Taking Points for CS HCR 22

HCR 22 creates the Alaska Northern Water Task Force to facilitate State of Alaska leadership in the development of United States' policies related to the opening of Arctic waters.

As many of you know, the Arctic is changing. The ice pack is depleting by 9% per decade. From outer space, NASA has observed that the rate of depletion is accelerating due to interactions between the ice, oceans and atmosphere.

The melting of the sea ice is opening waters that in the past were frozen year-round. This has caused tremendous change already, including:

- **increased ship traffic, and it is projected that the Bering and Chukchi seas will become major marine highways in the near future**
- **the presence of cruise ships**
- **possibilities for new fisheries**
- **increased access to natural resources**
- **questions of territorial rights (Russia sending a flag to the ocean floor)**

Arctic nations like Norway, Canada, Iceland and Russia are actively promoting and defending their interests in increasingly ice-free areas. The U.S. is taking steps, as well. The U.S. Coast Guard has seriously stepped up its activities in an effort to handle all the new activity in the northern seas and is beginning to implement its 5-year Arctic plan.

Senator Begich has introduced 7 pieces of legislation that deal with the Arctic, and Senator Murkowski has introduced 2 bills, one of which relates to creating a deep water port in northern Alaska. The White House has approximately 30 agencies dealing with Arctic issues, and it has created 2 task forces that touch specifically on northern waters issues: the Interagency

Ocean Policy Task Force and the Climate Change Adaptation Task Force. Finally, international bodies like the Arctic Council and the Inuit Circumpolar Council have been working in this area, as well as organizations like the Institute of the North, Commonwealth North, and the US Arctic Research Commission.

As the only Arctic state in this nation, Alaska has a unique role and interest in the development of U.S. Arctic policy. This bill foresees the creation of a joint federal/state commission that will guide interagency and inter-jurisdictional actions in the Arctic. It provides an opportunity for the Legislature to take a proactive role in shaping this commission, and in doing so, ensuring that Alaska's interests are strongly represented.

The task force will be made up of 11 members as follows:

- **2 senators appointed by the Senate President**
- **2 representatives appointed by the Speaker of the House**
- **7 members appointed jointly by the Speaker and Senate President:**
  - **5 public, 3 of whom reside in coastal areas and 2 at-large**
  - **1 Executive Branch of the AK Government**
  - **1 from a federal agency w/a significant role in addressing northern waters issues**

The task force will hold 7 meetings total in the communities that are most directly impacted by the increased activity in the Arctic: Nome, Kotzebue, Barrow and Unalaska. There will also be hearings in Anchorage. The task force will present its findings to the Legislature in January 2012, including legislative proposals for consideration.

FISCAL NOTE: $150K FY 2011, $75K FY 2012

Taking Points for HCR 22

26-LS1622\P – 4/3/2010

HCR 22 creates the Alaska Northern Water Task Force to facilitate State of Alaska leadership and regional coordination in the ongoing development of United States' policies related to the opening of Arctic waters.

As many of you know, the Arctic is changing. Recent warming trends are depleting the ice pack by 9% per decade. NASA has observed that the rate of depletion is accelerating due to interactions between the ice, oceans and atmosphere.

The melting of the sea ice is opening waters that were previously frozen year-round. Already, we have seen:

- **increased ship traffic, and it is projected that the Bering and Chukchi seas will become major marine highways in the near future**
- **an unannounced cruise ship docking in Barrow**
- **possibilities for new fisheries**
- **increased access to natural resources**
- **questions of territorial rights**

Arctic nations like Norway, Canada, Iceland and Russia are actively promoting and defending their interests in increasingly ice-free areas. The U.S. is taking steps, as well. In your bill packet, you will see that Senator Begich has introduced 7 pieces of legislation that deal with the Arctic, and Senator Murkowski has introduced 2 bills, one of which relates to creating a deep water port in northern Alaska. The White House has created 2 task forces that touch on northern waters issues: the Interagency Ocean Policy Task Force and the Climate Change Adaptation Task Force. Finally, international bodies like the Arctic Council and the Inuit Circumpolar

Council have been working in this area, as well as Alaska-based NGOs like the Institute of the North. + Commonwealth N.

As the only Arctic state in this nation, Alaska has a unique role and interest in the development of U.S. Arctic policy. This bill foresees the creation of a joint federal/state commission that will guide interagency and inter-jurisdictional actions in the Arctic. It provides an opportunity for the Legislature to take a proactive role in shaping this commission, and in doing so, ensuring that Alaska's interests are strongly represented.

The task force will be made up of 11 members as follows:

- **1 senator from along the Bering, Chukchi or Beaufort seas appointed by the Senate President (stayed same)**
- **3 reps (CRA had 2) from along the Bering, Chukchi or Beaufort seas appointed by the Speaker of the House**
- **7 members (CRA had 6) appointed jointly by the Speaker and Senate President representing the following entities:**
    - **Executive Branch of the AK Government**
    - **Mayors of the NSB, NAB, City of Nome and City of Unalaska (added)**
    - **US Coast Guard**
    - **A member of a federal agency w/a significant role in addressing northern waters issues (CRA had DOI)**

one more in Anc & one in D.C. for 2 members

The task force will hold 7 meetings (CRA had 5) total in the communities that are most directly feeling the impacts of the increased activity in the Arctic: Nome, Kotzebue, Barrow and Unalaska (one in each town, 3 in Anc). We will have hearings in Anchorage as well. The task force will present its findings to the Legislature in January 2012, including legislative proposals for consideration.

I thank the Committee for its time in considering creating this mechanism that will enable the State of Alaska to take a leadership role in the important issue of the northern waters and the opportunities the changing Arctic are presenting to us.

Taking Points for HCR 22 (HCRA) 3/30/2010

CS FOR HOUSE CONCURRENT RESOLUTION NO. 22(FIN)

IN THE LEGISLATURE OF THE STATE OF ALASKA

TWENTY-SIXTH LEGISLATURE - SECOND SESSION

BY THE HOUSE FINANCE COMMITTEE

Offered: 4/9/10
Referred: Rules

Sponsor(s): HOUSE COMMUNITY AND REGIONAL AFFAIRS COMMITTEE

A RESOLUTION

Establishing and relating to the Alaska Northern Waters Task Force.

BE IT RESOLVED BY THE LEGISLATURE OF THE STATE OF ALASKA:

WHEREAS Alaska is the only Arctic state in the nation; and

WHEREAS recent warming trends have resulted in the depletion of Arctic perennial sea ice by nine percent a decade; and

WHEREAS, according to the National Aeronautics and Space Administration, the rate of depletion is accelerating because of the interaction among the ice, oceans, and atmosphere; and

WHEREAS rapidly retreating sea ice is altering fish and wildlife habitats and affecting the accessibility and viability of certain species, on which many local communities rely for nutritional and cultural purposes; and

WHEREAS reduced sea ice is affecting polar route navigation by opening oceans previously frozen year-round; and

WHEREAS the new accessibility of the Northern waters is resulting in increased marine transportation, access to resources, tourism, fisheries, and the presence of United States government agencies in the North; and

WHEREAS the waters of Northern Alaska are of national security and strategic importance to the United States and the State of Alaska; and

WHEREAS, because of national security concerns, the United States Coast Guard is increasing its presence in the North and has plans to build new infrastructure to support its heightened activity, including housing and office facilities and possibly a deep water port; and

WHEREAS Northern Alaska contains important mineral and other resources both in state waters and on the outer continental shelf; and

WHEREAS commercial activities, including resource development, and the revenue they generate for the state may be significantly affected by the changing Arctic waters; and

WHEREAS those changes will affect local communities, businesses, the state, and the natural resources on which they rely; and

WHEREAS there is no comprehensive state plan for Alaska's Northern waters; and

WHEREAS various federal agencies and international bodies are working together to form a commission to address the changing ocean patterns and the opportunities and problems that may arise as a result of those changing patterns; and

WHEREAS the State of Alaska should be involved in the process of forming the commission; and

WHEREAS a comprehensive plan to address the warming ocean, including the economic, ecological, and security effects, will benefit the state and its residents;

BE IT RESOLVED by the Alaska State Legislature that the Alaska Northern Waters Task Force is created in the legislative branch and shall consist of 11 members as follows:

(1) two senators appointed by the President of the Senate;

(2) two representatives appointed by the Speaker of the House of Representatives; and

(3) seven members appointed jointly by the President of the Senate and the Speaker of the House of Representatives, as follows:

(A) five public members, three of whom reside in coastal areas of the state;

(B) one member representing the executive branch of state government;

(C) one member representing the federal government; and be it

FURTHER RESOLVED that a vacancy on the task force shall be filled in the manner of the original appointment; and be it

FURTHER RESOLVED that the legislators on the task force shall select a chair from among themselves and the chair may assign staff to provide support to the task force; and be it

FURTHER RESOLVED that the public members, and, if the member does not receive reimbursement for expenses from the federal government, the federal government member of the task force may receive per diem and travel expenses authorized for boards and commissions under AS 39.20.180; and be it

FURTHER RESOLVED that the task force may meet during and between legislative sessions and the duties of the task force include the following:

(1) assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;

(2) facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;

(3) identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and

(4) conduct hearings in the Northern region of the state to fulfill its purpose; and be it

FURTHER RESOLVED that the task force shall provide recommendations regarding the formation of the commission and shall deliver a preliminary report of its findings to the legislature by January 20, 2012, and deliver a final report to the legislature on January 30, 2012, together with legislative proposals for consideration; and be it

FURTHER RESOLVED that the task force shall be available for legislative hearings regarding its final report and recommendations; and be it

FURTHER RESOLVED that the continuation or termination of the task force shall be reevaluated during the Second Regular Session of the Twenty-Seventh Alaska State Legislature.

WHEREAS a comprehensive plan to address the warming ocean, including the economic, ecological, and security effects, will benefit the state and its residents;

BE IT RESOLVED by the Alaska State Legislature that the Alaska Northern Waters Task Force is created in the legislative branch and shall consist of 11 members as follows:

(1) one senator from an area along the Bering, Chukchi, and Beaufort Seas appointed by the President of the Senate;

(2) three representatives from areas along the Bering, Chukchi, and Beaufort Seas appointed by the Speaker of the House of Representatives; and

(3) seven members appointed jointly by the President of the Senate and the Speaker of the House of Representatives, as follows:

(A) one member representing the United States Coast Guard;

(B) one member representing the executive branch of state government;

(C) the 4 mayors of the North Slope Borough, Northwest Arctic

Borough, City of Nome, and City of Unalaska; and

(D) one member representing a federal agency with a significant role in addressing northern waters issues; and be it

FURTHER RESOLVED that the legislators on the task force shall select a chair from among themselves and the chair may assign staff to provide support to the task force; and be it

FURTHER RESOLVED that the municipal government and federal government members of the task force may receive per diem and travel expenses authorized for boards and commissions under AS 39.20.180 if they do not receive reimbursement for expenses from the municipal or federal government; and be it

FURTHER RESOLVED that the task force may meet during and between legislative sessions and the duties of the task force include the following:

(1) assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;

(2) facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;

(3) identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and

(4) conduct hearings in the Northern region of the state to fulfill its purpose; and be it

FURTHER RESOLVED that the task force shall provide recommendations regarding the formation of the commission and shall deliver a preliminary report of its findings to the legislature by January 20, 2012, and deliver a final report to the legislature on January 30, 2012, together with legislative proposals for consideration; and be it

FURTHER RESOLVED that the task force shall be available for legislative hearings regarding its final report and recommendations; and be it

FURTHER RESOLVED that the continuation or termination of the task force shall be reevaluated during the Second Regular Session of the Twenty-Seventh Alaska State Legislature.

CS FOR HOUSE CONCURRENT RESOLUTION NO. 22( )

IN THE LEGISLATURE OF THE STATE OF ALASKA

TWENTY-SIXTH LEGISLATURE - SECOND SESSION

BY

Offered:
Referred:

Sponsor(s): HOUSE COMMUNITY AND REGIONAL AFFAIRS COMMITTEE

A RESOLUTION

Establishing and relating to the Alaska Northern Waters Task Force.

BE IT RESOLVED BY THE LEGISLATURE OF THE STATE OF ALASKA:

WHEREAS Alaska is the only Arctic state in the nation; and

WHEREAS recent warming trends have resulted in the depletion of Arctic perennial sea ice by nine percent a decade; and

WHEREAS, according to the National Aeronautics and Space Administration, the rate of depletion is accelerating because of the interaction among the ice, oceans, and atmosphere; and

WHEREAS rapidly retreating sea ice is altering fish and wildlife habitats and affecting the accessibility and viability of certain species, on which many local communities rely for nutritional and cultural purposes; and

WHEREAS reduced sea ice is affecting polar route navigation by opening oceans previously frozen year-round; and

WHEREAS the new accessibility of the Northern waters is resulting in increased marine transportation, access to resources, tourism, fisheries, and the presence of United States government agencies in the North; and

WHEREAS the waters of Northern Alaska are of national security and strategic importance to the United States and the State of Alaska; and

WHEREAS, because of national security concerns, the United States Coast Guard is increasing its presence in the North and has plans to build new infrastructure to support its heightened activity, including housing and office facilities and possibly a deep water port; and

WHEREAS Northern Alaska contains important mineral and other resources both in state waters and on the outer continental shelf; and

WHEREAS commercial activities, including resource development, and the revenue they generate for the state may be significantly affected by the changing Arctic waters; and

WHEREAS those changes will affect local communities, businesses, the state, and the natural resources on which they rely; and

WHEREAS there is no comprehensive state plan for Alaska's Northern waters; and

WHEREAS various federal agencies and international bodies are working together to form a commission to address the changing ocean patterns and the opportunities and problems that may arise as a result of those changing patterns; and

WHEREAS the State of Alaska should be involved in the process of forming the commission; and

WHEREAS a comprehensive plan to address the warming ocean, including the economic, ecological, and security effects, will benefit the state and its residents;

BE IT RESOLVED by the Alaska State Legislature that the Alaska Northern Waters Task Force is created in the legislative branch and shall consist of nine members as follows:

(1) one senator from Northwest Alaska appointed by the President of the Senate;

(2) two representatives from Northwest Alaska appointed by the Speaker of the House of Representatives; and

(3) six members appointed jointly by the President of the Senate and the Speaker of the House of Representatives, as follows:

(A) one member representing the United States Coast Guard;

(B) one member representing the executive branch of state government;

(C) the mayors of the North Slope Borough, Northwest Arctic

Borough, and City of Nome; and

(D) one member representing the United States Department of the Interior; and be it

FURTHER RESOLVED that the legislators on the task force shall select a chair from among themselves and the chair may assign staff to provide support to the task force; and be it

FURTHER RESOLVED that the municipal government and federal government members of the task force may receive per diem and travel expenses authorized for boards and commissions under AS 39.20.180 if they do not receive reimbursement for expenses from the municipal or federal government; and be it

FURTHER RESOLVED that the task force may meet during and between legislative sessions and the duties of the task force include the following:

(1) assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;

(2) facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;

(3) identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and

(4) conduct hearings in the Northern region of the state to fulfill its purpose; and be it

FURTHER RESOLVED that the task force shall provide recommendations regarding the formation of the commission and shall deliver a preliminary report of its findings to the legislature by January 20, 2012, and deliver a final report to the legislature on January 30, 2012, together with legislative proposals for consideration; and be it

FURTHER RESOLVED that the task force shall be available for legislative hearings regarding its final report and recommendations; and be it

FURTHER RESOLVED that the continuation or termination of the task force shall be reevaluated during the Second Regular Session of the Twenty-Seventh Alaska State Legislature.

MEMORANDUM

Date: April 9, 2010

RE: Changes to House Concurrent Resolution 22, Northern Waters Task Force

---

Changes from HCR 22 to CS HCR 22 (FIN):

- P. 2, line 20 of the CS: Merges the first two Resolves from the original bill for better readability.
- P. 2 line 21 of the CS: Changes the configuration of the Task Force from 11 to 9 members
  - 2 senators (not 1)
  - 2 reps (same)
  - 7 members appointed jointly (not 6)
    - 5 public, 3 of whom reside in coastal areas (i.e. 2 at-large) (not the 4 mayors)
    - 1 executive branch (same)
    - 1 federal (not 2)
- P. 3, line 1 of the CS: Clarifies that vacancy shall be filled in the manner of the original appointment
- P. 3, lines 4-5 of the CS: Provides that the legislators on the task force shall select a chair from amongst themselves, rather than the task force selecting a chair from among the entire legislature.
- P. 3, line 4 of the CS: Adds that the chair of the task force may assign staff to the task force.

- P. 3, line 7 of the CS: Replaces municipal members with public members to conform with the changed task force configuration.

- P. 3, lines 13-14 of the original bill: Removes "FURTHER RESOLVED that the Bush Caucus chair may assign staff to provide support services for the task force; and be it".

- P. 3, lines 11-20 of the CS: Combines the two RESOLVED clauses before and after the one removed.

- P. 3, lines 19-20 of the CS: Adds "(4) conduct hearings in the Northern Region of the state to fulfill its purpose; and be it" (originally another FURTHER RESOLVED on p.3, lines 23-24 of the original bill.)

HCR22 establishes the Alaska Northern Waters Task Force in the Legislative Branch. The Task Force consists of nine members composed of three Legislators, one member from the Executive Branch, and five public members. It is anticipated that the Task Force will hold six meetings. Travel funding is included in this fiscal note and includes the cost for experts to attend the meetings. Meetings will be held in the Legislative Information Offices or local government facilities at no cost to the Task Force. The Bush Caucus Chair may assign staff of the Bush Caucus Chair to support the Task Force. The Task Force will assess and facilitate the creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters; inform and incorporate local stakeholders input into the process, and identify and coordinate efforts of mutual concern for federal, state, and local agencies. Funding for professional services contracts is included in this fiscal note. Costs to teleconference meetings and print the proposals and reports due in January 2011 will be absorbed in the Legislative Affairs Agency Budget.

Sponsor Statement
House Concurrent Resolution 22
Establishing the Alaska Northern Waters Task Force

House Concurrent Resolution 22 establishes the Alaska Northern Waters Task Force to facilitate regional coordination and State of Alaska leadership in the ongoing development of the United States' policies related to the opening of Arctic marine transportation routes, national security, and resource development. The task force will comprise Legislators from Northwestern Alaska, leaders from Arctic communities, and key federal agencies. Together, they will assess and facilitate the creation of a joint state and federal entity to coordinate United States and Alaska interests that result from the opening of Arctic waters.

Perennial ice in the circumpolar Arctic waters is reducing in size at a rate of nine percent per decade. Arctic nations such as Norway, Canada and Russia are proactively promoting and defending their interests in increasingly ice-free areas. As the only Arctic state in this nation, Alaska has a unique role and interest in the development and evolution of U.S. policy in its northernmost region.

The creation of the Alaska Northern Waters Task Force anticipates increased federal attention to navigation routes, resource development, military activity and commerce in the Arctic. HCR 22 foresees the future creation of a joint federal/state commission that guides interagency and inter-jurisdiction actions in

the Arctic. It provides an opportunity for Alaska's Legislature and Arctic communities to assume a proactive role in shaping such a body, and ensures that Alaska's unique interests are strongly represented.

In the execution of its responsibilities, the Alaska Northern Waters Task Force will hold hearings in the northern communities of Barrow, Nome and Kotzebue, as well as Anchorage. By meeting in these regions, the task force will be able to seek guidance and feedback from the residents of the regions most likely to experience impacts from increased activity in the Arctic.

The Alaska Northern Waters Task Force will deliver its findings to the Alaska Legislature in January 2012, including legislative proposals for consideration.

ANALYSIS: *(Attach a separate page if necessary)*

Work Draft 26-LS1622/T establishes the Alaska Northern Waters Task Force in the Legislative Branch. The Task Force consists of eleven members composed of four Legislators, one member from the Executive Branch, and seven public members. It is anticipated that the Task Force will hold seven meetings in the first year and three meetings in the second year. Travel funding is included in this fiscal note and includes the cost for experts to attend the meetings. Meetings will be held in Barrow, Nome, Kotzebue, Unalaska and Anchorage at Legislative Information Offices or local government facilities at no rental cost to the Task Force. The Task Force Chair may assign their staff to support the Task Force. The Task Force will assess and facilitate the creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters; inform and incorporate local stakeholders input into the process, and identify and coordinate efforts of mutual concern for federal, state, and local agencies. Funding for professional services contracts is included in this fiscal note. Costs to teleconference meetings and print the proposals and reports due in January 2012 will be absorbed in the Legislative Affairs Agency Budget.

Senator Begich - Inuvikput Package

Introduced August 3, 2009, the *Inuvikput Package* consists of seven pieces of legislation:

S.1560 Arctic OCS Revenue Sharing Act - Alaska Natives who have subsisted on marine mammals and other arctic resources for thousands of years would bear the direct risks of increased commercial activity in their waters. This bill directs a portion of federal revenues from offshore oil and gas development - the same share Louisiana receives from drilling in the adjacent Gulf of Mexico - to the State of Alaska with a percentage of those funds directed to those most affected.

S.1561 Arctic Marine Shipping Assessment Implementation Act - As the polar icecap recedes, the Arctic region is increasingly accessible to shipping and tourism. This bill is designed to ensure safe and reliable maritime transportation in the Arctic and protect its waters. It would boost the nation's investment in needed infrastructure, including replacement of America's aging fleet of icebreakers and building new forward operating air bases for the Coast Guard to assert our national interest in the region.

S.1562 Arctic Science, Coordination and Integration Act - Numerous scientists and agencies conduct important and needed research into various aspects of the Arctic but concerns remain that these efforts are not well coordinated and leave gaps in our understanding of Arctic issues. This bill calls on the National Research Council to undertake a study toward a comprehensive strategy to coordinate Arctic research and make recommendations to Congress on a long-term Arctic Ocean research plan.

S.1563 Arctic Ambassador Act - Russia, Canada, Norway and other Arctic nations are represented at the ambassadorial level before the Arctic Council and U.S. interests would benefit from an enhanced diplomatic presence in Arctic matters. This bill is intended to strengthen U.S. representation before the Arctic Council and other international forums by appointment of a U.S. ambassador to the Arctic.

S.1564 Arctic Oil Spill Research and Recovery Act - Vast energy reserves are believed to lie beneath Arctic waters and it is vital that any development of such resources be conducted in a responsible manner that protects the environment upon which residents of the region depend. This bill directs the Secretary of Commerce to conduct research to improve oil spill prevention, response and recovery in Arctic conditions and requires the Coast Guard to assess and reduce risk from such development.

S.1565 Arctic Health Research Act - People of the Arctic suffer from increased rates of alcohol abuse, diabetes, high blood pressure, and death from injury and suicide. This act would initiate a study into the mental, behavioral and physical health problems in the Arctic, institute an Arctic health assessment program at the Centers for Disease Control and create an "Arctic desk" at the National Institute of Health that was called for in 1984 but has never been established.

S.1566 Arctic Climate Change Adaptation Act - Alaska villages and public infrastructure are already suffering from coastal erosion, flooding, permafrost melting and other impacts of climate change. This bill would help the State of Alaska, Alaska Native organizations, affected Arctic communities and the private sector adapt to the impacts of climate change and assist in dealing with habitat restoration, clean energy development and other economic development activities.

Melting ice could mean new riches

Jill Burke
Mar 1, 2010

"It's not a question of if but when."

That's what Mead Treadwell, chairman of the U.S. Arctic Research Commission, told a New York City crowd Monday about the prospect of a booming northwest passage.

Treadwell made the remarks during a moderated panel discussion, "Will the Bering Strait become the Panama Canal of the North?" hosted by the Council on Foreign Relations at Alaska House New York. (Alaska House is a nonprofit organization founded by Alaska Dispatch publisher Alice Rogoff to promote education about Alaska and its Native culture and foster economic development within the state.)

The day's discussion, which pulled together Alaska's congressional delegates, regional leaders and industry representatives, centered on the sense of urgency seemingly missing both in the state and nationwide for developing the infrastructure -- like deep water ports and international rules -- that will be needed to tap into a new hustling, bustling Bering Strait.

Two of the world's largest mining operations are above the Arctic Circle, including the Red Dog zinc mine in Alaska off the coast of Kivalina, according to Treadwell -- and the Arctic is poised to deliver even more resources. Minerals, fishing, oil and gas, exploration and science, and tourism all have northern footholds. Capturing opportunities related to those activities with the prospect of shorter shipping routes as ice recedes is something Americans need to be thinking about now, Treadwell said.

The challenge is building the infrastructure. Deep water ports are needed to accommodate large container ships and provide an anchor for the military presence that will need to increase to keep pace with a rise in offshore activity near the United States' northern coast.

Participants, including Rogoff, suggested that developing port infrastructure for Alaska's western coast, from Adak to Barrow, could be an economic boom as important to the state as the trans-Alaska oil pipeline, particularly when even a handful of new port jobs has the potential to pull villages teetering on the brink of economic failure into sustainability.

Alaska Sens. Lisa Murkowski, a Republican, and Mark Begich, a Democrat, attended the event and told participants they are aware of the critical role Alaska is poised to play in a changing Arctic environment. Murkowski is pushing for a Department of Defense and Homeland Security feasibility study for a deep water port off Alaska's shores.

"This study will determine whether it is in the strategic interest of the United States, as I believe it is, to build a port and where it might be located. A deep water port would not only serve our military and Coast Guard needs, but as we develop our offshore oil and gas reserves and see more shipping, tourism and vessel traffic in the Arctic, a deep water port could provide valuable support," Murkowski said.

A full transcript of the day's discussion will be posted online at the Council on Foreign Relations' Web site.

United States Senator Lisa Murkowski

Monday March 01 2010

Murkowski Speaks at Arctic Policy Roundtable at New York Council on Foreign Relations

NEW YORK - U.S. Sen. Lisa Murkowski, R-Alaska, helped lead a discussion on U.S. Arctic policy at a roundtable forum today at the Council on Foreign Relations in New York City. Also participating in the discussion was U.S. Sen. Mark Begich, D-Alaska, a number of Arctic policy experts and several Alaskans, including Mayor Edward Itta of the North Slope Borough. Following is a text of Sen. Murkowski's remarks as prepared for delivery:

"Good afternoon. It is my distinct pleasure to be back at the Council on Foreign Relations today to discuss one of my favorite subjects, the Arctic. As all of us in this room are aware, the United States is an Arctic nation because of Alaska. But, what does it mean to be an Arctic nation? I believe that the Federal Government is just waking up to this reality and we are frantically trying to define exactly what that distinction means. In my view, being an Arctic nation means that the United States has certain obligations and responsibilities in the region to the land, the water and the people. And we all need to help our nation understand what those are.

"The pace of change in the Arctic demands that greater attention be focused on the region. The implications of the dynamic changing Arctic for the residents and important U.S. security, economic, environmental, and political interests, depend on it.

"One of those responsibilities I spoke of is to have the necessary infrastructure in the region. I recently introduced legislation that directs the Department of Defense and the Department of Homeland Security to study the feasibility, location and resource needs for an Arctic deep water port. This study will determine whether it is in the strategic interest of the United States, as I believe it is, to build a port and where it might be located. A deep water port would not only serve our military and Coast Guard needs, but as we develop our offshore oil and gas reserves and see more shipping, tourism and vessel traffic in the Arctic, a deep water port could provide valuable support. I will insure that the Navy and Coast Guard actively consult with the communities and leaders of the region, as well as the State of Alaska.

"As we all are keenly aware, while the Arctic is becoming more and more ice free in the summer months, Arctic ice is not going to completely disappear. One of the major challenges that we face is our aging ice breaker fleet. I was able to get an appropriation to refurbish the Polar Star last year, and the Coast Guard has embarked on a study to determine whether we need to rebuild or replace our aging polar class vessels, but no matter the result of the study, we must have the commitment of the Administration and Congress that ice breakers are a national priority. And I will do all I can to advocate that position.

"As you know, I am a strong proponent of ratification of the United Nations Convention on the Law of the Sea. The United States must ratify the treaty but we remain at a stalemate: the White House seeks to move forward and the Senate waits for stronger support from the

Administration. As the only Arctic nation not a party to the treaty, failure to ratify continues to keep the United States at a disadvantage internationally and outside the process, without a seat at the table.

"Even though we are not a party to the Treaty, the United States is making progress on mapping our extended continental shelf. The results of Coast Guard ice breaker HEALY's hydrographic missions in the Arctic have been remarkable and I have supported this initiative with appropriations and legislation to authorize more funding. I was gratified to see the cooperation in the Beaufort between with the HEALY and the Canadian icebreaker the Louie St. Laurent. This is yet one example of international cooperation in the Arctic.

"While I was pleased that the United States released its long awaited Arctic Regional Policy in early 2009, implementation is still lagging. It may be necessary for Congress to step in and help move the process. While certain branches of the government, like the Navy and Coast Guard, are developing and implementing their portions of the policy, it is still not nearly to the degree I would like. Certainly other Arctic and non-Arctic nations are moving much more quickly to develop policies and support them, than we are.

"I believe we are at a very critical time in the Arctic. As many of us have identified, there are two paths we can go down in regards to international relations -- one is a path of competition and conflict, and the other is one of cooperation and diplomacy. This decision, and the direction it takes, will require vision and dynamic leadership, both at home and abroad. I believe the United States, as one of the most powerful Arctic nations, must step up and provide it.

"A changing Arctic brings risks and challenges to the environment and indigenous people of the region. But it also brings opportunity and awareness, and if we can work to identify and minimize the risks, and use the opportunities to better the lives of the people of the Arctic region, we can all prosper.

"Thank you and I look forward to a lively conversation this afternoon."

Opinion: Visit to New York, D.C. gets Arctic message across

By EDWARD ITTA

We Inupiaq like to say that the Arctic Ocean is our garden. It feeds us with its bounty of whales, seals, walrus, ugruk, fish and other subsistence foods. Our harvest is better in some years than in others. Weather, ice and ocean currents all affect the amount of "crops" we are able to feed to our families from year to year.

These are times of change for the ocean. Offshore oil and gas exploration is gearing up. We have seen plenty of evidence that climate change may cause dramatic shifts in the polar ice cap and in our weather. Receding ice could open up new shipping routes between Europe and Asia. We may see increased ocean traffic from commercial fishing boats and tourist ships.

What can we do about it? As mayor, I believe the borough should be engaged in the planning, monitoring, research and mitigation efforts that are being crafted right now as government agencies at all levels respond with a new sense of urgency to challenges and opportunities in the Arctic Ocean. That's why I spent the past week in New York and Washington, D.C. I joined Senators Begich and Murkowski in New York and the three of us made presentations on adapting to climate change in the Arctic to a group of policymakers, business people, scientists and journalists, who then participated in a roundtable discussion.

Policymakers are eager to hear our views, because they recognize that we have the most intimate knowledge of the Arctic and the most to lose if the ocean is not adequately protected. My message to them was that we don't want offshore development, but if it is going to happen, we insist on participating in decisions that will govern offshore activities and precautions. I showed them the Arctic policy principles adopted by ICC in 1984 as an example of longstanding Inuit leadership on protecting the polar region.

In Washington, I met with several of the highest officials in the Interior Department, including Interior Secretary Ken Salazar; his assistant secretary for Land and Minerals Management, Wilma Lewis; Liz Burnbaum, director of the Minerals Management Service (MMS); and Bob Abbey, director for BLM. I stressed that if the government is going to allow OCS activity, then it should set the bar very high when it comes to clean and cautious operations in the water.

I said that the shutdown requirement MMS wrote into Shell's Camden Bay permit is a good step in the right direction, since it gives that requirement the force of law for the first time. I argued for larger deferral areas around traditional Barter Island and Cross Island whaling areas, a moratorium on leasing new acreage, zero discharge of drilling wastes, a cumulative impacts analysis, and the need for better baseline science.

I invited Secretary Salazar to visit the North Slope this summer so he can get a first-hand look at some of the places that mean so much to our people. He agreed to pay us a visit in August.

At NOAA, I talked with two key officials about their efforts in preparing a new Environmental Impact Statement concerning the effects of oil and gas activities in the Arctic Ocean. Rather than the annual Incidental Harassment Authorizations (IHA) that are now issued, they are looking at doing five-year Incidental Take Authorizations. They believe it will build certainty and flexibility into their mitigation requirements, and I can see their point. I told them that we need more monitoring and study of the effects of noise on migrating whales. I discussed the Obama administration's new planning initiative for oceans and coastal areas with the head of the President's Council on Environmental Quality (CEQ). CEQ is spearheading the president's effort to deal with climate change. How this new ocean planning program will work is still something of a mystery, but it has a high priority in the administration. I focused on the need to be sensitive about traditional uses of the coastal and ocean areas and to make sure our voices are heard as these large-scale management programs are designed.

At the U.S. Fish and Wildlife Service, we discussed the ongoing management plan for Steller's eiders. I pointed out that our people are conservationists by nature and that education efforts about threatened species can be much more effective than hardball enforcement tactics. I thanked them for establishing a liaison position in Barrow (now held by Emma Huntsman) and said I look forward to better communication between the community and the agency.

Although I spent time with Senators Murkowski and Begich in New York, I was able to meet with each of them again in D.C. I also met with Congressman Young. In each case, I went over a range of issues that we can work on together, and I thanked them for legislation they sponsored in response to my eight-point OCS policy position.

All in all, it was a very productive week. If our voice is going to be heard in the halls of political power, it will be because we take our message to the decision makers and state our point clearly and forcefully. My staff and I will continue to engage with the agencies that shape the regulatory framework for North Slope activities of all kinds. In these challenging times,

these changing times, I want to make sure they can't forget our concerns as they plan the future in offices that are thousands of miles from the Arctic.

Edward Itta is mayor of the North Slope Borough.

White House Climate Change Adaptation Task Force

In 2009, the White House Council on Environmental Quality (CEQ), the Office of Science and Technology Policy (OSTP), and the National Oceanic and Atmospheric Administration (NOAA) initiated the Interagency Climate Change Adaptation Task Force, which includes representatives from more than 20 Federal Agencies. When the President signed the Executive Order on Federal Leadership in Environmental, Energy, and Economic Performance, on October 5, 2009, he called on the Task Force to develop, within one year, Federal recommendations for adapting to climate change impacts both domestically and internationally.

Interim Progress Report

On March 16, 2010, the Task Force released an Interim Progress Report which outlines the Task Force's progress to date and recommends key components to include in a national strategy on climate change adaptation. These six components include:

1. Integration of Science into Adaptation Decisions and Policy
2. Communications and Capacity-building
3. Coordination and Collaboration
4. Prioritization
5. A Flexible Framework for Agencies
6. Evaluation

The Interim Progress Report is available for 60 days of public comment. Submit your comment here.

Workgroups

The Interagency Climate Change Adaptation Task Force formed workgroups to consider the capabilities of the Federal Government to respond to the impacts of climate change on various critical sectors, institutions, and agency mission responsibilities. Five initial workgroups began by reviewing existing policies, operations, procedures, and other tools that affect the Federal Government's response, and will suggest options for improving the government's capacity for adaptation to climate change. The five initial workgroups are focused on the following topics:

- **Agency Adaptation**: Develop recommendations on how agencies should plan and implement adaptation
- **Science Inputs to Policy**: Develop recommendations to couple the production of scientific and technical support to adaptation planning, prioritization, and resilience building within the USG, in the US, and internationally
- **Insurance**: Develop recommendations on opportunities for the United States Government to support insurance and adaptation issues
- **Water Resources Adaptation**: Develop recommendations on how Federal water management agencies should plan and implement adaptation actions related to climate impacts on water resources
- **International Resilience**: Develop recommendations on opportunities for the United States Government to support and lead international adaptation efforts

These workgroups have defined their scope and end products, and have begun initial analysis. Most workgroups have used stakeholder listening sessions to solicit feedback from various government and regional actors on adaptation issues within their respective issue area.

Listening Sessions

The five initial Interagency Climate Change Adaptation Task Force workgroups hosted twenty listening sessions with key stakeholders and experts. The listening sessions were designed to engage the expertise and recommendations of external organizations into the workgroup deliberations early in this review process.

Final Product

In October 2010, the Task Force will report to the President on the development of domestic and international dimensions of a U.S. approach to climate change adaptation and what Federal Agencies are doing to support this effort. The Task Force also will recommend additional aspects to consider in the development of a comprehensive national strategy.

White House Interagency Ocean Policy Task Force

On June 12, 2009, President Obama sent a memorandum to the heads of executive departments and federal agencies establishing an Interagency Ocean Policy Task Force, led by the White House Council on Environmental Quality. The Task Force is charged with developing a recommendation for a national policy that ensures protection, maintenance, and restoration of oceans, our coasts and the Great Lakes. It will also recommend a framework for improved stewardship, and effective coastal and marine spatial planning.

The oceans, our coasts, and the Great Lakes provide jobs, food, energy resources, ecological services, recreation, and tourism opportunities, and play critical roles in our Nation's transportation, economy, and trade, as well as the global mobility of our Armed Forces and the maintenance of international peace and security," President Obama wrote in the memorandum. "We have a stewardship responsibility to maintain healthy, resilient, and sustainable oceans, coasts and Great Lakes resources for the benefit of this and future generations."

"The challenges our oceans, coasts, and Great Lakes are facing are complex, and to meet these challenges we must have the participation of a wide spectrum of views from within the federal government," said Nancy Sutley, Chair of the White House Council on Environmental Quality. "The Task Force has a wealth of opportunity to make our oceans, coasts and Great Lakes healthier - both environmentally and economically."

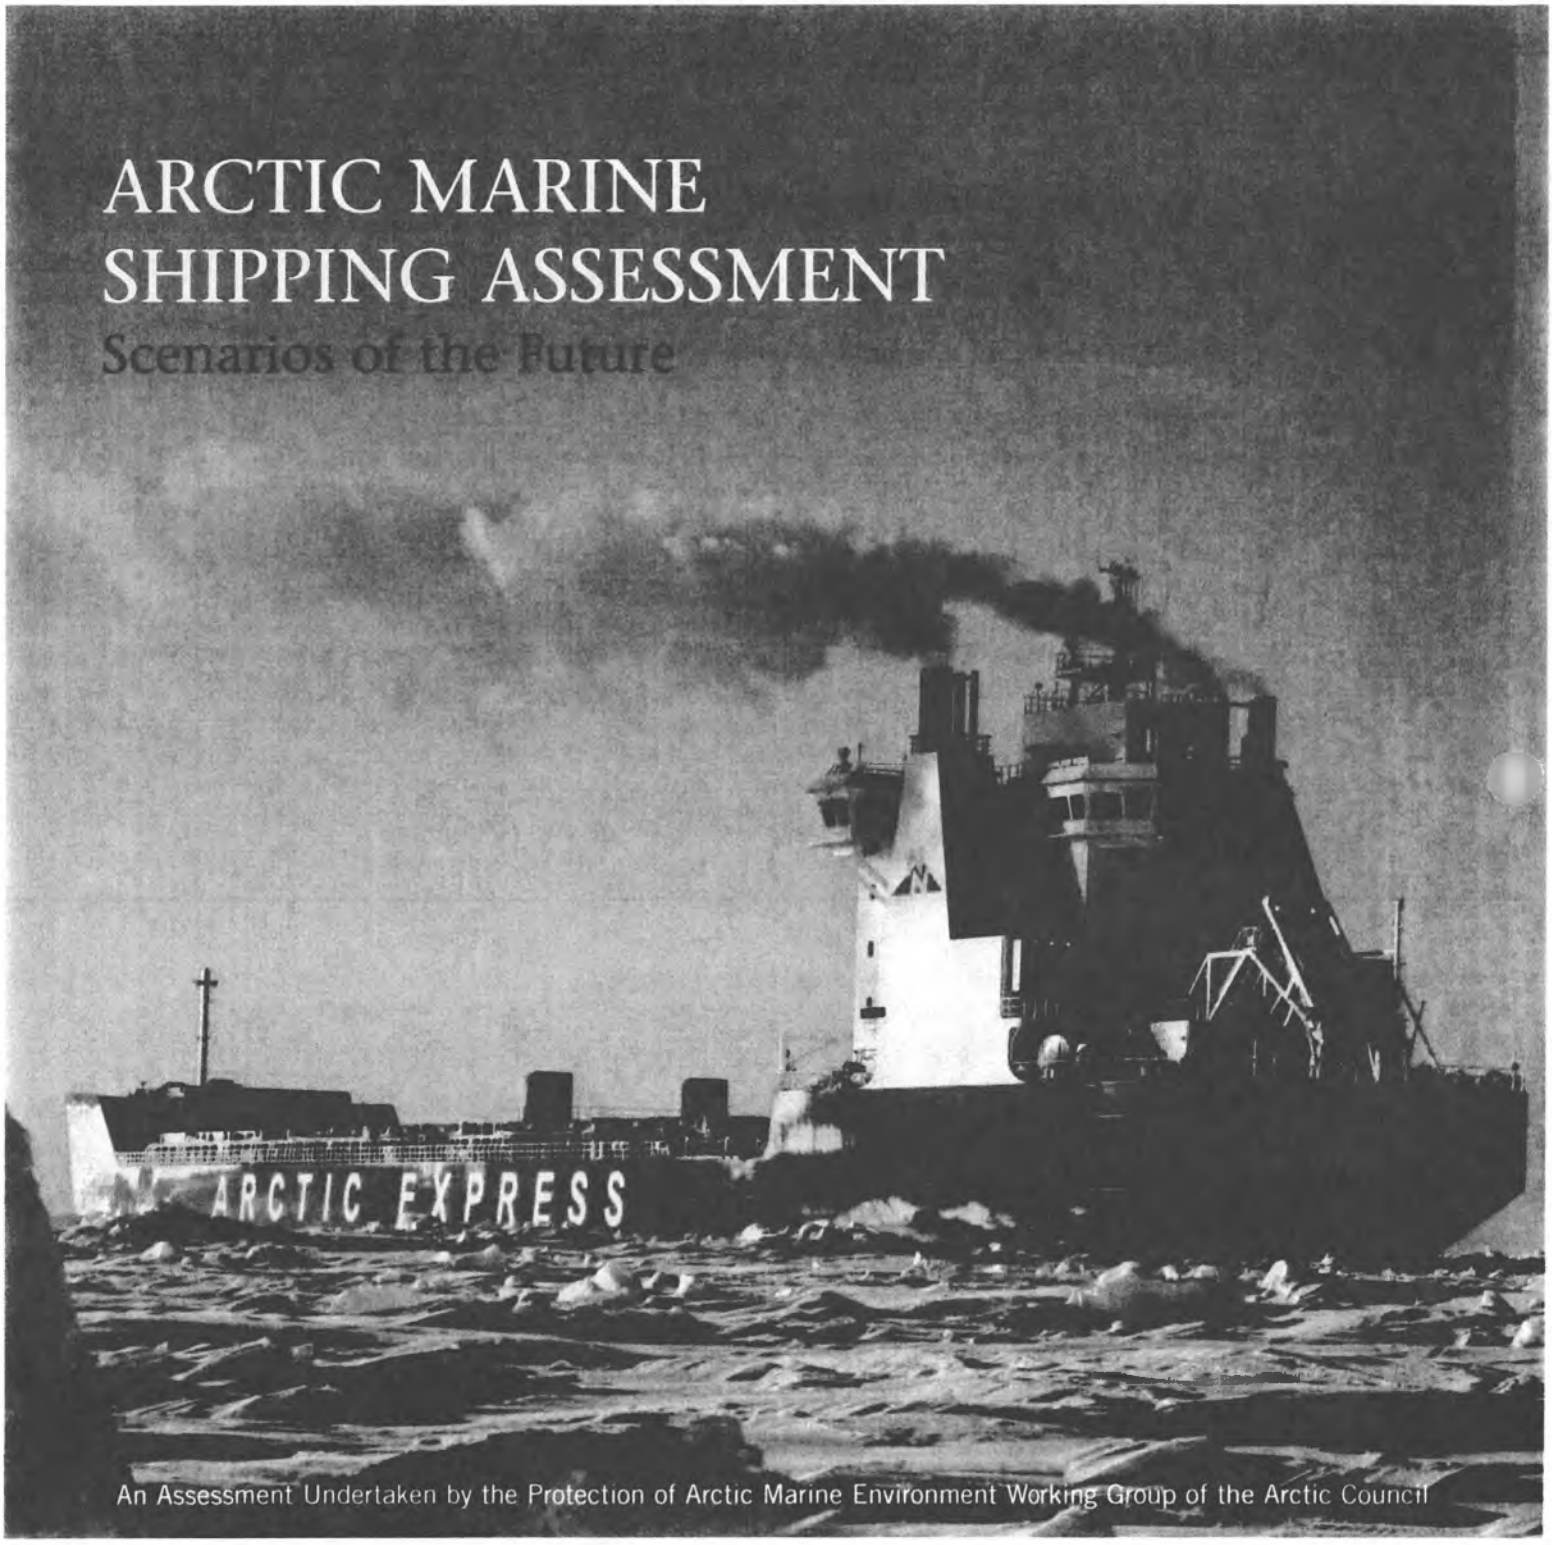
The recommendations and frameworks developed by the Task Force will be cost effective and improve coordination across federal agencies. The Chair will terminate the Task Force upon the completion of its duties.

