonstrate and incorporate what is known into development plans.

The proposed research will be done by the Agriculture Experiment Station, University of Alaska in cooperation with (CRREL) Cold Regions Research and Engineering Laboratory) and the U.S. Army.

The work will be done using existing greenhouse and crop facilities at the Fairbanks Agricultural Experiment Station and in facilities that are fortuitously being developed by the U.S. Army at Fort Wainwright to reduce thermal pollution and ice fog problems associated with the power generating facility.

The engineering and construction for much of this project is being done by the U.S. Army and Cold Regions Research and Engineering Laboratory (CRREL) at the Fort Wainwright South Power Plant. Heated "waste" water with temperatures of +70°F to +85°F in large quantities is available. Evaporation from the present large cooling ponds associated with this waste creates a severe ice fog problem in winter months. Efforts to reduce this thermal pollution problem are underway by dissipating the heat in soil by circulating the warm water through a buried grid of pipes. There would be a significant advantage to Alaska and the immediate community if these efforts could be used to conduct the developmental research necessary to demonstrate the use for the tremendous quantities of unused heat in the state.

### Introduction

The primary energy source for modern agricultural food, fiber and ornamental production remains the sun; however, man has learned that he can increase productivity of his crops by modifying the plants' environment for maximum capture of sunlight. This environment modification is largely dependent upon the use of fossil fuels to supply the required technological materials such as machinery, plastics, pesticides and petroleum for heating, farming, drying, processing and transportation.

Much of the energy required to produce intensively cultured crops in Alaska is in the form of heat requirements. This energy is needed to heat greenhouses and warm soils. If these heat requirements are supplied in Alaska we then have a plant growth environment that is technically superior which should create an economic advantage even in regards to competing on world markets for commodities that can be shipped. The advantage is due to the improved photosynthetic activity of leaves in sunlight and cool air conditions (10), and the longer period of this advantage. An analysis of Alaska's climate shows that during a similar calendar period corresponding to May through mid-September, there are 430 to 550 more hours of sunshine in Alaska than there are at latitudes similar to Minneapolis, Minnesota and Chicago, Illinois. The advantage

of this extra sunshine for rapid growth of adapted crops has been amply demonstrated by the production of the well-known 70-lb Alaskan cabbage and by numerous research studies in Alaska (7). Thus, the longer period of sunlight from March 20 to September 20 and the better internal plant condition for photosynthesis are advantages to growth if soil temperature or other factor does not limit the activity.

It has been demonstrated that one of the most critical environmental factors that limits the growth of many crops in Alaska is the soil temperature (4,5,6,7). Soil temperatures that seldom rise above 13-18°C. at the 10 cm. soil depth during the growing season impede seed germination and severely limit the growth of certain economic plants. The optimum soil temperatures for most cultivated crops ranges from between 21 and 30°C. Increased soil temperatures resulting from the use of clear polyethylene on the soil, electric heating cables and buried styrofoam give greatly increased growth of crops and earlier maturation (7). Clear polyethylene mulches cause soil heating by solar radiation because of the entrapped layer of still air, reduced moisture evaporation and the lower transmission by polyethylene of the heat radiation from soil as compared to the high transmission of incoming solar radiation. The improved soil temperatures allow the crops to take full advantage of the long sunlight days, and often higher yields are measured than those produced in the best commercial production areas of the nation.

Research in climates such as Minnesota show that soil warming by waste heat does provide some improved growth rate and some extension of the growing season (1,2). Due to normally warm soils during mid-summer in Minnesota that are near optimum for plant growth, waste energy can only be used during the spring and again in the fall. Alaska, with the much colder soils throughout the year and the greater sunlight during the growing season, offers greater advantages for waste heat utilization for the production of high value crops.