The time period to submit comments to the Task Force has closed, but you can read comments from others. The Task Force's Interim Framework is open for comment through Friday, February 12, 2010.

Read the President's Proclamation on National Oceans Month

ARCTIC MARINE SHIPPING ASSESSMENT

Scenarios of the Future



An Assessment Undertaken by the Protection of Arctic Marine Environment Working Group of the Arctic Council

Scenarios on the Future of Arctic Marine Navigation in 2050

Arctic Marine Shipping Assessment (AMSA)

The Arctic Council – an intergovernmental forum that addresses environmental protection and sustainable development issues, as well as challenges faced by the Arctic governments and people – is conducting an assessment of current and future Arctic marine activity. The lead countries for AMSA are Canada, Finland and the United States with the Arctic Council's working group on Protection of the Arctic Marine Environment (PAME) responsible for the assessment. A key element of AMSA is the creation of a set of scenarios, or plausible futures, for Arctic marine navigation.

Scenario Framework

The high-level scenario summaries were created at two AMSA/PAME Scenarios Workshops held in San Francisco (April 2007) and Helsinki (July 2007). The workshops were designed and facilitated by Global Business Network of San Francisco. Through brainstorming, work in small groups and spirited plenary discussion, workshop participants collectively agreed that the two factors detailed below – Governance and Resources & Trade – are the most important and uncertain in shaping the future of Arctic marine navigation in mid-century. By crossing these two critical uncertainties, participants formed the scenario matrix illustrated to the right. This framework also allows the incorporation of many of the uncertainties explored at the workshops, while still creating four different scenario spaces that are plausible and relevant to the range of Arctic stakeholders. When completed, the scenario stories willbe posted on the PAME website, www.pame.is.

Governance

This uncertainty axis describes the degree of relative *Governance stability*, both within the Arctic region and internationally.

← **Less stability** implies shortfalls in legal structure and transparency, as well as a propensity for stakeholders to work on a more unilateral basis rather than by collaborating in a cooperative, international fashion.

→ **More stability** implies not only efficiently operating legal and regulatory structures, but an international atmosphere more conducive to collaborative and cooperative development.

Resources & Trade

This uncertainty axis describes the level of demand for Arctic natural resources and trade. Framing this in a global context exposes the scenarios to a broader range of potential market developments, such as the rise of Asia or political instability in the Middle East.

↑ **More demand** implies exactly that – higher demand from more players and markets around the world – for natural resources and commerce in the Arctic.

↓ **Less demand** is also straight forward, with fewer global players interested in utilizing Arctic commerce and natural resources.

Development of the AMSA scenarios is being facilitated by Global Business Network of San Francisco.
Support for this effort has been provided by: Aker Arctic Technology, BP Shipping, Finnish Ministry of Foreign Affairs, Institute of the North, Transport Canada, U.S. Arctic Research Commission, U.S. Department of State and U.S. National Oceanic & Atmospheric Administration.

Northern Waters Commission

A Call to Action

China declares itself an Arctic nation. Building an icebreaker.

Canada renames the much sought-after Northwest Passage the "Canadian Northwest Passage."

Two new-built container ships cut the shipping time from East Asia to Rotterdam in half. Sea route across northern Russia. Icebreaker escorts not needed.

Norway seeks talks with Alaskans.

Canada – Alaska border dispute flares up.

Iceland envisions a transshipment role for itself.

Russia claims undersea territories and resources.

Disclaimer.
This paper is NOT -- repeat NOT -- a treatise on global warming or explanations for it. This is a look at Alaska's potential role in new strategies and opportunities brought forward by receding sea ice in Northern Waters,

Discussion

Reports clearly indicate that the sea ice in Northern latitudes is receding.

No matter what the cause might be, what meaning does that fact have for Alaska and the United States?

Other nations and their governments are already hard at work on their own interests. Russian, Canada, Norway, Iceland and even our own Federal government are players.

These governments and their commercial partners are at the table. What should the State of Alaska and the Alaskan people be doing? We are not very active yet, but we should be.

How and when do we claim our place at the table? Or should we maintain a subordinate, quasi-colonial posture? Most are repulsed by the very thought of the latter.

The situation in Northern Waters could be summed up as follows.

The waters north and northwest of Alaska have strategic importance for at least these four reasons:

1. **Protection of routes of ocean transit.**
2. **Mineral and other resource rights, sub-surface and on-shore.**
3. **Territorial rights and claims by foreign governments.**
4. **Rights and welfare of local inhabitants.**

As governments, the interests listed above are shared by the Federal government and the State of Alaska.

Some independent Federal agencies are taking actions, and some bilateral or multilateral international forums exist. Not all these agencies are coordinating with one another.

Although these shared interests are critical, yet, as of now, there is no organized Federal-State mechanism for handling or even discussing these matters.

Fortunately, there is an approach that is time-proven and very successful.

Suggestion

1. Use the very successful Fishery Management Council model, on which Federal and State appointees sit, deliberate, form policy and approve actions.

2. Feds and State agree to form a **Northern Waters Commission** (working title).

3. A balanced membership is formed comprised of Federal and State of Alaska appointees.

The **Northern Waters Commission** would be the forum at which to discuss policy issues, such as those listed in the four strategic areas above.

Regular meetings would be held, just as with the North Pacific Fishery Management Council, in a balanced atmosphere, with advice and input from staff, local governments, public agencies and the public.

Initial discussions about the **Northern Waters Commission** have been held with members and staff of our Congressional delegation, members of the State Legislative and Executive branches, the US Arctic Research Commission, the Mayor of the North Slope Borough, and experienced members of the public.

There is universal acknowledgement of the general issues involved with receding sea ice, and there is a real interest in the course of action outlined above as a means of addressing those issues.

As further background, in New York City a March 1, 2010 conference was held at the Council on Foreign Relations on the general subject of the retreating sea ice in the North. Senators Murkowski and Begich both made statements there, as well as Mayor Edward Itta.

Many notables were at the conference including the Norwegian Ambassador to the United Nations; David Rockefeller Jr.; Theodore Roosevelt IV; Nome Mayor Denise Michels; Alaska State Representative Carl Gatto; Bering Straits Native Corporation executive Gail Schubert; Alaska Native Arts Foundation chair Alice Rogoff; US Arctic Research Commission chair Mead Treadwell; and former Alaska Commissioner of Commerce, Community and Economic Development Bill Noll.

There was also an evening reception on March 1st at the Alaska House New York on the same subject. Mead Treadwell, Alice Rogoff and Bill Noll shared the podium at the reception. Mead gave a great power point presentation, followed by a lively Q&A.

About 80 had attended the Council on Foreign Relations event. Follow up is expected. As one example, an officer from Norway's General Consulate requested bilateral talks with Alaskans on this general subject.

Here is a link to the text of the afternoon session at Council on Foreign Relations, including the remarks by Senator Murkowski, Senator Begich and Mayor Itta:
http://www.cfr.org/publication/21623/adapting_to_climate_change_in_the_arctic_coordinating_a_federal_state_and_private_sector_response.html?breadcrumb=%2Fbios%2F13363%2Fscott_g_borgerson

Here is a link to the evening session at Alaska House New York:
http://www.ustream.tv/recorded/5121092

So, the question is, what to do next?

Recommendation

The State of Alaska perform work to create a report that will be the basis for taking actions deemed prudent to protect the interests of Alaska and Alaskans and advance these interests in the face of the receding sea ice.

There are and will be opportunities for people and businesses. Will Alaska play the role of a colony or foil for Federal and international protagonists? Or will Alaska step into the breach and take its rightful place alongside the sovereign powers already working for their own ends?

Proposed Scope of Work

A. The current and recent commercial and recreational marine transits passing Alaska over the top across Russia and Canada. The nature of this shipping and its potential. The economics.

B. Estimated oil, gas and other minerals in Northern Waters and their value.

C. Territorial claims to sea, sub-sea or land areas and resources.

D. Current actions by the US Coast Guard and the US Navy. Port potentials.

E. Other commercial potential such as tug support, pilotage, and ice breakers.

F. Shoreside support needs and potential for commerce. Infrastructure.

G. Social and economic potentials for local residents, businesses and governments.

H. Federal agencies currently involved in any way. International forums.

I. Existing Federal laws and regulations, and those pending in Congress.

J. The Law of the Sea Treaty: situation report.

K. The North Pacific Fishery Management Council budget and funding source.

L. Public hearings in key Northern locations.

Respectfully submitted.

William C. (Bill) Noll, Owner

Former Mayor of Seward

Former Alaska Commissioner of Commerce, Community and Economic Development

Founding president, Seward Association for the Advancement of Marine Science, dba Alaska Sealife Center

AMENDMENT #1

OFFERED IN THE HOUSE BY REPRESENTATIVE JOULE

TO: CSHCR 22(CRA)

Page 2, line 21:

Delete "nine"

Insert "12"

Page 2, line 22:

Delete "one senator from Northwest Alaska"

Insert "two senators from an area along the Bering, Chukchi, or Beaufort Sea"

Page 2, line 24:

Delete "two representatives from Northwest Alaska"

Insert "three representatives from areas along the Bering, Chukchi, or Beaufort Seas"

Page 2, line 26:

Delete "six"

Insert "seven"

Page 3, line 1:

Delete "and City of Nome"

Insert ", City of Nome, and City of Unalaska"

Page 3, lines 2 - 3:

Delete "the United States Department of the Interior"

Insert "a federal agency with a significant role in addressing northern waters issues"

Larry Hartig, DEC

301 will be joined by firearm

- lots of activity going on
- consider all the groups like Arctic Council, APG, Ad-Hoc Wking Grp
- jurisdictional boundaries
- possible limits on fed agencies participation

Could have value in communication aspect on local level & among leg levels.

sukugee = don't know my people → Rep. Thomas

Andy Mack, NSB Cw + Ext Affairs

(5) expect Exec. Order soon to form nat'l policy - this is tremendous mechanism to do this.

- Arctic Oil + Gas Guidelines, subject to or adopted by AC

Tom Okleasik, NWAB

Piichuq — here now

(5)

Bill Noll, Anc

(5) New FN says it's well-funded for local partic. but not enough

Meade Treadwell, USARC chair

9th yr, chair since 06

- "Safe, secure, reliable" shipping plan
- open invitation Kim (Ken) Taylor for ex officio member

3 pts for why impt:

(1) as citizen see state interest in fed decisions

(2) fed coop ← int'l + nat'l decisions happening

2011 S+R 1st binding treaty of AC!

IMO met in London to set mandatory codes in Arctic waters doesn't know what dept in state gov looks at it.

(3) reviewing boundaries in dn (a) Law o' Sea (b) Canada boundaries

pilotage issues

(3) investment ports, etc + research w/ AK having huge role

- approaching markets - he went to Iceland to see about ports
  Iceland wants twin tender w/ AK before Jamaica ports.
  Joint investment

Feds won't be precluded from participating, at least USARC won't. US Coastguard Empl. Act.

CS FOR HOUSE CONCURRENT RESOLUTION NO. 22( )

IN THE LEGISLATURE OF THE STATE OF ALASKA

TWENTY-SIXTH LEGISLATURE - SECOND SESSION

BY

Offered:
Referred:

Sponsor(s): HOUSE COMMUNITY AND REGIONAL AFFAIRS COMMITTEE

A RESOLUTION

Establishing and relating to the Alaska Northern Waters Task Force.

BE IT RESOLVED BY THE LEGISLATURE OF THE STATE OF ALASKA:

WHEREAS Alaska is the only Arctic state in the nation; and

WHEREAS recent warming trends have resulted in the depletion of Arctic perennial sea ice by nine percent a decade; and

WHEREAS, according to the National Aeronautics and Space Administration, the rate of depletion is accelerating because of the interaction among the ice, oceans, and atmosphere; and

WHEREAS rapidly retreating sea ice is altering fish and wildlife habitats and affecting the accessibility and viability of certain species, on which many local communities rely for nutritional and cultural purposes; and

WHEREAS reduced sea ice is affecting polar route navigation by opening oceans previously frozen year-round; and

WHEREAS the new accessibility of the Northern waters is resulting in increased marine transportation, access to resources, tourism, fisheries, and the presence of United States government agencies in the North; and

WHEREAS the waters of Northern Alaska are of national security and strategic importance to the United States and the State of Alaska; and

WHEREAS, because of national security concerns, the United States Coast Guard is increasing its presence in the North and has plans to build new infrastructure to support its heightened activity, including housing and office facilities and possibly a deep water port; and

WHEREAS Northern Alaska contains important mineral and other resources both in state waters and on the outer continental shelf; and

WHEREAS commercial activities, including resource development, and the revenue they generate for the state may be significantly affected by the changing Arctic waters; and

WHEREAS those changes will affect local communities, businesses, the state, and the natural resources on which they rely; and

WHEREAS there is no comprehensive state plan for Alaska's Northern waters; and

WHEREAS various federal agencies and international bodies are working together to form a commission to address the changing ocean patterns and the opportunities and problems that may arise as a result of those changing patterns; and

WHEREAS the State of Alaska should be involved in the process of forming the commission; and

WHEREAS a comprehensive plan to address the warming ocean, including the economic, ecological, and security effects, will benefit the state and its residents;

BE IT RESOLVED by the Alaska State Legislature that the Alaska Northern Waters Task Force is created in the legislative branch and shall consist of 11 members as follows:

(1) one senator from an area along the Bering, Chukchi, or Beaufort Seas appointed by the President of the Senate;

(2) three representatives from areas along the Bering, Chukchi, or Beaufort Seas appointed by the Speaker of the House of Representatives; and

(3) seven members appointed jointly by the President of the Senate and the Speaker of the House of Representatives, as follows:

(A) one member representing the United States Coast Guard;

(B) one member representing the executive branch of state government;

(C) the mayors of the North Slope Borough, Northwest Arctic

Borough, City of Nome, and City of Unalaska; and

(D) one member representing a federal agency with a significant role in addressing northern waters issues; and be it

FURTHER RESOLVED that the legislators on the task force shall select a chair from among themselves and the chair may assign staff to provide support to the task force; and be it

FURTHER RESOLVED that the municipal government and federal government members of the task force may receive per diem and travel expenses authorized for boards and commissions under AS 39.20.180 if they do not receive reimbursement for expenses from the municipal or federal government; and be it

FURTHER RESOLVED that the task force may meet during and between legislative sessions and the duties of the task force include the following:

(1) assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;

(2) facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;

(3) identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and

(4) conduct hearings in the Northern region of the state to fulfill its purpose; and be it

FURTHER RESOLVED that the task force shall provide recommendations regarding the formation of the commission and shall deliver a preliminary report of its findings to the legislature by January 20, 2012, and deliver a final report to the legislature on January 30, 2012, together with legislative proposals for consideration; and be it

FURTHER RESOLVED that the task force shall be available for legislative hearings regarding its final report and recommendations; and be it

FURTHER RESOLVED that the continuation or termination of the task force shall be reevaluated during the Second Regular Session of the Twenty-Seventh Alaska State Legislature.

GovTrack.us is a project of **Civic Impulse, LLC**.

(c) LESSEE DEFINED.—In this section, the term "lessee" means the holder of a lease (as defined in section 1331(c) of title 43, United States Code), who, prior to giving the written notice in subsection (a)(1), has entered into a binding agreement to employ a suitable vessel documented or to be documented under 12111(d) of title 46, United States Code.

(d) SAVINGS PROVISION.—Nothing in subsection (a) may be construed to authorize the employment in the coastwise trade of a vessel that does not meet the requirements of 12111 of title 46, United States Code.

SEC. 311. ARCTIC MARINE SHIPPING ASSESSMENT IMPLEMENTATION.

(a) PURPOSE.—The purpose of this section is to ensure safe and secure maritime shipping in the Arctic including the availability of aids to navigation, vessel escorts, spill response capability, and maritime search and rescue in the Arctic.

(b) INTERNATIONAL MARITIME ORGANIZATION AGREEMENTS.—To carry out the purpose of this section, the Secretary of the department in which the Coast Guard is operating is encouraged to enter into negotiations through the International Maritime Organization to conclude and execute agreements to promote coordinated action among the United States, Russia, Canada, Iceland,

Norway, and Denmark and other seafaring and Arctic nations to ensure, in the Arctic—

(1) placement and maintenance of aids to navigation;

(2) appropriate marine safety, tug, and salvage capabilities;

(3) oil spill prevention and response capability;

(4) maritime domain awareness, including long-range vessel tracking; and

(5) search and rescue.

(c) COORDINATION BY COMMITTEE ON THE MARITIME TRANSPORTATION SYSTEM.—The Committee on the Maritime Transportation System established under a directive of the President in the Ocean Action Plan, issued December 17, 2004, shall coordinate the establishment of domestic transportation policies in the Arctic necessary to carry out the purpose of this section.

(d) AGREEMENTS AND CONTRACTS.—The Secretary of the department in which the Coast Guard is operating may, subject to the availability of appropriations, enter into cooperative agreements, contracts, or other agreements with, or make grants to individuals and governments to carry out the purpose of this section or any agreements established under subsection (b).

(e) ICEBREAKING.—The Secretary of the department in which the Coast Guard is operating shall promote safe maritime navigation by means of icebreaking where needed to carry out the purposes of this section.

(f) DEMONSTRATION PROJECTS.—The Secretary of Transportation may enter into cooperative agreements, contracts, or other agreements with, or make grants to, individuals to conduct demonstration projects to reduce emissions (including black carbon and other emissions that could contribute to climate change) or discharges from vessels operating in the Arctic.

(g) AUTHORIZATION OF APPROPRIATIONS.—There are authorized to be appropriated—

(1) to the Secretary of the department in which the Coast Guard is operating—

(A) $5,000,000 for each of fiscal years 2011 through 2015 for seasonal operations in the Arctic; and

(B) $10,000,000 for each of fiscal years 2012 through 2015 to carry out agreements established under subsection (d); and

(2) to the Secretary of Transportation $5,000,000 for each of fiscal years 2011 through 2015 to conduct demonstration projects under subsection (f).

(h) ICEBREAKERS.—

(1) ANALYSES.—Not later than 90 days after the date of enactment of this Act or the date of completion of the ongoing High Latitude Study to assess Arctic polar ice-breaking mission requirements, which ever occurs later, the Commandant of the Coast Guard shall—

(A) conduct a comparative cost-benefit analysis of—

(i) rebuilding, renovating, or improving the existing fleet of icebreakers for operation by the Coast Guard,

(ii) constructing new icebreakers for operation by the Coast Guard, and

(iii) any combination of the activities described in clauses (i) and (ii), to carry out the missions of the Coast Guard; and

(B) conduct an analysis of the impact on mission capacity and the ability of the United States to maintain a presence in the Arctic regions through the year 2020 if recapitalization of the icebreaker fleet, either by constructing new icebreakers or rebuilding, renovating, or improving the existing fleet of icebreakers, is not fully funded.

(2) REPORTS TO CONGRESS.—

(A) Not later than 90 days after the date of enactment of this Act or the date of completion of the ongoing High Latitude Study to assess Arctic ice-breaking mission requirements, which ever occurs later, the Commandant of the Coast Guard shall submit a report containing the results of the study, together with recommendations the Commandant deems appropriate under section 93(a)(24) of title 14, United States Code, to the Senate Committee on Commerce, Science, and Transportation and the House of Representatives Committee on Transportation and Infrastructure.

(B) Not later than 1 year after the date of enactment of this Act, the Commandant shall submit reports containing the results of the analyses required under subparagraphs (A) and (B) of paragraph (1), together with recommendations the Commandant deems appropriate under section 93(a)(24) of title 14, United States Code, to the Senate Committee on Commerce, Science, and Transportation and the House of Representatives Committee on Transportation and Infrastructure.

Northern Waters Task Force Internal Documents and Presentations

Northern Waters Task Force

An Introduction

NWTF: Introduction

The Northern Waters Task Force (NWTF) was created by HCR 22 during the 2010 legislative session.

NWTF: Membership

- The NWTF is comprised of legislators, leaders of Arctic communities, and members of key state and federal agencies.
- Membership includes:

Rep. Reggie Joule
Kotzebue, Chair

Sen. Bert Stedman
Sitka, Vice-Chair

Sen. Lyman Hoffman
Bethel

Rep. Bob Herron
Bethel

NWTF: Membership

DEC Commissioner
Larry Hartig

Mayor Edward Itta
North Slope Borough

Chris Hladick
Unalaska City Manager

Mayor Denise Michels
Nome

Chuck Greene
Vice-President, NANA Corp.

Dave Kubiak
Alaska Marine
Conservation Council

Alternates: Sen. Donald Olson; Rep. Bryce Edgmon; Richard Glenn, *Arctic Slope Regional Corp*oration; Commissioner Cora Campbell, *Alaska Dept. of Fish & Game; Rear Admiral Ostebo, Federal Liaison*

NWTF: Duties

- According to the resolution the task force will:
  - Create a state and federal commission responsible for overseeing development
  - Facilitate regional coordination, cooperation, and outreach in creating a commission to keep local stakeholders informed and able to engage
  - Identify and coordinate efforts of mutual concern for federal, state, local and international agencies
  - Conduct hearings in the northern region of the state to fulfill the above purposes

NWTF: Meetings

- Past Meetings
  - Anchorage- October 1st, 2010
    - *Introduction of issues and organizational meeting*
  - Barrow- December 2nd-3rd, 2010
    - *Local, regional and international perspective on the Arctic*
  - Juneau - March 14th, 2011
    - *Organizational meeting*

- Upcoming Meetings
  - Girdwood – June 19th-21st
    - *Arctic Imperative*
  - Kotzebue and Nome – July 5th-6th
  - Unalaska – August 24th-27th
  - Bethel – October

On the web at *www.housemajority.org/joule*

NWTF: Why monitor the Arctic?

- Loss of sea ice has led to increased human activity in the Arctic and has raised a variety of concerns about future development
- Forecasts predict the possibility of an ice-free Arctic within 20-30 years
- An ice-free Arctic would create new challenges and opportunities for
    - Arctic inhabitants
    - Communities
    - State of Alaska
    - United States
    - other countries

NWTF: Areas the task force is addressing

- Arctic Governance
- Oil, Gas and Mineral Development
- Arctic Fisheries
- Marine Transportation
- Arctic Research
- Arctic Infrastructure

NWTF: Arctic Governance

- The United States is an Arctic country by virtue of Alaska's geography
- Eight countries have territory north of the Arctic Circle
  - Finland
  - Sweden
  - Iceland
  - United States
  - Canada
  - Russia
  - Norway
  - Denmark (Greenland)
- The last five countries are on the Arctic coast

NWTF: Indigenous Engagement

- Seven of the eight countries in the Arctic are home to indigenous peoples.

- The indigenous populations have a unique and vast knowledge of the Arctic region and environments developed over a long period of time.

NWTF: Questions to Consider

- How does the US govern the Arctic internally while cooperating with the state and local Arctic communities and peoples?

- How do we govern the Arctic region cooperatively
  with other Arctic nations?

NWTF: Oil, Gas and Mineral Exploration

- A 2008 US geological survey estimates 13% of the earth's undiscovered oil reserves and 30% of the undiscovered gas reserves are in the Arctic.
- The majority of the oil is likely be offshore.
- <u>In perspective, this equates to:</u>
  - 90 billion barrels of oil
  - 1,700 trillion cubic feet of natural gas
  - 44 billion barrels of natural gas liquids

NWTF: Question to consider

- How do we develop our resources responsibly while maintaining sustainable environments and thriving Arctic communities?

- How do we develop Arctic resources cooperatively with other nations

  while maintaining sustainable environments and thriving Arctic communities?

NWTF: Arctic fisheries

- Alaska and the Arctic contain some of the worlds largest and most valuable fisheries.

- Scientists are discovering that a number of sub-arctic species, such as cod, herring and pollock,

  are expanding their habitation further north and creating commercial fishing opportunities.

- The North Pacific Fisheries Management Council currently bans commercial fishing in the Arctic.

NWTF: Question to consider

- Should commercial fishing be banned in the Arctic?
- Who will manage and monitor Arctic fisheries for sustainability?
- How would you manage an Arctic Ocean fisheries management area with other countries?

NWTF: Marine Transportation

- Diminished sea-ice has led to increases in commercial shipping on two trans-Arctic sea routes.
- An estimated 6,000 individual vessels operate in the Arctic (2009, AMSA).
- Tourism and passenger vessels visits are increasing.
- In 2007, an estimated 2.4 million cruise ship passengers traveled to Arctic destinations.

NWTF: Question to consider

- Who will govern shipping, security and safety in the Arctic Ocean?
- How do you govern shipping cooperatively with other nations?

NWTF: Infrastructure

Arctic Infrastructure Investment and Long-term Planning

The increase in human activity will require new infrastructure to support increased activities in

- fishing
- oil and gas development
- marine transportation

NWTF: Question to consider

- What infrastructure is needed to support increased activity in resource development, transportation, fisheries and national security?
- How can the infrastructure development be accomplished cooperatively with local communities to meet everyone's needs?
- Who is responsible for long-term planning and monitoring?

NWTF: Research

- What research needs to be done to ensure sustainable development while protecting the region?
- How do we work collaboratively with other Arctic countries on research to obtain the best available data?
- How do we decide what research is important?
- What research is still missing?

Question motivating workshop: What are the existing and future challenges in coordinating and managing multiple uses of the Chukchi and Beaufort Sea and how might different ways of working together affect our success?

Strengthening Institutions Workshop Model 1: Alaska Ocean Management at Present

Context of this institutional alternative: Across the U.S., the management systems related to balancing human uses of the U.S. marine environment are maintained by separate agencies and their mandates within defined jurisdictions, typically related around sectors (e.g., fishing, oil and gas, etc.). Feedback from stakeholder groups is similarly clustered among sectors, rather than across the system as a whole. This pattern of agencies and stakeholders creates some efficiency with regard to decisions on individual projects and permits, but also requires supplemental rules dealing with competing or incompatible uses and may duplicate some types of public participation. At the same time, cooperative arrangements such as the Alaska Eskimo Whaling Commission Conflict Avoidance Agreement and others have arisen over time to fill in management gaps where specific coordination is needed. This alternative describes the existing Alaska Coastal Management Program and the other agencies and institutions responsible for managing and conserving ocean resources.

Alaska Ocean Management at Present: the State convenes

What is the focus?
The focus of collaboration in the present-day is to maintain a networked approach to balancing human uses of the environment through existing regulatory programs. The Alaska Coastal Management Program (ACMP) is a hub through which allowable uses are permitted and evaluated for impacts against coastal resources. As new challenges (e.g., climate change and Endangered Species Act-listed species) have arisen or agencies are directed to operate at a landscape scale rather than an agency or species-scale, new collaborative structures have formed to promote close cooperation of agency research efforts along the coastal zone (e.g., North Slope Science Initiative, climate change landscape cooperative – though these efforts focus mostly on terrestrial resources).

Who collaborates and how?
DNR's Division of Coastal and Ocean Management (DCOM) is the hub of the network, linked to state and federal agencies such as: the Bureau of Ocean Energy Management, the National Oceanic and Atmospheric Administration, the Alaska Department of Fish & Game, Alaska Department of Environmental Conservation, U.S. Fish & Wildlife Service, the Environmental Protection Agency, the Coast Guard, and the Department of Defense. Coastal districts are then linked into the process through ACMP coastal management plan development and ACMP consistency

reviews of proposed projects. Many existing institutions (laws, policies and regulations) require or otherwise allow coordination across agencies, such as the Outer Continental Shelf Lands Act, the Coastal Zone Management Act, the Clean Air Act, the Clean Water Act, etc. The state receives notices, along with the other agencies, of proposed federal actions that allow agencies with different mandates and expertise to weigh in on the nature and probability of any adverse impact. Consistency across the whole network (DCOM and linked agencies) could be guided by the Governor's Ocean Policy Coordinator but this position has not been staffed in recent years.

The network links its planning and decision-making process to multiple sources of research and information relating to marine science and knowledge of human uses of the seas. Specific types of development projects, or specific permits, require monitoring of environmental quality as a condition of approval.

Two key processes involve participation of local coastal jurisdictions. The first is the development of a local coastal plan. Local coastal plans are created to guide development and conservation, and submitted to the Alaska Coastal Management Program for approval. District plans include enforceable policies and may contain designated areas that are to be conserved for subsistence or other sensitive resources. Once the plan is approved, the consistency review process becomes the main vehicle for coordinating management. The consistency review process uses local coastal plans in force and other data sources to evaluate the compatibility of proposed development and uses with existing lawful uses of the marine environment or desired uses. Even if a coastal district does not have a plan in force, some deference is given to issues of local concern, if the issue is documented in writing, is not already adequately governed by state or federal authorities, and the local district has demonstrated expertise. The consistency review process is designed to build understanding and consensus. Projects that are found to be inconsistent at the local level can be appealed through the Coastal Management Program within the Division of Coastal and Ocean Management. Coastal districts that disagree with a consistency determination may also file an appeal. Both type of appeals are heard by the DNR Commissioner.

In addition to specific project reviews, coastal districts are involved in the Alaska Coastal Management Program Working Group made up of eight agency representatives, six Department of Natural Resources division contacts, and four coastal resource district representatives. The working group meets via teleconference monthly to disseminate information, discusses interagency disagreements, and coordinate assistance to the coastal districts.

Why collaborate?

The collaborative nature of the ACMP is designed to allow Alaska and local regions to air their views related to federally-permitted activities within the coastal zone. Other agencies are brought into the network as needed for their input and/or approval. A key benefit to the consistency review is to balance development and

conservation needs along the coast, to build consensus and reduce conflict relating to coastal development. The development of coastal plans is geared towards building consensus on priorities at the local, regional, and state level but the process also fosters open dialogue related to which activities are deemed to be incompatible. Through this aspect of collaboration, future decision-making is expected to be less contentious.

How are conflicts resolved?
During implementation of the consistency review process, conflicts between local coastal districts and the Division of Coastal and Ocean Management are resolved through an internal appeals process, and if that does not resolve the issue, through elevating decisions to the Commissioner's Office.

Question motivating workshop: What are the existing and future challenges in coordinating and managing multiple uses of the Chukchi and Beaufort Sea and how might different ways of working together affect our success?

Strengthening Institutions Workshop Model 2: Co-management plus

Context of this institutional alternative: Whaling communities have been responsible for regulating their bowhead whale subsistence hunts since 1986 through a cooperative agreement with the National Oceanic and Atmospheric Administration. As development activity, vessel traffic and research has increased in the Beaufort and Chukchi Seas, the AEWC have taken on more responsibility in making sure that incompatible activities are separated either in space or time through voluntary agreements with private sector interests (e.g. oil and gas companies). These agreements (for all subsistence-hunted marine mammal species) in turn allow the National Marine Fisheries Service, the U.S. Fish & Wildlife Service and the Bureau of Ocean Energy Management, Regulation and Enforcement to make required findings through their regulatory processes that subsistence is not impacted by development activities. AEWC Chairman Harry Brower Jr. has described these coordination agreements (Conflict Avoidance Agreements) as a type of marine spatial planning. This alternative builds on the CAA as a mechanism for coordinating human uses in the marine environment, but also strengthens consultation and adds an expanded monitoring program.

Co-management plus: the Arctic Seas Council Convenes

What is the focus?
The focus of collaboration in this alternative is twofold: coordinating multiple uses of the marine environment and building a hub for ecosystem-based monitoring.

Who collaborates and how?
In this alternative, a co-management organization similar to the Alaska Eskimo Whaling Commission, coordinates human uses of the Beaufort and Chukchi Seas that may affect subsistence by establishing a linked but separate organization to hold pre and post-open water season meetings dedicated to coordination of uses in the Beaufort and Chukchi Seas. Pre and post-open water meetings would become formalized through MOUs as the primary venue for coordination across marine species, government agencies, the private sector, and researchers. In these two meetings, the AEWC commissioners are joined by Beaufort and Chukchi village representatives from the Eskimo Walrus Commission, the Nanuuq Commission, the Ice Seals Committee, the Alaska Beluga Whale Committee, representatives of each village tribal government, the North Slope Borough, the Northwest Arctic Borough, and the North Slope Borough Science Advisory Committee. The new group takes the name, "The Arctic Seas Council" to reflect their broad mandate and vision focused around ecosystems rather than species.

The subsistence rights-holders would have voting rights, the other members would be observers. The Arctic Seas Council would standardize the Conflict Avoidance Agreement (CAA) process to engage in pre-open water season consultations in a timely and predictable fashion. All companies, agencies and researchers requiring a CAA or a Plan of Cooperation (POC) would be expected to apply by a set deadline, and the group would consider all of the activities together. In the past, many companies, agencies and researchers have waited too long to engage in the process, requiring a lot of ad-hoc meetings in the spring subsistence season. As this season is an important one for preparing for whaling, walrus hunting and ice seal hunting, standardizing the process allows everyone greater time to focus on their preparations. The final agreed CAA could then be taken to individual villages for their approval.

In the pre-open water meeting, the Arctic Seas Council would review development proposals, vessel tracking, whaling GPS data, marine mammal tagging data and other information to support decision-making related to solving spatial or temporal conflicts between proposed uses. If desired, the resulting areas and strategies for avoiding conflict could be converted into a GIS format and distributed to each party in an appropriate format.

The post-open water season meeting would be convened by the Arctic Seas Council and cooperating federal and state agencies as a public meeting. Results of activities would be discussed and monitoring systems would be evaluated. Changes in the next year's CAA would be discussed and recommendations prepared for the next year's pre-open water season meeting.

In order to foster ecosystem-based management and adaptive management, the Arctic Seas Council database could become a common gathering point for integrating scientific data across monitoring schemes and traditional knowledge studies. A scientific and traditional knowledge working group would be kept apprised of monitoring and synthesis efforts across agencies and organizations. This work would also be coordinated with the Canadian Beaufort Sea Partnership and Russian marine scientists. This working group could also be convened with additional experts to create decision support tools or answer other questions. The AEWC science hub could be funded as a research center similar to the Alaska Climate Center recently developed by the Department of the Interior.

Why collaborate?
Collaboration can help to avoid conflicts over subsistence resources and other activities, helps to protect community well-being, avoids incompatible activities, and provides more certainty for communities and industry by working out compromises in advance. For instance, the reduction of shipping vessel speed and coordination of ship movements conserve both bowhead whales and community access to whales. In exchange for standardizing the CAA process across sectors, both industry and subsistence hunters could gain a higher level of certainty.

How are conflicts resolved?
Any conflicts arising during deliberation on the Conflict Avoidance Agreement would be solved through consensus. If the group is unable to reach consensus, each private sector stakeholder who requires a CAA would need to sign CAAs with all parties separately.

Question motivating workshop: What are the existing and future challenges in coordinating and managing multiple uses of the Chukchi and Beaufort Sea and how might different ways of working together affect our success?

Strengthening Institutions Workshop Model 3: Marine Systems Knowledge Cooperative

Context of this institutional alternative: At present, the governance systems managing human uses of the U.S. marine environment are fragmented along agency and jurisdictional lines and are often out of sync with spatial and temporal characteristics of the marine system[1]. In a sector by sector approach, the impacts of one sector on another are only considered implicitly and often resolved politically without full information. In an ecosystem-based management approach, tradeoffs between sectors can be made explicit and transparently evaluated. This alternative builds on the National Ocean Council Priority Objectives for strengthening the knowledge base in Alaska to conserve resources but also for adapting to climate change, ocean acidification, changing transportation issues, and responding to emerging national security requirements and foreign policy goals unique to the Arctic.

Marine Systems Knowledge Cooperative: NOAA Convenes

What is the focus?
The focus of collaboration in this alternative is to build a more systematic approach to understanding and predicting change in the Beaufort and Chukchi Seas and to use the growing knowledge base to understand and manage trade-offs.

Who collaborates and how?
In this alternative, NOAA convenes an advisory group made of up of four major groups with management responsibilities or vested interests: 1) federal and state agencies, 2) Alaska Native village councils and major organizations, 3) industry, and 4) NGOs. The Advisory group would take the name, "Marine Systems Knowledge Cooperative". The group would establish a research cooperative, drafts a set of priority research questions, and creates a work plan and budget plan to oversee the development of an integrated assessment of the baseline conditions found in the Chukchi and Beaufort Seas. The assessment is conducting using existing authorities. Establishment of baseline conditions would help stakeholders understand the ecosystem, investigate the resilience and vulnerability of the area and use that information as a decision-making tool.

---

[1] Crowder, L.B. et al. 2006. Resolving mismatches in U.S. ocean governance. Science 4(313):617-618

Meetings of the advisory group would be held biannually at first, but emergency meetings could be called at the request of the chairman. The meetings would be run by consensus, and where consensus isn't possible, through strong majority voting.

In order to foster ecosystem-based management and adaptive management, a scientific and traditional knowledge working group would keep track of monitoring and synthesis efforts across agencies and organizations, coordinated with the Canadian Beaufort Sea Partnership and Russian marine scientists. This working group could also convene with additional experts to create decision support tools or answer other questions.

Why collaborate?
Collaboration would bring knowledge from different sectors, agencies and sources to bear on important questions relating to management under current and future challenges and uncertainties. Together with the science and traditional knowledge working group, the advisory council builds a stronger knowledge base to conserve resources and sustainably exploit others, better understand the resilience of coastal communities, and avoid incompatible activities. By pooling resources and focusing on high priority research areas, the advisory council would be able to leverage cooperation and expected gains into successful federal grants in an era of dwindling funding.

How are conflicts resolved?
Any conflicts arising during deliberation on the strategic plan would be solved through consensus, and if not achievable, then by a strong majority vote. Reports of the science and traditional knowledge working group could be published independent of the advisory council's review.

Question motivating workshop: What are the existing and future challenges in coordinating and managing multiple uses of the Chukchi and Beaufort Sea and how might different ways of working together affect our success?

Strengthening Institutions Workshop Model 4: Regional Ocean Roundtable

Context of this institutional alternative: At present, the governance systems managing human uses of the marine environment are fragmented along agency and jurisdictional lines and are often out of sync with characteristics of the marine system[2] and priorities of local stakeholders. Feedback from stakeholder groups is similarly fragmented among sectors, and not across the (social and ecological) system as a whole. Using a marine spatial management approach, tradeoffs between sectors can be made explicit and transparently evaluated. This alternative builds on the existing Alaska coastal management program to strengthen the cross-scale (local, regional, state, and federal) cooperative management structure that allows local and regional expertise to guide the evaluation of trade-offs and relies on democratic deliberation to guide management decision-making.

Regional Ocean Roundtable: Chukchi and Beaufort Seas Regional Roundtables Convene

What is the focus?
The focus of collaboration in this alternative is to build an inclusive advisory body to:

1. serve as a venue for updating local coastal plans through new sources of data
2. to reduce conflict with a new decision-making process and
3. to guide future planning efforts.

Who collaborates and how?
In this alternative, each coastal region establishes a collaborative advisory body, the Regional Ocean Roundtable, made up of:

- borough representatives,
- Alaska Native government entities (village councils, regional tribal organizations, co-management groups),
- state and federal agencies

The advisory body's purpose is to plan for better coordination of compatible uses of the marine environment. The group establishes a research agenda to:

1. update the inventory coastal and marine resources in the coastal district areas and adjacent waters that affect the area by supporting the using ShoreZone mapping and data collection effort for the region,

---

[2] Crowder, L.B. et al. 2006. Resolving mismatches in U.S. ocean governance. Science 4(313):617-618

2. expand the determination of human uses that occur in the coastal districts and adjacent waters through research that integrates Indigenous science, and traditional knowledge, and

3. adopt an existing or develop a method of explicitly evaluating effective ways to balance resource development.

The group links its planning and internal decision-making process to an existing marine science knowledge network (e.g., NSF-funded, UAF, NPRB, AOOS and/or other groups) that is broadened to include Indigenous scientists and traditional knowledge holders.

Including methods for monitoring efforts in the planning and decision-making process allows decision-makers to more accurately predict and evaluate impacts from development or other human uses of the marine environment. This planning and research approach is accomplished using existing authorities. Local coastal plans are revised using updated data, and submitted to the Alaska Coastal Management Program for approval. A new regulatory process is introduced that requires approval from the DNR Commissioner within 45 days, with an appeal process back to the Chukchi or Beaufort Regional Ocean Roundtable within a 90-day period if the Commissioner does not approve the plan.

The new plans aim to guide decision-making, and regulatory bodies agree to adhere to the plan to the greatest extent possible, given existing authorities. The consistency process uses the plans to identify issues of local concern and evaluate the compatibility of proposed development and uses with existing lawful uses of the marine environment or desired uses either in time or in space. The area designation process is strengthened to allow for more deference to local concerns.

Meetings of the Regional Ocean Roundtable are held quarterly during planning stages. The meetings would be run by consensus, and where consensus isn't possible, through strong majority voting. Once the plan is approved, the consistency review process remains the main vehicle for coordinating management. Pre-consistency review assistance meetings are held for large or controversial projects and involve the advisory body as well as the project proponent. These meetings are designed to build understanding and consensus. Projects that are found to be inconsistent at the local level can be appealed to the Alaska Coastal Management Program within the Division of Coastal and Ocean Management. The Regional Roundtable is connected to state and federal agencies and to the National Ocean Council to coordinate across jurisdictions.

Why collaborate?

Collaboration brings knowledge from different sources of expertise to bear on important questions relating to ocean conservation. Together with the marine science, Indigenous science and traditional knowledge networks, the Regional Ocean Roundtable builds a stronger knowledge base to conserve resources and sustainably and safely develop others, better understand the priorities and values of

coastal communities, and avoid incompatible activities. By using the planning stage to build consensus on priorities, making sure there is transparency in the process by which activities are deemed to be incompatible, future decision-making could reduce conflict and enable greater certainty.

How are conflicts resolved?
Any conflicts arising during deliberation on the coastal district management plan would be solved through consensus, and if not achievable, then by a strong majority vote. During implementation of the consistency review process, conflicts between local coastal districts and the Division of Coastal and Ocean Management are resolved through consensus, or, if required, by elevating decisions to the Commissioner's Office. Any conflicts arising during deliberation on the coastal district management plan would be solved through consensus, and if not achievable, then by an appeals process to the Commissioner's office, and finally, to the Chukchi or Beaufort Regional Ocean Roundtable.

Question motivating workshop: What are the existing and future challenges in coordinating and managing multiple uses of the Chukchi and Beaufort Sea and how might different ways of working together affect our success?

Strengthening Institutions Workshop Model 5: Coastal Zone Management Plus

Context of this institutional alternative: At present, the governance systems managing human uses of the marine environment are fragmented along agency and jurisdictional lines and are often out of sync with characteristics of the marine system[3] and priorities of local stakeholders. Feedback from stakeholder groups is similarly fragmented among sectors, and not across the (social and ecological) system as a whole. When new or growing uses are introduced into regional waters, managing the seascape often becomes more complex than existing regulatory frameworks are designed to handle. As a result, ad-hoc arrangements often become the standard method of doing business whether or not they are adequate to the task. This alternative builds on the Alaska coastal management program to build a new, comprehensive approach to governing multiple uses of the oceans built through extensive stakeholder engagement and the construction of marine knowledge for decision support tools.

Coastal Zone Management Plus: The State Convenes

What is the focus?
The focus of collaboration in this alternative is to build a comprehensive network of stakeholders, rights-holders and decision-makers to coordinate ocean uses, understand environmental change and create applied science and traditional knowledge-based tools for decision-making.

Who collaborates and how?
In this alternative, the Division of Coastal and Ocean Management is given a new mandate to develop a new way to coordinate competing uses of the ocean. The Division creates three bodies: an advisory body (the Alaska Ocean Advisory Council) of local, regional, tribal and state government officials to create new a new management system, a public-private partnership organization to build public consensus for the goals and process of ocean management (the Alaska Ocean Partnership) and a scientific and traditional knowledge research advisory group (the Alaska Ocean Research Advisory Council). The Ocean Science Advisory Council establishes a research agenda to 1) inventory coastal and marine resources in the coastal district areas and adjacent waters that affect the area using ShoreZone maps for the region, 2) determine which human uses are occurring in the coastal districts

[3] Crowder, L.B. et al. 2006. Resolving mismatches in U.S. ocean governance. Science 4(313):617-618

and adjacent waters through research, and 3) adopt an existing or develop a method of explicitly evaluating trade-offs.

Including monitoring efforts and a broad set of ecological and social indicators in the planning and decision-making process allows decision-makers to more accurately predict and evaluate impacts from development or other human uses of the marine environment. The explicit linkage of monitoring with policy processes allows active adaptive management. Local coastal plans are revised using updated data, and submitted to the Alaska Coastal Management Program for approval.

Meetings of the Alaska Ocean Advisory Council are held monthly during planning stages for a new Alaska Ocean Policy Act adopting a vision, goals, objectives and updated regional coastal district plans. The meetings would be run by consensus, and where consensus isn't possible, through strong majority voting. Once regional plans are approved, the consistency review process remains the main vehicle for coordinating management.

The Alaska Ocean Partnership would hold extensive public input-gathering sessions across the state in open forums, online, and through cross-sectors focus groups to understand the policy preferences of the public and various stakeholder bodies in order to inform the Alaska Ocean Policy Act. Through multi-stakeholder dialogues and outreach, the Partnership builds social capital across sectors and acts as a non-partisan broker of credible science for cooperative ocean management.

The Alaska Ocean Research Advisory Council would convene expert working groups looking at special management issues related to economic, ecological and socio-cultural uses of the oceans. The working groups and the council as a whole would be tasked with documenting baseline conditions, creating monitoring schemes, and constructing decision support tools.

Why collaborate?
Collaboration brings different sectors, stakeholders and knowledge from different sources of expertise to bear on important questions relating to ocean conservation. Together with the Alaska Research Advisory Council and the Alaska Ocean Partnership, the Alaska Ocean Advisory Council builds a stronger knowledge base to conserve resources and sustainably exploit others, better understand the priorities and values of coastal communities, and avoid incompatible activities. By using the planning stage to build consensus on priorities but also the transparency by which activities are deemed to be incompatible, future decision-making is expected to be less contentious.

How are conflicts resolved?
Any conflicts arising during public deliberation on the Alaska Oceans Policy or within the two advisory councils would be solved through consensus, and if not achievable, then by a strong majority vote. A professional mediator could be brought in for seemingly intractable conflicts.

Arctic Deepwater Port Charette
May 16-17, 2011

An Arctic Deepwater Port charette was co-convened by the US Army Corps of Engineers and the Alaska Department of Transportation and Public Facilities on May 16-17, with approximately 35 people representing state, federal, and university interest in attendance. The purpose of the workshop was to scope out the criteria, potential locations, and rationale for a deep draft Arctic port in Alaska. The workshop reflected on the November 2009 and January 2011 Alaska Regional Ports workshops as background for what existing port needs were identified and where future deepwater ports could be sited.

Introductory messages by Colonel Koenig and Commissioner Luiken set the cooperative and collaborative approach of this charette by having both the state and federal government invested in the process. The findings would also provide the needed information for Senator Begich in furthering his package of Arctic bills.

The key elements of the workshop were broken out into sessions of 6 tables with rotating members to discuss and itemize aspects of:

Define Arctic Geography:

Defining the Arctic area of consideration, with many alternatives offered of the area south of the Bering straits. Everyone agreed that North of the Bering Straits was Arctic. It was noted that Nunivak Island needed to be included to the southeast and that Provideniya, Russia offered an international Arctic Port adjoining the area of discussion. With the new SAR mission, Provideniya could be an important bilateral or multi-lateral consideration in defining the geographic realm of an Arctic Port.

Consensus was that the Aleutian Islands Pacific great circle route was generally not to be considered for an Arctic deepwater port, although the point was made that transshipment of goods could be staged from both Dutch Harbor and Adak as deepwater ports on the great circle route.

Arctic Vessel Parameters:

Vessel parameters included the breadth of vessels presently using the Arctic, including the large bulk carriers employed at Red Dog Mine, the large gas liquid concentrates tanker that transited the Bering Straits in 2010, and the small cruise ships that are transiting the Northwest Passage. Research vessels, oil exploration vessels, and other public and military vessels were identified, although the vast majority of the traffic would be for summer, open water use only. The role of tugs and barges for supplying arctic communities was noted as a significant activity that would benefit from increased deepwater port access to improve lightering into the Arctic rivers and shallow coastal areas.

The offshore operations for oil and gas development and the nature of vessels and equipment employed raised the question of whether an Arctic Port would be needed, when the vessels could maintain an Arctic offshore operation without a dependence on a land based facility. The use of gravel islands in Prudhoe Bay was noted.

Port Siting Criteria:

An exercise of the 6 tables identifying 9 primary criteria for siting of an Arctic Port was conducted. These Siting Criteria were: national security, environment, economic development, infrastructure, life safety, sustainability, land ownership, spill response, socioeconomics. While consensus was not arrived at for the individual priorities, general consensus showed that the environmental (physical) conditions at the site were key for both the planning and operation of the site, as well as determining the environmental impacts. This information included weather, ice, mapping and ability for seasonal versus year round use, as well as the distribution of fauna and traditional use patterns. A significant amount of data and models exist that can help define the environmental conditions and consideration for development.

Of these criteria, different interpretations of criteria terms stimulated discussions as to the importance of "life safety" when linked to "national security "and "spill response" or "sustainability" when linked to "economic development, environment, or socioeconomics".

National security, search and rescue, and marine pollution response were rated low priorities by several as wherever a port is built; the respective entities will use it, but will not have the money to invest in the initial development. Creating a national interest would be key for federal investment.

A list of potential sites was developed with options for a matrix of what the site conditions and environmental factors may show, as well as the fit to the key elements prioritized in site selection. 9 sites were easily identified. It was generally agreed that one large port would not be developed, but numerous small sites would be eventually developed with purposes of importing materials, goods and supplies, exporting of natural resources and development or rock and gravel sources.

Potential sites noted in discussions were:

- Merkoryuk on Nunivak Island,
- St. Michaels in Norton Sound above the Yukon River mouth
- Cape Darby for rock and gravel
- Cape Nome for rock and gravel
- Nome with deepening existing port
- Teller and Port Clarence, as deep water shelter south of Bering Straits
- Cape Blossom in Kotzebue Sound
- Delong Mountain Transportation System for the Red Dog mine
- Prudhoe Bay

In addition, the bilateral use of Provideniya, Russia was noted as a marginally functional port at the entrance to the Bering Straits, but relevant for search and rescue under the new Arctic Council SAR Agreement.

The potential for offshore lightering with moorings to improve the efficiency of river transport for support of villages and in development of natural resources and particularly mines well removed from tidewater.

In addition, encouragement was offered by Congressman Young to think "out of the box" and recognize that "saving to prosperity" did not build wealth, but building things and developing resources through investment built wealth.

Steve Borell, Alaska Miners Association presented the development of Arctic minerals and the value of defining a transportation system for transporting minerals from the mine site to tidewater. He detailed his previous studies into a railroad from the Ambler and Northwest Arctic to tidewater in Norton Sound. The essential and cost effective role of rail service from mineral deposits has been proven in remote locations worldwide and could again prove itself in Alaska's Arctic. The challenges of reaching deepwater remain, with Cape Darby in northern Norton Sound offering a conceivable location. Steve concluded that the resources are available, the seasonality of shipments provides a challenge, but the warming of the Arctic and diminished ice cover is allowing for a larger shipping season.

The Charette concluded with thoughts on how to move forward. These included:

- Convene a steering committee to move forward on the findings of this charette and the previous two regional port workshops.
- Plan an industry focused ports meeting to add private development and investment sectors to discuss past studies and identify sites for future studies.
- Review environmental data and model projections for Arctic regions on seasonality.
- Identify projects (low-hanging fruit) that can be developed into a pilot project, including offshore mooring buoys at a resource or lightering location.

A press release has been prepared by ADOTPF and posted at http://www.dot.state.ak.us/comm/pressbox/arch_2011/PR11-2528.shtml.

Materials and reports from the workshop will be posted and join the results from the 2011 Regional Ports Workshop.

Arctic Fisheries

- Fishing moratorium
- Need for research and baseline data collection to inform future decision making

Shipping

- Vessel monitoring and tracking
- What are international search and rescue capabilities?
- What are the Coast Guard's capabilities for search and rescue?
- What are local and state capabilities for search and rescue?
- International shipping rules and agreements
- Navigation aides
- National Security

(These are proposed ideas forwarded by task force members to begin the discussion)

2. Set and finalize hearing schedule:

Bethel

International Forum Girdwood NWTF invited June 20-21st

Kotzebue and Nome: July 5-7th in conjunction with Trade Fair

Unalaska: August 24-26th with the legislative fly-in

Final Recommendations Meeting: September in Anchorage

(4) Conduct hearings in the Arctic & Sub-Arctic regions of Alaska to fulfill its purpose.

The task force will provide final recommendations to the Legislature by January 30, 2012.

Arctic Governance

- Who is making decisions and how does the NWTF get heard
- Laws of the Sea
- Boundaries Disputes
- International agreements for shipping, search and rescue, oil and gas activities and spill response
- What does multi-jurisdictional cooperation in the Arctic look like?
- How does the State of Alaska and its people be heard and involved
- International research agreements and sharing of information
- How does the Arctic Council fit in

Oil and Gas Development and Research

- Proposed development
- Spill response capabilities and technology
- What are Coast Guard capabilities to respond to oil spill?
- What are industries capabilities to respond?
- What are local capabilities to respond?
- Ecosystem research and baseline data

Arctic Infrastructure Investment and Long Term Planning

- What investments need to be made
- Who should be making the investments

The Alaska State Legislature created the Alaska Northern Waters Task Force (ANWTF) in 2010 to assess development of state and federal northern waters.

The Alaska Northern Waters Task Force is comprised of legislators, leaders from Arctic communities, and representatives of key federal and state agencies. Members of the task force are Representative Reggie Joule, Chair; Senator Bert Stedman, Vice-Chair; Representative Bob Herron; Senator Lyman Hoffman; Dept. of Environmental Conservation Commissioner Larry Hartig; North Slope Borough Mayor Edward Itta; Unalaska City Manager Chris Hladick; Nome Mayor Denise Michels; NANA Corp. Vice-President Chuck Green; and Alaska Marine Conservation Council Chair Dave Kubiak. Alternates include Senator Donald Olson; Representative Bryce Edgmon; Richard Glenn from Arctic Slope Regional Corporation and Cora Campbell, Commissioner of Fish & Game.

The task force has held meetings in Anchorage and Barrow to bring together Alaskans and Arctic stakeholders

The duties of the task force are:

(1) Assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;

(2) Facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;

(3) Identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and

October 12, 2011 – The following draft outline is intended to serve as basis for: a) a white paper or letter detailing the State of Alaska's view on Arctic shipping to the CMTS (Committee on the Marine Transportation System) as they work to fulfill a Congressional mandate to help design a shipping regime for the Arctic Ocean, b) potential testimony to the U.S. House Transportation Committee on November 15, 2011, where Lt. Gov. Treadwell has been requested to speak about Arctic Council work on Arctic shipping and the State's view on icebreakers (invitation letter forthcoming), c) potential written testimony to the U.S. Senate Energy Committee (hearing on November 19 or 20, invitation forthcoming, per call from Committee staff 10/11/11).

I. **Introduction – Change is here:** Arctic shipping is coming quickly, because of changes in technology, changes in global markets for natural resources, and changes in Arctic environmental conditions. This year's traffic may total 18 Northern Sea Route voyages of major cargoes.

- **a. Changes in technology:**
  - i. Double ended ships are more efficient icebreakers.
- **b. Changes in global markets for natural resources:**
  - i. European producers are seeking Asian markets.
  - ii. Iron ore in Norway is being shipped to markets in Asia
  - iii. Our own Red Dog Mine lead and zinc serves markets in Asia Europe, and North America and could, theoretically, provide a back haul cargo to Europe on ships traveling the Northern Sea Route.
  - iv. Arctic shipping may provide access to other resources, such as Northwest Alaska coal or North Slope propane.
  - v. Offshore oil exploration in 6 of the 8 Arctic countries is expanding ice operations.
- **c. Changes in Arctic environmental conditions:**
  - i. 2011 was second lowest Arctic ice minimum in recorded history.
  - ii. Navigation through ice cover is much easier with less multi-year ice.

II. **Challenges and opportunities:** the State of Alaska sees these changes in the Arctic as both a challenge and an opportunity.

- **a. One challenge is the current double standard in Arctic shipping in the Bering Sea:**
  - i. Ships engaged in oil and gas exploration or delivering to U.S. national ports are more likely subject to strong regulation by the USCG, EPA and NOAA, but international shipping is less subject to these regulations.
  - ii. We face the prospect of increasing international ship traffic through the Bering Strait with minimal requirements to prepare for oil spills, maintain air quality, or requirements to care for wildlife and subsistence needs.
  - iii. Article 234 Law of the Sea may rectify this situation if the U.S. ratifies. Arctic Council efforts could also help rectify.
- b. **U.S. Arctic policy calls for a shipping regime that is "safe, secure, and reliable."**
  - i. Alaska's efforts towards this goal:
    1. Western Alaska Port Study with Army Corps of Engineers
    2. Marine Pilot Board review of ship safety
    3. State comments on Bering Strait traffic study and co-sponsorship of Aleutian risk-assessment study

4. Potential state financial support for USCG forward basing, hangar/port facilities
5. State financial support for AIS (Automatic Identification System) network placed on Alaska's coast and maintained by Marine Exchange of Alaska
6. Statewide Digital Mapping Initiative supports coastal mapping
7. State sponsored feasibility study for container shipping between Adak and Iceland (2006)
8. Statewide broadband study may identify ways to improve communications capabilities for Arctic operations

ii. Federal government efforts we are watching closely:
1. CMTS charged by 2010 Coast Guard Authorization Act to develop integrated picture of Arctic shipping regime
2. Ocean policy review
3. USCG high latitude study
4. US Navy Arctic road map
5. NOAA bathymetric work in Bering Strait
6. Port Study with Corp of Engineers
7. White House Arctic Policy Implementation Group

iii. International efforts pursued by federal and state governments jointly through Arctic Council process:
1. Implementation of 2009 AMSA recommendations
   a. Arctic nations seek enforceable standards for ship construction through the International Maritime Organization's proposed adoption of the Mandatory Polar Code
   b. Arctic Council's Search and Rescue agreement; implementation exercise in October 2011
   c. Expected oil spill response agreement; negotiations begin in Norway October 2011
   d. Arctic Council's PAME (Protection of the Arctic Marine Environment) working group's proposed ballast water moratorium in Arctic Ocean
   e. Arctic Council's SDWG (Sustainable Development Working Group) Arctic transportation infrastructure study is pending before Senior Arctic Officials
2. U.S.-led efforts to provide notices to mariners in Arctic Ocean
3. U.S. National Ice Center/NOAA/Navy/USGC ice forecasting
4. Weather forecasting improvement sought with greater cooperation with Russia

III. What's missing?

a. Icebreakers:

i. Governor Sean Parnell's testimony to the U.S. Senate Subcommittee on Homeland Security Appropriations, 8/20/09:

> "Melting sea ice and increased military and commercial activity require a greater Coast Guard presence. The Coast Guard needs to move north and improve its capability — our heavy ice-class

icebreakers are on their last legs. To provide homeland security the Coast Guard must have new Arctic-class icebreakers equipped for search and rescue missions, border protection, law enforcement, fisheries enforcement, infrastructure and environmental protection."

1. No action by Congress or Executive branch for new icebreaker capacity
2. Prime Minister Vladimir Putin announced on 9/23/11 that Russia will be building 9 new icebreakers to work toward their goal of making Northern Sea Route as important to commerce as the Suez Canal.

ii. Rep. Young, Sen. Begich announced on 10/11/11 introduction of legislation authorizing Coast Guard to lease and operate two new icebreakers.

b. There have been no substantive U.S. discussions about creating an international commercial regime similar to St. Lawrence Seaway model, whereby two nations commit to infrastructure, safety, and marketing for a joint seaway.

c. There has been no Senate ratification of the Law of the Sea, which guarantees freedom of navigation and allows regulation of ice-covered seas.

IV. U.S. must understand …

a. This is a huge opportunity, and a long time coming.

i. 500 year search for Northwest Passage
ii. 40% distance savings
iii. Good for global environment – use less fuel
iv. Good for global economy – market efficiencies

b. How will U.S. respond to this opportunity?

Joint agreement with Russia on oil spill prevention or pending infrastructure? Joint investment with other Arctic nations?

c. Alaska can help to responsibly take advantage of the opportunities on behalf of the nation

i. Encouraging discussions
ii. On the front lines
    1. Closely watching Korea's plans to ship LNG directly via the Mackenzie Delta
    2. Aleutian ports forming relationship with global shipping community
    3. With Russian energy traveling past, will this allow less expensive energy for Western Alaska?

d. This is an issue of national security:

i. U.S. must have an Arctic presence.
ii. We must have the same USCG protection in the Arctic as in the rest of the nation.
iii. Energy potential:
    1. "Do we want to leave it to the Russians to mind the store?"
    2. Decrease dependency on foreign imports to U.S.

EXECUTIVE OFFICE OF THE PRESIDENT
NATIONAL OCEAN COUNCIL
WASHINGTON, D.C. 20503

December 20, 2010

The Honorable Reggie Joule
Alaska State Legislature
P.O. Box 673
Kotzebue, AK 99752

Dear Representative Joule,

Thank you for your October 26, 2010, letter concerning the recently established National Ocean Council (Council). We appreciate the creation of the Alaska Northern Waters Task Force (NWTF) and the duties it has taken on.

As you know, on July 19, 2010, President Obama signed Executive Order 13547 adopting the *Final Recommendations of the Interagency Ocean Policy Task Force* (Final Recommendations) and directed Federal agencies to take appropriate steps to implement them. As described in the Final Recommendations, the Council's Governance Coordinating Committee (GCC) will consist of eighteen members from states, Federally-recognized tribes, and local government.

The Council has formally requested nominations for the GCC from States, state and local governmental organizations, Federally-recognized tribes, and regional and national tribal organizations. The Alaska Governor's Office has provided nominations for the Alaska representative to the GCC. The Council has also received nominations from the National Conference of State Legislators (NCSL) for the State legislative representative to the GCC. The Council will consider these nominations over the next several weeks along with the nominations received for other GCC seats.

The GCC members will serve one- or two-year terms. While the nomination solicitation process for the first term of GCC membership has closed, there is opportunity for the NWTF to provide input to the Alaska Governor's Office and NCSL on nominees for future terms.

We appreciate your interest in and support for the Council and the National Policy for stewardship of the ocean, our coasts, and the Great Lakes.

Sincerely,

Sherburne B. Abbott
Associate Director for Environment
Office of Science and Technology Policy
Co-Chair, National Ocean Council Deputy Committee

Michael Boots
Associate Director for Land and Water Ecosystems
Council on Environmental Quality
Co-Chair, National Ocean Council Deputy Committee

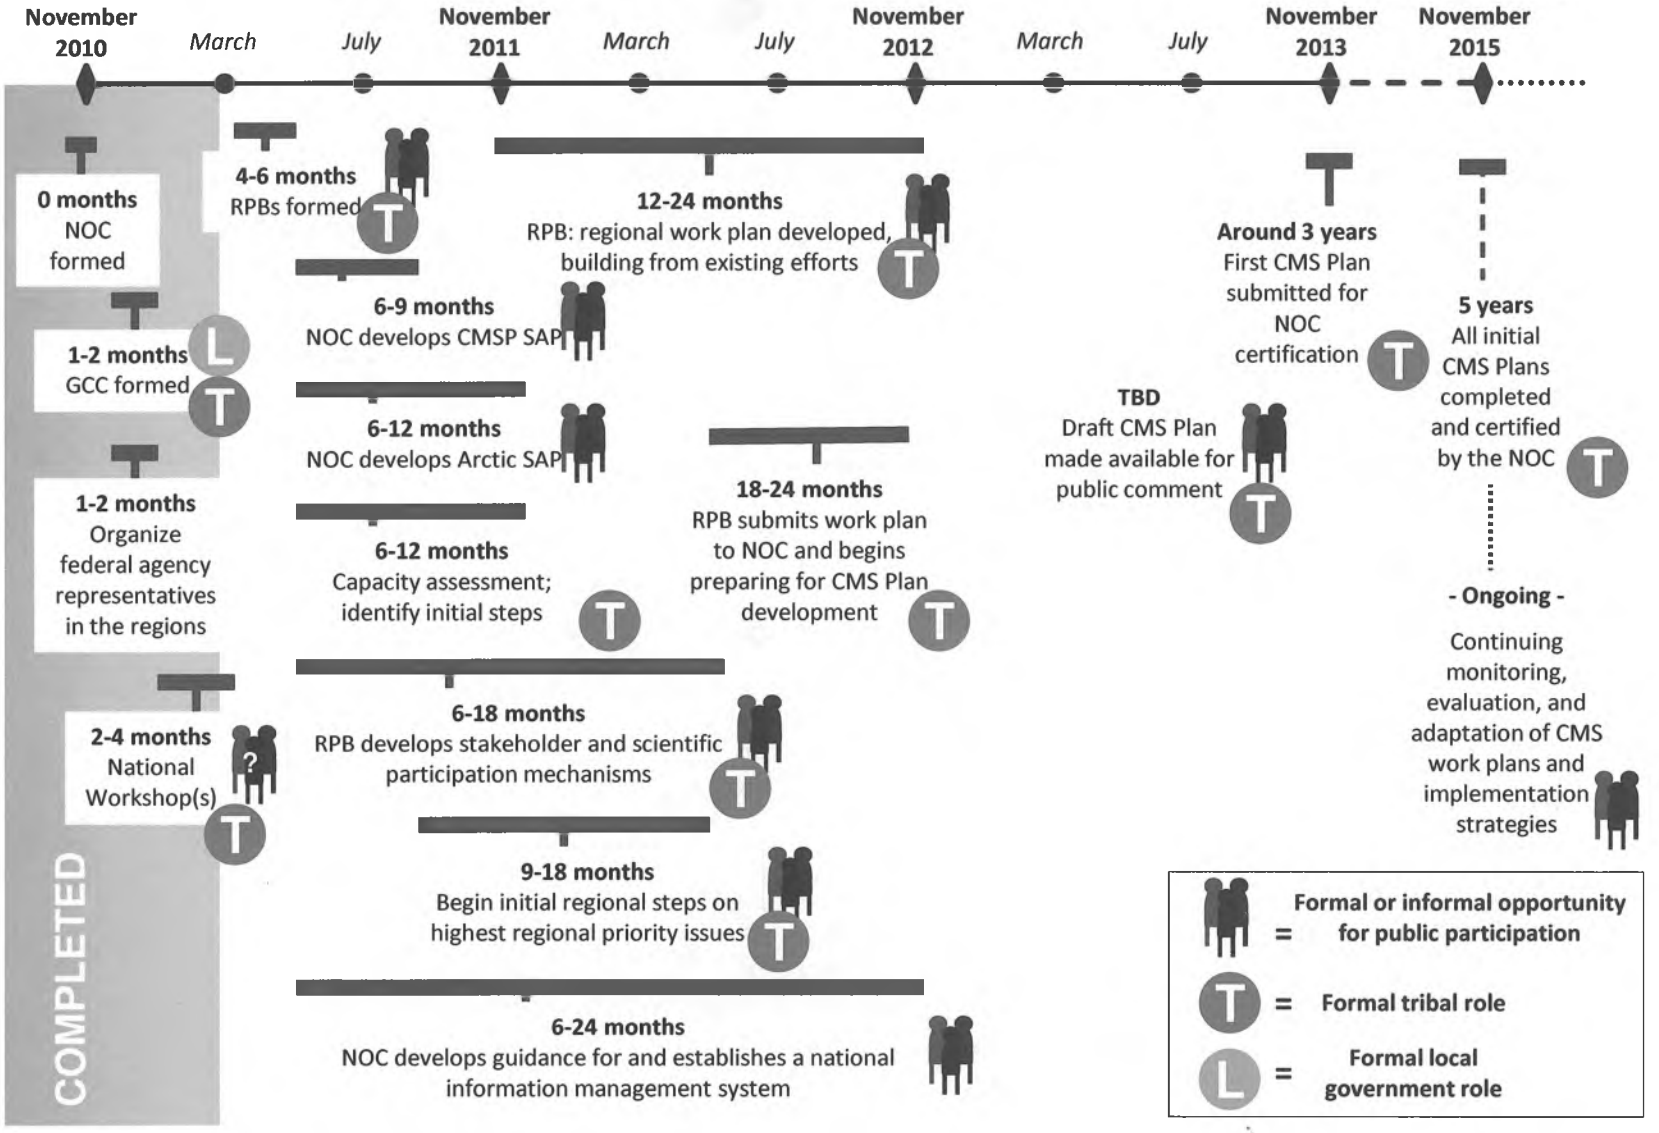
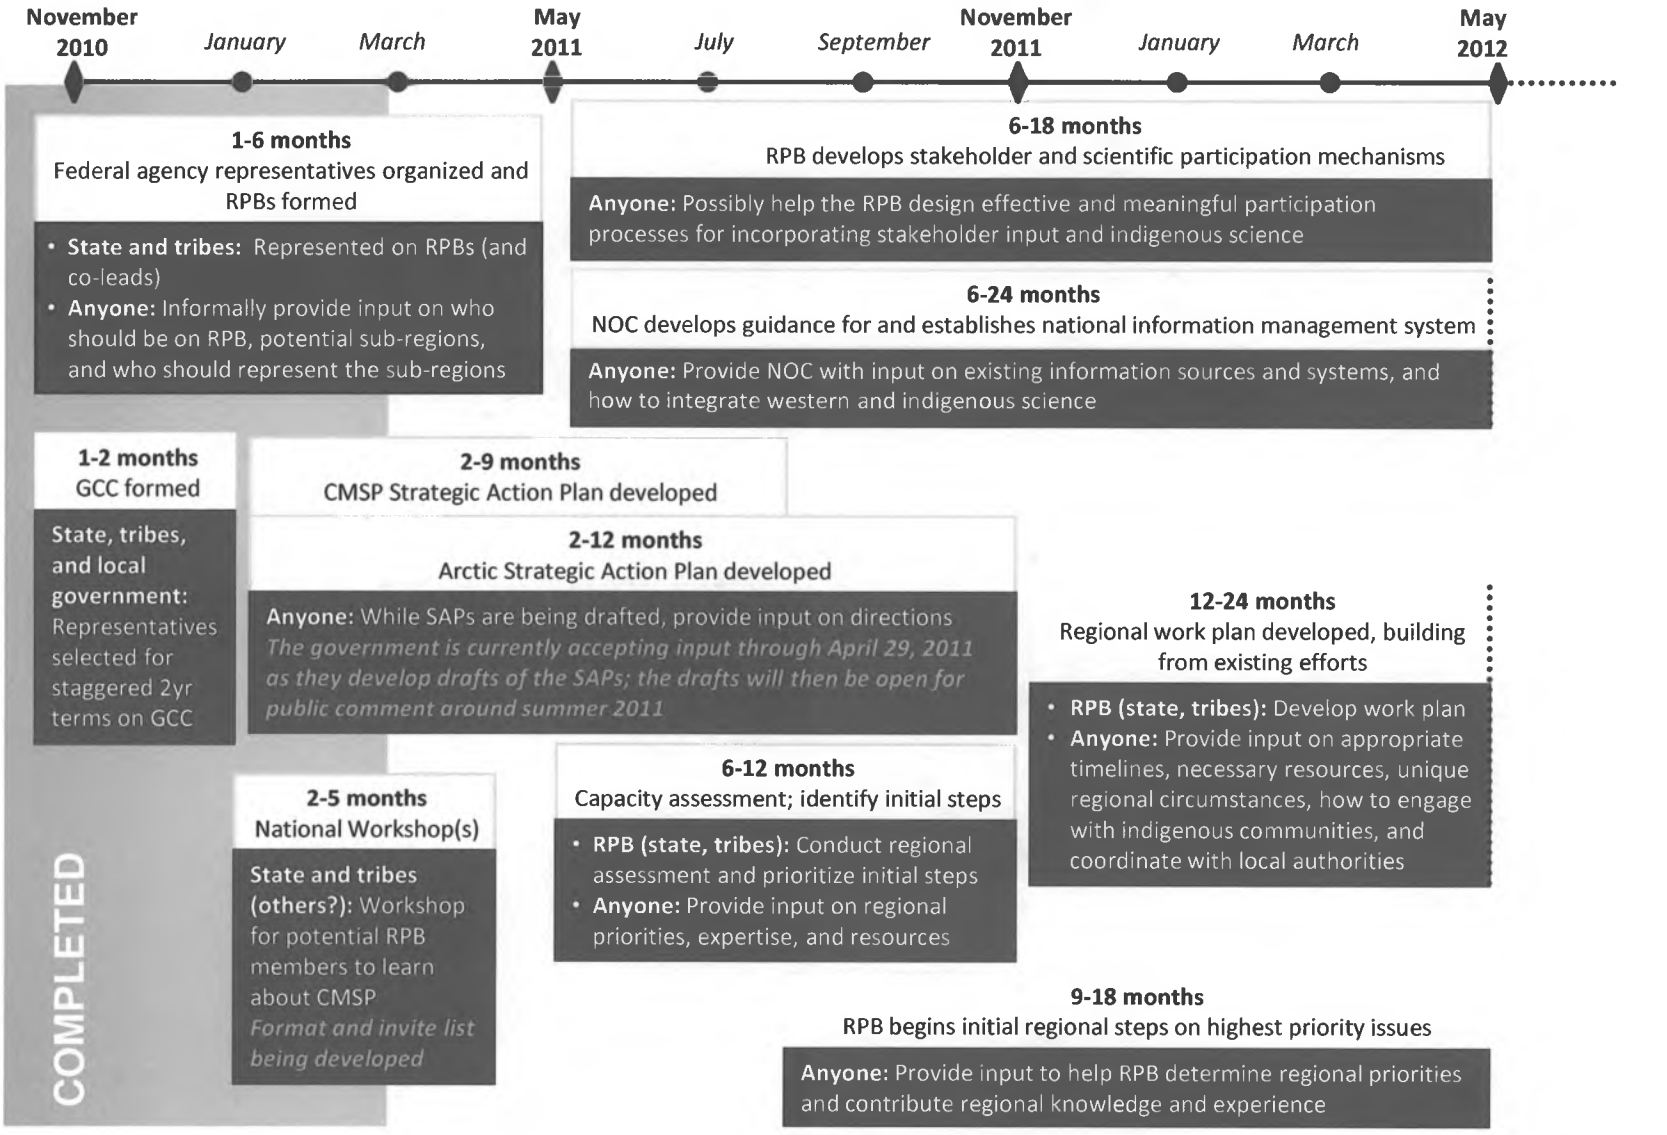
5-YEAR CMSP TIMELINE (AS OUTLINED IN THE FRAMEWORK)

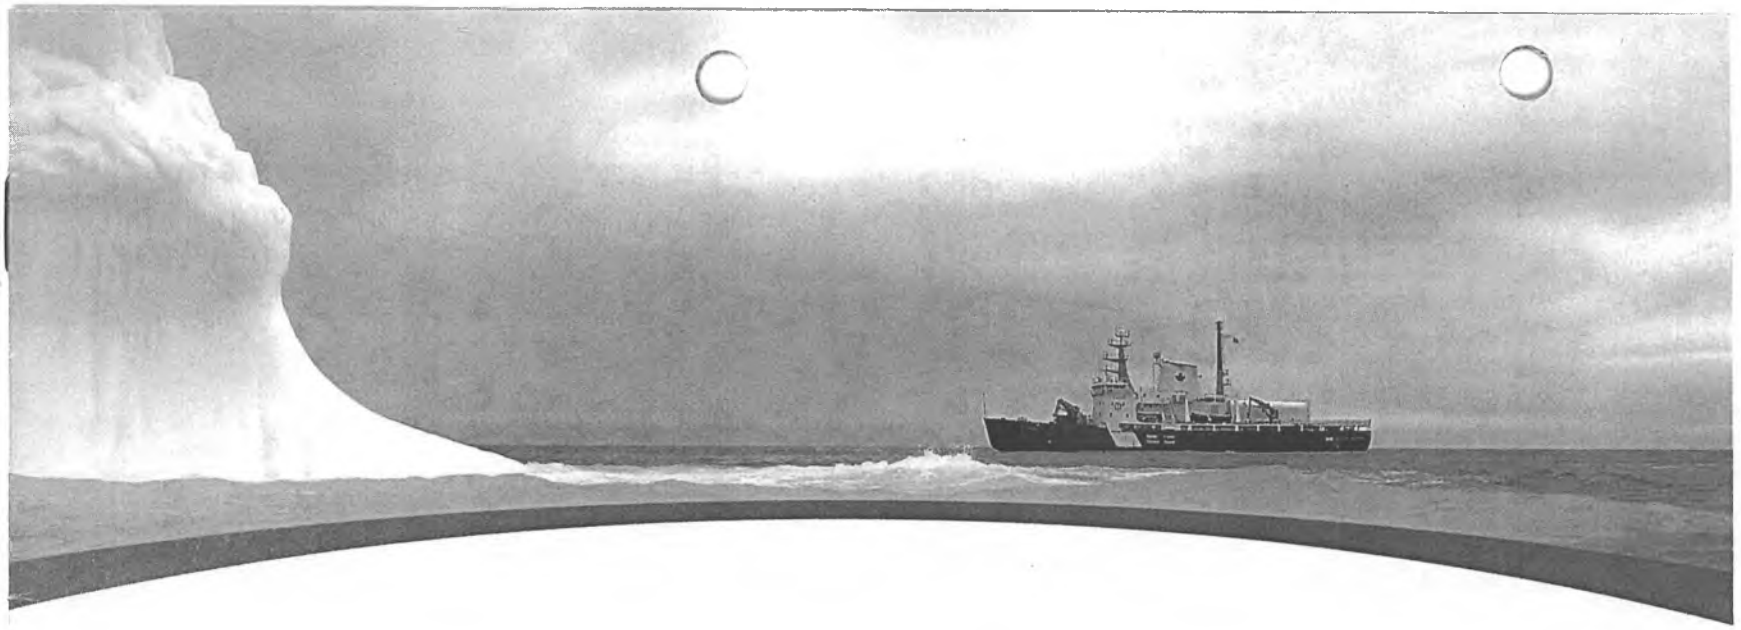
ENVIRONMENTAL LAW INSTITUTE
DRAFT - MARCH 2011



18-MONTH CMSP TIMELINE (AS MODIFIED BY ONGOING PROCESSES)

ENVIRONMENTAL LAW INSTITUTE
DRAFT - MARCH 2011





STATEMENT ON CANADA'S ARCTIC FOREIGN POLICY

Canada's vision for the Arctic is of a stable, rules-based region with clearly defined boundaries, dynamic economic growth and trade, vibrant Northern communities, and healthy and productive ecosystems.

The international dimension of Canada's NORTHERN STRATEGY

Government of Canada / Gouvernement du Canada

Canada

CANADA'S ARCTIC FOREIGN POLICY

provides the international platform from which to project our national interests in the world across all four pillars of the Northern Strategy: EXERCISING OUR SOVEREIGNTY, PROMOTING ECONOMIC AND SOCIAL DEVELOPMENT, PROTECTING THE ARCTIC ENVIRONMENT, AND IMPROVING AND DEVOLVING GOVERNANCE. We will pursue our interests at the international level through leadership and stewardship.

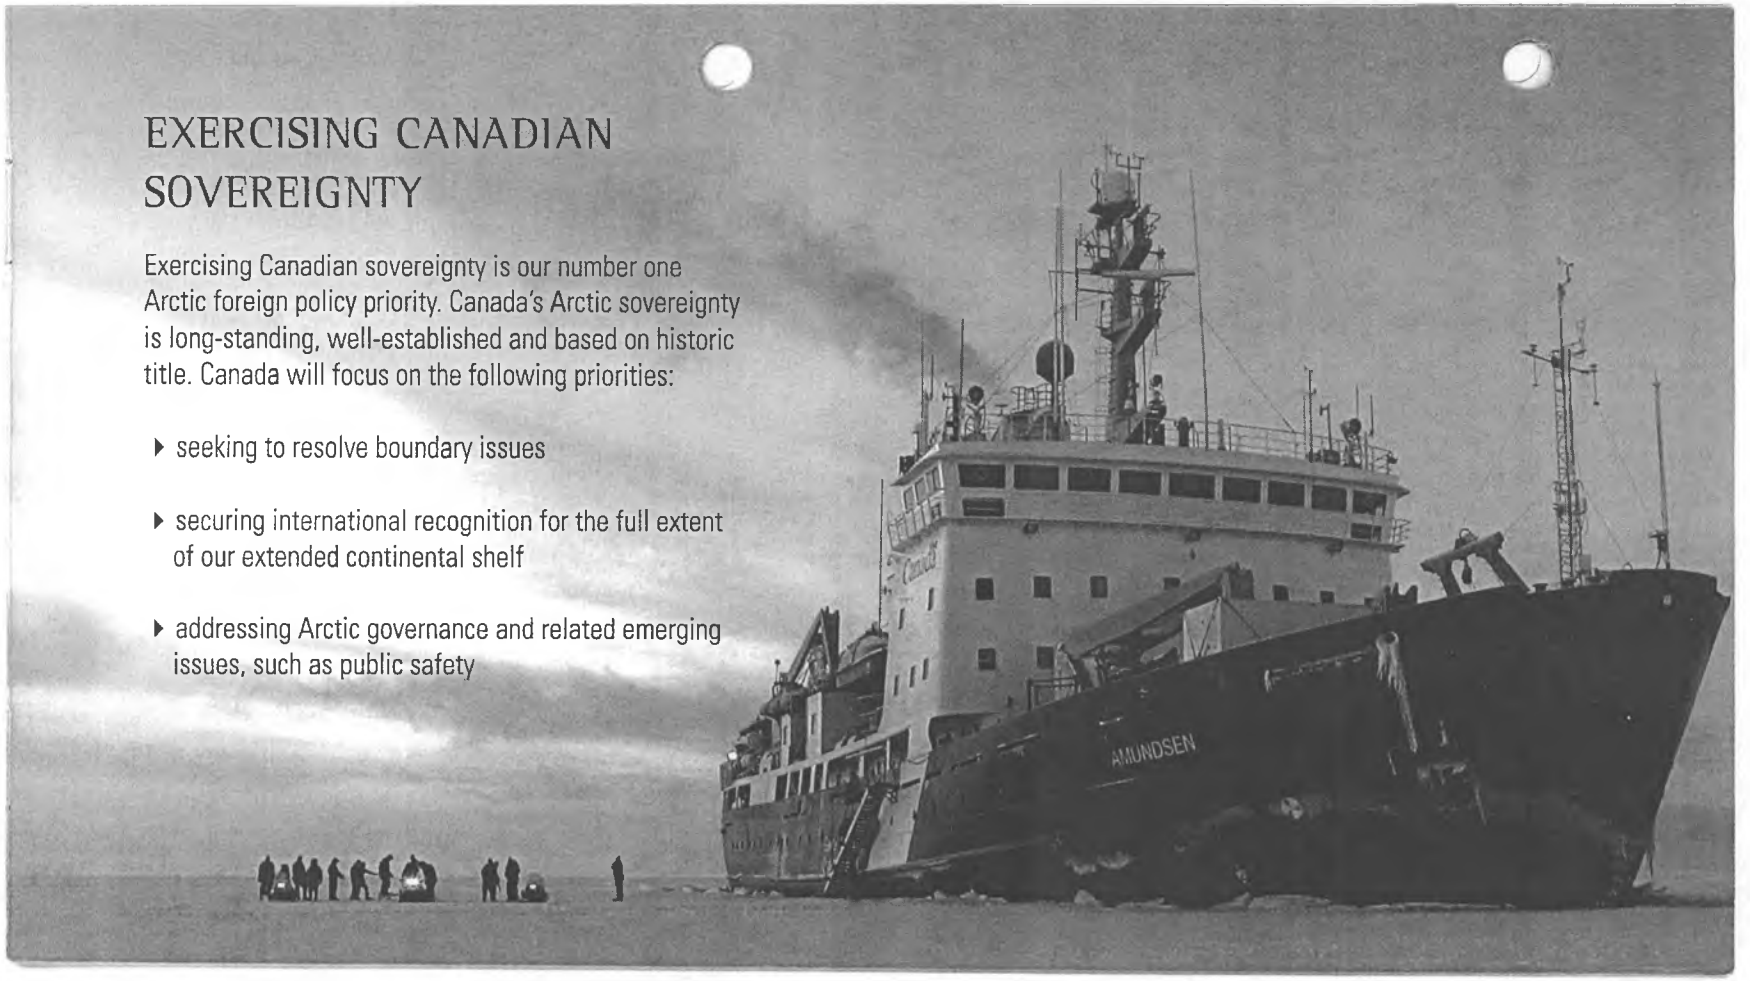
OUR APPROACH

- Canada will show leadership and work with others to demonstrate responsible stewardship to build a region responsive to Canadian interests and values, secure in the knowledge that the North is our home and our destiny.
- Canada will maintain control of our Arctic lands and waters and will respond when others take actions that affect our national interests.
- Canada will never waver from our commitment to protect our North. Cooperation, diplomacy, and respect for international law will remain hallmarks of Canada's approach.