The feasibility for the use of low temperature waste heat for heating of greenhouses has been reported (3, 10, 11). A large greenhouse industry has developed in Iceland using warm water from geothermally heated springs for heating. A viable seasonal greenhouse industry has developed in Alaska using fossil fuels for a heat source. There is a significant need to expand this industry utilizing waste heat from industrial and geothermal sources. The rising cost and scarcity of fossil fuels to heat greenhouse units is a major threat to the stability and continuance of the nation's greenhouse vegetable and ornamental units. These factors appear to be blocking expansion and may actually terminate the greenhouse industry in areas where alternative methods of heating cannot be found.

Energy from industrial sources, usually in the form of hot water at temperatures from 21 to 70°C, is normally wasted by discharging it into the air or into bodies of water. These point sources of unused heat represent a poor stewardship of our resources and cause an environmental impact of considerable concern. A systematic approach to the utilization of unused heat suggest its' use in district heating of

houses, businesses and greenhouses, and in warming field soils for crop production.

Extent of unused heat: The efficiency of modern fossil fueled electrical generator plants is approximately 40%, while that of nuclear plants ranges between 30 and 33%. Thus, of the total energy available from the original fuel source slightly over one-third is presently used. The remaining two-thirds is rejected by being discharged into the environment. About 85 percent of the rejected heat is discharged into water bodies and 15 percent is discharged into the environment through the stack. Enormous quantities of very high temperature steam will be exhausted from the Energy Resources of Alaska refinery at North Pole, Alaska. Each pumping station along the trans-Alaska oil pipeline will exhaust large quantities of heat. It has been estimated that the 12 pumping station and liquefaction plant for a trans-Alaska gas line may exhaust approximately 36 million BTUs per second.

Facilities:

The Agricultural Experiment Station 40' x 90' existing greenhouse with attached head house will be used to produce test plants and for initiating the greenhouse work. One 30' x 40' section of the greenhouse will be slightly modified to simulate conditions that will be associated with a source of hot water.

The major plot work will be done at Fort Wainwright near the Power plant cooling pond. The U.S. Army and CRREL are concerned about the vapor pollution problems associated with the cooling pond and about the thermal waste. They have agreed to support a joint effort to the extent that they will provide engineering and most of the construction for the study site. The Agricultural Experiment Station wishes to cooperate by supplying the horticultural research effort.

CRREL has leveled the land adjacent to the site, added peat soil amendment to our specifications and are presently in the final stages of installing the distribution system and the piping to heat some test plots. There presently are 3 test plots 50' x 150' that will be heated with adjacent control plots. CRREL presently has plans to construct greenhouse facilities adjacent to these test plots to transfer the technology from the Agricultural Experiment Station greenhouse to an operational system.

Tasks:

To determine proper crop varieties and productive capacity of vegetables under the proposed system of near optimum soil temperature.

To determine the amount of season extension that can be achieved both in the greenhouse and out of doors using soil heating with and without plastic canopies.

To determine the proper fertility and irrigation practices necessary for this type of system.

To examine the possibility of growing commercial cut flowers such as roses, carnations and chrysanthemums by using a system that has heat provided in the soil and that would grow for 9 months and during the dark months of November, December and January would be held at a storage temperature of approximately 35°F. During the dark period the greenhouse would be modified with heat saving shields similar to those used in Europe so that heat loss could be reduced.

To determine if unusual disease and insect problems may develop as a result of the warmer environment.

Additional Project Objectives;

Concurrent with the horticultural objectives, data will be produced that will be useful for improving the collection and distribution system for waste energy in northern conditions.

Information will be gathered on thermal and vapor pollution abatement.

Personnel:

The Principle Investigator and leader for the Agricultural Experiment Station effort will be Dr. Donald H. Dinkel, Professor of Plant Physiology. The legislation is largely to provide research assistance to Dr. Dinkel.

The Principle Investigator and leader of the CRREL effort will be Dr. Terry McFadden.

No Fiscal Impact

The department already provides the licensing function to private enterprise under the existing law. The minimal cost of extending this service to the public sector can be readily absorbed with virtually no increase in costs.