EXERCISING CANADIAN SOVEREIGNTY

Exercising Canadian sovereignty is our number one Arctic foreign policy priority. Canada's Arctic sovereignty is long-standing, well-established and based on historic title. Canada will focus on the following priorities:

- seeking to resolve boundary issues
- securing international recognition for the full extent of our extended continental shelf
- addressing Arctic governance and related emerging issues, such as public safety



PROMOTING ECONOMIC AND SOCIAL DEVELOPMENT

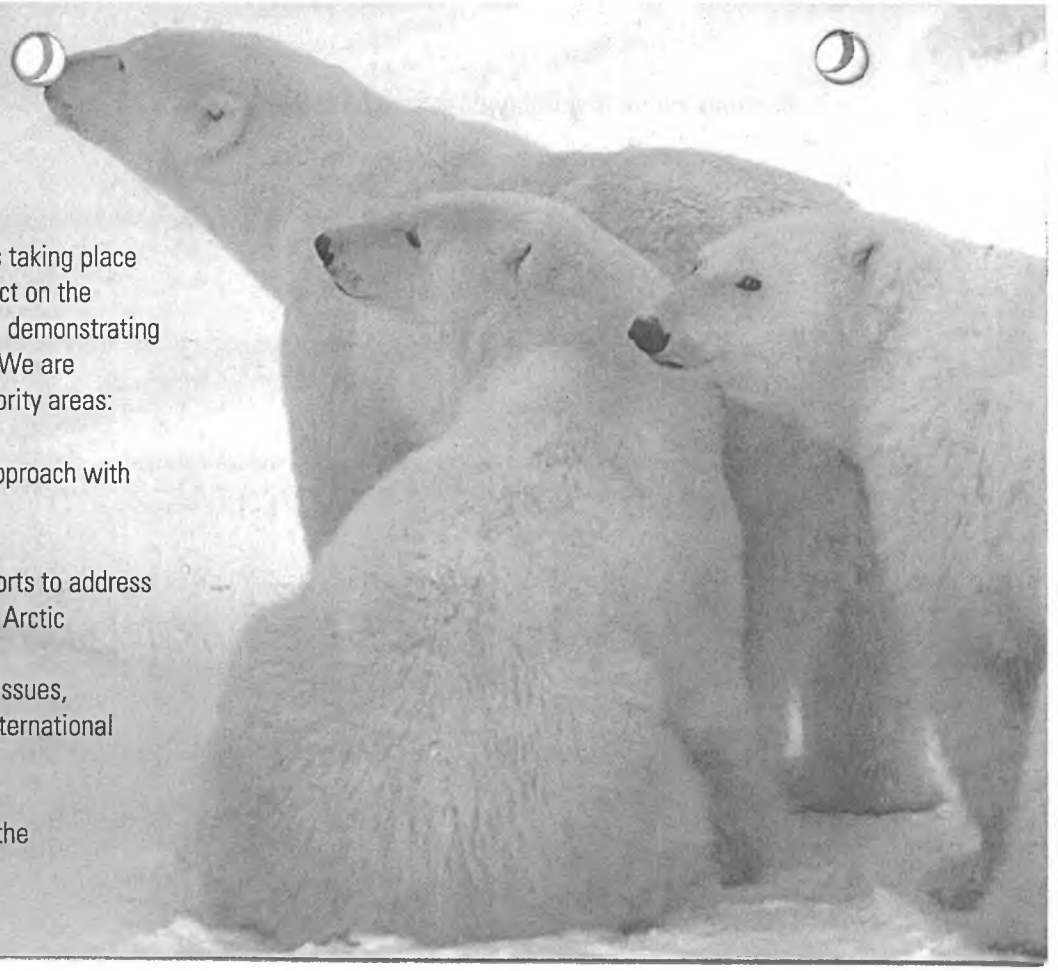
The people of the North are at the heart of Canada's Arctic foreign policy. Canada will actively promote Northern economic and social development internationally on three key fronts:

- taking steps to create the appropriate international conditions for sustainable development in the Arctic region
- seeking trade and investment opportunities that benefit Northerners and all Canadians
- encouraging a greater understanding of the human dimension of the Arctic to improve the lives of Northerners

PROTECTING THE ARCTIC ENVIRONMENT

The Arctic environment is being affected by events taking place far outside the Arctic but having a significant impact on the region's unique and fragile environment. Canada is demonstrating stewardship in this magnificent ecological region. We are pursuing action internationally in the following priority areas:

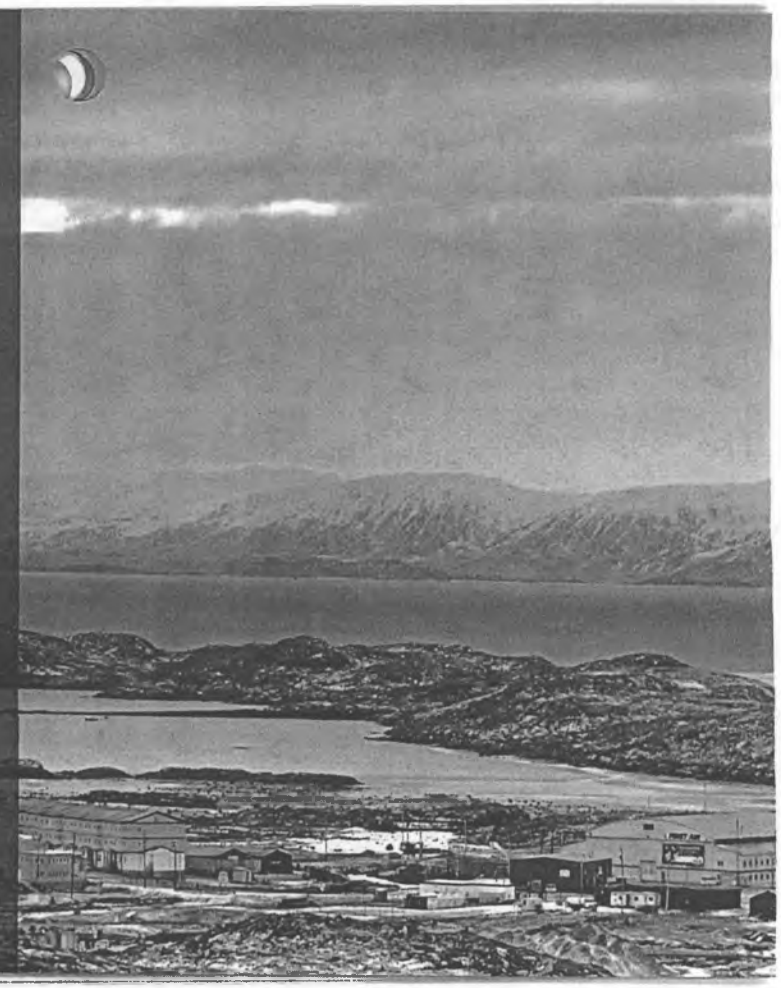
- promoting an ecosystem-based management approach with our Arctic neighbours and others
- contributing to and supporting international efforts to address the causes and effects of climate change in the Arctic
- enhancing efforts on a range of environmental issues, including the promotion and strengthening of international standards
- strengthening Arctic science and the legacy of the International Polar Year



IMPROVING AND DEVOLVING GOVERNANCE

The Government of Canada is committed to providing Canadian Northerners with more control over their economic and political destiny. Canada's Arctic foreign policy bolsters our domestic efforts toward strong governance in the North in the following three ways:

- providing opportunities for Northerners to actively participate in shaping Canadian foreign policy on Arctic issues
- continuing to support the participation of Indigenous Permanent Participant organizations at the Arctic Council
- providing Canadian youth with opportunities to participate in the circumpolar dialogue



OUR STRATEGY

The rapid pace of change and growing importance of the Arctic requires that we strengthen our capacity to deliver on Canada's priorities on the international scene. Facing the region's challenges and seizing its opportunities often requires finding ways to work with others: through bilateral relations with neighbours in the Arctic, through regional mechanisms like the Arctic Council and through other multilateral institutions.

Enhancing key bilateral relationships

Canada will pursue a more strategic engagement with the U.S., our premier partner in the Arctic, and will work closely with Denmark, Finland, Iceland, Norway, Russia, Sweden, and in priority areas. The Arctic has also attracted the interest of non-Arctic states and entities. The key foundation for collaboration will be acceptance of and respect for Arctic states' sovereignty and the perspectives and knowledge of Northerners.

Pursuing a strengthened Arctic Council

The Arctic Council is the leading forum for cooperation on Arctic issues. Canada's key priorities for strengthening the Council include pursuing a greater policy dialogue, ensuring that research continues to focus on key emerging issues, and engaging with other member states to address the structural needs of the organization.

Working through multilateral institutions

Canada will work through all relevant multilateral institutions toward global solutions for issues such as polar shipping regulations, climate change and mercury emissions.

Spotlight on Canada-U.S. Collaboration:
Arctic Marine Shipping and the Environment

SUMMARY OF PROCEEDINGS

February 24, 2011

... an increasingly busy Arctic calls for a rapid response to some of the uncertainties that exist. It is important that policy makers and administrators – in Alaska, Canada and the United States – recognize and understand those challenges.

The Institute of the North, in partnership with the Consulate of Canada, hosted its inaugural Arctic Policy Forum on February 24, 2011. Setting the stage for a quarterly event, the evening reception provided a networking opportunity for Alaskans to connect around Arctic issues. Future events will feature multiple perspectives intended to develop in attendees a common understanding of Arctic issues.

This first forum featured Consul Jennifer Loten of the Consulate of Canada in Anchorage who highlighted Canada's Arctic Foreign Policy. This international platform will allow Canada to demonstrate responsible stewardship in the Arctic and comprises four pillars: exercising sovereignty, promoting economic and social development, protecting the Arctic environment, and improving and devolving governance. Watch the video of her presentation at www.institutenorth.org.

The following day, the Institute of the North coordinated a symposium hosted by the Government of Canada and focused on Arctic marine shipping and the environment, and highlighting opportunities for U.S. – Canada collaboration. Recommendations from the Arctic Marine Shipping Assessment (AMSA) formed the backdrop as experts from Alaska and Canada shared some of the latest information from work across the Arctic. Panel discussions provided an excellent analysis of the gaps in Northern infrastructure and how to address them; circumpolar environmental response capacity, including coastal planning and environmental management; and vessel tracking systems.

The symposium opened with a compelling overview by Alaska Lt. Gov. Mead Treadwell of why the Arctic – and collaboration and leadership in the region – matters, and that message was reinforced by speakers throughout the day. Not only is the

Lunchtime Keynote on Public Diplomacy and Collaboration: Hot Ideas for a Cool Climate

- Education: creating new curricula
- Field trips to the Arctic for thought leaders across boundaries
- Slogan, logo, creative event
- Arctic World Games
- Global commons in the Arctic needs to be communicated
- International Arctic Corps – comprising international scientist, business leaders, grad students
- Arctic Chamber of Commerce
- International Arctic Prize
- Arctic Development Book for the private equity community
- Increased outreach for the Arctic Council

Community input is a valuable component of responsible, relevant public policy.

Arctic home to the peoples and communities living there but it has a profound impact on the economies of its nations, many of which rely on natural resource development. At the same time, an increasingly busy Arctic calls for a rapid response to some of the uncertainties that exist. It is important that policy makers and administrators – in Alaska, Canada and the United States – recognize and understand those challenges.

AMSA was the first Arctic Council document to require consent from all eight of its nation members: U.S., Canada, Russian Federation, Norway, Finland, Sweden, Iceland and Denmark through Greenland and the Faroe Islands. The report was foundational in that it provided a baseline for data on Arctic marine traffic, as well as recommendations of areas for focus and governance. AMSA emphasized the necessity for Arctic infrastructure and understanding the use and challenges as Arctic shipping increases. Following the 2009 report, subsequent discussion and work have contributed toward a roadmap to address the recommendations. The Arctic Council has recognized the importance of AMSA findings by committing to two additional years to continue implementation.

Another partnership to note is that of the Pacific Northwest Economic Region (PNWER) and its recent formation of an Arctic Caucus. PNWER recognizes the value of the U.S. – Canada economic partnership, particularly of its Northern regions, which have large geographic areas with small populations and rich natural resources. Alaska and Northern Canada are essential to a successful Arctic and the sub-regional work being conducted through PNWER helps ensure that success. The State of Alaska's formation of the Northern Waters Task Force complements these efforts.

In developing infrastructure, it is important to plan for the long term and involve communities early and throughout the plan. Community input is a valuable component of responsible, relevant public policy. Infrastructure is a broad term that may include government services, such as icebreakers or search and rescue; private services, such as salvage; or information, such as weather, ice, and safe navigation

In addressing gaps, policy makers should recognize that Information, Skills, Systems and Assets (ISSA) are essential to implementing AMSA negotiated recommendations.

products. The infrastructure deficit noted in AMSA is of concern to Northern communities, both in their ability to develop strong economies and vibrant communities, and in their ability to respond in case of crisis. In addressing gaps, policy makers should recognize that Information, Skills, Systems and Assets (ISSA) are essential to implementing AMSA negotiated recommendations.

Commonly articulated between all panels was the importance of the planning process and the necessity for cohesion in closing the gaps. The U.S. and Canada share common ecosystems objectives for the Arctic region – prevention, preparedness, response and recovery – yet each nation has a different approach in shaping policy. Panelists highlighted examples such as Canada's Beaufort Region Environmental Assessment and the Beaufort Sea Partnership; and tools like the U.S. Environmental Response Management Application. Cross border collaboration through the CanUS North Exercise in 2010 and the resulting CanUS North Joint Plan was spotlighted as a link through which to coordinate response information and technology. The readiness exists; however, the resources remain limited and one speaker called for cohesion between U.S. and Canadian investments to fill the gaps without overlaps.

The readiness exists; however, the resources remain limited...

Current and future polar orbiting ice observing satellite imagery will allow efficiency in monitoring Arctic shipping and may foster investment. With increased traffic, tracking vessels can improve safe and environmentally sound operations. One U.S. speaker pointed to the Bering Strait as "Alaska's Gibraltar"– a major transit and potential chokepoint for traffic into and out of the North Pacific Arctic – and spoke of the need for Arctic domain awareness. By contrast, Canada's 1970 Arctic Water Pollution Policy Act was extended into mandatory registration for ships with the 2010 implementation of NORDREG through which the Canadian Coast Guard ensures that ships in the Canadian Arctic meet AWPPA regulatory requirements.

It was clear from the active engagement throughout the day that the symposium was unique in offering the opportunity for policy and science to co-mingle. And while there was considerable discussion around the US and Canada's well managed disputes, the forum demonstrated that there is value in detailed exchanges on these questions outside of the decision-making arena.

Canada was pleased to sponsor the inaugural forum and looks forward to participating in future events.

The Arctic Policy Forum is a quarterly event convened by the Institute of the North, designed to connect policy makers and administrators, academics, community members and other stakeholders in Alaska to one another and to new and emerging policy issues in the Arctic. These respond to the Institute of the North's mission to act as an advocate for Alaska in Arctic infrastructure and policy.

Consulate of Canada Consulat du Canada

June 16, 2011

Rep. Reggie Joule
State Capitol
Juneau, AK 99801

Dear Representative Joule

The Arctic is fundamental to Canada's national identity, and Canada is strongly engaged in the Arctic, both internationally and here in North America. In 2008, Prime Minister Stephen Harper released Canada's Northern Strategy, a document outlining Canada's domestic priorities for the Arctic including enhancing economic development, public safety and environmental protection. Conscious that we cannot accomplish our goals for the Arctic in isolation, and understanding the critical role our arctic neighbours play in the evolving Arctic, Canada released its Arctic Foreign Policy in 2010. Recognizing our historic relationship and the close bond our nations enjoy, this document explicitly recognizes the United States as Canada's premier partner in the Arctic.

Alaskans and Canadians have inhabited the Arctic for millennia, and share not only a border but knowledge of opportunities and challenges associated with the region. Canada and Alaska have collaborated to address challenges and to achieve shared objectives in the Arctic, from marine search and rescue missions and arctic science to trans-border road maintenance. This partnership has yielded benefits across the region and on both sides of the border.

As the Arctic gains prominence on the international stage, Canada and the U.S. are poised to expand their partnerships to advance shared interests. Together, Canada and the U.S. can exercise leadership by promoting environmental stewardship, strengthening arctic science, and encouraging a greater understanding of the human dimension of the Arctic.

As part of our ongoing advocacy efforts in Alaska, the Government of Canada has produced a brief publication highlighting U.S. and Canada's collaboration in the Arctic. This flier will serve as a reference for the many existing partnerships that enhance the ability of Canada and the U.S. to effectively govern and serve as stewards of the North.

I hope you will take a few moments to review the flier and learn more about the dynamic and historic relationship that links Alaska and its Arctic neighbour to the east. Should you have any questions regarding the content of this flier or other Canada/U.S. issues, please contact the Consulate of Canada in Anchorage.

Sincerely yours,

Jennifer Loten

Canada

CANADA-U.S. COLLABORATION IN THE ARCTIC

Canada and the United States have long collaborated in the Arctic as neighbors and friends. In the harsh environment of the Arctic, the two nations break sea ice for each other, fight forest fires, perform search and rescue, build transportation and technological infrastructure, and maintain a sophisticated system of early warning to reinforce continental security. As stated in Canada's Arctic Foreign Policy, the United States is Canada's premier partner in the Arctic.

With the unique conditions in the Arctic and the limited infrastructure available, coordination and cooperation between Canada and the United States are vital in achieving mutual goals. Collaboration in the realms of science, technology, environmental protection, infrastructure, and surveillance is underwritten by myriad agreements that together create a sound framework for the economic development and security of the Arctic, consistent with the objectives laid out in Canada's Northern Strategy Statement of July 2009 and United States National Arctic Policy.

© 2001 Her Majesty the Queen in Right of Canada, Natural Resources Canada / Sa Majesté la Reine du chef du Canada, Ressources naturelles Canada

▶ Transportation

Transportation challenges include great distances between communities, limited air and highway connections, weather conditions, status of the ice pack/river ice for marine travel, and the high cost of road construction and maintenance.

Canada–U.S. Highway Collaboration

The United States, Alaska and Yukon governments have signed formal agreements to build and maintain highway linkages which, in some cases, have included absorbing the costs for work done in the other's jurisdiction. These bilateral and sub-federal agreements keep roads passable, paved, plowed, and patrolled for those who travel in the Arctic.

The Government of Yukon and the Alaska Department of Transportation and Public Facilities collaborate on highway engineering and operational issues and share technology and experience with respect to constructing and maintaining highway infrastructure in a northern environment.

The Government of Yukon also collaborates with the Alaska University Transportation Center (AUTC) on permafrost research related to highways, including the Beaver Creek Permafrost Test Site on the Alaska Highway.

Canada–U.S. Arctic Marine Collaboration

An estimated 6,000 ships navigate the Arctic Ocean annually, with roughly 120 ice-free days. The United States Coast Guard reported a total of 122 vessels traveling in United States waters of the Arctic and 278 vessels traveling in the Bering Strait in 2009.

Transport Canada works with the United States Coast Guard to share information about vessel risk, on-vessel incidents, shipping activity, and design criteria. The International Maritime Organization is currently updating the *Guidelines for Ships Operating in Arctic Ice-covered Waters*, under which both Canadian and United States jurisdictions are expected to operate.

Joint Military Operations

The *Canada-United States Civil Assistance Plan* provides a framework for Canada Command and United States Northern Command (USNORTHCOM) to operate binationally.

U.S. Northern Command

USNORTHCOM operations areas include air, land, and sea approaches across the continental United States, Alaska, Canada, and Mexico, as well as offshore to approximately 500 nautical miles. Headquartered in Colorado, the USNORTHCOM Commander is also the North American Aerospace Defense Command (NORAD) Commander and is appointed by and responsible to both the United States President and the Canadian Prime Minister. The Command Center coordinates a worldwide system of sensors designed to provide intelligence on any aerospace threat.

Canada Command

Canada Command, headquartered in Ottawa, Ontario, is responsible for all domestic and continental Canadian Forces operations. The Command also coordinates military support to Canadian civil and law enforcement authorities.

NORAD

In the 1950s, the United States and Canada constructed the "DEW Line," a network of 58 stations along the 69th parallel north to detect an attack over the Arctic.

NORAD was founded in 1958 as a binational command between the governments of Canada and the United States. It is the most significant joint military activity between Canada and the United States in the Arctic. Through outstanding binational cooperation, NORAD has proven itself effective in its roles of watching, warning, and responding. NORAD plays a important role in the defense of Canada and the United States by evolving to meet the changing threat.

In 2006, a new agreement included a maritime warning mission that entails a shared awareness and understanding of the activities conducted in United States and Canadian maritime approaches, maritime areas and inland waterways. NORAD shares information across borders and, in the case of a threat, initiates response by the appropriate national commands or agencies.

NORAD's forces consist of the Alaskan NORAD Region, Canadian NORAD Region, and Continental NORAD Region.

Alaskan NORAD Region (ANR)

The Alaskan NORAD Region (ANR) conducts aerospace control within Alaska and 200 miles offshore. ANR is active 24 hours a day and has the capability to intercept, escort, divert, direct landings and use force if necessary. ANR also assists in the detection and monitoring of aircraft suspected of illegal drug trafficking.

The ANR Region Operations Control Center is located at Joint Base Elmendorf Richardson in Anchorage. It is operated binationally by United States Air Force, United States Air National Guard, and Canadian Forces personnel.

Protecting the Arctic

In 2007, ANR was named NORAD's outstanding unit, receiving the Partridge-Slemon Award. In the same year, an ongoing operation demonstrating ANR's vigilance and readiness to defend North American air sovereignty was initiated. Fighters from the Alaskan NORAD Region and Canadian NORAD Region are launched in response to aircraft that enter North America's Air Defense Identification Zone. While aircraft do not generally violate United States or Canadian airspace, NORAD-integrated air defense assets in Alaska and Canada are able to detect and intercept aircraft, including Russian heavy bombers carrying out training exercises near the coasts of Alaska and Canada.

Joint Task Force North (JTFN)

As part of its partnership to enhance North American security in response to the events of September 11, 2001, Canada and the United States worked together to develop independent Canadian and US military organizations called Joint Task Force North (JTFN). These units function independently in Canada and the United States, under Canada Command in Canada and in the United States under USNORTHCOM. Under these separate commands, each JTF provides support to domestic law enforcement agencies in the identification and interdiction of threats, including international terrorism, narcotics trafficking, and illegal alien smuggling. Each country's JTFN also works closely with NORAD.

Joint Task Force Alaska (JTF-AK)

Joint Task Force Alaska (JTF-AK), headquartered at Joint Base Elmendorf Richardson in Anchorage, consists of soldiers, sailors, airmen, United States Coast Guardsmen and United States Department of Defense civilian specialists. JTF-AK works with the United States Department of Defense and other federal agencies to evaluate events and locations throughout Alaska for their potential vulnerability as targets for aggression. JTF-AK also provides intelligence to military commands and civilian agencies throughout Alaska and the United States to aid in homeland security awareness and planning. JTF-AK's civil support mission includes disaster relief operations in response to fires, hurricanes, floods and earthquakes.

States Navy and the United States Coast Guard participated in the military exercise portion of Operation NANOOK 2010, Exercise NATSIQ, in order to increase interoperability, exercise a collective response and build the combined capability of the Arctic nations to operate together.

Canadian Joint Task Force North (JTF-North)

Canadian Joint Task Force North (JTF-North), headquartered in Yellowknife, Northwest Territories, exercises Canadian sovereignty and security through routine and contingency operations in the North. It contributes to the growth and development of ...thern residents through the Junior ...adian Ranger and Cadet programs, ...nds Canada's capacity to respond rapidly and effectively to safety and security emergencies, and assists with environmental stewardship.

Combined Efforts

Operational-level engagement between the Joint Task Forces in Canada and the United States ranges from regular communication, to reciprocal visits and briefings on Arctic issues, to combined exercises. They also keep each other informed on search and rescue and disaster response operations taking place in their areas of operation and share information on Arctic marine traffic.

Operation NANOOK 2010

In August 2010, the ...adian Forces held the ...h annual Operation NANOOK in Resolute Bay, Nunavut. The United

Canadian Rangers

Canadian Rangers are part-time reservists who provide a military presence in Canada's remote, isolated and coastal communities. They bring local expertise, guidance and advice to the Canadian Forces during operations and exercises. In sharing their traditional knowledge of the land and environment, the Rangers are a major contributor to the training and effectiveness of the Canadian military in the Arctic.

At the invitation of USNORTHCOM/ NORAD, a group of Canadian Rangers and staff traveled to Colorado in 2009 to deliver a briefing at NORAD headquarters as part of its Aboriginal Awareness week.

Coast Guards

The Canadian Coast Guard Central and Arctic Region is headquartered in Sarnia, Ontario, and maintains a working partnership with the 17th United States Coast Guard district, headquartered in Juneau, Alaska. The two coast guards conduct joint exercises, operations, planning and delivery of services, and participate in the annual Canada-United States Coast Guard Summit. The two forces perform icebreaking for each other when requested. They also work together on a variety of public safety, law enforcement, search and rescue, research, and environmental preparedness and response activities.

Joint Canada - United States Extended Continental Shelf Surveys

Canada and the United States cooperate on scientific and technical work needed to map the outer limits of the continental shelf beyond 200 nautical miles in the western Arctic Ocean. The surveys require significant planning by scientists and officials from Canada's Extended Continental Shelf Program and the United States Extended Continental Shelf Task Force. The research trips have been used to support other scientific endeavors such as ice, seal and seabird surveys and research on sea-ice coverage, water salinity, and micro-organisms.

▶ Public Safety

Border Patrols and Law Enforcement

Following the events of September 11, 2001, the United States and Canadian governments focused attention on customs enhancements and plans to increase the security and efficiency of border processes. In December 2001, the *Canada-United States Smart Border Declaration* established specific measures to identify and address security risks with minimal impact on the movement of legitimate goods and services across the border. The United States and Canadian agencies responsible for border security maintain close communications.

The Royal Canadian Mounted Police (RCMP) delivers police and law enforcement services in Canada, including local community services and federal enforcement. RCMP personnel work in their areas of specialization with Alaska State Troopers, Homeland Security, border enforcement, and the FBI.

Canada-United States Cross-Border Forum

Established in 1997, the Canada-United States Cross-Border Forum brings together provincial, state, and local partners. Numerous law enforcement sub-groups (intelligence, border enforcement, organized crime, prosecutions, interoperability, and mass marketing fraud) are active throughout the year. The Forum has improved Canada-United States law enforcement cooperation and information-sharing to reduce terrorism and organized crime.

Arctic Security Working Group (ASWG)

Jointly chaired by Public Safety Canada and Joint Task Force North Yellowknife, ASWG brings together Canadian domestic agencies, as well as provincial and territorial administrators to share mainly unclassified information relating to the Arctic and to collaborate on emergency management and security. United States officials also participate.

Disaster and Emergency Response

Alaska, Oregon, Idaho, Washington, British Columbia and Yukon created the *Pacific Northwest Emergency Management Arrangement* to allow for cross-border mutual aid in times of disaster or emergency. The treaty addresses cross-border planning and exercises, emergency operations and support centers, damage and impact assessment, disaster recovery administration, community outreach, search and rescue, medical assistance, debris clearance, resources and donation management, and security.

Yukon River Flood of 2009

Canada-United States emergency response collaboration was tested in May 2009 when an unusually warm spring thaw caused flooding along the Yukon River, destroying the Alaska community of Eagle. Canada gave the United States hydrological information that enabled Alaska to warn Eagle residents to prepare an evacuation. After the disaster, Canadians from Dawson City were among the first responders in Eagle, volunteering for clean-up and staying throughout the summer to help repair the extensive damage.

Environment and Resource Management

Canada and Alaska have many thousands of square miles of national parks and refuges that share a border. Glacier Bay National Park, Wrangell St. Elias National Park, Tatshenshini-Alsek Wilderness Park, and Kluane National Park form the largest internationally protected area in the world – a UNESCO World Heritage Site. Along the Arctic coast, the Arctic National Wildlife Refuge is an extension of Canada's Ivvavik and Vuntut National Parks.

Joint efforts to monitor the environment and resource development are an increasingly important element of the Canada-United States collaboration in the Arctic.

▶ Regional Relations

Indigenous and Northern Issues

In March 2010, the Department of Indian and Northern Affairs Canada and the United States Department of the Interior signed a Memorandum of Understanding with a goal of improving the quality of life of Indigenous groups in both countries. A joint work plan will focus on economic development, policy and legislation experience, preservation of Indigenous cultures, education, emergency preparedness, and law enforcement.

Yukon River Inter-Tribal Watershed Council

The Yukon River Inter-Tribal Watershed Council (YRITWC) consists of 70 aboriginal groups and tribes from Canada and the United States dedicated to the protection and preservation of the Yukon River watershed. The YRITWC facilitates the development and exchange of information, coordinates efforts between Indigenous peoples and tribes, undertakes research, and provides training, education and awareness programs to promote the health of the watershed and its Indigenous peoples.

State of Alaska/Yukon Government Cooperation

The governments of Alaska and Yukon have a number of joint agreements regarding natural resources and transportation. The tourism programs *Joint Yukon Alaska* and *Tourism North* were also established to facilitate and encourage travel to the Arctic region.

6. IMPLEMENTATION AND FOLLOW-UP 57

Preface

The Kingdom of Denmark is centrally located in the Arctic. The three parts of the Realm – Denmark, Greenland and the Faroe Islands – share a number of values and interests and all have a responsibility in and for the Arctic region. The Arctic makes up an essential part of the common cultural heritage, and is home to part of the Kingdom's population.

The Kingdom and its populations have over several hundred years developed modern and sustainable societies based on democratic principles. The development has affected all sectors of society - from education, health and research to the environment, trade and shipping. At the same time, huge and sweeping changes are taking place today in the Arctic. Due to climate change and technological developments, vast economic potential is becoming more accessible.

It is our common objective that the Arctic and its current potential must be developed to promote sustainable growth and social sustainability. This development must take place firstly to the benefit of the inhabitants of the Arctic and go hand in hand in safeguarding the Arctic's environment.

With new opportunities come new challenges. The Arctic has to be managed internationally on the basis of international principles of law to ensure a peaceful, secure and collaborative Arctic.

The purpose of this strategy is, on the basis of an already strong engagement in the Arctic, to reinforce the foundation for appropriate cooperation on the many new opportunities and challenges that the Arctic is facing.

The Kingdom is already a vigorous and important actor in the strategically vital international cooperation on the future of the Arctic and in that connection attaches great importance to creating transparency in and understanding for cooperation.

In the Kingdom's strategy for the Arctic 2011-2020, the Government, the Government of the Faroes and the Government of Greenland have set out the most important opportunities and challenges as we see them today and in the near future. On that basis we have defined our common political objectives for the Arctic.

We will – through close cooperation in the Kingdom and with our international partners - work towards the common overall goal of creating a peaceful, prosperous and sustainable future for the Arctic.

1. Introduction

1.1. A REGION IS OPENING UP

One of the most significant global issues over the past 10 years is the vast changes in the Arctic region. The world has again turned its attention to the Arctic, this time mainly because of the climate effects in the Arctic, the economic potential of the region, and the geopolitical implications of changes in the Arctic. The political, economic and social development is already underway, including the flourishing of advanced democratic societies, and the future of the Arctic will be radically different from the reality we know today.

Warming in the Arctic is occurring faster than anywhere else on the planet, and the average temperature in the Arctic has surpassed all previous measurements in the first decade of the 21st century. Sea ice has been shrinking, and the melting of Greenland's ice sheet and other Arctic ice caps will contribute more and more to the rise in global sea levels. Climate change has major implications for the global, regional and local climatic and environmental conditions and requires decisive global action.

The Arctic and the global community are presented with both new challenges and new opportunities.

Climate change poses new challenges to the peoples of the Arctic and puts pressure on the natural environment. Warming will especially change the basis of the Arctic inhabitants' lifestyles and the indigenous Arctic peoples' culture. Moreover, the harvesting of living resources plays a pivotal role in the Arctic, and changes for example in fish stock productivity and distribution is of great importance to the economy. Glaciers in the Arctic and the Greenland ice sheet increasingly contribute to the global rise in sea levels, and changes and dynamics in Arctic systems are crucial to global climate trends. Thus, they are of particular significance for the adaptation to climate change on a global scale and thereby also for the entire Kingdom. Increased economic activity and renewed geopolitical interest in the Arctic results in a number of key challenges to ensuring a stable, peaceful and secure region characterized by dialogue, negotiation and cooperation.

Climate change and technological developments are also opening new possibilities for the Arctic. Among them is increased access to the exploitation of oil, gas and minerals, but also new shipping routes which can reduce costs and CO_2 emissions by freight between the continents. It is estimated that the Arctic may contain up to 30% of the world's undiscovered gas resources and about 10% of undiscovered oil resources, and that ships sailing between East Asia and Western Europe could save more than 40% in transportation time and fuel costs by navigating the northern sea lanes north of Siberia rather than the southern route through the Suez Canal. Furthermore, climate change could provide access to new fishing grounds in the Arctic where rising sea temperatures can pull fisheries towards the North. Commercial opportunities in the Arctic are enormous, not least for the Greenland, Faroese and Danish industries, which to a great extent already possess the skills that will be far more in demand with the development of the Arctic region.

Overall we can expect a multi-faceted boom in activities in the Arctic over the coming decades. New opportunities and challenges must be handled proactively - with care, with long-term accountability and with respect for the Arctic societies, the rights of Arctic indigenous peoples, the

FACTS ABOUT THE ARCTIC

The Arctic covers more than a sixth of the Earth's total land mass plus the Arctic Ocean which the Arctic coastal states border. Unlike Antarctica, which also has relatively low temperatures year round, the Arctic region is populated by people, including more than 30 different indigenous peoples such as the Inuit who originate from the Thule culture. The Arctic has a unique wildlife, largely associated with the sea, including marine mammals such as seals, whales and walruses.

Arctic climate and the environment. The basis for the future of the Arctic is being created now, and the Kingdom must play a key role in the future international cooperation that lies ahead.

1.2. JOINT STRATEGY FOR THE ARCTIC

The Kingdom consists of three parts - Denmark, the Faroe Islands and Greenland - and, by virtue of Greenland, is centrally located as a coastal state in the Arctic. This involves specific rights and obligations in the region. Today, both the Faroe Islands and Greenland have extensive self-government and the division of legislative and administrative powers between the Kingdom's three parts requires good cooperation and a joint strategy to meet the opportunities and challenges in the Arctic.

The Faroe Islands and Greenland have had home rule since 1948 and 1979, respectively. Home rule arrangements have been continuously modernised, most recently by the Takeover Act on Power of Matters and Fields of Responsibillity and the Act on Faroes Foreign Policy Powers of 2005 in the Faroe Islands and the Greenland Self-Government Act of 2009. Considerable parts of the separation of powers that are central in an Arctic context are matters that fall within the exclusive powers of the respective Faroese and the Greenland authorities. The Kingdom thus comprises significant political diversity and also accommodates cultural differences.

The Kingdom's Arctic strategy intends no change in the power-sharing that exists between Denmark, the Faroe Islands and Greenland, including responsibility for policy areas taken over and their funding. Regardless of these individual distinctions, the Kingdom has a common interest in addressing the challenges and utilising the opportunities arising from the Arctic region's rapidly changing conditions and growing interest from the world. One of the areas Greenland has taken over is mineral resources. Decisions on development, exploration and exploitation of resources in Greenland are taken by the Greenland authorities. However, revenues from mineral activities will benefit both the Greenland and Danish people, given that cf. Self-Government Act for Greenland there will be a reduction of the annual block grant in line with possible revenues from mineral resources.

A strategy for the Arctic region is first and foremost a strategy for a development that benefits the inhabitants of the Arctic - involving common interests relating to for example international agreements, and regional and global issues. Such a development incorporates a fundamental respect for the Arctic peoples' rights to utilise and develop their own resources as well as respect for the indigenous Arctic culture, traditions and lifestyles and the promotion of their rights. Denmark and Greenland's cooperation on Arctic indigenous peoples dates back to 1973 when the Arctic Peoples' Conference at Christiansborg Palace in Copenhagen became a launching point for the international organising of indigenous peoples.

Cooperation between Denmark and Greenland helps in creating new opportunities for the Arctic indigenous peoples. Greenland's self-government model, natural resource management, climate policy, environmental policy and preservation of its cultural heritage is a model of inspiration for many of the world's indigenous peoples. This situation constitutes an essential element in the Kingdom's international efforts to promote indigenous rights and aspirations. Denmark and Greenland will continue constructive cooperation to strengthen indigenous peoples' rights to control their own development and their own political, economic, social and cultural situation.

It is a central goal of Greenland, the Faroe Islands and Denmark that decisions regarding management and utilisation of resources and protection of the environment are taken in accordance with international obligations, and are based on the best scientific advice that supports healthy, productive and self-sustaining communities. Based on good collaboration within the Kingdom, policies and mechanisms must be organised in close cooperation with other Arctic nations and other stakeholders with an interest in the Arctic.

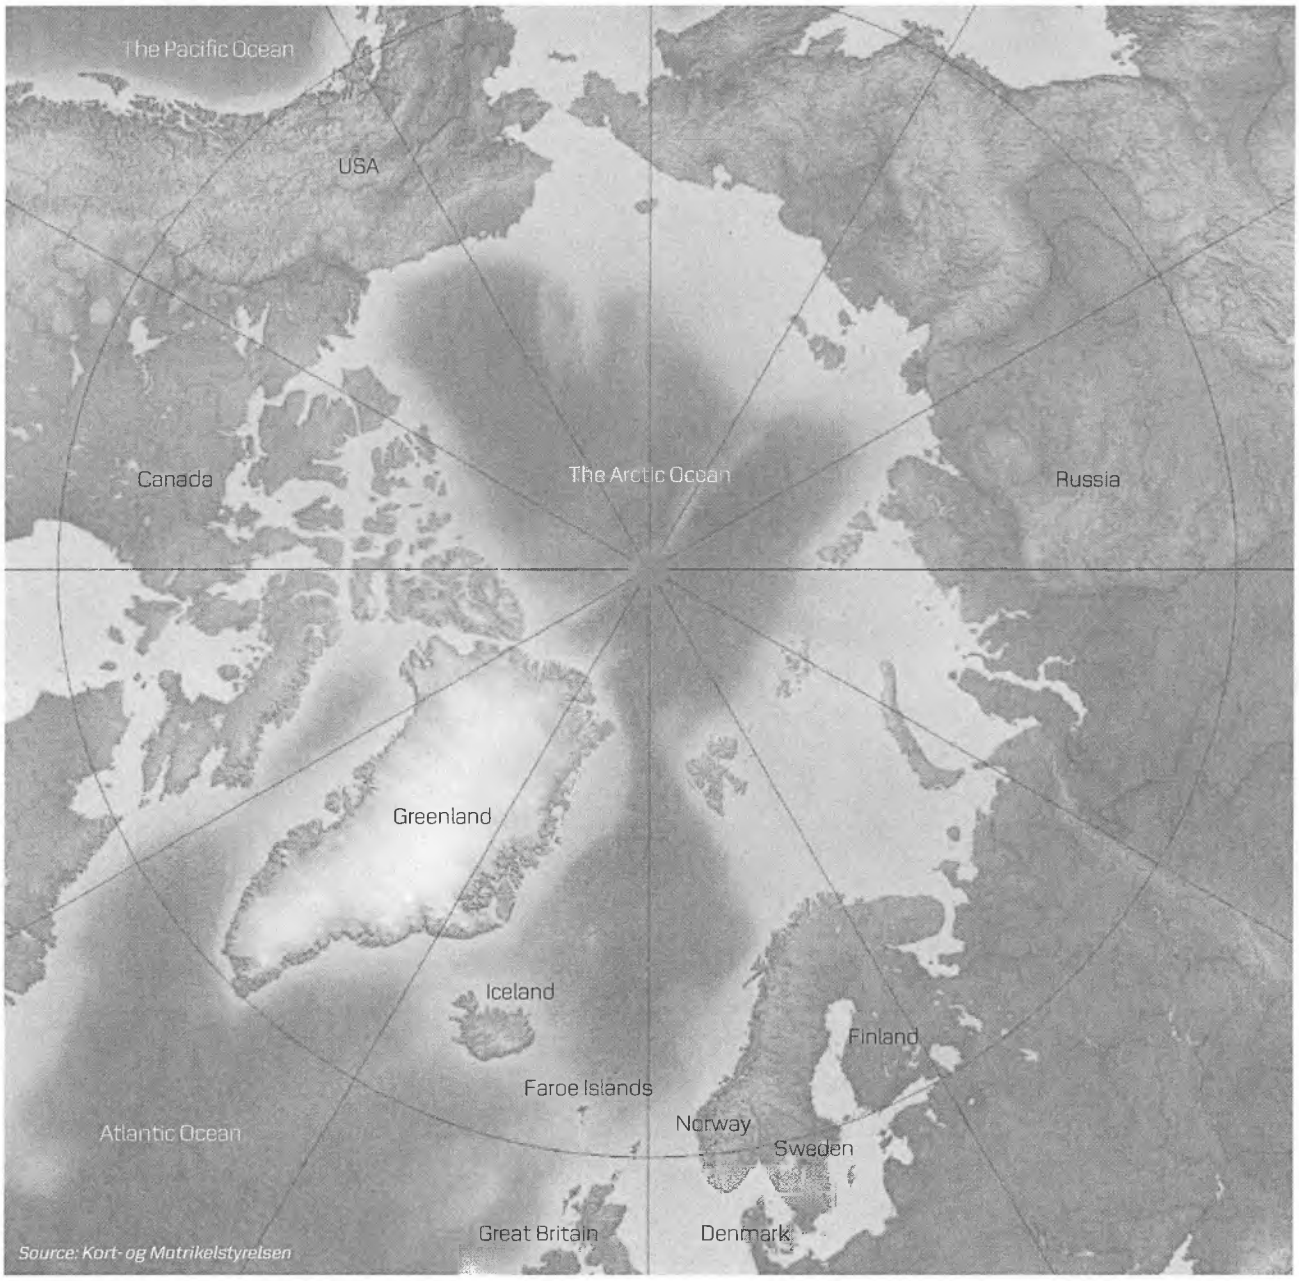
The premise of this strategy stems internationally from the Arctic Council Declarations and the Ilulissat Declaration of 2008, in which the coastal states of the Arctic Ocean committed themselves politically to giving negotiation and cooperation pride of place in handling disputes, challenges and opportunities in the Arctic, and thus hopefully once and for all dispelling the myth of a race to the North Pole.

The Kingdom's approach to security policy in the Arctic is based on an overall goal of preventing conflicts and avoiding the militarization of the Arctic, and actively helping to preserve the Arctic as a region characterized by trust, cooperation and mutually beneficial partnerships.

In an equal partnership between the three parts of the Danish Realm, the Kingdom will work overall for:

TERMINOLOGY

The strategy uses the terms "The Kingdom" and "Danish Realm" for both the formal relations between Denmark, Greenland and the Faroe Islands and in a broader and more informal sense. Naalakkersuisut is, pursuant to the Self-Government Act of Greenland, the name of the Government of Greenland.



- A peaceful, secure and safe Arctic
- with self-sustaining growth and development
- with respect for the Arctic's fragile climate, environment and nature
- in close cooperation with our international partners.

The Greenlandic-Danish report, "Arctic in a time of change", of May 2008 and targets contained herein remains an important basis for the Kingdom's various activities in the Arctic.

The purpose of this strategy is to focus attention on the Kingdom's strategic priorities for future development in the Arctic towards 2020. The aim is to strengthen the Kingdom's status as global player in the Arctic.

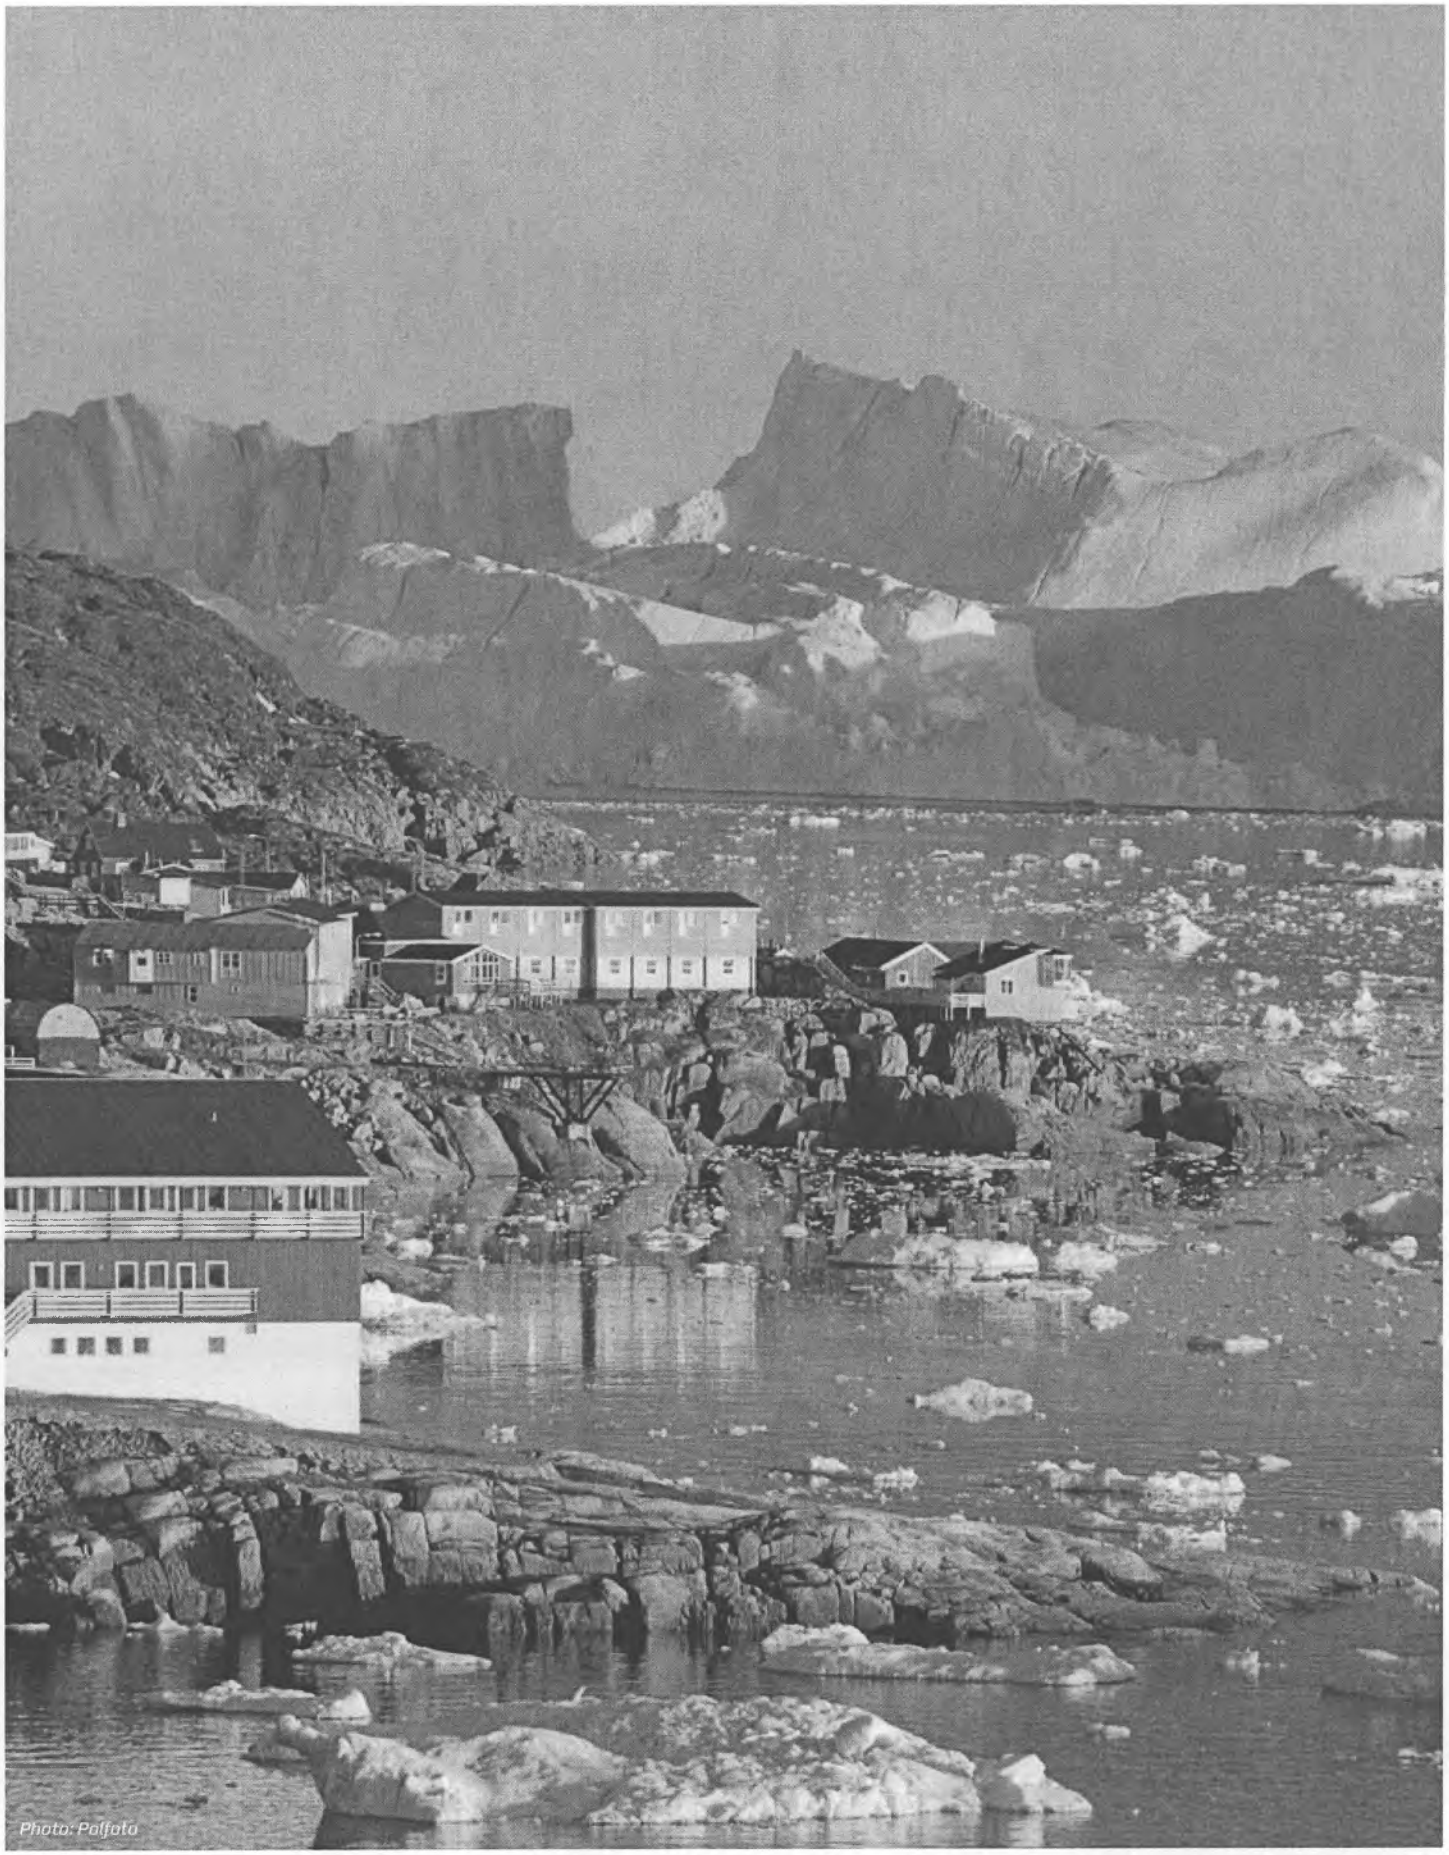


Photo: Polfoto

2. A peaceful, secure and safe Arctic

- International law and established forums of cooperation provide a sound basis for conflict resolution and constructive cooperation in the development of the Arctic. The Kingdom must help in shaping the future of cooperation on joint challenges and new opportunities in the Arctic.
- Maritime safety is a fundamental priority. The extreme Arctic conditions require preventive measures including training and ship safety, as well as regional cooperation on search and rescue.
- The Danish Armed Forces undertake important tasks in the Arctic including the enforcement of sovereignty, and attach in this respect great importance to confidence building and cooperation with Arctic partner countries.

Climate change and rising global demand for oil and gas have resulted in a sharp rise in international interest in the Arctic, and the coastal states of the Arctic Ocean have increased their endeavours to ensure their rights to the greater part of the as yet unexplored Arctic subsoil. At the same time, the prospect is that for a large part of the year, it will be possible to navigate both the Northeast Passage and the Northwest Passage. The rising strategic interest and activity in the Arctic region necessitates a continued prioritising of a well-functioning international legal framework for peaceful cooperation, a special need for enhanced maritime safety, and persistent focus on maintaining the Arctic as a region characterised by peace and cooperation.

2.1. BASIS FOR PEACEFUL COOPERATION AND WITH EMPHASIS ON THE UN'S CONVENTION ON THE LAW OF THE SEA

The growing international interest in the Arctic has led to increased focus on legal controls in the area. However, the Arctic is not a legal vacuum. The Arctic has been inhabited for thousands of years, in contrast to the Antarctic which is uninhabited. Regions in the Arctic under national jurisdiction are governed by the coastal states legislation. The Arctic is also subject to a number of international laws, in particular the UN Convention on the Law of the Sea in1982 (UNCLOS), which contains detailed regulation of for example navigational rights and management of resources.
In recognition of the significant changes that the Arctic faces, Denmark and Greenland arranged a conference in Ilulissat in May 2008 for the five coastal states of the Arctic Ocean. Its aim was to confirm the responsibility of the five coastal states for managing the development of the Arctic. The conference resulted in the Ilulissat Declaration in which the five coastal states of the Arctic Ocean undertook to enshrine close cooperation in developing the Arctic into international law. The five coastal states' cooperation covers areas such as sea rescue, continental shelf claims and environmental protection.

Even though the existing regulation in international law, particularly the UN Convention on the Law of the Sea, lays a solid foundation for coastal states' cooperation

on the development of the Arctic, there may be a continuous need for more detailed regulating of certain sectors. An example is the agreement on search and rescue adopted at the Arctic Council Foreign Ministers' Meeting in May 2011 in Nuuk.

The UN Convention on the Law of the Sea 1982 is the global international legal instrument in relation to the sea around the Arctic, in that the Convention defines states' rights and responsibilities in relation to their use of the oceans. Denmark ratified the Law of the Sea Convention on behalf of the Kingdom on 16 November 2004 and to date the Convention has been ratified by 161 states. Of the five coastal states of the Arctic Ocean, only the U.S. is not (yet) a party to UNCLOS, though part of the Convention is an expression of customary law and therefore binding on countries not party to the Convention. Moreover, the United States, by Presidential Directive of 9 January 2009 specially approved the Convention as a means of resolving border issues concerning the continental shelf in the Arctic.

Under the UN's Convention on the Law of the Sea, coastal states have the right to create an exclusive economic zone. In this zone, the coastal state has exclusive right to explore and exploit natural resources of the sea as well as the seabed and its subsoil, and any other economic exploitation. The coastal state may also exercise environmental jurisdiction in the zone. The exclusive economic zone can extend to a maximum of 200 nautical miles (approx. 370 km). Denmark and Greenland have an exclusive economic zone while an exclusive economic zone has not yet been declared in the Faroese fisheries territory.

Under article 76 of the UN's Convention on the Law of the Sea, a coastal state has the possibility of extending its continental shelf beyond 200 nautical miles if within 10 years of the Convention coming into force for the state concerned, it can document to the Commission on the Limits of the Continental Shelf (CLCS) established pursuant to the Convention, that a number of scientific criteria are met. The coastal state will then have the right to living and non-living resources on and under the seabed beyond 200 nautical miles, subject to an obligation to make payments or contributions to the International Seabed Authority pursuant to Convention Article 82.

The Kingdom thus has a deadline of 16 December 2014 to submit data and other material to the CLCS as a basis for the extension of the continental shelf beyond 200 nautical miles. The time limit can however be exceeded in special cases under a decision made by the convention partners in 2008, as long as preliminary information is submitted to CLCS before the deadline expires.

To document the claim on the continental shelf the Danish Realm has launched a continental shelf project that is based in the Ministry of Science, Technology and Innovation and is run in cooperation with the Government of the Faroes and the Government of Greenland, the Prime Minister's Office, the Ministry of Foreign Affairs, and the Ministry of Finance. The project includes the participation of the Danish, Faroese and Greenland authorities and scientific institutions, and is charged with identifying areas where the rights to new seabed claims can be made, and to collect, interpret and document the data necessary to submit a claim to the CLCS. The Kingdom has submitted documentation to the CLCS for claims relating to two areas near the Faroe Islands and by 2014 plans to submit documentation on three areas near Greenland, including an area north of Greenland which, among others, covers the North Pole.

The budget for the continental shelf project until 2014 is app. DKK 350 million spread over 12 years. The actual work of the project is a collaboration between Jarðfeingi (Faroe Directorate of Geology and Energy), the Danish Maritime Safety Administration, DTU Space (Institute for Space Research and Technology), National Survey and Cadastre and the Geological Survey of Denmark and Greenland (GEUS). Jarðfeingi, together with GEUS, is project manager for the Faroese Continental Shelf Project (half funded by the Faroe Islands) while GEUS is the project manager for the Greenland part where the Bureau of Minerals and Petroleum in Nuuk and ASIAQ (Greenland's Survey) take part.

The continental shelf project is very much an example of a project that is feasible

ILULISSAT DECLARATION

The Ilulissat Declaration is a landmark political declaration on the Arctic's future. It was adopted in Ilulissat, Greenland on 28 May 2008 by ministers from the five coastal states of the Arctic Ocean - Denmark / Greenland, Canada, Norway, Russia and the U.S. The Ilulissat Declaration sends a strong political signal that the five coastal states will act responsibly concerning future development in the Arctic Ocean. The states have a political commitment to resolving disputes and overlapping claims through negotiation. The five countries also confirmed that they will strengthen their cooperation in important areas. This applies to both broad cooperation that in particular takes place in the Arctic Council and the UN's International Maritime Organization (IMO), and to the practical everyday cooperation on issues such as search and rescue, environmental protection and navigational safety.

due to all parties', including both the Faroe Islands and Greenland's, willingness and ability to cooperate and the will to achieve the project's targets. Furthermore, the project is an example of how different institutions can cooperate across the Kingdom and benefit from one another. The continental shelf project also has exemplary research cooperation with other countries, such as the Swedish Polar Research Secretariat with which it has carried out many data collection expeditions with the Swedish ice-breaker Oden. The project also has fruitful research-based cooperation with Canada and Russia.

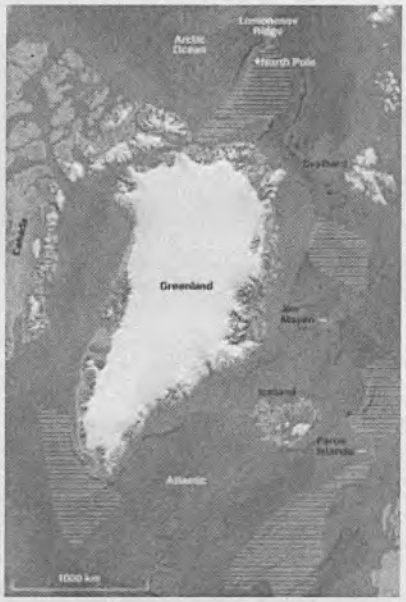
The Kingdom's claims on the continental shelf will in some areas overlap with other country's continental shelf claims. There is close collaboration with other coastal states in the Arctic Ocean to solve unresolved boundary issues beyond 200 nautical miles. As highlighted in the Ilulissat Declaration, unresolved boundary issues in the Arctic will be resolved in accordance with international law.

Besides maritime boundary issues, the Kingdom has an unresolved issue relating to the sovereignty of Hans Island (Hans Ø) as both the Kingdom and Canada claim sovereignty over the island. In September 2005, Denmark/Greenland and Canada made a joint statement on Hans Island, and frequent consultations on the island are in progress. Pending a permanent solution to the issue, the dispute will be handled professionally as would be expected between two neighbouring countries and close allies.

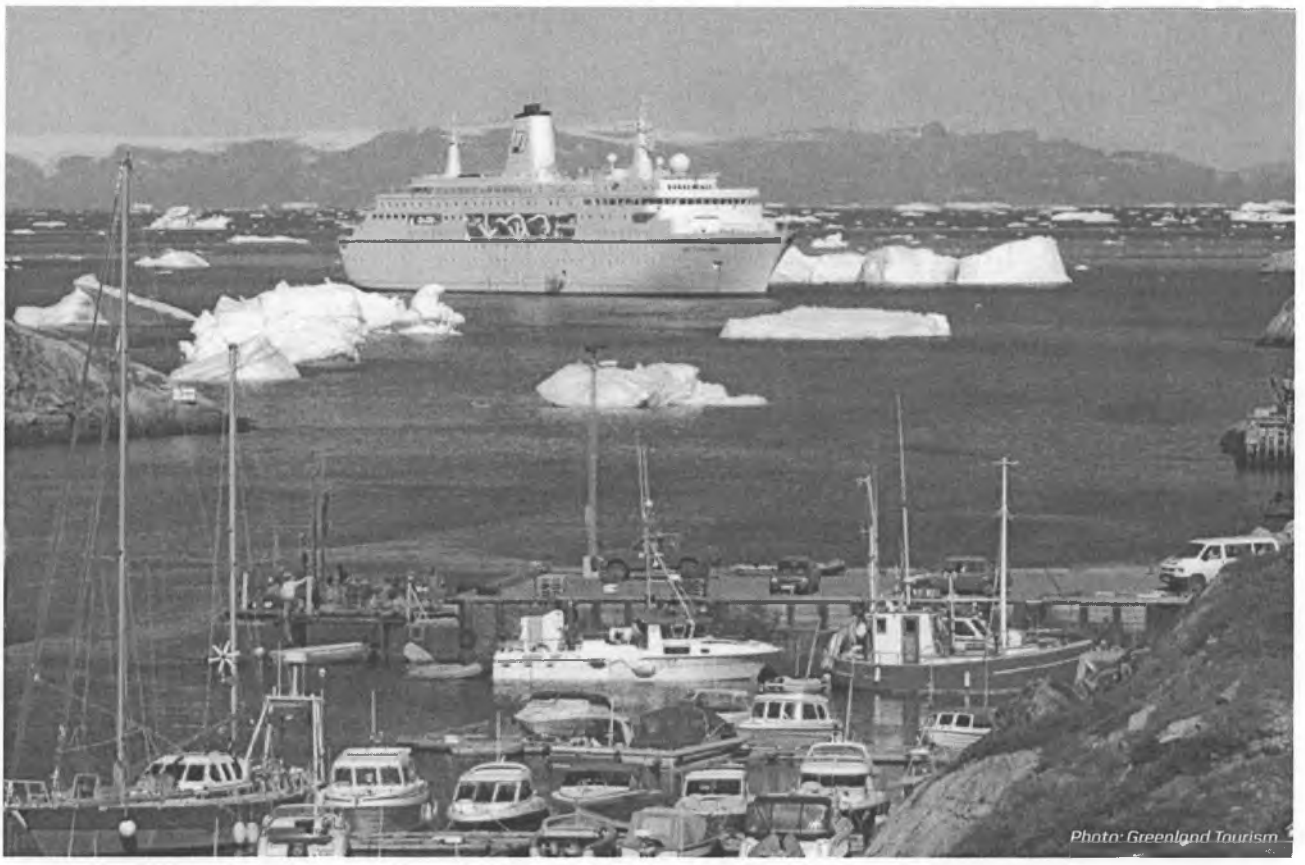
- The Kingdom will work for peaceful cooperation between the coastal states of the Arctic Ocean in accordance with the Ilulissat Declaration.
- The Kingdom will advance concrete international legal regulation of the Arctic in areas where needed.
- The Kingdom will seek to resolve outstanding unresolved boundary issues and actively work to reduce the processing time of the Commission on the Limits of the Continental Shelf and thereby ensure greater assurance of coastal states' continental shelf claims in the Arctic.
- The Kingdom will continue work on the Continental Shelf Project in order to promote its claim pursuant to the UN's Convention on the Law of the Sea.

THE CONTINENTAL SHELF PROJECT IN PRACTICE

Since 2006 the Danish Realm has conducted a series of expeditions in the Arctic Ocean as part of the continental shelf project. A factor common to the expeditions is close cooperation with other countries. Canada, Russia and the U.S. have also been conducting scientific studies in the Arctic Ocean these years in preparation for an extension of their respective continental shelves. The expeditions "LORITA" (2006), "LOMBAG" and "LOMGRAV" (2009), for example, were based on Canadian logistics. LOMROG I and II expeditions in 2007 and 2009 were carried out with the Swedish icebreaker Oden, in cooperation with Sweden and Canada. In 2007, the expedition was for a period supported by a Russian nuclear icebreaker. Another factor these expeditions have in common is that in addition to the collection of data relevant to the continental shelf project, emphasis is also placed on scientific output and follow-up research in other fields. Thus, ice cores have been collected, ice thickness measured, samples of DNA and bacteria collected, geology, oceanography, plankton ecology all studied, and the accumulation of mercury measured. All collections are conducted in cooperation with Danish, Greenland, Swedish and American research institutions and have led to increased knowledge of the Arctic Ocean's plate tectonics, palaeoclimatology, physical oceanography and ecosystems. Further expeditions are planned under the auspices of the Continental Shelf Project in 2011 and / or 2012.



Source: Ministry of Science, Technology and Innovation / www.a76.dk



2.2. ENHANCED MARITIME SAFETY

Navigation in the Arctic is increasing, including in the waters around Greenland and the Faroe Islands. Less ice coverage, especially in the summer months, has led to a significant growth in maritime traffic, including cruise ships to areas of Greenland which until a few years ago were not possible to navigate. In 2010, 43 cruise ships berthed in Greenland ports, compared with 32 in 2009. Furthermore, shipping trade in Faroese waters has increased considerably. Shipping in Faroese waters has risen by 5-6 times from 2008-2010 and 40-50 sizeable cruise ships now call at Faroese ports each year.

Shipping operators are exploring new areas still further north as ice conditions permit. Meanwhile, prices of raw materials and not least a long-term expectation of a shortage of oil and natural gas have led to increased trade in the exploration and exploitation of natural resources. The melting of sea ice in the summer also allows for new shipping routes through the Northeast and the Northwest Passage which could ultimately yield significant savings in transportation time by the maritime transport of goods between Europe and Asia. It is believed that the waters around Greenland and the Faroe Islands will experience a significant increase in maritime traffic in the coming years.

The increasing maritime activity is closely linked with economic development in the Arctic. For the sake of the fragile environment in the Arctic, it is important to build sustainable growth. For shipping, which is a global industry, this means that internationally high safety standards must be established for ships navigating in the Arctic. Furthermore, in terms of shipping policy, it is important that the Kingdom is working to promote shipping in the Arctic under high standards where international regulation ensures that ships are competing within a uniform framework.

Because of the extreme conditions in sparsely populated Arctic regions, prevention of marine vessel accidents is crucial in the Arctic. Regardless of climate changes, it will still be necessary to take account of ice, low temperatures, extreme weather and the risk of grounding. It is therefore vital that ships are built and equipped so they can operate under these conditions. Despite increasing intensity, marine traffic

will still be spread over a vast geographical area far from ports. Therefore, ships should first and foremost use their own rescue equipment if an accident should occur, until the resources offered by the authorities responsible in the area can be deployed to assist. Therefore, preventive measures must be set in place that allow for the continued and increased navigation in the Arctic, while at the same time effectively preventing and minimising marine accidents and mitigating damage to the environment and nature.

It is important to implement preventive safety measures, not least for the cruise ships that sail with many passengers, and often with limited local knowledge. Here, experience shows that other ***cruise ships*** in the vicinity are crucial to saving lives. The Kingdom is working to promote cooperation on maritime safety in all key forums, particularly in the International Maritime Organisation (IMO), where binding rules for navigation in the Arctic are drawn up, but also through enhanced cooperation in the Arctic Council.

To increase the safety of ships navigating in Arctic waters, Denmark has introduced improved port State control of cruise ships planning to sail to Greenland. Moreover, other countries have been urged to do the same when these ships enter their ports before sailing to the Arctic. Furthermore, the Ministry of Economic and Business Affairs has entered into an agreement with the Government of Greenland (Naalakkersuisut) on the establishment of a liaison committee in order to ensure that a high safety level of navigation in Greenland waters is sustained and developed, whether this takes the form of international shipping or in the form of domestic navigation to and from Greenland ports. The liaison committee will prepare a joint plan in 2011 to ensure this.

Increased maritime traffic also places greater demands on ***infrastructure*** as marine vessels require support in the form of a sound infrastructure. The Government of Greenland has focused on this challenge with the establishment in 2009 of a Transportation Commission and in the coming years will address requirements in this area, based on the recommendations in the commission's report in 2011.

Updating nautical charts will be an important factor under the auspices of the Danish Realm. In the future, ships will increasingly use electronic nautical charts and make use of satellite-based navigation systems such as GPS which impose stricter requirements on the accuracy of charts. In particular, a thorough knowledge of water depth is necessary to navigate safely at sea. In 2009 an agreement was made between the Minister of Environment and the Government of Greenland about a renewal of the nautical charts for Greenland, which means that the charts for most of Southwest Greenland (from Cape Farewell to Uummannaq) - the busiest Greenland waters - will be corrected and digitized no later than 2018. Due to the vast sea areas, large areas of the Greenland waters will be unsurveyed beyond 2018 while still greater areas become accessible to shipping as the ice melts. For reasons of safety at sea the Kingdom will furthermore continue to prioritize the work of the International Hydrographic Organization (IHO), such as in the regional commission on the Arctic which was established in 2010.

Similarly maritime safety is supported by ensuring the availability of reliable information on weather, sea conditions and ice. The Greenland Ice Services at the Danish Meteorological Institute was established in 1959 as one result of the shipwreck of M / S "Hans Hedtoft". The Service's main task so far has been to map the ice conditions in the Cape Farewell area for the safe navigation of cargo ships between Greenland and Denmark. Because of changing climatic conditions and altered distribution of sea ice in Greenland waters, the navigational pattern of ships has changed dramatically. Combined with the growth of cruise ship activity and oil exploration, there is a need for intensified ice and weather warning alerts further north in both West and East Greenland. It will therefore be a priority that the existing Ice Services be adapted to the increased requirements for observation, forecasting and dissemination of ice conditions in Greenland waters.

Furthermore, enhanced surveillance of maritime traffic in the Arctic will contribute to improved prevention of accidents and coordination of the rescue efforts. It also provides greater opportunity to intervene before an accident can occur. Currently, ships sailing to Greenland must report to the so-called GREENPOS reporting system, which requires ships in Greenland waters to continuously report their position to the Greenland Command. Larger ships already send their positions via the satellite-based LRIT (Long Range Identification and Tracking) system. Surveillance is expected to be improved, for example by using new technology with satellite reception of ships' AIS signals (Automatic Identification System) as almost all larger ships are equipped with AIS.

The Faroese Maritime Authority follows international developments and handles Faroese interests in the IMO because of its status as an associate member of IMO. With the introduction of AIS and LRIT, which are based on IMO mandatory requirements, it has been possible to improve the monitoring of foreign and Faroese vessels in Faroese waters. In addition to this, cooperation has been established between Denmark, Greenland, the Faroe Islands, Norway and Britain for the mutual exchange of AIS data in the North Atlantic region.

Over a number of years, both the Faroe Islands and Greenland have entirely or in part been responsible for the monitoring of the marine environment and pollution control in territorial waters. Furthermore, the Faroe Islands has responsibility for search and rescue services. In light of increased activity in the region further knowledge and exchange of findings and cooperation will be needed to solve these tasks.

- The Kingdom will promote cooperation with other Arctic states and other key countries with significant maritime interests in major marine policy issues concerning the Arctic, such as maritime safety. Cooperation with other Arctic states must support a sustainable maritime growth, for example by establishing a better knowledge base on navigation in the Arctic.

- The Kingdom will reinforce concrete preventive measures to improve safety of navigation in the Arctic. In particular this involves endeavours, in cooperation with the other Arctic States, for adoption by the IMO of a mandatory Polar Code to ensure high safety levels in Greenland waters, regardless of the ships' nationality and for a requirement that crews have the requisite skills for navigation in Arctic waters.

- To work for the inclusion of requirements in the polar code under IMO auspices that cruise ships coordinate their navigations with the emergency services, including other cruise ships, which could come to the rescue if a maritime incident occurs. The Kingdom will work in the Arctic Council to gather knowledge of cruise lines' own safety standards for navigation in order to promote "best practices" for the navigation of cruise ships in the Arctic, and also consider the need for increased focus on port State control prior to cruise ships sailing to the Arctic.

- The Kingdom will continue preparing new nautical charts for Greenland to avoid maritime accidents in Greenland waters and to support mineral resource activities. The Kingdom will support the surveying of the Greenland waters and cooperation with other coastal states of the Arctic Ocean within the Arctic Hydrographic Commission. Maritime safety must also be supported by ensuring the availability of reliable information on weather, sea and ice in collaboration with other Arctic states, better information about navigation in Greenland waters and the tightening up of port State control of ships sailing to the Arctic, and finally working for the international dissemination hereof.

- The Kingdom will work to introduce binding global rules and standards for navigation in the Arctic and it is a high priority to reach agreement on a global regulation of shipping via the IMO, cf. Ilulissat Declaration. Should it prove that agreement on global rules cannot be reached, and in view of the especially vulnerable Arctic environment and the unique challenges of security, the Kingdom will consider implementing non-discriminatory regional safety and environmental rules for navigation in the Arctic in consultation with the other Arctic states and taking into account international law, including the Convention on the Law of the Sea provisions regarding navigation in ice covered waters.

- The Kingdom will work to strengthen cooperation with neighbouring countries on monitoring, search and rescue, such as supporting the implementation of the joint Arctic cooperation agreement on strengthening coordination and data-sharing in relation to search and rescue, entered into under the auspices of the Arctic Council in May 2011.

- Given the clear correlation between the rise of maritime activity and economic development in the Arctic, efforts will be strengthened to involve Greenland citizens in tasks within areas of maritime safety, such as surveying, buoying, and search and rescue at sea, perhaps by establishing a voluntary coastal rescue service.

- The Kingdom will examine the need for the establishment of new shipping routes, and implement this to the extent it promotes maritime safety and marine protection. For example, there is particular need to establish recognized routes in Faroese waters for both cruise ships, tankers and other vessels with respect to safety and the environment.

NAVIGATION IN GREENLAND

There are many different maritime activities in Greenland waters. In particular, cruise tourism has increased markedly: From 15,654 passengers in 2004 to 30,271 passengers in 2010. There is also an increasing activity of vessels used for oil exploration and marine studies, just as the shipping of minerals with bulk carriers is expected to rise significantly. Additionally, there is considerable local traffic with fishing vessels, passenger transport, supply of Greenland towns, etc..

THE NEW SHIPPING LANES

The continued melting of ice in the Arctic Ocean is expected over a 10 to 20 year period to result in the opening (at least during parts of the year) of the Northwest Passage over North America and the Northeast Passage over Russia. The economic benefits of these new routes are potentially significant. The opening of the Northwest Passage will reduce the distance from Seattle to Rotterdam by almost 25% compared to the route via the Panama Canal. The possibility of navigating the Northern Sea Route via the Northeast Passage will reduce the distance between Rotterdam and Yokohama by over 40% compared to the route via the Suez Canal. Furthermore, the opening of these alternative routes means that the military and commercial shipping will no longer be dependent on passage through the political unstable Middle East nor the piracy-infested routes through the South China Sea, the Malacca Straits and the Gulf of Aden.

Danish pioneers: In September 2010, the heavy ice class bulk carrier, "Nordic Barents", of the Danish shipping company, Nordic Bulk Carriers, sailed via the Arctic and the Northeast Passage to Asia as the first cargo ship ever to do so. The voyage, with 41,000 tons of iron ore concentrate from Kirkenes in northern Norway to China was around 30% shorter than if the ship had used the traditional route via the Mediterranean and the Indian Ocean and took place in close cooperation with the Norwegian Tschudi Shipping Company and the Russian authorities. In August 2008, the Danish cable ship "Peter Faber", assisted by Canadian pilots, sailed as the first commercial vessel through the Northwest Passage thus saving 15 days on its voyage from Japan to Newfoundland in order to lay cables between Greenland and Canada.

THE POLAR CODE

The Polar Code will supplement the international maritime safety and environmental conventions which already apply in the Arctic with additional rules on rescue equipment, fire fighting, ice navigation and navigation in uninhabited areas to allow for Arctic conditions. The Polar Code must also allow for the changing requiretments imposed by geography and seasons. The work is taking place at the International Maritime Organisation (IMO) and the rules are expected to come into force in 2013-2014.

AGREEMENT ON AERONAUTICAL AND MARITIME SEARCH AND RESCUE IN THE ARCTIC COUNCIL AND PREPAREDNESS IN GREENLAND

At its meeting of foreign ministers in May 2011, the Arctic Council adopted a mutual agreement on Search and Rescue (SAR), which aims to strengthen coordination of rescue efforts, so in the event of an accident, it is possible to receive rapid assistance from neighbouring countries' emergency services. The Ministry of Economic and Business Affairs, Ministry of Transport and Ministry of Justice have overall responsibility for the SAR response in Greenland. The daily operational management is handled by the Greenland Command, the Air Rescue Service and the Chief of Police office in Greenland.

2.3. EXERCISING OF SOVEREIGNTY AND SURVEILLANCE

The Arctic is and must be a region characterized by peace and cooperation. Even though the working relationship of the Arctic Ocean's coastal states is close, there will be a continuing need to enforce the Kingdom's sovereignty, especially in light of the anticipated increase in activity in the region. While the Kingdom's area in the Arctic is covered by the NATO treaty Article 5 regarding collective defence, the enforcement of sovereignty is fundamentally a responsibility of the Realm's central authorities. Enforcement of sovereignty is exercised by the armed forces through a visible presence in the region where surveillance is central to the task. In addition, the armed forces play an important role in the provision of a range of more civilian-related duties. Within the entire spectrum of tasks, the Kingdom attaches great importance to confidence building and cooperation with Arctic partner countries.

The long-term political agreement on defence (Danish Defence agreement 2010-2014) involves a stronger focus on the tasks of the Danish Armed Forces in the Arctic. The agreement includes four overriding initiatives that must be viewed in light of climate change and increased activity that would foreseeably result in an increase of tasks for the armed forces.

Firstly, the Armed Forces North Atlantic command structure will be streamlined by the amalgamation of the Greenland Command and the Faroe Command into a joint service Arctic Command.

Secondly, the ability of the armed forces to conduct operations in the Arctic environment will be strengthened through the establishment of an Arctic Response Force. The response force would not be established permanently, but designated from existing armed forces and emergency preparedness units with Arctic capacity or the potential to develop one. The range of tasks of the Arctic Response Force is for defined periods and in defined areas anticipated to strengthen the armed forces' enforcement of sovereignty and surveillance, for instance through military exercises. The force could also be deployed in other situations such as in assistance to the Greenlandic society.

Thirdly, a risk analysis of the maritime environment in and around Greenland is to be conducted in the light of an anticipated expansion of traffic and activity in the Arctic.

Fourthly, towards 2014 a comprehensive analysis of the armed force's future tasks in the Arctic is to be carried out, including opportunities and potential for closer cooperation with partner countries in the Arctic concerning surveillance and the like. In this connection it is to be examined whether the Thule Air Base may play a larger role in regard to the tasks performed in and around Greenland by the Danish Armed Forces in cooperation with other partner countries.

The Danish Defence aspires, as other public institutions, to reflect the surrounding community. Indeed, it is a Danish-Greenland hope that citizens of Greenland can be increasingly involved in the tasks of the armed forces and with that, participate in a wide range of training opportunities, whether they be basic training, civil/military specialist and management training programs or customized further education at all levels. The armed forces will thereby also greatly benefit from Greenland local knowledge.

- The armed forces must be visibly present in and around Greenland and the Faroe Islands with regard to the enforcement of sovereignty and surveillance. The North Atlantic command structure is to be streamlined by the establishment of an Arctic Command and an Arctic Response Force is to be designated from existing units.

- The Kingdom will reinforce confidence-building in cooperation with other Arctic states to maintain the Arctic as a region characterized by cooperation and good neighbourliness, just as the Kingdom will continue to play an active role in creating and promoting new collaborative initiatives between countries in the Arctic. The Kingdom will stress the potential for increased cooperation on surveillance.

- The possibilities to enhance cooperation in regard to the armed force's tasks will be looked into, including the involvement of Greenland's citizens in the handling of key tasks of the armed forces in the Arctic. The possibilities for targeted information and recruitment campaigns and the establishment of customized courses will be studied.

KEY TASKS OF THE ARMED FORCES IN THE ARCTIC

Enforcement of state sovereignty is a fundamental task of the armed forces in all parts of the Kingdom. Sovereignty enforcement is the primary task of the Danish Armed Forces in the Arctic and the level of presence in the area is determined accordingly. Units from the army, navy and air force carry out tasks in the Arctic. They undertake surveillance and enforcement of sovereignty of Greenland and Faroese territorial waters and air space, as well as the Greenland exclusive economic zone and the fishing zones to ensure that no systematic violations of territory can take place. Likewise, the Sirius Patrol oversees the National Park in Northeast Greenland and enforces sovereignty there.

As part of its presence, the armed forces is building a habitual picture of activities in the waters around Greenland and the Faroe Islands. The armed forces presence and overview of activities in the Arctic establishes a basis for solving many other tasks , including providing assistance to the Greenland community. Activities in the Arctic are largely related to the ocean as a transportation route and to the utilisation of marine resources.

Climate change in recent years, in particular the melting of ice masses, has resulted in an increase in the navigable areas and the commercial activities that follow in Greenland in the summer from mid-May to mid-October and this trend looks set to continue. In winter, there has not been a corresponding change of activities in the area. How this development will affect the armed forces' tasks is analysed as part of the Defence Agreement 2010-2014.

The armed forces adapts its deployment of vessels, aircraft and other capacities in accordance with the distinct difference in seasonal activity. Because of the enormous dimensions of the Arctic, international cooperation is an important element in resolving the armed forces' tasks in the Arctic.

3. Self-sustaining growth and development

- Mineral resources shall be exploited under the highest international standards of safety, health, environment, preparedness and response, and transparency with high returns for society.
- The use of renewable energy sources must be increased significantly.
- Living resources, including fish, shellfish and marine mammals shall be harvested in a sustainable manner based on sound science.
- New opportunities in the Arctic must be exploited in close cooperation with industry, and an optimal regulatory framework will be created for exports and investments.
- The Kingdom's Arctic research will be at the global forefront, and research and training efforts must support the development of industry and society in the Arctic.
- The Kingdom will promote Arctic cooperation on health and social sustainability, including research and best practices in areas of shared challenges.

It will be an overriding political priority for the Kingdom and particularly in Greenland over the next ten years to seize the many opportunities in the Arctic to create more growth and development. The huge economic potential in the Arctic must be realized while appreciating its human impact, i.e. the economic and social integration of the population and with sensitivity to environmental concerns, thereby creating a healthy, productive and self-sustaining community. Greenland is already a fast-changing society and peoples in the Arctic, including the Greenlanders, may have to adapt to even more extensive changes in the future due to climate change, societal developments and the restructuring of industry. Integration into the new opportunities in the Arctic will place great demands on the populations' adaptability and mobility. It will also be a significant challenge for Greenland to develop policies which, apart from the goal of social and societal-related sustainability, deal with the prospect of significant foreign labour migration.

There is a close correlation between on the one hand realising the potential of natural resources, new trade and investment opportunities, and enhanced research and education contributions while on the other promoting health and social sustainability, which are the areas specifically addressed in this chapter. This concerns a number of strategic priorities for the Kingdom in relation to economic and societal development in the Arctic, but also other important areas such as enhanced economic development and diversification of the economy. This applies i.a. to the development of the tourist industry and bolstering the overall development with adequate infrastructure.

Today, ***tourism***, second only to fisheries, is the most important export industry in Greenland, and the tourist industry has potential for growth in the future. This ap-

plies both to land-based tourism and the cruise-liner business. Among the benefits of the latter is that even small towns and villages along the coast can be involved in tourism. The land-based tourism generates by far the greatest revenue but is currently dependent on only a few markets, primarily the Danish. Therefore Greenland's Tourist Board is working on the development of a new national brand that more clearly defines Greenland as an adventure destination focusing on sustainable tourism and which to a greater extent appeals to the global market.

GEOLOGICAL SURVEY OF DENMARK AND GREENLAND GEUS

The Geological Survey of Denmark and Greenland (GEUS) is responsible for the scientific exploration of the geological survey of Denmark and Greenland, including their respective shelf areas. GEUS will conduct research at the highest international level on issues of importance to the exploitation and protection of Denmark and Greenland's geological natural resources. GEUS also carries out mapping, monitoring, data collection, data management and the presentation of these issues. GEUS provides geological advice to public authorities on nature, environment, climate, energy and mineral resource related questions and participates in the authority's regulatory work within these areas. GEUS is a national geological data centre and in that capacity makes data and knowledge available to the authorities, educational institutions, businesses and individuals. GEUS's tasks in relation to Greenland are generally defined in the Self-Government Act and are described in the Mineral Resources Act for Greenland.

Infrastructure is a key element in the development of the Greenland society and to ensure long term sustainable development, the Government of Greenland set up a transportation commission in 2009 for the socio-economic analysis of the entire infrastructure in Greenland. The Commission's recommendations of April 2011 will form an important element in future policy decisions on the evolution of Greenland infrastructure. This will include decisions on the location of ports and airports. These projects will be costly and therefore private funding is seen as a possibility, just as mining projects located near urban areas could be included in potential funding of larger local infrastructure projects.

3.1. HIGH STANDARDS FOR THE EXPLOITATION OF MINERAL RESOURCES

Studies from the U.S. Geological Survey, among others, estimate that there may be enormous, as yet unproven oil and gas resources in the Arctic, just as previously major discoveries were made of gas especially (in Russia) but also oil (in Alaska). Specifically, it is estimated that the Arctic may contain up to 30% of the world's undiscovered gas resources and approx. 10% of the oil resources. Approximately 97% of oil and gas resources are believed to lie within the Arctic States' exclusive economic zones, and are thereby allocated.

In Greenland's case, it is estimated that 31 billion barrels of oil and gas off the coast of Northeast Greenland and 17 billion barrels of oil and gas in areas west of Greenland and east of Canada could be discovered, though the probability is greater for discoveries in Northeast Greenland. Greenland is also rich in mineral deposits, including zinc, copper, nickel, gold, diamonds and platinum group metals, and has substantial deposits of so-called critical metals, including rare earth elements, several of which are important components of high-end technology, including green energy technologies.

The mineral resources sector in Greenland has significantly matured over the last 10-15 years as a result of a long-term and deliberate strategy. After the adoption by Parliament Act No. 7 of 7 December 2009 on mineral resources and activities of relevance hereto, the mineral resources sector was fully taken over by the Greenland Self-Government on 1 January 2010 and is a key element to building growth industries and a self-sustaining economy. In 2008, Greenland had already adopted the Parliament Act No. 6 of 5 December 2008 on Greenland's Mineral Resources Fund, which is inspired by the Norwegian model so that oil and gas revenues also benefit future generations.

The vision is to exploit mineral resources in the Arctic under the best international practices, and in continued close cooperation with relevant authorities of the Danish Realm and international partners. Greenland and the Faroe Islands shall be attractive areas for exploration, and the management of mineral resources must be competent and efficient in ensuring that such mineral resources are explored and exploited under the highest standards of safety, health, environment, emergency preparedness and transparency. The mineral resource industry must be developed while strongly taking into consideration the fragile Arctic environment so it contributes to sound economic development, including the creation of new jobs and a maximum return to society. Mineral resource activities will also be carried out with sufficient preparedness that the public is kept from harm (based on the polluter-pays-principle) and that the Kingdom's international obligations can be met in case of major unscheduled incidents. This should be a model for resource exploitation across the whole of the Arctic.

In the oil and gas sector, licensing rounds have been held biannually since 2002 and alongside rising oil prices in recent years, there has been a breakthrough in the international interest in Greenland's oil potential. An area of more than 200,000 km² offshore South and West Greenland is now covered by 20 exploration and exploitation licenses, and in 2010 seven new exploration licenses were issued in Baffin Bay off the coast of Northwest Greenland. A licensing round for oil exploration off the coast of the northernmost part of East Greenland will be held in 2012/2013. In the coming years in particular, there will be a need to maintain the level of activity offshore of West and Northwest Greenland, while ensuring a broad professional knowledge building in the more inaccessible areas off Northeast Greenland. With respect to oil and gas finds and subsequent production, a number of new challenges and tasks will emerge. As a result, coordination and cooperation with neighbouring Arctic states with similar challenges will be a major priority.

In 2000 the first licenses for exploration of the Faroese shelf were issued. Subsequently there were two licensing rounds in 2005 and 2008. In total, 17 licenses have been issued, of which 12 are currently active with a total of 11 licensees. Of the 7 wells drilled so far, 5 contain hydrocarbons, but finds on a commercial scale have not yet been confirmed. There is still unexplored potential for exploration in structures that could potentially contain large amounts of hydrocarbons. Currently there are two outstanding drilling commitments, of which the first well will be drilled in 2012.

The current relatively modest level of activity has already had favourable effects on the Faroese economy through direct and indirect taxes in connection with drilling and area fees. Another significant benefit is the boost in commercial competencies and employment opportunities which wholly or partly are attributable to exploration activity on the Faroese Continental Shelf. One condition for acquiring a license is that a commitment must be entered into to finance activities that build up local competencies. This enhancement of competence must be commercially oriented though not necessarily be related to the oil industry. The arrangement should be seen as an investment in both the present and future, and already several hundred projects, both large and small, have been carried out. This has created a solid basis for local involvement provided that commercial discoveries are made on the Faroes.

In the ***mineral sector***, exploration in Greenland in recent years has especially targeted gold, zinc, iron, copper, diamonds, rubies and a number of critical metals, including rare earth elements. The prospects are bright that the development of the mineral sector can significantly underpin the development of an economically self-supporting Greenland. The Government of Greenland is expecting that a number of mature projects developed with foreign partners and partial involvement of Danish companies will create over 1,000 new jobs by 2015. Regarding radioactive minerals, the Self Government follows a zero-tolerance policy, which means that it does not permit the exploration and exploitation of deposits that contain radioactive elements, either as a main product, by-product or residue. In 2010 an amendment was made to the standard terms for exploration, which permits the carrying out of feasibility studies, including environmental, health and safety studies of deposits containing radioactive elements.

- Greenland will continue the successful licensing policy and strategy of competitive tenders in the oil and gas sector. Sets of rules will be continually adapted to optimize safety, health, environment and transparency standards through the use and improvement of best available techniques and practices. This will include inspiration from other countries' regulations, not least the Norwegian NORSOK standards.

- Cooperation will be expanded with authorities in similar areas, including Norway and Canada, and participation in relevant international fora such as the Arctic Council's working groups is to be given high priority.

- The Kingdom will work actively in the United Nation's Maritime Organisation (IMO) or other international fora, for the establishment of an international liability and compensation convention and a possible international compensation fund for pollution damage caused by offshore oil exploration and exploitation.

- Terms and conditions for licenses to exploit must be reasonable for both larger and smaller companies, resilient to fluctuating market conditions as well as simple and easy to administrate for companies and authorities.

- Mineral sector activities must be conducted responsibly as regards environmental, health and safety concerns, and an appropriate supervisory body must ensure compliance hereof.

OIL AND GAS ACTIVITIES IN GREENLAND

High standards for activities

In connection with the exploration and exploitation of oil and gas resources regulated by the Greenland Mineral Resources Act, the licensee must ensure that ***safety, environmental and health risks*** are identified, assessed and reduced as much as practically and reasonably possible.

The Bureau of Minerals and Petroleum (BMP) guidelines and terms of approval are based largely on the Norwegian NORSOK standards which determine how the licensee can comply with international best practice in relation to specific operational procedures and practices. The BMP follows strict compliance with international standards, supplemented by an emergency committee broadly composed of authorities of the Danish Realm (including the Danish Armed Forces and the Danish Maritime Authority) and Greenland authorities. The Emergency Committee monitors the precautionary actions taken by the licensee, and is responsible for coordinating the authority's efforts in accident and emergency situations on offshore installations.

Thus, permission is only given for exploration and exploitation activities provided that the Government of Greenland is fully assured that the activities are performed properly in a safe and healthy manner and stringent requirements are made of licensees regarding their own capacity to deal with accidents and emergencies. Under the Mineral Resources Act, the responsibility for clean-up operations and compensation always lies with the party causing damage, whereby a number of stringent requirements are imposed following international standards regarding financial guarantees and insurance for oil and mineral activities.

Before new offshore areas are designated as oil / gas licensing areas, the Government of Greenland sets in motion the preparation of ***strategic environmental impact assessments*** in order to ensure that any oil / gas activities can be implemented on an environmentally sustainable basis. The strategic environmental impact assessments are prepared on a scientific basis by the National Environmental Research Institute and Greenland's Institute of Natural Resources. In connection with an application for the carrying out of concrete oil / gas activities which are likely to have a significant impact on the environment, such as exploration wells, the licensee is required to conduct a specific assessment of the environmental impact (EIA). The EIA report is submitted for public hearing and must be approved by the Government of Greenland before the application to carry out the activity can be approved.

Under the Mineral Resources Act, companies seeking a license for exploitation must also prepare an ***Assessment of Societal Sustainability*** (SSA report). The report must, for example, describe the utilisation of Greenland manpower and enterprises in the project, including how the proportion of Greenland employees and subcontractors can be increased through training and skills development.

Cooperation with Cairn Energy

Scottish Cairn Energy's exploratory drilling for oil in waters west of Qeqertarsuaq and Nuussuaq Peninsula is presently the most advanced project, and collaboration between the company and the authorities has been very positive. The self-government has used Norwegian consultants for the regular monitoring of compliance with stringent safety requirements, and similarly the self-government has established cooperation with the Canadian government in the area. Cairn Energy has also complied with the Greenland authority's demands for financial guarantees in case of an accident, oil spill or a major environmental emergency. Cairn Energy, affected municipalities and Greenland's Self Government have also entered into a cooperation agreement on recruiting Greenland labour in the future, including initiatives which develop relevant courses as part of the self-government's efforts in using the resident workforce and local businesses wherever possible in the future.

Licensees in oil and gas sectors in Greenland

As of 1st January 2011 there were 20 active exclusive right licenses for exploration and exploitation of oil and gas in the sea around Greenland. During 2012-2013 a licensing round will be carried out covering offshore Northeast Greenland. There is great interest from a number of different companies and as of January 2011 the licensees are: NUNAOIL (Greenland), DONG (Denmark), Maersk Oil (Denmark), ExxonMobil (U.S.), Chevron (U.S.), Husky (CAN), Cairn Energy (UK), PA Resources (SVE), ConocoPhillips (U.S.), Shell (NL), Statoil (NOR), GDF Suez (FRA) and Petronas (Malaysia).

OIL ACTIVITIES IN THE FAROE ISLANDS

High standards for activities

The execution of exploration activities in the Faroes takes place with continuous regard for the environment and the existing fishing industry. Safety procedures for example are on par with the Danish, Norwegian and British. This includes requirements for the licensees regarding their technical and economic expertise as a part of their responsibilities. Furthermore, exploration activity must always live up to best practices in the industry and be geared to the circumstances of the specific drilling location. To be updated on developments in safety matters, the Faroe Islands is a member of NSOAF (North Sea Offshore Authorities Forum), an association of offshore safety authorities in countries in Western Europe with an oil industry. As the exploration activity on the Faroese shelf is geographically close to activity in the UK and Norwegian waters, the emergency preparedness is also tied to response equipment on the respective British and Norwegian continental s helves. To a great extent, this places emergency preparedness on the Faroese shelf on a par with that in Norway and the UK.

Authorities' responsibility for oil drilling in the Faroe Islands

The Faroese Ministry of Trade and Industry has overall responsibility for exploration activity in the Faroes. The everyday management is delegated to Jarðfeingi (Faroese Earth and Energy Directorate), which also deals with public sector geological interests, and has an advisory function regarding energy issues.

Umhvørvisstovan (the Environment Agency) is responsible for the Faroese marine environment act and the Faroe Islands Marine Rescue Coordination Centre (MRCC) Torshavn is responsible for coordination regarding incidents offshore.

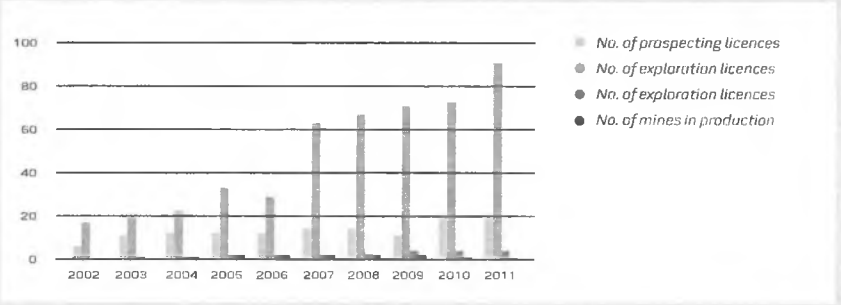
Oil companies active in the Faroe Islands

Atlantic Petroleum (FO), Cieco (Korea), Dana Petroleum (UK), DONG (DK), ENI (ITA), Exxon Mobil (US), Faroe Petroleum (FO), First Oil Expro (UK), OMV (Østrig), Sagex Petroleum (NOR), Statoil (NOR).

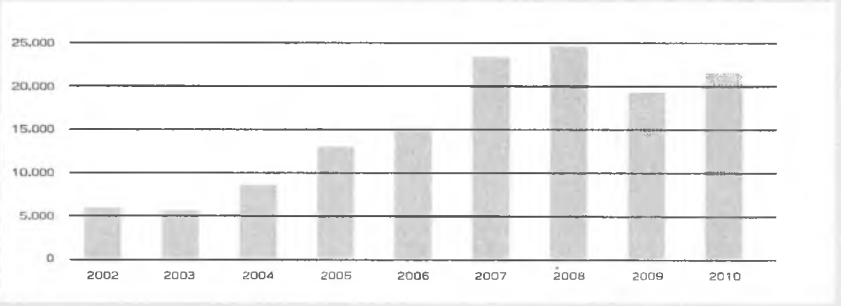
GREENLAND'S STRATEGY FOR MINERALS

The Government of Greenland's strategy and plan of action for exploration and exploitation of hard minerals is described in the sectoral plan "Mineral Strategy 2009". The main objectives of the strategy are that all projects must be implemented socially sustainably, and ensuring that:

1) The society will receive a competitive share of profits gained from mining.
2) Greenland manpower and enterprises are used to the greatest possible extent.
3) All mineral activities are to be conducted properly in terms of safety, health and the environment.
4) The population is ensured participation and knowledge in the development of the mineral sector.
5) The development proceeds with respect to Greenland values.



Development of mineral activities in Greenland



Area (km²) covered by exploration licenses

CRITICAL METALS / RARE EARTH ELEMENTS AND DEPOSITS IN GREENLAND

A raw material/ mineral is considered 'critical' if it is used for purposes for which there are no other satisfactory alternatives. A given mineral resource's criticality is dynamic and is determined by issues of supply, demand and the potential reuse of the resource. New technology can change the requirements. The time span from exploration to the opening of a new mine will generally not be less than 10 years; therefore the mining industry has difficultly in keeping pace with market requirements for new resources. There may be various reasons why it can be difficult to obtain a given commodity, for example:

1) Geological conditions;
2) Technical factors;
3) Social conditions;
4) Political factors, and
5) Economic conditions – i.e., whether or not the raw material is available on the market.

Mining Opportunities in Greenland
Overview of critical minerals (short term) [1]

Mineral	Area	Rating of resource
Antimony	East Greenland	Moderate
Beryllium	South Greenland	Low
Cobalt	-	Low
Fluorspar	East Greenland	Low
Gallium	East Greenland	Moderate
Germanium	-	Unknown
Graphite	West- and East Greenland	Moderate
Indium	-	Low
Lithium	-	Low
Magnesium	-	Low
Manganese	-	Low
Niobium	South Greenland	Large
PGM 2	West- and East Greenland	Large
REE 3	South Greenland	Large
Tantalum	South Greenland	Large
Tellurium	-	Unknown
Tungsten	East Greenland	Moderate

Overview of mineral resources which can be critical in the long term
Known deposits in Greenland [4]

Mineral	Area	Rating of resource
Aluminium	-	Low [5]
Zinc	South, West and North Greenland	Moderate
Nickel	East Greenland	Moderate
Manganese	-	Low
Iron	South, West and North Greenland	Large
Chrome	Southwest Greenland	Moderate
Molybdenum	East Greenland	Large
Vanadium	South and East Greenland	Large
Titan	South and East Greenland	Large
Copper	North and East Greenland	Large
Uranium [6]	South Greenland	Moderate

[1] Estimated by the EU, respectively (Raw Materials Supply Group. EU 2010), U.S. (Minerals, Critical Minerals, and USE economy 2008) and UNEP (Critical Metals for Future Sustainable Technologies and their recycling potential; UNEP 2009), respectively. [2] PGM = Platinum Group Metals. [3] REE = rare earth elements. [4] Estimated by the EU (Raw Materials Supply Group. EU 2010). [5] Can be high with other technology. [6] Greenland currently has zero-tolerance policy on uranium and thorium.

GREENLAND'S COMMITMENT TO RENEWABLE ENERGY

In 1990, the use of renewable energy in Greenland was almost zero, but since 1993, Greenland's Self-Government has annually invested an average of approx. 1% of GDP in the development of hydropower and other renewable energy sources. Today, renewable energy makes up 60% of the public energy supply via the power supply company, Nukissiorfiit. When the Ilulissat hydroelectric plant comes into operation in 2013 as expected, the proportion will rise to approx. 70%.

The Greenland hydroelectric power plants:

- Buksefjord Power Station at Nuuk (1992/2008) with an output of 45 MW;
- Tasiilaq hydroelectric plant (2005) with an output of 1.2 MW;
- Qorlortorsuaq hydroelectric plant (2008) with an output of 7.2 MW;
- Sisimiut hydroelectric plant (2009) with an output of 15 MW;
- Ilulissat hydroelectric plant (to be inaugurated in 2013) will have an output of 22.5 MW.

Through the annual Greenland Finance Act account for the Support of Research and Development of Renewable Energy a number of concrete projects are supported, including the installation of solar panels and wind turbines, installation of remote readers and the dissemination of renewable energy. Since 1993, an average of 1% of GDP has been invested annually on the development and establishment of hydropower.

3.2. EXPLOITATION OF RENEWABLE ENERGY POTENTIAL

The Kingdom will pursue ambitious and active energy and climate policies. The energy policy objectives of Greenland, Denmark and the Faroe Islands respectively are to create security of supply, to reduce emissions of greenhouse gases and air pollution while creating a basis for commercial development. A shared ambition is to significantly increase the harnessing of renewable energy sources. Denmark's commitment to renewable energy targets under the EU is 30% by 2020. Greenland will increase its share of renewable energy to 60% of total energy production by 2020. The Faroe Islands will increase the use of renewable energy, including the target of 75% of electricity production based on renewable energy by 2020.

Greenland has a tremendous natural potential for renewable energy, which among other things can be utilised for the development of emerging industry. An example is the designing, in collaboration with the American company, Alcoa, of an aluminium smelting plant in Maniitsoq which will be operated solely by hydropower. Increasing focus in Greenland is placed on small-scale solutions for renewable energy to be used in smaller towns and settlements where there is currently no access to hydropower. The Government of Greenland provides support for developing renewable energy projects, including micro hydropower plants, and solar and wind power projects that aim at a green and self-sufficient Greenland energy supply. Furthermore, the utilisation of renewable energy in the transport sector is being explored. The development of renewable energy sources is a key issue in Greenland's international cooperation.

- Denmark, Greenland and the Faroe Islands will increase the share of renewable energy sources in the energy supply in order to increase the security of supply, reduce emissions of greenhouse gases and air pollution, and thus create the basis for enhanced commercial development and knowledge sharing through training and participation in projects.
- The Government of Greenland will continue to promote the utilisation of renewable energy in Greenland. In the smaller towns and settlements, the development of local energy solutions based on renewable energy must be supported. The Government of Greenland will also promote Greenland's potential to house industrial production based on renewable energy.

3.3. SUSTAINABLE EXPLOITATION OF LIVING RESOURCES

The Arctic regions are unique ecosystems that represent important values biologically and socially. The natural resources have shaped the development of Arctic fishing and hunting cultures and traditions, and the utilization of fish and marine mammals has always formed the bedrock of Arctic societies and economies. Historically, supply-related and cultural considerations are fundamental to the Arctic population's relationship to the exploitation of living resources, whether fish or marine mammals. The exploitation of living marine resources is one of the essential economic factors in both Greenland and the Faroe Islands.

The structure, function, diversity and integrity of the ecosystem in the Arctic are crucial to the productivity. The Arctic must therefore be managed so as to ensure a healthy marine ecosystem with economically sustainable species and stocks. Ecosystem-based management means that management of the ecosystem is based on a holistic approach where all parts of the ecosystem and all impacts, including those from human activities, are taken into account in management. The management of living marine resources in the Arctic must ensure a high return within the ecosystem's capacity, ensure minimal impact on the ecosystem, and guarantee respect for the ecosystem's capacity for future production of living resources.

Greenland and the Faroe Islands' ***fishery*** takes place mainly in the North Atlantic, the Denmark Strait and the David Strait. Greenland's fishery is based on a quota system whose aim is to ensure a sustainable exploitation of certain stocks. Therefore, an annual "Total Allowable Catch" (TAC) of the principal species is stipulated, based on biological advice and respecting socio-economic concerns, commercial interests and international obligations. The biological advice is provided by the Greenland Institute of Natural Resources and a number of regional organizations, particularly the ICES and NAFO.

Faroese fishing of pelagic stocks and fishing in other waters under bilateral and multilateral agreements is mainly based on quota systems, while for groundfish fisheries around the Faroe Islands there is a special system of fishing days and areas which are closed as required. Besides their own expertise, the Faroese also draw on international advice, particularly ICES. Greenland and the Faroe Islands each have agreements with one another and also with the EU, Norway and Russia, and the Faroe Islands furthermore with Iceland. The Faroe Islands, though also Greenland, shares fishery stocks with close neighbours and exports of fish and fish products form a large part of the economy of both countries. The Faroe Islands' export of fish and fish products represents approx. 90% of total exports and for Greenland, approx. 85% of total exports.

The Greenland fishery industry is facing a structural challenge of adjustment, including the need of larger and more modern vessels and the need for future regulation of the industry in relation to ownership provisions and access to capital. This restructuring process will also cause an outflow of labour to other industries and make demands on social policy. Greenland's Self-Government has initiated a project concerning the consequences of climate change on the fishing and hunting industry with a view to identifying opportunities for adaptation that manage the challenges while exploiting new opportunities. The adaptation of industry and retraining initiatives in for example the fisheries industry, might be one element of a new phase of partnership between Greenland and Europe.

A key element in fishery management is control and enforcement. Control operations are undertaken by the Greenland and Faroese authorities who monitor that both Greenland and Faroese, and relevant international fishery regulations are complied with by all vessels in their respective waters, as well as by Greenland and Faroese vessels operating internationally. The inspection of vessels and catches at sea is undertaken by the Danish Armed Forces and the Faroe Islands Fisheries Inspection ***Fiskiveiðieftirlitið***. Furthermore, regional cooperation on inspections remains a priority.

General increases of temperature in the Arctic and rapid melting of ice can make new areas of the Arctic Ocean potentially attractive for fishing. This presents new challenges with regards to national and international regulation of these areas due to insufficient data about them. In addition, illegal, unreported and unregulated fishing is a serious threat to marine ecosystems which has considerable implications for conservation and rational management of marine resources. It is a huge task for small communities with large ecosystems to provide adequate expertise for the management and control of fishery. In the Arctic, there is relatively limited knowledge of fish stocks and fishery opportunities, which means that the precautionary principle should be applied to protect the environment and fishery resources.

Hunting is an integral part of the Arctic community and a sustainable exploitation of hunting resources is important for the local economy and for cultural self-identity. The best possible basis for decisions should be ensured in the exploitation of these resources nationally and internationally. Similarly, it is essential that hunters have confidence in the basis for decision-making so that limitations on hunting are observed. The Greenland seal-hunting industry is currently under pressure partly because the European and North American markets for sealskin have

KEY ORGANIZATIONS AND OTHERS IN THE FISHERY AND HUNTING SECTOR

- ICES - International Council for the Exploration of the Sea: International organization that is responsible for coordinating and promoting marine research in the North Atlantic and adjacent seas, the Baltic and North Sea. The organization has 20 member states, including Denmark, with the Faroe Islands and Greenland.
- NAMMCO - North Atlantic Marine Mammal Commission: Regional management organization for marine mammals with Norway, Iceland, the Faroe Islands and Greenland as members. NAMMCO has observer status in the Arctic Council.
- NAFO - Northwest Atlantic Fisheries Organization: Regional fisheries management organization that provides science-based advice, as well as managing and regulating fishing in the Northwest Atlantic. NAFO consists of 12 members at present, including Denmark in respect of the Faroe Islands and Greenland.
- NEAFC - Northeast Atlantic Fisheries Commission: Regional fisheries organization that provides science-based advice and manages and regulates fishery beyond 200 miles in the North Atlantic and up to the North Pole. NEAFC currently consists of 5 members, including Denmark in respect of the Faroe Islands and Greenland.
- IWC - International Whaling Commission: International Management Organisation which regulates hunting of large whales. Denmark, the Faroe Islands and Greenland are members. Greenland allocates quotas on large whales by means of the so-called "Aboriginal Subsistence Whaling quota"

virtually collapsed after pressure by special interest groups on consumers. Internationally, there is very limited understanding for the catch of marine mammals. This is also true of the Greenland catch of large whales, which is regulated by the International Whaling Commission in accordance with the exemption that applies to indigenous peoples.

- All living resources must be developed and exploited sustainably based on an ecosystem management that ensures a high return in the long term, and is in compliance with international obligations, while at the same time the Arctic communities' rights are defended in support of the fishing and hunting industry. Management must be based on scientific advice that is founded on the collection, processing and analysis of data, including from hunters and industry.

- The Kingdom will work internationally for the Arctic indigenous peoples' right to conduct hunting and to sell products from seal hunting, as long as it is based on sustainable principles.

- Denmark, Greenland and the Faroe Islands will work to ensure that the utilisation of living resources, including marine mammals, is founded upon an ecosystem-based management model that places emphasis on scientific foundation and sustainability.

- Work continuously to ensure regular scientifically based monitoring of living resources in the Arctic with the involvement of its citizens. The precautionary principle should apply in cases where there is a lack of adequate knowledge about development in previously ice-covered areas.

- Effective management and control regimes must be pursued to counter illegal, unreported and unregulated fishery and hunting, and also work for international agreements on potentially attractive Arctic high seas not yet covered by the conservation and management systems. The parts of the Danish Realm will work to ensure that in general fishery does not commence where a conservation and management system is not available.

- The parts of the Danish Realm will work to strengthen international cooperation on scientifically based management of shared fish stocks and fishery in international waters with a view to promoting consensus on sustainable management plans and allocation formulas for the benefit of all relevant parties.

- The parts of the Danish Realm will work towards the introduction of a special regional form of control for a prudent fishery in large ecosystems in sparsely populated areas where there is no historical data and where it is particularly challenging to collect data and carry out control. Methods must be developed for sustainable management in situations of scientific uncertainty, whereby models are developed that support a learning management system based on the precautionary principle.

WHALING

Denmark is in a rather unique situation when it comes to whaling, since the Kingdom's three parts - Denmark, the Faroe Islands and Greenland - each have their own whaling policy. This particular situation is similar to the U.S. and Russia, which also distinguish between population groups that rely on whaling and the rest of the territory. The Faroe Islands and Greenland's maritime policy is based on the principle of being able to live off marine resources in a sustainable way, whether it be fish, seals or whales. Each part of the Danish Realm is empowered to regulate the exploitation of whale resources in their own waters - though some whale species are subject to decisions to which the Kingdom is bound under the framework of the International Whaling Commission (IWC). The entire Danish Realm is thus bound by the IWC's current ban on commercial hunting of large whales.

In the Faroe Islands and in Greenland there is general support for a principled policy and the political priority is to ensure the populations' right to hunt. In the Danish part of the realm, many people are fundamentally hesitant about whaling and whaling is not practised in Danish waters, although there is understanding for the situation of Greenland and the Faroe Islands. In Danish waters, EU rules apply, i.e. a total ban on whaling. In Greenland, the hunting of small as well as large whales is operated in connection to the society's food supply. Large whales are covered by the IWC's regulatory powers. As a member of the IWC, the Kingdom therefore seeks, at intervals, to obtain backing in the IWC for quotas of relevant species of whales in Greenland. The Faroe Islands has previously operated commercial hunting of large whales, but has for many years only operated non-commercial hunting of small whales, mostly pilot whales, which are not subject to the IWC. The Faroe Islands, however, continues to see sustainable commercial whaling as a right and supports the right of other nations in this respect.

3.4. STRONGER INTEGRATION IN INTERNATIONAL TRADE

New opportunities for economic development in the Arctic are leading to increasing interest from international investors in the area. The Government of Greenland has set itself clear targets to attract more foreign investors, and to ensure that the exploitation of Greenland's natural resources in the future will constitute a major source of revenue for the Greenland society. The new trading opportunities can contribute to the diversification of Greenland's economy and create the basis for economic sustainability and prosperity. For the Faroe Islands in particular, the opening of the Northeast Passage will unfold new opportunities as a result of increased navigation. The Government of the Faroes has decided to set up a working group to assess the Faroese strategic opportunities associated with increased enterprise in the Arctic and North Atlantic area.

The heightened international interest requires the creation of attractive regulatory frameworks for investments. Therefore, Greenland is working to conform to international trade rules and obligations and create a healthy investment environment. This will not only strengthen Greenland as an attractive investment destination, but also give Greenland more opportunities to penetrate new markets. By virtue of the Kingdom of Denmark's membership, Greenland and the Faeroe Islands come under the World Trade Organisation. Since the end of 2005, Greenland has worked continuously to bring Greenland law into compliance with WTO rules. Due to its OCT status (Overseas Countries and Territories) Greenland goods have duty-free access to the EU. The Faroe Islands has duty-free access to the EU for the majority of its goods pursuant to an agreement on mutual tariff exemption in 1991, renewed in 1996. Faroe trade with the EFTA countries, Norway and Switzerland (and Liechtenstein), is covered by free trade agreements concluded in the early 1990s. As regards Iceland, the Faroe Islands entered into a more comprehensive economic cooperation agreement in 2005 (Hoyvík Agreement).

Many Arctic regions are favourably located in relation to the world's two largest markets (the EU and U.S.), especially Greenland. The opportunities for a closer association to the surrounding markets must gradually be expanded as the extent of sea ice decreases. Trading requires infrastructure, and it is essential that the infrastructure be developed to support growing trade. In Greenland, the Transportation Commission has analysed the future needs for adapting the infrastructure and its recommendations of April 2011 will form a weighty element in the basis for decisions on the development of Greenland's infrastructure.

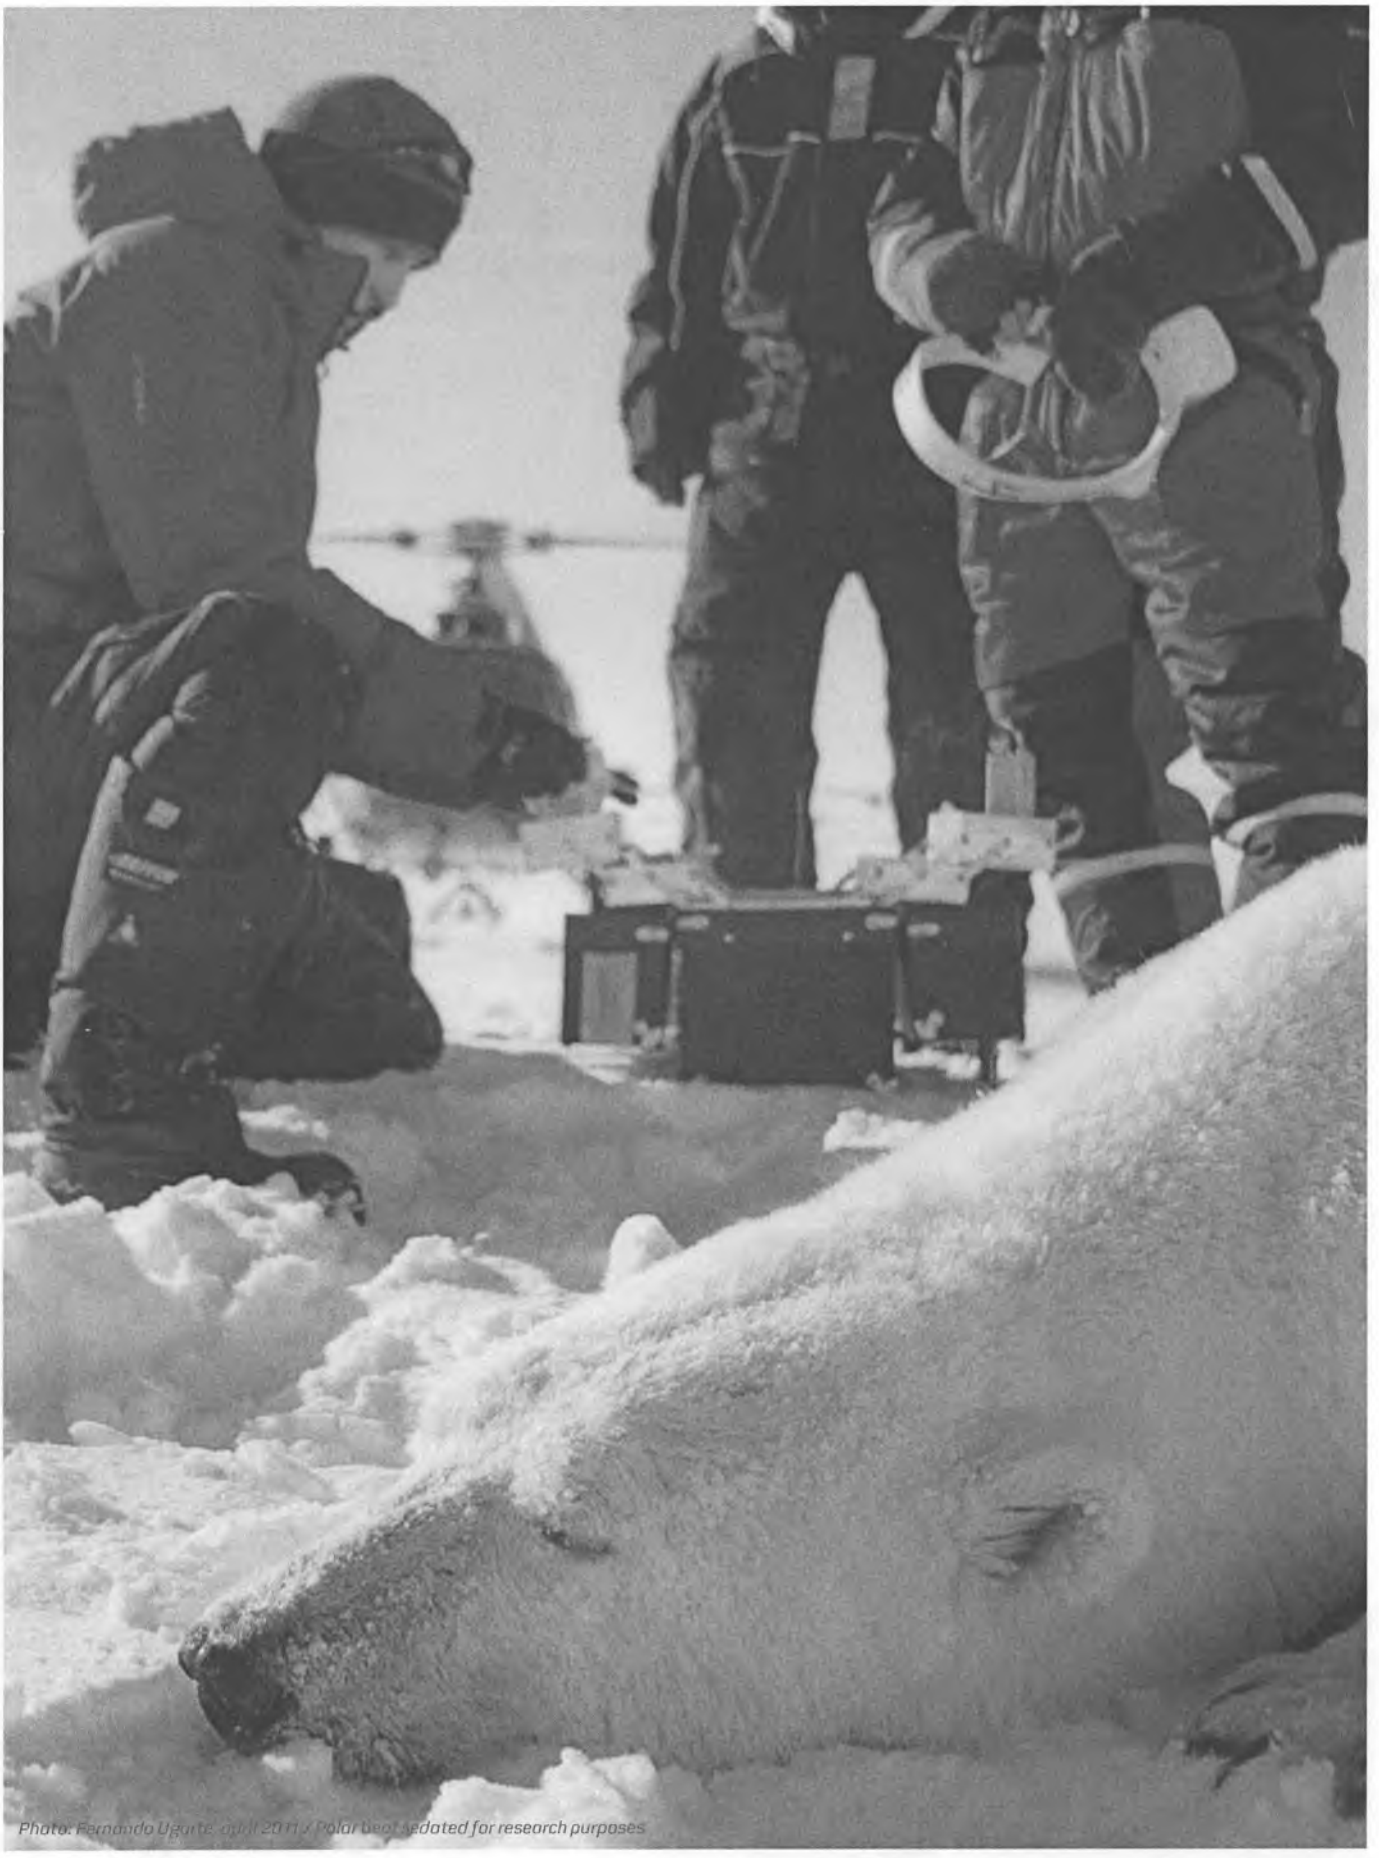

Photo: Fernando Ugarte, april 2011 / Polar bear sedated for research purposes

- A close collaboration with the business community must be ensured regarding the increased opportunities in the Arctic. The markets for Greenland and Faroese export goods are to be expanded, and internal and external barriers to exports removed.

- Inside the Kingdom's individual customs territories, the closest possible alignment must be ensured with international trade regulations and obligations, in particular the WTO's regulations.

- Cooperation must be strengthened concerning Greenland adaptation, as deemed appropriate, to the bilateral trade agreements which Denmark enters into via the EU, and the Kingdom will work to maintain - and wherever possible expand - preferential access for products from Greenland and the Faroe Islands in the EU and third countries, including entering into agreements on reciprocal free trade between the Faroe Islands and new third countries.

- Trade relations with the outside world must be managed through an ongoing infrastructure development.

3.5. KNOWLEDGE-BASED GROWTH AND DEVELOPMENT

Greenland now plays a prominent role in international research because of the unique opportunities to study processes of global importance, including the planet's geological history, natural climate variations and global warming. Interest in Arctic research has been increasing rapidly in recent years, which has resulted in major national and international research programs and increased Arctic research funds from among others the Nordic Council of Ministers and the EU. Nordic, European and wider international research and educational cooperation will also be given high priority in the future.

Global warming affects the Arctic directly, including the Greenland ice sheet, sea ice and ocean currents, which in turn have far-reaching implications for global climate trends. Meanwhile, climate change also has direct consequences for the Arctic in terms of changing circumstances for the fishing and hunting industry, the potential for mining and exploitation of hydrocarbon resources, and also navigational options for tourism and transport.

Greenland offers so many unique opportunities for research in nature, geography, biology as well as the interplay between nature and humans. It is vital that research into and monitoring of the ice sheet and research on climate and environmental processes in the Arctic are disseminated and used internationally. It is also essential that research findings are of practical use by Arctic peoples in supporting the rapid cultural, social, economic and industrial development that other peoples have had generations to adapt to. Therefore, Arctic research findings must clearly be promoted to the benefit of the Arctic populations, not least the Arctic indigenous peoples. Here, social science and health research will play a key role.

The Faroe Islands lies at the gateway to the Arctic. Nearly 90% of the total oceanic heat transfer towards the Arctic flows through this area, and the heat brought into the Arctic keeps large marine areas free of ice and far warmer than they would otherwise have been. This is the basis for the huge pelagic fish stocks that feed in the area , keeping surrounding land masses warmer than the global average at this latitude. In the Arctic and subarctic oceans, the water cools and then most sinks and returns to the world's oceans as a cold deep-water current that transports carbon dioxide, oxygen and heat from the atmosphere into the deep water masses, which are a prerequisite for all deep-water fauna. This interconnected system of ocean currents is essential to the relationship between the oceans, the global climate and not least the Arctic, but it is driven by sensitive mechanisms that can easily be weakened as the Arctic warms. The international scientific community has put considerable resources into charting patterns of ocean currents, following their changes and working out methods to predict their development and future impact on climate, living resources and humans. The Kingdom will seek to play an active and leading role in the continuation of this research effort.

There is a long tradition in the Danish Realm for Arctic research and close cooperation in meeting challenges. Danish, Greenland and Faroese universities, and research and scientific centres take part in numerous international research projects within a broad spectrum of paleoclimatic studies, research into Arctic ecosystems, oceanography, glaciology, geophysics, geology, social sciences and health sciences, and similarly a number of monitoring programs and Arctic research stations conduct an essential monitoring of climate impacts on the Arctic.

In addition, a joint research initiative by the Danish-Greenland-Faroese Continental Shelf Project provides data collection on the seabed and opportunities for follow-up research in other fields.

Research into Arctic technology, which mainly takes place at the Arctic Technology Centre in Sisimut West Greenland in cooperation with the Technical University of Denmark (DTU), is another area with potential, including requirements for the use of renewable energy in power systems and the development of Arctic infrastructure.

In 2009, the Ministry of Science and the Government of Greenland set up an interdisciplinary climate research centre in Nuuk. The centre works in partnership with

the Commission for Scientific Research in Greenland (KVUG), the Greenland Institute of Natural Resources and the University of Greenland. The centre focuses on basic research about the Arctic climate and the effects of climate change including the need for mitigation and adaptation strategies, and currently has approx. 80 Greenland, Danish and international researchers affiliated on a permanent or flexible basis.

Nordic, European and wider international research and education cooperation is to be given high priority. For example, Danish and Greenland researchers are participating in the top Nordic research initiative on climate, environment and energy, which is one of the Nordic Council of Ministers' globalization initiatives. The Kingdom also supports the running of the University of the Arctic - an association of circumpolar universities that offers a rich variety of courses relevant to Arctic students. Bilaterally, education, language and research constitute key elements in Joint Committee cooperation between Greenland, Denmark and the U.S. - and Greenland is increasingly taking part in promising bilateral research and education partnerships, as for example with Canada.

Research and education are closely connected - and must be tightly linked with economic and industrial development. For instance, in January 2011, the Government of Greenland set up a new mineral resources school by reorganising the Mining and Construction School in Sisimut. The mineral resources school will function as a knowledge centre for the entire mining resource sector and develop training within the oil industry. The Government of Greenland also has ongoing initiatives where research is used for the training of the population. Among other things, a summer school in Kangerlussuaq has been launched in cooperation with the United States under its auspices, where foreign scholars teach pupils at secondary level in scientific research topics. Finally, as part of the existing partnership agreement with the EU, Greenland receives about 25 million Euros annually in budget support for the education sector, in particular targeting the special educational drive where the societal needs are greatest.

It will remain a key priority to support the future economic and social sustainability with educational initiatives. Besides the mineral resource sector, initiatives concerning new opportunities and challenges in the maritime sector will also be central.

- The Kingdom will maintain its leading position internationally in a number of research fields concerning the Arctic, and will promote national and international Arctic research.

- The Kingdom will work to promote the participation of Danish, Greenland and Faroese academic and scientific institutions in international research and monitoring activities. This includes the quantification of global and regional impacts of climate change in the Arctic, such as how Arctic ecosystems, sea ice and ice sheets respond to climate change and also the consequences and importance of climate change for the populations and communities in and outside the Arctic.

- Research and monitoring in the Arctic puts a strain on resources and logistics and therefore international cooperation on such projects must continue to be encouraged, as well as pursuing flexible administration that facilitates access to the regions and minimizes administrative burdens on projects.

- Research in the Arctic must also help to support the cultural, social, economic and commercial development. Knowledge and data must be built up even more, firmly embedded, and also used in the Arctic where research partnerships in for example natural resources and broader social science fields will be prioritized. The extensive research by foreign researchers must be disseminated to a greater extent to relevant institutions and communities.

- Within the Kingdom, cooperation between research institutions must constantly be consolidated and developed, and researchers have to be familiar with available options for funding of Arctic research. Continuity and stability in the research environment must be assured, for example, by the recruitment of young researchers.

- Greenland targets that by 2020, at least 2 / 3 of school leavers will have gained training leading to formal qualifications, and the Government of Greenland will prioritise supplementary further education as new requirements arise. In particular, the Self-Government will develop education and training in the mineral resources area, so Greenland will increasingly be able to offer relevant and qualified manpower in the offshore and mineral industry.

- Possibilities will be considered for closer involvement of Greenland's citizens in the armed force's education and training and tasks in the Arctic, including customized programs in Greenland with emphasis on the maritime domain.

- International training and exchange cooperation will be a strategic priority for Greenland, particularly with the U.S. and Canada as well as the EU, where a new phase in the partnership could involve further adaptation to trade and industry and / or retraining initiatives.

INFORMATION A PREREQUISITE FOR PROGRESS - BUILDING UP OF GEOGRAPHICAL INFRASTRUCTURE

The establishment of a well-developed infrastructure of geographical information is important for the development of the Arctic. Compiling geographical information and obtaining a complete picture of what is happening at a given location (maps, charts, records, etc.) is very important to the carrying out of the authorities' activities and for people's access to information. The building up of a geographical infrastructure is based on the principles that data must only be produced once and that all additional data should be collected and maintained and made available in the most effective manner. To manage this, the Greenland self-government has set up NunaGIS. The objective of NunaGIS is to gather all essential information across Greenland in a digital atlas, and link this information to a data and organizational infrastructure, also called SDI (Spatial Data Infrastructure). Work is being done internationally to establish a common geographical infrastructure for the entire Arctic region by building an Arctic SDI where basic topographical data from all the Arctic countries can be assembled, displayed and linked with other information on the climate, wildlife, vegetation etc.

TOPOGRAPHICAL MAPPING

There is an agreement between the National Survey and Cadastre (KMS) and Greenland's Self-Government to jointly find a method to establish data for the topographical mapping of Greenland at 1:100.000 and maintain these maps in a simple manner. Since it is a vast land area to be covered, traditional methods that have been used for mapping in Denmark are in some cases are too costly, and therefore new technologies for mapping, including use of satellite images, need to be explored. There is also agreement between Umhvørvisstovan (Environmental Office) in the Faroe Islands and KMS that there must be an updating and modernization of the topographical map, so that new data from the Faroese authorities can be combined with existing topographical maps of the Faroe Islands.

NEEM ICE CORE DRILLING

North Greenland Eemian Ice Drilling, NEEM (2007 - 2011) is an international research project coordinated by the Centre for Ice and Climate, a scientific research project at the Niels Bohr Institute at Copenhagen University, funded by the Danish National Research Foundation. The goal of NEEM drilling in Northwestern Greenland is to retrieve an ice core reaching back through the last interglacial period, the Eemian, which ended about 115,000 years ago. The climate in Greenland was warmer during the Eemian period than it is today, and is therefore considered as an analogue for the future climate which is expected to be warmer because of global warming. Ice cores from the Eemian period may thus contribute to understanding climate dynamics in the future. Previous drilling in other parts of the Greenland ice sheet (e.g., DYE-3, GRIP, GRIP2 and NGRIP) have also aimed at acquiring knowledge about past climate changes, but none of the ice cores obtained from previous drills have contained a complete uninterrupted series of Eemian ice layers. On 27 July 2010 NEEM reached bedrock at a depth of 2537.36 m. The researchers expect that the lowest meter of the ice core will be rich in DNA and pollen and thus be able to give insights into vegetation that existed in Greenland during the last interglacial period and perhaps earlier. Further analysis of the approx. 2.5 km-long ice core will be undertaken by the Centre for Ice and Climate in collaboration with international research groups.

CLIMATE RESEARCH CENTRE'S COLLABORATION WITH CANADA

In 2010 Greenland's Climate Research Centre began collaborating with the University of Manitoba, Canada where the head of the Climate Research Centre was awarded the post of Canada Excellence Research Chair in Arctic Geomicrobiology and Climate Change. Thus, a new and extensive Greenland-Danish-Canadian climate research collaboration was launched which is bringing together a number of the world's leading scientists in climate research in the Arctic. In addition, in early 2011 steps were taken to establish a new "Centre for Arctic Research" at Aarhus University with close ties to Greenland's Climate Research Centre, which creates the basis for a highly integrated and coordinated climate research collaboration between Denmark, Greenland and Canada around much of the Arctic region. The new collaboration will be structured in a new joint research partnership, the 'Arctic Science Partnership', with the participation of Greenland's Climate Research Centre, the University of Manitoba and the University of Aarhus. Overall, this provides unique opportunities for comprehensive research, educational cooperation and synergy between the three centres.

SUMMER SCHOOL IN KANGERLUSSUAQ AND THE ARCTIC STATION

In July 2011 the first summer school in Kangerlussuaq is going to be held for high school students from Greenland, Denmark and USA. The summer school is taking place under the auspices of the trilateral "Joint Committee" cooperation between Greenland, Denmark and USA. Greenland is providing facilities; the manager is Danish, while the teachers are American scientists who freely devote 2-4 days to train the students in scientific disciplines. The purpose of the summer school is to arouse interest in science among young people, to improve their language skills and to give the Greenland students the opportunity to make contact with Americans and Danes of the same age and learn about educational opportunities in the U.S. and Denmark. The project is targeting two of the three priority areas which the Joint Committee has agreed upon in 2010-2011, namely to improve access for Greenland's students to U.S. institutions of learning and to improve English skills in secondary schools in Greenland.

In July 2000, and 2001, so-called pre-research schools were held for high school students at the Arctic Station on Disko Island in West Greenland, where researchers covered a wide range of scientific topics. The purpose of the schools at the field station was to motivate students to pursue science in higher education. The result was extremely positive and several students subsequently chose higher education courses in geology and biology. Pre-research schools at the Arctic Station will resume in 2012.

3.6. ARCTIC COOPERATION ON HEALTH AND SOCIAL COHERENCE

It is a shared core value in Denmark, Greenland and the Faroe Islands to promote the population's health and also prevent and treat illness, suffering and disability with respect for the individual, his/her integrity and independence. The parts of the Danish Realm prioritize preventative and public information efforts to improve diet, increase the number of physically active people, reduce smoking and harmful alcohol consumption and also to maintain focus on risk groups to combat the increase in lifestyle diseases. Furthermore, the parts of the Danish Realm prioritise the monitoring of the population's state of health.

Greenland today is facing a dual challenge from both old patterns of disease characterized by relatively high infant mortality, accidents, and acute and chronic infectious diseases such as tuberculosis, as well as a new Western pattern of disease dominated by chronic and lifestyle-related diseases.

In the field of environmental medicine, Greenland faces the challenge of the long-range trans-boundary pollution, which increasingly impacts on traditional food resources and the population's health, just as the training of professionals as well as recruitment and retention of health professionals is a continuing challenge.

In 2011 Greenland has launched a health reform which is expected to be fully implemented in 2013. Through the regionalization of the healthcare system, the health reform will lead to greater and more equitable access to healthcare for the population, improved financial management and better opportunities for recruitment and retention of health professionals. The health reform is underpinned by the telemedicine network which was developed with the help of Alaskan and Norwegian inspiration.

The Danish Realm supports cooperation which can improve people's living conditions and health in a sustainable way, including knowledge-exchange and the increased use of new technological capabilities, both within the Kingdom and Nordic cooperation and in cooperation with existing and new partners in the rest of the Arctic. This applies generally, but also focusing especially on vulnerable sections of the population, including children and the elderly, and also the mentally ill. The Danish Realm will continue jointly to review healthcare policy and other health-related challenges, including specialized treatments, among other things as a follow-up to the Danish-Greenlandic agreement in September 1998 on the continuation and expansion of cooperation in the health area. The Danish Realm also supports Arctic research cooperation concerning the development of best practices, public health and health-related consequences of pollution.

Some Arctic communities are also facing difficult social issues. To deal with adverse social trends, the emphasis on social coherence and integration is central to development in the Arctic. Denmark and Greenland are cooperating closely on projects and knowledge-exchange in the social sector. Greenland is also sharing its experience on family matters and gender equality with, among others, the Nunavut region of Canada. Furthermore, the Nordic Council of Ministers has been focusing on changes in the Arctic from a gender perspective.

- The Kingdom will continue to develop cooperation in the health area, including emergency and specialist treatments within the Kingdom – and in the case of Greenland also with Iceland - and training and recruitment within the Kingdom and through Nordic and Arctic cooperation.

- The cooperation between Arctic partners on common challenges should be further developed, especially based on a Greenland context. Enhanced Arctic cooperation could include, research, evaluation and also exchange of "good / best practices" regarding infectious diseases, public health, telemedicine, a culturally attuned health service and environmental medicine.

- It will be a priority to increase cooperation in the Nordic and Arctic arena on public health preparedness concerning disaster situations and other urgent challenges to public health.

- In cooperation with the international research and scientific communities, the Kingdom will continue to focus on monitoring the state of public health, as well as the effect of climate change and global pollution on public health and social conditions in Greenland. Greenland has a special responsibility for advice and internal dissemination of the monitoring and research findings generated in the Kingdom and internationally.

- The Kingdom will promote Arctic cooperation and knowledge sharing on social coherence, including the participation of the population in new opportunities in the Arctic, and their involvement in international debates on the future of the Arctic.

TOWARDS CLOSER COOPERATION ON ARCTIC HEALTH

The first Arctic Health Ministers' Meeting took place on 16th February 2011 in Nuuk with Denmark and Greenland as hosts. The Arctic countries are facing a number of common challenges in health and wish to work together to find the right solutions and exchange knowledge and share experiences. This applies particularly to prevention, telemedicine and research, as well as mental illness and the prevention of abuse and suicide. The meeting led to the "The Arctic Health Declaration" which expresses agreement on closer cooperation on health issues such as the sharing of "best practices" and that the indigenous peoples in the Arctic to a larger extent should be involved in research, health promotion and prevention.

4. Development with respect for the Arctic's vulnerable climate, environment and nature

- The Kingdom will pursue a vigorous and ambitious knowledge building on climate change in the Arctic and its consequences in order to foster global and local adaptation to far-reaching change.
- The Arctic nature and environment must be managed based on the best possible scientific knowledge and standards for protection, and international cooperation in this endeavour must be promoted.

The Arctic has increasingly become a part of the international agenda, and global developments have in turn increasingly become a part of the Arctic. With the Arctic Council's publication of Arctic Climate Impact Assessment from 2005, the world discovered the magnitude and consequences of climate change in the Arctic. However, 20 years earlier, the realization that heavy degradable man-made pollutants and heavy metals lead to pollution and the accumulation of toxins in animals and humans in the Arctic, had already spurred the creation of the Arctic Council as well as international agreements in 1998 that regulate pollutants. There is rightly an increased international focus on environmental regulation in the Arctic, including nature conservation, biodiversity and the marine environment. There is also considerable attention to the growing impact of toxic substances like mercury and persistent organic pollutants (POPs), which can have harmful effects on public health as well as ecosystems and biodiversity.

The following focuses on the strategic priorities to improve knowledge building on the consequences of rapid climate change in the Arctic, and to strengthen the protection of the environment and biodiversity in the Arctic.

4.1. IMPROVED UNDERSTANDING OF THE CONSEQUENCES OF CLIMATE CHANGE IN ARCTIC

Recent scientific studies conclude that warming in the Arctic since 1980 has been twice as much as the rest of the globe and that in 2005-2010 the Arctic had the highest average temperatures since records began in 1840. Global climate models predict that warming will continue. The effects of continued warming of Greenland's climate, ice sheet and ocean are studied using regional climate models with a view to facilitating adaptation to climate change. Arctic warming means that snow and ice are steadily melting faster and the permafrost is disappearing in the southern part of the Arctic. The effects of these changes are extensive - including rising sea levels, potential changes in the atmospheric content of greenhouse gases, potential changes in global ocean currents, and so on - and climate change in the Arctic is of crucial importance to global climate and environmental conditions.

In order to anticipate how global climate and environmental conditions will evolve, it is crucial to understand how climate

change affects the Arctic, and in turn how changes in the Arctic affect global climate trends. Such knowledge is essential for the adaptation to climate change in the Arctic and the rest of the world. The Kingdom is also working to support and promote the conclusion of a global agreement on limiting emissions of greenhouse gasses.

- In cooperation with the international research and scientific community, the Kingdom will strengthen the effort to quantify global and regional impacts of climate change in the Arctic, including knowledge about how Arctic ecosystems, sea ice and ice sheets respond to climate change. Such efforts include monitoring and research activities with the involvement of Greenland, Faroese and Danish research centres.

- Research and monitoring must reinforce the knowledge base on climate change impacts and their significance for the populations and communities within and without the Arctic as well as incorporating local and traditional knowledge. Furthermore, cooperation must be strengthened on identifying measures to adapt to climate change within the Kingdom.

- The Kingdom will assist in reinforcing the rights of indigenous peoples in negotiations towards a new international climate agreement by promoting the visibility of indigenous peoples' situation and also ensuring that the principles of the UN Declaration on the Rights of Indigenous Peoples from 2007 are observed.

ARCTIC CLIMATE IMPACT ASSESSMENT (ACIA) AND SNOW, WATER, ICE AND PERMAFROST IN THE ARCTIC (SWIPA)

In 2005, the Arctic Council released a major scientific work on climate change and its consequences in the Arctic - Arctic Climate Impact Assessment (ACIA). The ACIA- report pointed out that climate change in the Arctic will have major consequences for the Arctic environment and peoples of the Arctic and that the first signs of change are already visible. In 2011 the Arctic Council published a follow-up of the ACIA report: Snow, Water, Ice and Permafrost in the Arctic (SWIPA) which specifically focuses on the impact of climate change on snow, ice and frost conditions in the Arctic within the last ten years. The work, based on scientific articles and data is carried out by 200 of the world's leading Arctic researchers. SWIPA results confirm the predictions contained in the ACIA report, but in some areas the pace of change is happening much faster than expected. SWIPA shows the following: that the years between 2005-2010 were the warmest yet measured in the Arctic; that the summer sea ice could disappear within 30-40 years; that the Greenland ice sheet and other Arctic ice caps are continuously melting faster; that global sea level rises at the end of this century may be 0.9 to 1.6 m with a significant contribution from Arctic ice; and that changes in snow, ice and frost conditions fundamentally change the Arctic ecosystem, which will be particularly challenging for local communities and traditional lifestyles.

REGIONAL CLIMATE MODELLING IN THE ARCTIC

In cooperation with the Climate Research Centre in Nuuk, the Danish Meteorological Institute (DMI) is developing and applying a model for the climate system with high resolution (detail) to assess future climate change in the area around Greenland. The project is supported by the Commission for Scientific Research in Greenland (KVUG). The model system is initially envisaged as a tool to focus on increasing basic knowledge about the climate in the Arctic, with emphasis on Greenland and to assist in a better understanding of the effects of climate change. The model system focuses mainly on the inland ice and its interaction with the surrounding seas, but also contributes to knowledge of permafrost conditions and the interplay between weather, sea and ice more generally. The latter is taking place as a pilot project focusing on the Nuuk area where a range of activities at the Climate Research Centre are concentrated. This can be utilised for model verification and a greater interaction in the Greenland society with regards to climate change adaptation initiatives.

PROGRAMME FOR MONITORING OF THE GREENLAND ICE SHEET - PROMICE

The contribution from the Greenland ice sheet to global sea rise levels has accelerated over the past ten years and the net loss of ice is now at about 200 Gt / yr. The ice sheet will most likely be the main contributor to the rise in global sea level over the next hundred years, according to the Arctic Council SWIPA report from 2011. Changes in ice sheet mass balance may further affect ocean circulation in the North Atlantic and the marine resources around Greenland. To establish a better knowledge base, a long-term national monitoring of the ice sheet called PROMICE was launched in 2007. The goal of PROMICE is to determine the ice sheet's mass loss, explain why and provide data and observations to the global research effort in this area through:

- A network of automatic weather stations directly on the ice sheet
- Direct measurements of ice height and ice thickness from aircraft
- Mapping of ice flow from satellite
- Direct, continuous measurements of outlet glacier flow rate
- Observation-based modelling of melting and the formation of icebergs
- Monitoring of the smaller ice caps and glacier's mass loss
- Operation of database with free online access to all data collected

PROMICE is a collaboration between GEUS, the Danish Technical University and Asiaq, Greenland's Survey.

4.2. PROTECTING THE ENVIRONMENT AND BIODIVERSITY

The Arctic nature and wildlife are unique and fragile. This is due to the fact that ecosystems have evolved under low temperatures in the Arctic. Global warming is leading to increasingly ice-free seas in summer periods, and the lower prevalence of sea ice can have a major impact on the living conditions and distribution of species associated with sea ice. Similarly, longer periods of open water will result in increased activity, such as shipping in areas that previously couldn't be navigated, just as increased mineral exploitation, fishing and tourism pose a risk of pollution and accidents.

Increased shipping may also pose a risk of an increased influx of invasive species. To this must be added the slow degrading of problematic chemical substances that are often long-range transported. Climate change may likewise cause direct impacts on terrestrial biodiversity, while a number of climate-related and non climate-related anthropogenic impacts can affect biodiversity. This applies, for example, to increased traffic and its associated disturbance and erosion, fragmentation of habitats, and increasing use of areas in open land for commercial and recreational purposes.

On this basis, we can anticipate greater pressure on the Arctic ecosystems and fragile biodiversity. At the same time, there is an accumulation of pollutants through the food chain which could have major implications for the Arctic society. It is therefore essential, in collaboration with international partners, to ensure monitoring and studying of the environmental and health impacts to which the Arctic peoples, the Arctic ecosystem and biodiversity are exposed. It is equally important to ensure knowledge-building by the monitoring and study of migratory species (eg. whales, polar bears, migratory birds), ecosystems and biodiversity to be used in international conservation work. This will ensure the best possible foundation for future management in Greenland that is based on sustainable utilisation and protection of the Arctic environment.

Parameters such as migration routes, area utilization and core habitats may also change in line with anticipated changes in climate and ice conditions. Further analysis could lead to more accurate identification of problem areas and to possible future changes. Identifying these areas and estimates of future changes will be of great importance for the implementation of necessary adjustments to ensure sustained and effective protection of nature and the environment.

As regards environmental pressures and impacts, it remains necessary to ensure the monitoring and study of, for example, persistent organic pollutants (POPs), mercury, oil, particulates and other pollution to which the Arctic populations and ecosystems are exposed. Many years of continuous data collection of environmental impacts in the area provides important in-

formation both about the effect of existing international agreements on the reduction of long-range transboundary pollutants and information for use in future environmental work in the EU and other international fora. The impact of local pollution in the Arctic region has so far been minimal. One consequence of these environmental challenges is that it is necessary to ensure that future monitoring is conducted in a way that assesses all threats and impacts in the Arctic in an integrated way.

Efforts are to be focused on the national implementation of international agreements entered into on nature and the environment, and on safeguarding the marine environment against pollution for example by enhancing maritime safety. In doing this, it is essential that the highest international environmental standards are employed in the harvesting of resources in the Arctic, and that due to the special navigational conditions, the best possible prevention of maritime accidents in the Arctic and possible pollution that results can be ensured.

- Nature and the environment must be managed based on the best possible knowledge base. This is ensured through a long term monitoring and systematic collating of research findings. The protection of biodiversity under international standards must be enhanced by identifying important and ecologically sensitive areas.

- Efforts will be made to ensure the rights of the Arctic countries and access to the exploration and utilisation of biological resources in the Arctic, since the Kingdom is especially interested in protecting and utilising the genetic and biological resources in the Arctic under the Convention on Biological Diversity.

- The continued monitoring of long-range transboundary pollutants and their impact on ecosystems and humans in the Arctic must continue. Likewise, continued monitoring and also the prioritization of monitoring species and ecosystems must be assured. Furthermore, it is important to do an overall assessment and monitoring of all the threats to and impacts on the Arctic for the protection of nature and the environment.

- The most recent knowledge about pollutants in the Arctic is to be made available and applied proactively. Focus must be enhanced on the use of available information in international fora relating to global negotiations of agreements such as the UNEP's global mercury convention and the Stockholm Convention and other relevant agreements on persistent organic pollutants.

- Prevention of marine pollution in the Arctic must be reinforced. This includes better international sharing of knowledge and experience on preventative steps and cooperation, especially in the Arctic Council and the IMO on joint prevention measures.

- The Kingdom will participate in protecting the marine environment as soon as possible by implementing and ratifying the HNS Protocol on compensation and liability for damages arising from hazardous and noxious substances, and also the Ballast Water Convention which will help in protecting the marine environment from invasive species.

- Moreover, towards 2014, the Kingdom will carry out a risk-analysis of the maritime environment in and around Greenland, including the risk of oil and chemical contamination caused by the expected expansion in traffic and activity in the area. Based on the risk analysis, the Kingdom will assess to what extent it may be useful to strengthen the protection of the maritime environment in the Arctic. Possible initiatives could include increased international sharing of knowledge and experience on pollution control, enhanced preparedness for the prediction of drifting oil spills and strengthened international cooperation on maritime emergency preparedness.

ARCTIC ENVIRONMENT MINISTERS MEETING IN JUNE 2010

In June 2010, an Arctic Environment Ministers meeting was held in Ilulissat in Greenland with the Danish Minister for the Environment and the Member of Naalakersuisu for the Environment and Nature as hosts. Following up on the meeting, the Kingdom started work on identifying vulnerable marine areas and is looking at ways to protect them against the effects of shipping. Twelve vulnerable marine areas around Greenland have been identified, and it was decided that 6 of these must be investigated more closely. The work will initially focus on three high-priority fragile marine areas, namely:

1) Nordvandspolyniet (off Northwestern Greenland),
2) Disko Bay and Big Halibut Bank (West Greenland) and
3) Ittoqqortoormii (Scoresby Sound) and surrounding areas (East Greenland).

GREENLAND ECOSYSTEM MONITORING

The Arctic is characterized by a harsh climate with extreme light and temperature conditions, short summers and snow and ice cover in winters. The ecosystems and the species that live in the Arctic have had to adapt to these extreme conditions and high natural variability from year to year. Knowledge of how Arctic ecosystems function, how the systems affect the surroundings, what year-on-year variation in, for example, weather conditions means and how systems alter as a consequence of climate change requires large-scale study programs over long periods. At the Zackenberg research station and a similar station in Kobbefjord near Nuuk, multidisciplinary studies and research are being conducted that help to illuminate the workings of the Arctic's ecosystem and its development. For example, changes in biodiversity, the system's intake / release of greenhouse gases and their resilience in the light of climatic development. Together, the two programs are called the Greenland Ecosystem Monitoring and are carried out in collaboration between Greenland and Danish academic and research institutions, including ASIAQ, Greenland Climate Research Centre, the Greenland Institute of Natural Resources, University of Copenhagen, Geological Survey of Denmark and Greenland, and Aarhus University.

GREENLAND ENVIRONMENTAL ATLAS OF AREAS PARTICULARLY SENSITIVE TO OIL SPILLS

Commissioned by the BMP in Greenland, the Danish Environmental Research Institute has developed an Environmental Atlas which is an atlas of Greenland marine areas and fjords that are particularly sensitive to oil spills. The atlas enables oil companies and the Greenland Self-Government to ensure the best possible emergency preparedness in case of an oil spill in order to mitigate damage to nature and the environment.

The atlas forms an essential part of the overall preparedness that is being established in connection with oil exploration. It contains information about the local wildlife, local fishing and hunting interests and archaeological sites that are especially sensitive to potential oil spills. In addition, the atlas contains data on the physical environment - such as coastal types, oceanography - logistics and ways to control oil pollution. The atlas covers the entire area from Cape Farewell (60 ° N) in the south to the southern part of the Upernavik area (72 ° N).

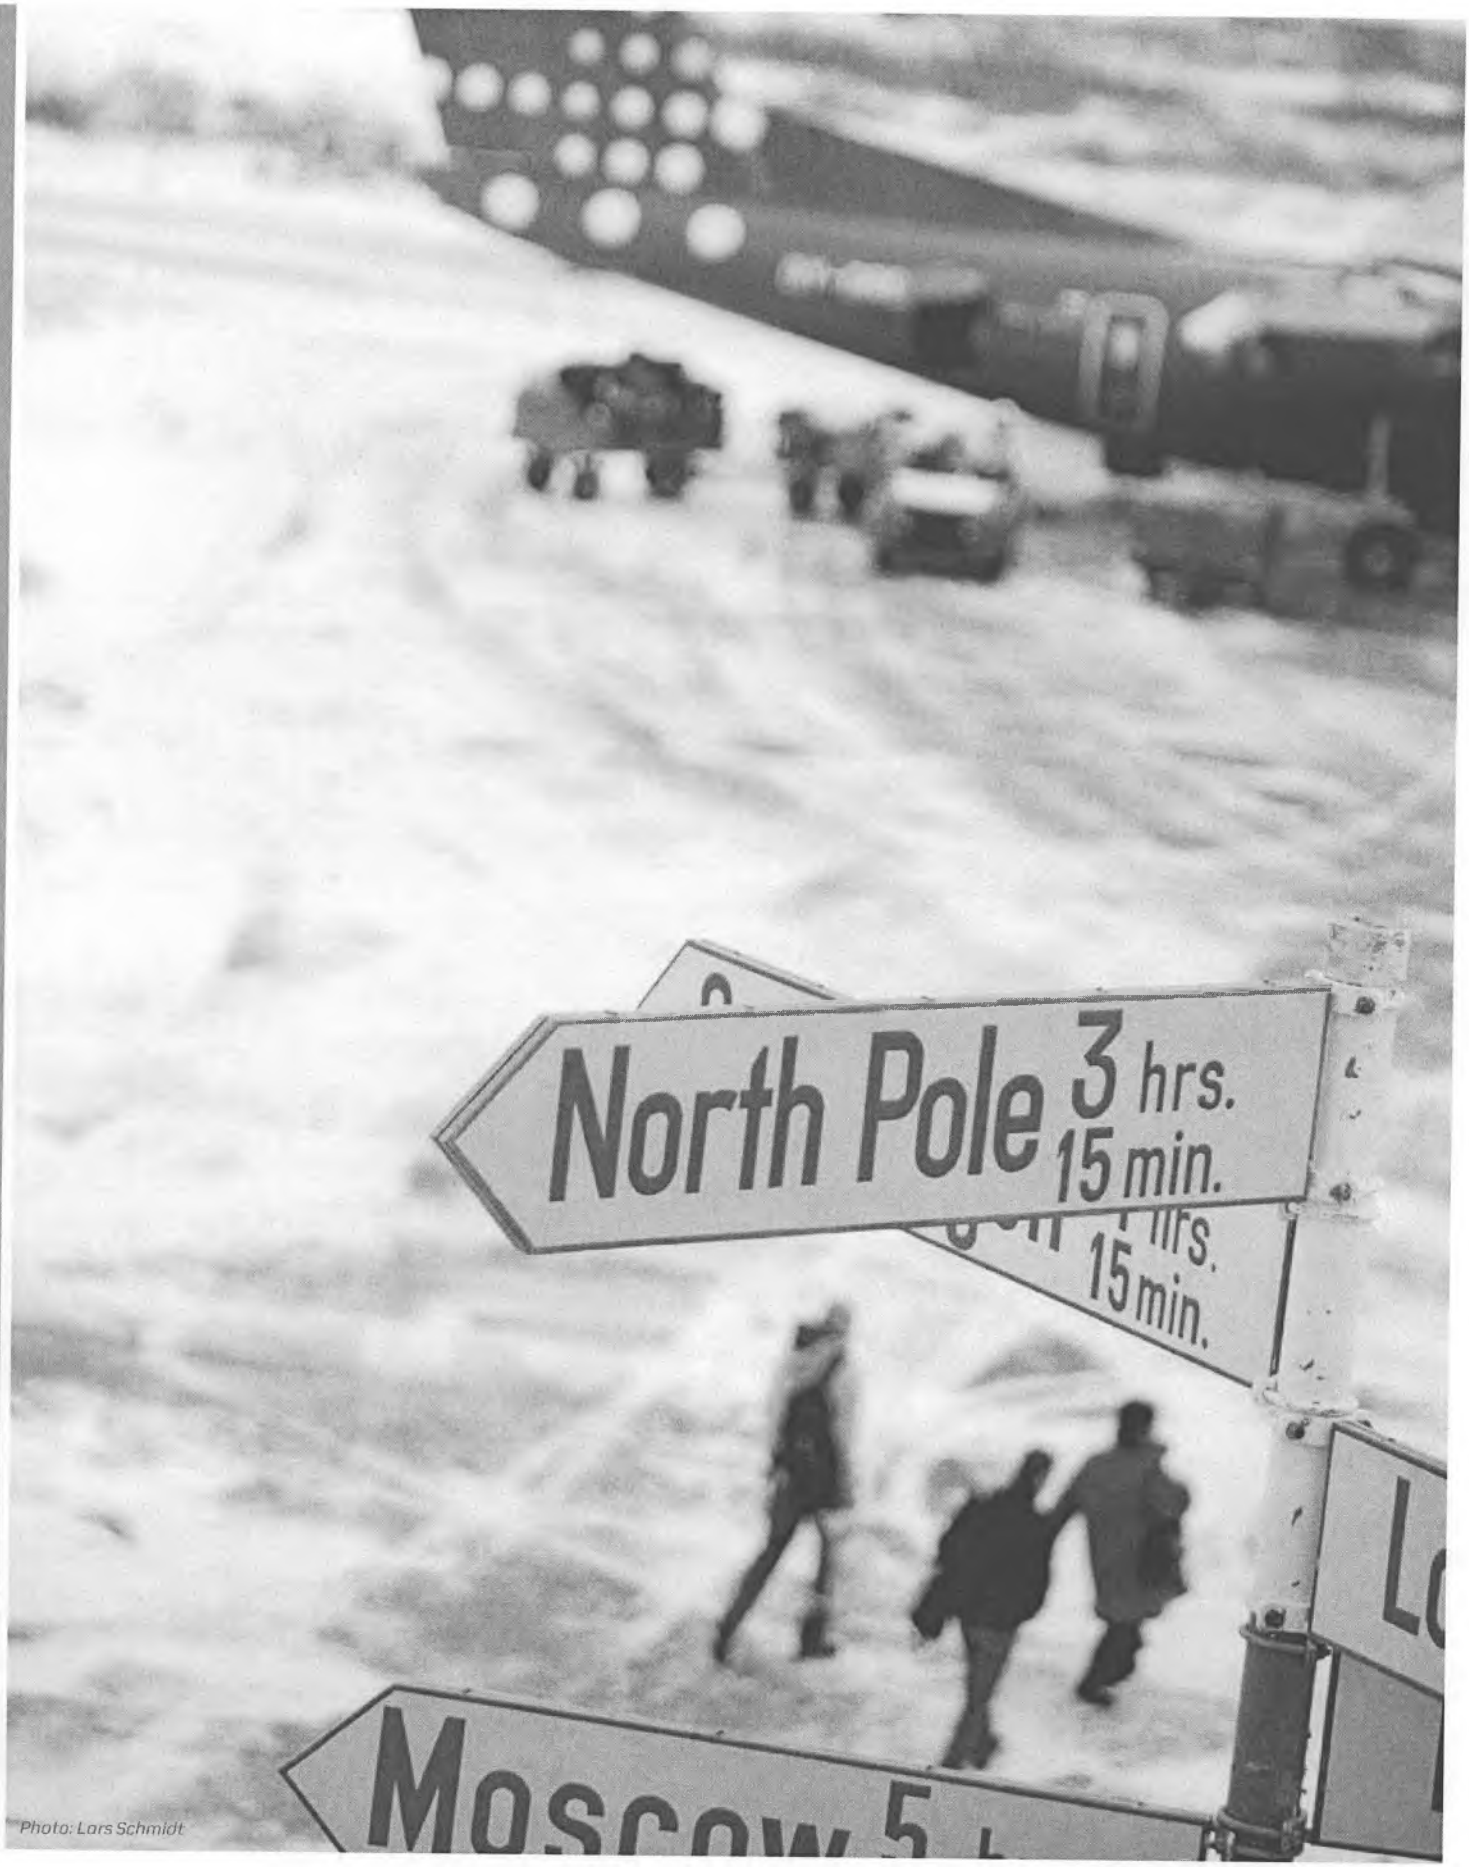

Photo: Lars Schmidt

5. Close cooperation with our international partners

- The Kingdom will prioritize global cooperation relevant to the Arctic, including, in particular, an ambitious focus on climate change, protection of nature and the environment, strict global maritime rules, and continue giving high priority to indigenous peoples' rights.
- The Kingdom will enhance cooperation in the Arctic Council. Cooperation with the EU is to be promoted and the Arctic to be given more weight in the Nordic context. "Arctic 5" is an essential complementary regional forum for the coastal states of the Arctic Ocean.
- To optimise the safeguarding of interests, the Kingdom will upgrade bilateral cooperation and dialogue regarding the Arctic, both with established and new partners.

International interest in the Arctic will continue to rise in coming years. A growing number of states, corporations, civil society organizations and international organizations will engage themselves in the region. This requires a solid and effective regional and global cooperation that constantly adapts to new opportunities and conditions. It is natural that the Kingdom plays a key role in shaping the future international architecture of the Arctic. Many international agreements and cooperation fora are relevant to the Arctic and whose interests require active safeguarding by the Kingdom. For example, this concerns world trade within the WTO, environmental and nature conservation within UNEP, in research, health, and in security and defence matters in NATO among others.

The Kingdom's Arctic strategy will form the basis of our cooperation with international partners on the Arctic and Arctic issues. A number of themes and organizations discussed in this chapter will make up the Kingdom's strategic priorities in foreign policy on the Arctic. The point of departure will be that today we have the requisite international legal basis and that the Arctic continues to be a region of cooperation. In particular, we will build on the Kingdom's firm tradition of cooperation with our Arctic neighbours, in parallel to the prioritising of other relevant collaborations globally, regionally and bilaterally.

5.1. GLOBAL SOLUTIONS TO GLOBAL CHALLENGES

The Kingdom will pursue a vigorous and ambitious climate policy to tackle the challenges that climate change poses in the Arctic and other vulnerable regions. The Kingdom's climate policy stems from the UN's Climate Change Convention (UNFCCC), whose goal is to stabilize atmospheric greenhouse gases at a level that prevents climate change that is dangerous to humanity. In negotiations on a future global climate agreement, the Kingdom continues to work towards achieving the common objective of limiting global temperature increases to a maximum of 2 degrees above pre-industrial levels.

Denmark shares the EU's ambition of reducing total global greenhouse gas emissions by at least 50% in 2050 compared to 1990, as well as reductions for the industrialized countries of 25-40% and 80-95% in 2020 and 2050, respectively - both compared to 1990. The target requires that sufficient global reductions in greenhouse gas emissions are achieved in the short and longer term. The government's ambition is that Denmark should become independent of fossil fuels by 2050 and that Denmark's binding renewable energy target under the EU in 2020 is 30 percent.

Greenland aims to reduce greenhouse gas emissions by 5% in the period 2013-2020 for the society, as it looks today, and as regards energy supplies that at least 60% of total energy production in civil society must be based on renewable energy by 2020. Activities within the minerals and hydrocarbons sector that are currently being developed, are not covered by the reduction of emission goals, but will be developed in accordance with international principles of sustainability.

Faroese climate policy, which involves a reduction of greenhouse gas emissions of at least 20% by 2020 compared to 2005, will entail that 75% of electricity production must be based on renewable energy by 2020. The effects of climate change are already being felt, and the Kingdom underlines the importance that adaptation measures are carried out in order to mitigate the already unavoidable climate impacts.

- The Kingdom will work towards the conclusion of an ambitious global climate agreement that includes reduction commitments and actions which, in accordance with current and future assessments of the UN's climate panel, are consistent in keeping the global temperature rise to a maximum of 2 degrees above pre-industrial levels.
- The Kingdom will continue, for example, through the Arctic Council, to contribute with knowledge and information inputs on Arctic climate change to the relevant international forums in which a global climate agreement under the UNFCCC is to be promoted. This also includes the need for climate change adaptation initiatives in the Arctic.

The Kingdom's global policy on nature and the environment in relation to the Arctic is particularly focused on the Convention on Biological Diversity and the Ramsar Convention on Wetlands of International Importance. Denmark, the Faroe Islands and Greenland have a long tradition of working together in global fora such as the Ramsar and Biodiversity Convention. The aim is to promote the protection and sustainable harnessing of the Earth's biological diversity and to ensure regeneration and preservation of the ecosystem services that underpins communities and well-being. Under the Biodiversity Convention of October 2010 in Nagoya, Japan, three important agreements were adopted to preserve biodiversity globally. The agreement contains the Nagoya protocol on access to genetic resources and benefit-sharing (ABS), the Strategic Plan for Biodiversity 2011-2020, and the Resource Mobilization Strategy.

Furthermore, reaching a global mercury agreement has long been a priority of the Kingdom. Mercury is a toxic heavy metal that accumulates in the food chain. In the Arctic region especially, mercury is a threat to public health since local and traditional diet such as seal, whale, sea birds and eggs can contain high levels of mercury. Under the auspices of the Arctic Council, there is particular focus on monitoring the levels and effects of mercury, and these findings are a part of the basis of global negotiations.

- The Kingdom will work to ensure that the 20 intermediate objectives of the strategic plan under the Biodiversity Convention are implemented focusing on problem areas of particular relevance to the Faroe Islands and Greenland. The Kingdom will bolster the knowledge base for the international protection and sustainable use of biodiversity and ecosystem services among others through The Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) and the Global Biodiversity Information Facility (GBIF).
- The Kingdom will work in relevant global fora in order to reduce pollutants brought by sea and air to the Arctic. The Kingdom will work for a globally binding mercury agreement under the auspices of UNEP and work to strengthen existing chemical agreements such as the Stockholm Convention on persistent organic pollutants and the LTRAP protocol.

Greenland and Denmark have a tradition of close and constructive cooperation in ameliorating the conditions of the world's **indigenous peoples**. Indigenous peoples are in some situations particularly exposed to human rights violations when new challenges arise, such as climate change. To the extent that their rights are recognized, which in itself has been difficult at times, one of the major challenges is to ensure respect for and observation of these rights. Denmark and Greenland possess experience and historical background, giving them sound credentials to work together to promote indigenous peoples' rights. The effort has resulted in the UN, at the initiative of Denmark and Greenland, having established a Permanent Forum on Indigenous Issues which has functioned since 2002.

This forum has already proved its worth as a venue for governments and representatives of indigenous peoples worldwide and is the only forum where individuals and groups of indigenous peoples are

represented. The forum actively seeks to raise awareness of the situation of indigenous peoples within the UN system. Moreover, Denmark and Greenland have also actively participated in negotiations on the UN Declaration on the Rights of Indigenous Peoples, adopted in 2007. The Declaration is an important starting point for future work in ensuring the rights of indigenous peoples and their survival through respect for their culture, language and way of life.

- The Kingdom will promote and protect indigenous peoples' rights. Denmark / Greenland are working to ensure that the principles outlined in the UN Declaration on the Rights of Indigenous Peoples of 2007 are carried out in practice.

- Denmark and Greenland also support the work being done by the UN special rapporteur for indigenous peoples, while also working to ensure that the Expert Mechanism on Indigenous Peoples' Rights (EMRIP) under the UN's Human Rights Council contributes positively to promote and protect indigenous peoples' rights.

UN International Maritime Organization (IMO) is the UN's specialised agency for maritime safety and security of international shipping and the prevention of pollution by ships. The IMO has 169 members, including Denmark, and 3 associate members, including the Faroe Islands. The IMO is absolutely critical to the global establishment of technical requirements of ships to avoid distortion in the world's free trade. It is a fundamental principle of the IMO that ships must be treated equally, whichever flag they fly.

The IMO is working to introduce the highest possible standards for health, safety and environment. Only by establishing global requirements can it be ensured that safety standards are not compromised. In recent years there has been a particular focus on the environmental agenda in the IMO, including the protection of sensitive marine areas, increased regulation of oil transportation, requirements of the ships' fuel and emissions, and not least the climate change agenda. In these areas, the Kingdom is playing a significant role in ensuring the creation of solutions that benefit both the environment and shipping.

- The Kingdom will ensure in the IMO that the Arctic and Greenland conditions are taken into account in the IMO's work and decisions regarding development opportunities for the maritime industry, increased maritime safety, protection of the marine environment and coastal zone, and also reduced emissions of greenhouse gases and reduction of air pollution.

DANISH / GREENLAND CONTRIBUTION TO INDIGENOUS PEOPLES' RIGHTS

Greenland and Denmark have for many years worked closely to promote indigenous peoples' rights. Denmark's first strategy in 1994 to support indigenous peoples was prepared based on a Danish / Greenland initiative, and just working with Greenland has helped to give Denmark a high international profile in the field.

Denmark and Greenland have historically been active in a number of relevant international forums where indigenous peoples' rights are discussed. These include the annual sessions of the UN Permanent Forum on Indigenous Issues, which was also created on a Danish/ Greenland initiative and the UN Expert Mechanism on Indigenous Peoples' Rights (EMRIP). Denmark / Greenland were also important players in the adoption of the UN Declaration on the Rights of Indigenous Peoples.

The establishment of the Self-Government arrangement for Greenland in 2009 is an illustration of Denmark's implementation of the UN Declaration. Finally, Denmark/ Greenland participates actively in negotiations in the UN Human Rights Council and General Assembly, among others, on resolutions relating to indigenous peoples' rights.

In 2011, a review of Denmark's strategy for support to indigenous peoples was finalised. The review concludes that the Danish / Greenland cooperation has led to groundbreaking institutional results and to improved living conditions for indigenous people.

5.2 ENHANCED REGIONAL COOPERATION

It is a central goal of the Kingdom to strengthen cooperation in the Arctic Council. As the only organization that has all 8 Arctic states as members and additionally 6 organizations of indigenous peoples as equal partners, the Arctic Council is the primary organ for concrete cooperation in the Arctic. The Council's work originates from collaboration on environmental issues, but over time has been extended, for example, to include sustainable development and the populations' living conditions. Recently, the Arctic Council has been instrumental in the development of a binding agreement between the 8 members on search and rescue (SAR) with the Faroe Islands and Greenland as "co-signatories," which is needed because of the increased access to areas that were previously covered by ice.

The Kingdom wants to ensure a future - oriented Arctic Council, i.e. that the Council has an increasingly direct impact on the Arctic peoples. The Arctic Council must evolve from a 'decision-shaping' to a 'decision-making' organisation. The Council's function as an instrument exerting influence on nation states and international organizations should be reinforced, and where feasible, the possibility of real decision-making ought to be developed. It is also important to ensure cooperation with all countries and organizations that are of importance to the Arctic and can contribute to cooperation within the Council. During the chairmanship of the Arctic Council 2009-2011, the Kingdom has worked for a strengthening of the Council including the establishment of a permanent, jointly-funded secretariat and the admission of new permanent observers.

- The Arctic Council must be reinforced as the only relevant political organization that has all Arctic states and peoples as members. At the same time the Arctic Council must cooperate with all relevant countries and organizations with interest in the Arctic. The Kingdom will emphasize that the human dimension, i.e. people's living conditions and well-being, is given increasingly more space in cooperation.

The Kingdom will retain the **"Arctic 5"** format consisting of the coastal states of the Arctic Ocean - Canada, Denmark / Greenland, Norway, Russia and the US - as a forum for issues primarily relevant for the five coastal states, currently the continental shelf issue. All three parts of the Realm are participating in the continental shelf issue while the Faroe Islands is ensured continued opportunity for scrutiny of any other activities in this forum. **"Arctic 5"** have met twice at ministerial level in 2008 and 2010, and in some cases at departmental level. Common to these meetings was that they concerned matters relating primarily to these coastal states.

- The Kingdom will promote its Arctic strategy in all relevant meeting formats, including any future meetings under "Arctic 5" auspices concerning specific action on joint issues.

Based on the European Commission's communication of November 2008, the European Union (EU) adopted in December 2008 and December 2009 the Council's conclusions on the Arctic and the European Parliament adopted in early 2011 a report on a sustainable EU policy for the Arctic. Both the Council's conclusions and the report are an expression of the growing interest that the EU has for the Arctic. Thus, the ground has been prepared for the EU to develop an overall Arctic strategy. The EU currently has interests in the Arctic in the form of, among others, research and fisheries and has indirect influence on the Arctic through e.g. its environmental laws. Furthermore, the EU and its member countries have interests in transportation and access in order to benefit from natural resources in the Arctic, including oil, gas and minerals and critical metals such as rare earth elements.

Denmark, the Faroe Islands and Greenland work to ensure a broad and close partnership with the EU. It will be in the Kingdom's interest to leave its mark on the shaping and implementation of EU policies, for example, in energy, climate, fishing, hunting, exploitation of minerals and the relationship to the populations and indigenous peoples in the Arctic. For the parts of the Kingdom that are not in the EU it will be of interest to participate in relevant EU programs where desirable and possible. Furthermore, it will be important that the EU's involvement in the Arctic takes place on the Arctic populations' own terms. We must seek to avoid further cases where the laws, traditions, cultures and needs of Arctic societies are neglected, as for example in the EU's ban on the import of seal products.

It is of particular importance to promote good relations between Greenland and the EU and expand the cooperative relations which exist between the parties involved. In addition to this, endeavours must be made to make the Faroe Islands more visible to the EU as part of the Arctic cooperation. The Kingdom will work to ensure that the EU has a place in the Arctic, including in relevant institutions such as the Arctic Council where the Kingdom supports the EU's wish for observer status.

- The Kingdom will actively contribute to the shaping of EU policies relevant to the Arctic and Arctic challenges, and in this context seeks to ensure the Arctic peoples' rights and interests. The Kingdom will contribute towards the EU having a space in international discussions on the Arctic.

- The Kingdom collectively and each part of the Danish Realm will advance the

development of cooperative relations between the EU and Greenland and the Faroe Islands, respectively.

The Nordic Council of Ministers has allocated a grant for collaborative projects concerning the Arctic region and contributes financially to the Arctic Council's work. In addition, a number of collaborative projects of Arctic relevance are being carried out in the Nordic Council of Ministers' various ministerial councils. The Kingdom wants the Arctic aspect of the Nordic Council of Ministers' work both directly and through ministerial councils to be given greater weight, both politically and financially.

- The Kingdom will promote the Arctic as a cross-disciplinary focus area of the Nordic Council of Ministers' work.

Important cooperation in and about the Arctic is being undertaken in a wide range of organizations other than the above-mentioned, for example through **NORA**, the Nordic Atlantic Cooperation (Faroe Islands, Greenland, Iceland and coastal Norway), **West Nordic Cooperation** (Iceland, the Faroe Islands and Greenland) and in **sector organizations**, such as NAMMCO (North Atlantic Marine Mammal Commission - consisting of Iceland, Norway, Greenland and Faroe Islands). To this must be added organizations that cover fishery, environmental or scientific interests.

- The Kingdom will seek to promote cooperation in and around the Arctic in the range of organizations representing regional or sector-organized interests, especially NORA, West Nordic cooperation and NAMMCO.

FACTS ABOUT THE ARCTIC COUNCIL

On the initiative of the Finnish government, officials met from the eight Arctic states (Canada, Russia, USA and the five Nordic countries) in Rovaniemi in 1989 to discuss cooperation and measures to protect the Arctic environment. This led to the adoption of the ***Arctic Environmental Protection Strategy*** (AEPS) in 1991. At the AEPS Ministerial Meeting in 1993 in Nuuk, the participating category of "Permanent Participants" was introduced covering the Arctic indigenous peoples. In 1996, cooperation was expanded in the setting up of the Arctic Council in Ottawa, Canada, from a narrow environmental focus to a broad program covering all aspects of sustainable development. With this, the focus was expanded from a solely environmental one to include more general living conditions of peoples in the Arctic. Arctic Council members include, besides the eight Arctic States, six organizations representing indigenous peoples in the Arctic, the so-called permanent participants. Moreover, a large number of countries and organizations participate as observers. The Arctic Council's traditional driving force has been the Council's six working groups that monitor developments in the Arctic on various parameters and prepare scientific reports with expertise, recommendations and suggestions for follow-up in the Arctic Council and other international bodies.

The Danish Kingdom's chairmanship of the Arctic Council in 2009-2011 was an important priority for Denmark, Greenland and the Faroe Islands. The Foreign Ministers meeting hosted by Denmark / Greenland in Nuuk in May 2011 was in terms of substance the most weighty and with the greatest ministerial participation in the Arctic Council's history. At the meeting the Nuuk Declaration was adopted, which among other things determines the role and criteria for admission of new observers, establishes a permanent secretariat for the Arctic Council in Tromsø in Norway, sets up a task force to develop an instrument for preventing and managing potential oil spills in the Arctic and mandates an enhanced communication effort for the Arctic Council. Furthermore, the ministers signed an agreement on search and rescue in the Arctic (SAR), which as the first legally binding agreement under the auspices of the Arctic Council adds a new dimension to the Council's work and bodes well for strong future cooperation in the Arctic region.

THULE - FUTURE ARCTIC HUB AND COLLABORATION PLATFORM?

The melting of the polar icecap and the consequent increased activity in the Arctic will lead to greater need for the presence of and entail more tasks for the armed forces in the area around northern and north-western Greenland. Under the defence agreement of 2010-2014, the armed forces is carrying out a streamlining of the North Atlantic operational command structure (see section 2.3), and in the course of the duration of the agreement it must be considered whether the Thule base may play a larger role in regard to the tasks of the armed forces in and around Greenland in cooperation with other partner countries. Thule Air Base is, with its deep water port, airport and well-developed infrastructure (including tank and storage capacity, workshop, hospital, quarters, support and office facilities), a unique capability in the Arctic region north of the Arctic Circle.

There is thus already an existing opportunity to provide the logistical prerequisites for increased presence in the area around the northerly and north-westerly Greenland. Furthermore, Thule Air Base has the potential to become a broader platform for supporting the collaborative intentions of the Illulisat Declaration of 2008 between the 5 coastal states in the Arctic Ocean. Collaboration on the logistical facilities in Thule could thus eventually include assignments and emergency preparedness in relation to the maritime environment, a base for exercises in connection to joint procedures such as search and rescue services, and also be a platform for joint research in the Arctic.

5.3. BILATERAL SAFEGUARDING OF THE KINGDOM'S INTERESTS

The rapid changes and the increasing importance of the Arctic where new opportunities and challenges are constantly arising and a number of new actors are registering their interest in the region, requires that we also make a gear-shift in bilateral safeguarding of the Kingdom's interests in the Arctic. We will also work closely on a bilateral basis with all our partners. The bilateral cooperation is also a good platform to promote multilateral initiatives in the Arctic, of which the continental shelf project is a good example.

Canada, USA, Norway and **Iceland** will remain key partners for close cooperation in areas such as the exploitation of resources, maritime safety, climate and environment, indigenous peoples, research, education, health and defence. Furthermore, we will maintain close contact with **Finland** and **Sweden** on Arctic issues.

In addition, the Kingdom also wants to further expand and develop cooperation with **Russia**, which has been increasingly engaged in international cooperation in the Arctic. For example, under the auspices of the Danish-Russian governing council, there is great mutual interest in closer cooperation on strengthening the safety of navigation in Arctic waters. Enhanced cooperation with Russia could also incorporate scientific collaboration, for example, on the continental shelf. It could also include the exchange of findings on economically, socially and environmentally sustainable development, as well as confidence building and studies on potential cooperation between the Danish and Russian defence, particularly in the maritime area.

Beyond the Arctic states, other legitimate stakeholders also have increasing interests in the Arctic. These interests are particularly linked to research on climate change, new international transportation opportunities, as well as opportunities to profit from the exploitation of supply-related energy and mineral resources in the Arctic. Among these stakeholders is the EU, but also the three **Northeast Asian countries**, China, Japan and South Korea. Both China and South Korea have significantly increased their research-related engagement in the Arctic, including the construction of icebreakers and the establishment of permanent research stations on Svalbard.

It is encouraging that the three Northeast Asian countries are joining the consensus among the coastal States that the United Nations Convention on the Law of the Sea must be the central foundation for the legal regulation in the Arctic. The Kingdom supports their respective wishes for observer status in the Arctic Council. Bilateral dialogues have also been established, especially on maritime law issues such as claims on the continental shelf in the Arctic region and unresolved boundary issues. Furthermore, special collaborative projects have been set up, for example between the University of Copenhagen and a number of Chinese universities within natural science, and a budding collaboration between the Danish Technical University and Harbin Institute of Technology on Arctic technology.

Global interest in the Arctic will inevitably increase even more in the coming years.

More countries will want to gain insight into and influence on international cooperation in the Arctic as its strategic, economic and energy-related potential becomes clearer. Here the Kingdom can play a major role in promoting an open and inclusive dialogue in bilateral relations. The Kingdom will strengthen the dialogue with new stakeholders in the Arctic and benefit from the resources and expertise that they bring along through cooperation in commerce and R & D. Alongside this, the new actors will be integrated into the norms and values that the Kingdom and other coastal states in the Arctic Ocean believe should apply to the Arctic.

- In order to efficiently pursue the Arctic strategy's diversified goals and interests, the Kingdom will develop close bilateral partnerships with our Arctic neighbours. As a major actor in the Arctic, the Kingdom will play a part in fostering new bilateral collaborations and dialogues on opportunities and challenges in the region.

JOINT COMMITTEE COOPERATION WITH THE USA

Joint Committee cooperation between Greenland, Denmark and the U.S. arose from the Igaliku Agreement, signed in 2004 by then U.S. Secretary of State Colin Powell, then Minister for Finance and Foreign Affairs Josef Motzfeldt and then Danish Foreign Minister Per Stig Moeller in the South Greenland village of Igaliku. The Igaliku Agreement consists of three parts:

- An agreement on the update of the defence agreement of 1951 and the establishment of an advisory group hereto (Permanent Committee)
- A joint statement on cooperation regarding environmental issues at Pituffik (the U.S. base at Thule)
- An agreement on technical and economic cooperation (Joint Committee cooperation)

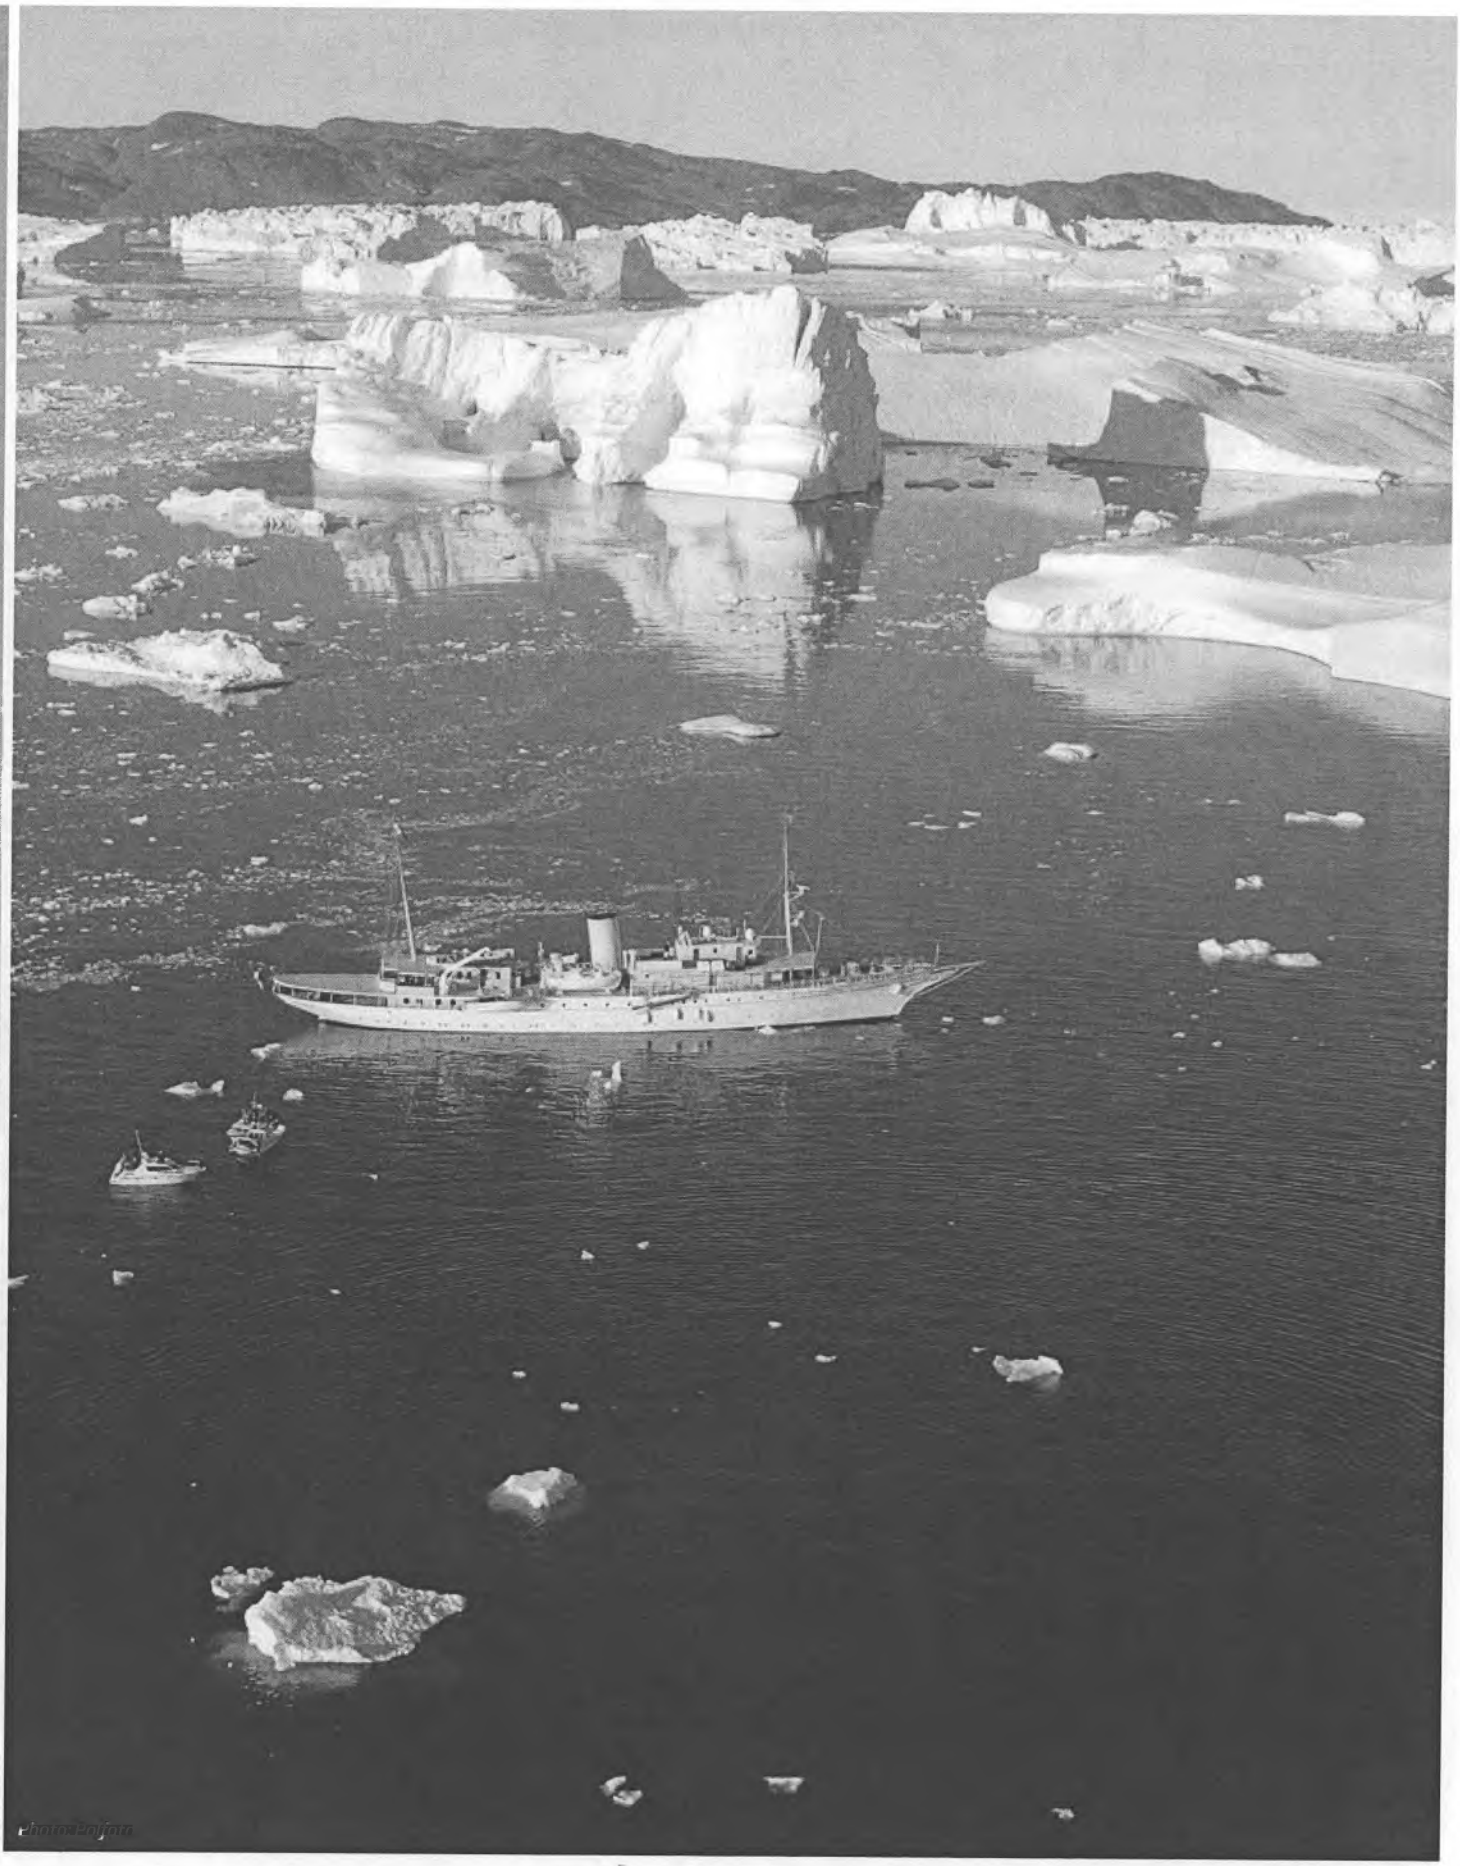
The Joint Committee is a tripartite forum for Greenland, USA and Denmark which aims to strengthen and promote economic and technical cooperation between Greenland and the U.S. with special focus on research, health, technology, education, culture and tourism.

CLOSE COLLABORATION WITH CANADA

Denmark / Greenland, as part of the ***Continental Shelf Project*** in 2002, collected data in three areas north of Greenland. These collections have been conducted in close collaboration with among others Canada, and the close cooperation has led to very successful measurements. In mid-2010 it was decided to intensify the bilateral technical cooperation via the establishment of a joint task force which among other things must explore ways to coordinate submissions of claims to the Commission for Continental Shelf Limits (CLCS).

In May 2010 Denmark and Canada signed a bilateral Memorandum of Understanding (MoU) on enhanced operational defence cooperation in the Arctic, focusing on joint military exercises, staff exchanges and cooperation in rescue operations. The agreement serves as a catalyst for intensifying day-to-day collaboration between Greenland's Command, Joint Task Force North in Yellowknife and MARLANT Maritime Forces Atlantic in Halifax. It is expected that close Danish - Canadian military cooperation will be further enhanced over the coming years partly via mutual exchange of findings in survival techniques in the Arctic, patrolling and surveillance and partly via continued participation in joint military exercises.

As a direct consequence of the oil disaster in Louisiana, the Greenland Bureau of Minerals and Petroleum and the National Energy Board of Canada, which are responsible for determining the respective regulations for Greenland and Canadian exploitation of ***oil and natural gas*** in the Arctic, entered into a bilateral agreement in 2010. The agreement formalises cooperation between the two authorities on information exchange of regulatory policy, specific oil and natural gas drilling and the overall development of their respective energy markets. The agreement specifies that the parties will meet at regular intervals. Similarly, it paves the way for the exchange of personnel, the carrying out of joint emergency exercises, building up of a joint emergency response, and that henceforth data and reports are shared. The formalized collaboration is a big step forward as both Greenland and Canada will obtain prior knowledge of initiatives which due to their geographical proximity will affect the counterpart. Furthermore, Denmark and Canada are party to the CANDEN-agreement on environmental cooperation, which ensures information exchange in case of oil spills and marine pollution, among other things.



6. Implementation and follow-up

- In order to ensure effective implementation, a steering committee is to be set up for the Kingdom's Arctic strategy, reinforced foreign policy coordination and cooperation, and intensified public diplomacy / public relations work regarding the Arctic.

The Kingdom's strategy for the Arctic marks an important milestone towards 2020 and beyond and aims to contribute to a sound foundation for positive development in the Arctic into the future. The Kingdom consists of three societies, each with their own political priorities and social structures. Therefore, the strategy's implementation in each individual area will be adjusted to each part of the Realm's unique legislation, political priorities and budget issues.

The Kingdom's Arctic strategy falls within the existing division of competences and responsibilities between the State and Greenland's Self-Government, and the State and the Government of the Faroes.

A chief aim of the Arctic strategy is to promote information exchange and coordination of efforts in all areas related to development in the Arctic, and thereby to obtain a clearer focus on common priorities and promote collaboration internally and externally where there is mutual interest. The strategy will thus provide the framework for Arctic-related activities of the Kingdom and the three parts of the Realm towards 2020.

A number of measures will be initiated immediately to ensure the effective implementation of the strategy:

- A cross-disciplinary Steering Committee is to be established for the Arctic Strategy, consisting of representatives of the government (ministries with Arctic activities), the Government of Greenland and the Government of the Faroes at high level. The steering committee is to meet on a biannual basis as a minimum. The Ministry of Foreign Affairs will serve as chairman and secretariat of the steering committee in close collaboration with the Government of Greenland and the Government of the Faroes and the Prime Minister's Office. In order to promote the coordination of activities and safeguarding of the Kingdom's interests in the Arctic, the Foreign Ministry will appoint a special Representative for the Arctic.
- In collaboration between the Government, the Government of Greenland and the Government of the Faroes concrete efforts are to be initiated to bolster foreign and security policy coordination and cooperation with regard to the Arctic. In addition to the existing dialogue mechanisms (also at ministerial level) and the establishment of a cross-disciplinary platform qua steering committee for the Arctic strategy, elements could include enhanced dialogue regarding multilateral and global economic organizations and issues, more systematic cooperation through the network representation abroad, establishment of an exchange mechanism between the Department of Foreign Affairs in Nuuk and the Foreign Ministry in Copenhagen and also joint public diplomacy / advocacy efforts (see below).
- At the same time, the Arctic strategy represents an ambition for intensified and more systematic outreach efforts both in the three parts of the Realm and internationally, for example via the

representations abroad. This key endeavour, in the form of public diplomacy / advocacy initiatives such as seminars, cooperation with think tanks, etc., could focus on issues such as how climate change affects the Arctic, the Arctic as a region of cooperation, the new trade opportunities in the Arctic, the Kingdom's cultural and political diversity, international law and the Arctic, etc. The Foreign Ministry will allocate resources hereto.

The Foreign Ministry, on behalf of the Government and in cooperation with the Government of Greenland and the Government of the Faroes, will report annually on developments in the Arctic and the status of the Strategy's implementation. The aim is to carry out a mid-term evaluation of the Strategy in 2014-2015 and consider the preparation of a new strategy in 2018-2019.

Preliminary Build-out Plan for Alaska Ocean Observing System September 2011

National Federation of Regional Associations for Coastal and Ocean Observing

Alaska Ocean Observing System

INTEGRATED OCEAN OBSERVING SYSTEM

PRELIMINARY BUILD-OUT PLAN FOR

ALASKA OCEAN OBSERVING SYSTEM

SEPTEMBER 2011

THEMATIC ISSUES AND PRODUCTS

Introduction

Document organization: Guidance and directions for developing this build out plan were provided by the national Integrated Ocean Observing System (IOOS) and the National Federation of Regional Associations for Coastal and Ocean Observing (NFRA). Accordingly, each Regional Association develops a build out plan centered on four theme areas. The theme areas are: Marine Operations; Climate Variability and Change; Ecosystem, Fisheries and Water Quality; and Coastal Hazards. A fifth theme area was added for Integrated Products intended for issues that cross two or more of the original themes. For each theme area, the build out document identifies the important regional issue, priority products and services identified by regional stakeholders, and information requirements. The build out document is organized so that products within each major category can be compared among other Regional Associations. The AOOS plan describes only those major products that can be delivered by the end of the 10- year planning horizon (2021) and represents a "bare-bones" system rather than an "optimal" system.

Supplementary Material: Please refer to the following material for additional guidance:

- RA Build Out Guidance Document
- Terms and Definitions: Please refer to the Terms and Definitions Appendix in the Guidance Document

Geographic Regions, Areas, and Sites: For the purposes of this build out plan, AOOS will adopt a geographically nested design where each of Alaska's three ocean basins is considered a Region, each Region will have several Areas (Fig. 1), and each Area may have observation platforms at one or more Sites. In this document the Chukchi and Beaufort Seas are combined into the Arctic Ocean. Observations and products intended to address issues at the Regional scale are coarser than those developed to address issues at the Area scale. Fine scale observations (e.g. Sites) will generally inform larger scale issues (e.g. Areas). In some cases, thematic issues may be adequately addressed, in the context of available funding and resources, at the scale of a Region (e.g. ocean acidification, sea level rise, etc.). In other cases, the issue may only be relevant at the scale of Areas (e.g. coastal inundation, wave height, marine weather, etc.).

The National Weather Service already provides general weather and wave nowcasts and forecasts for all of Alaska. Similarly there are existing ocean circulation models for the North Pacific, Gulf of Alaska, Bering Sea, and Arctic Ocean. However, while a few of these models are quasi-operational, most are research-oriented. There are several observational platforms that serve the needs of Regional scale thematic issues such as the time series at GAK1 in the Gulf of Alaska and M2 in the Bering Sea for climate variability. However, stakeholder workshops in 2010 identified a need for more intensive observations and

forecasts of higher spatial resolution at the scale of Areas. Areas identified for more intensive observing and modeling efforts represent (1) relatively populated embayments and coastlines, (2) places of concern due to industrial activities,or (3) the need for more ecological understanding. The Areas are sized to be tractable for the deployment of atmospheric and oceanic instrumentation packages and for the development of higher resolution model domains based on lessons learned from the Prince William Sound demonstration. Over a 10-year AOOS build out to address the thematic issues and products, the nested design will provide coarser scale observations and forecasts for the Regions and more intensive observations and finer scale forecasts at a minimum of five Areas.

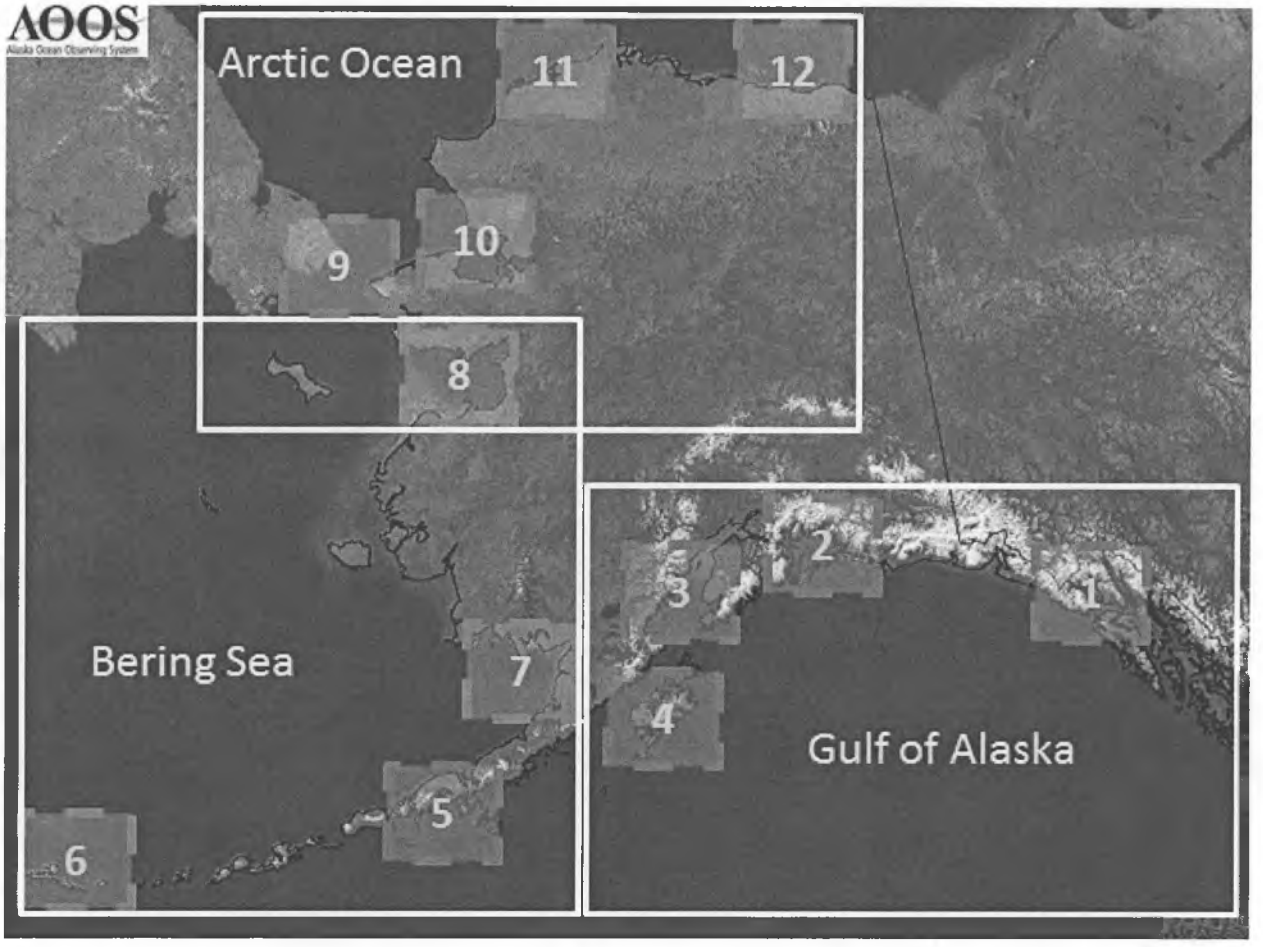

Figure 1. Areas of proposed intensive observing system development within each of the Alaska regions (Areas of existing emphasis are underlined): **Gulf of Alaska:** (1) Southeast, (2) Prince William Sound. (3) Cook Inlet, (4) Kodiak, (5) Unimak Pass; **Bering Sea**: (6) Adak/Western Aleutians, (7) Bristol Bay, (8) Norton Sound; and **Arctic Ocean**: (9) Bering Strait. (10) Kotzebue Sound, (11) Chukchi Sea. and (12) Beaufort Sea.

In each Region the build out will proceed with a prioritization of thematic issues. In some cases a thematic issue may already be adequately addressed at the Regional scale through products developed at the Data Management and Communications level with little or no additional infrastructure investment (e.g. climate variability and change, sustainable fisheries, ecosystem health, etc.). In other cases some limited infrastructure development may be needed to augment an existing effort (e.g. ocean acidification, harmful algal blooms, water quality, etc.). Several issues may only be addressed with considerable investment at the most intensive scale of observation and model resolution (e.g. real-time surface currents, forecasting storm surges, etc.).

In general, thematic issues at coarser Regional scales will be less costly to address and more tractable than those at finer Area scales. But several issues can only be addressed at the Area scale and the development steps will proceed from (1) identification (see Fig. 1) of an Area of focus (within one or more of the three Alaska Regions), (2) identify site(s) within an area for additional observations or weather (met stations, buoys, etc.), waves (e.g. wave buoys), and ocean conditions (e.g. buoys, moorings, routine glider deployments), (3) develop numerical simulations of actual conditions (nowcasts) and provide area specific forecasts using data assimilation techniques where practicable. Information products provided by these efforts will lead to developing additional decision support tools for coastal hazards (e.g. tsunami warning, coastal erosion, inundation, etc.), climate change and variability, and ecosystem assessments and management.

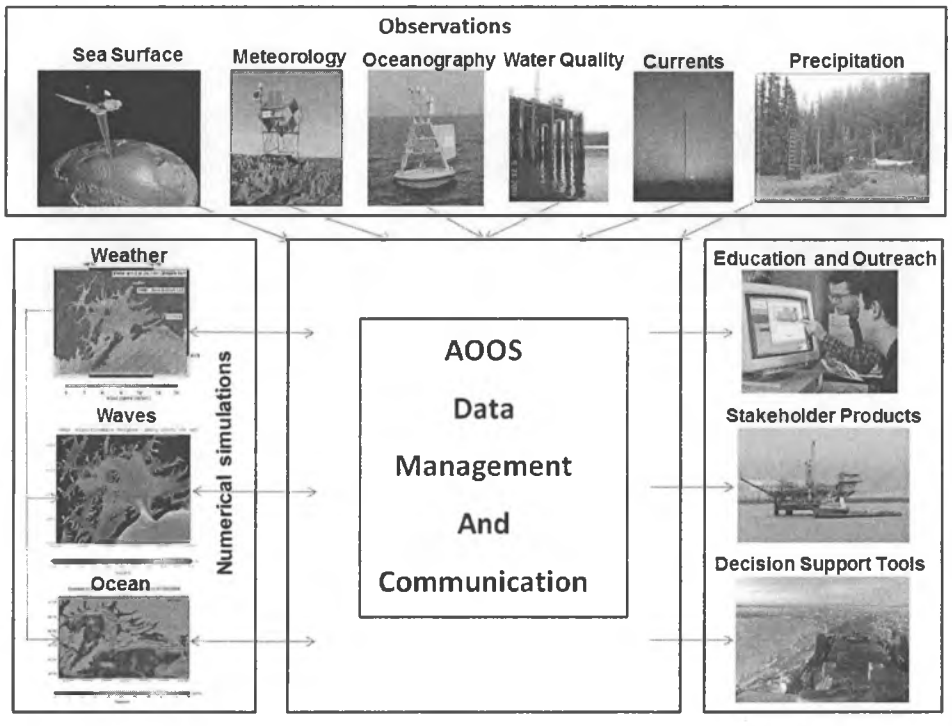

Figure 2. Conceptual strategy of the AOOS build out.

The AOOS advisory committees and Board will identify and select (respectively) successive or simultaneous build out areas based on annual budget allocations and stakeholder prioritization. A general strategy for the build out of AOOS is shown in Figure 2, where weather simulations are first developed based on weather observations, then ocean models are developed based on ocean observations and weather forecasts, etc. These observational and forecast components are conceptually described in this document. Every phase of development must have a data management and communication (DMAC) strategy (described elsewhere) so that all the observations are accessible to the computers running the models and to the public from the AOOS web site. The success of AOOS will, to some extent, depend on an integrated education and outreach (E&O) program (described separately).

1. Marine Operations

Issue 1.1 Safe and efficient commercial shipping and recreational boating.

Description of the issue: Many areas frequented by vessels in Alaska have no fine scale observations or forecasts of atmospheric or oceanic conditions, or cost effective communications for mariners to receive recent weather or wave and currents information.

Importance to the region: Alaska's maritime operations are diverse, spanning many government, industrial, and recreational user communities. The state is home to a $6 billion commercial fishing industry, offshore oil exploration in the Arctic as well as development and production in Cook Inlet, a Marine Highway System (ferries) serving otherwise isolated coastal communities in the Gulf of Alaska, cruise ships carrying a million passengers per year, and active charter and recreation fleets. AOOS hosted a workshop in May 2010 to discuss the important marine operations issues for Alaska. A summary and report of this workshop can be found at www.aoos.org/workshops-and-reports/.

Who are the impacted and targeted users: Stakeholders and interested organizations are represented by the University of Alaska Fairbanks, U.S. Coast Guard (Search and Rescue), Marine Exchange of Alaska (Vessel Tracking System), the Alaska Energy Authority (Tidal Energy), the U.S. BOEM (Offshore Oil Development), the Prince William Sound and Cook Inlet Citizens Advisory Councils (Oil Spill Response), the National Weather Service (Weather and Sea State), Alaska Association of Harbormasters and Port Administrators (Tsunami Warning), the Oil Spill Recovery Institute (Oil Spill Research), offshore oil and gas companies such as Shell and ConocoPhillips (Offshore Oil Production), the Southwest Pilot's Association (Risk Assessment), and commercial shipping interests (Insurance Risk).

1.1.1 PRODUCTS AND SERVICES: Weather and sea state conditions for mariners

Site-specific weather conditions (see Table 1) will be collected using a low cost meteorological sensor array measuring key IOOS atmospheric variables. This array may be similar to the standardized weather stations used by the NOAA NERRS in the System Wide Monitoring program or the experimental array at Cape St. Elias (http://denali.micro-specialties.com/CapeStElias/CSE%20Metadata.htm), although, depending on funds available, these could also be standard NWS weather stations or the SnoTel stations now used in Prince William Sound and Cook Inlet. The design will include, at a minimum, wind speed and direction, air temperature, and barometric pressure. Precipitation will also be an important variable in many areas. Some installations with immediate access to sufficient power supplies and internet bandwidth may be augmented with webcams for qualitative sea state and ice observations.

Once weather stations are deployed and observations are available, numerical models can be developed or expanded to simulate area-wide synoptic weather conditions. Observational data will be critical for evaluating model performance. AOOS has taken a lead role in developing collaborations with the University of Alaska Anchorage and Fairbanks campuses to develop Weather Research Forecasting (WRF) atmospheric circulation models that now provide statewide, regional (e.g. GOA, Bering), and area scale (e.g. Prince William Sound and Cook Inlet) nowcasts/forecasts. There is an on-going effort to integrate the nowcasts/forecasts with the National Weather Service regional forecasts. The WRF nowcasts and forecasts are disseminated through the AOOS Model Explorer (www.aoos.org). The wind nowcasts/forecasts are used directly and also as input to area-scale synoptic wave and ocean circulation models. The performance of wind nowcasts/forecasts are evaluated by site-scale weather observations, and subsequently inform wave and ocean circulation models.

Site-specific sea state conditions are observed with wave buoys. AOOS collaborated with the NDBC, Scripps, and the US Army Corp of Engineers in 2011 to deploy the first CDIP wave buoy in Alaska as part of an expanding effort to provide observations of sea state to mariners. This buoy is providing measurements of wave height, period, and direction to aid in validating a synoptic wave model for Cook Inlet. This wave buoy is intended as a demonstration of the technology in Alaska, and if successful will be used in other areas around the state.

Synoptic sea state conditions are obtained using wave models linked to the AOOS wind nowcast/forecast models and wave buoy observations. In the near term, AOOS will continue collaborating with Texas A&M University on developing Simulating Waves in the Nearshore (SWAN) wave model domains for Prince William Sound and Cook Inlet. In the longer term, to economize the modeling effort, AOOS may seek a contract for a coupled approach with the wave modeling conducted in tandem with the atmospheric modeling from one location.

TABLE 1.1.1 INFORMATION REQUIREMENTS (FOR WEATHER AND SEA STATE):

Geographic Focus			Observations and models				
Regions	Areas	**	Platform	Parameters	Time step	Resolution	Spatial
Gulf of Alaska	Cross Sound/Icy Strait	1	Land	Wind speed	15 min	Point	Site*
	Prince William Sound	**2**	Land	Wind direction	15 min	Point	Site*
	Cook Inlet	**3**	Land	Temperature air	15 min	Point	Site*
	Kodiak	4	Land	Pressure air	15 min	Point	Site*

1.1.2 PRODUCTS AND SERVICES: Improved wind and ocean current nowcasts/forecasts

AOOS will continue funding the development of a Data Assimilating Regional Ocean Modeling System (ROMS) forecasting model for Prince William Sound, the north Gulf of Alaska (GOA), and the northeastern Pacific Ocean. The NOAA CO-OPS is developing a ROMS domain for Cook Inlet. WRF and ROMS nowcasts and forecasts are produced daily, and images, analysis, and model output are disseminated by NASA's Jet Propulsion Lab (JPL) and are also available on the AOOS Model Explorer (www.aoos.org).

Experiments in Prince William Sound have shown that ROMS performance is improved through data assimilation of fresh water discharge and ocean conditions. Fresh water discharge relies on improving hydrological forecasts. Observations of ocean conditions are provided by a suite of fixed and mobile instruments such as moorings, gliders, and HF radar arrays (see 1.3.1).

TABLE 1.1.2 INFORMATION REQUIREMENTS (FOR WIND AND OCEAN CURRENTS NOWCASTS/FORECASTS):

1.1.3 PRODUCTS AND SERVICES: Improved sea ice extent and trajectory nowcasts/forecasts

As Arctic sea ice retreats, and northern oceanic passages stay open for longer periods, more vessels are passing through Alaska waters. These vessels take shipments to international destinations, as well as supporting increased economic development in western and northern Alaska, and touring the Arctic for recreation. In 2011, an ice free passage along the north coast of Russia is expected for up to three months allowing cargo and cruise ships direct access between Russian and US west coast ports (www.arcus.org/search/seaiceoutlook/2011/august). For example, the Russian gas producer Novatek plans to send the 120,000-ton tanker Vladimir Tikhonov along Russia's Arctic Coast to the Bering Strait in August — the largest ship of its kind to ever traverse the Northern Sea Route.

The NWS and ARCUS now provide sea ice maps that depict the location of fast ice and the ice shelf based on satellite image analysis. But highly mobile broken ice continues to be problematic especially for vessels in transit. AOOS will explore using ice radars, bottom mounted ice thickness sonars and numerical modeling to develop a sea ice trajectory

nowcast/forecast as an aid to vessels working in the Arctic (see: www.crrel.usace.army.mil/sid/hopkins_files/Seaice/Cook_inlet.htm).

TABLE 1.1.3 INFORMATION REQUIREMENTS (FOR SEA ICE EXTENT AND TRAJECTORY NOWCASTS/FORECASTS):

Issue 1.2: Search and Rescue

Description of the issue: The United States Coast Guard (USCG) must often conduct time-consuming searches for lost, missing, or distressed vessels and persons in Alaska's coastal oceans. Search and rescue (SAR) and minimizing the loss of life, injury and property damage by rendering aid to the distressed in the maritime environment have always been a Coast Guard priority. Coast Guard SAR response involves costly multi-mission stations, cutters, aircraft and boats linked by communications networks.

A SAR responder is faced with many challenges, including acquiring atmospheric winds, oceanic currents, sea surface temperature, craft/personal conditions, and other information that may not be precisely known. The USCG adopted a new Decision Support Tool (DST) in early 2007 known as the Search and Rescue Optimal Planning System (SAROPS) for planning search and rescue operations. SAROPS uses a sophisticated, cutting-edge animated grid model to project how/where floating persons or objects might move. It allows searchers to define the situation, access environmental data such as wind and water current patterns, compute drift models, simulate environmental hazards, and develop a comprehensive search plan with available resources. The two most important input parameters for SAROPS are: (1) atmospheric surface (10-meter) wind (both speed and direction); and (2) ocean surface current (both speed and direction). Currently, SAROPS accesses these data sets through the Applied Science Associates' Environmental Data Server (EDS), that manages a number

of global and regional wind and current data sets. These include both observations and computer forecast models. For the northeastern Pacific area, the EDS is presently accessing NOAA NCEP's Global Forecast System (GFS) and North America Mesoscale (NAM) 10-meter surface winds fields. Providing higher resolution forecasts would improve the SAROPS model for use in Alaska.

Importance to the region: See 1.1.

Who are the impacted and targeted users: See 1.1

1.2.1 PRODUCTS AND SERVICES: Real time surface currents sent to the USCG EDS for use in SAR operations

The success of SAR operations critically depends upon the quality of the surface wind and current data sets accessible through EDS. Of particular interest is the measurement of surface currents from HF radars. The accuracy of surface current measurements with HF radars has been reported to be between 4 to 20 cm s-1 making this an ideal tool both for direct observation as well as data assimilation by numerical models.

Observational data need to be assimilated into models for more precise predictions. Furthermore, a single model realization without measures of uncertainties will be of very limited use. Finally, the data have to be readily available for both nowcast and forecast fields, in a timely manner, using a standard format.

The challenge in Alaska is to maintain continuous real-time operation of these systems at remote sites. To address the technical challenge, HR radars have now been designed with more reliable power supplies and telecommunications.

1.2.2 PRODUCTS AND SERVICES: Improved communications of vessel location and weather and sea state

Most vessel traffic (per capita) in Alaska now has access to emergency VHF radio broadcasts and much of it is within cell phone coverage areas; however, the area represented is less than 15% of Alaska's waters. The lower 48 states now have 99% VHF coverage out to 20 miles. The USCG does not intend to fully implement Rescue 21, the new national VHF distress communication system, in Alaska and most commercial vessels will continue relying on HF radio and satellite telephone (or internet). The USCG will not be fully implementing the vessel Automated Information System (AIS) in Alaska either, and will rely on industry to provide additional communication infrastructure. The Alaska Marine Exchange is implementing the regional AIS infrastructure and in the future may be adding Rescue 21 Digital Selective Calling to selected new and existing AIS relay stations (Fig. 3). A significant contribution by AOOS to maritime safety in Alaska would be to facilitate the expansion of AIS relay stations in the three ocean basins, and to augment existing weather stations with AIS transmitters to communicate weather conditions directly to mariners at sea.

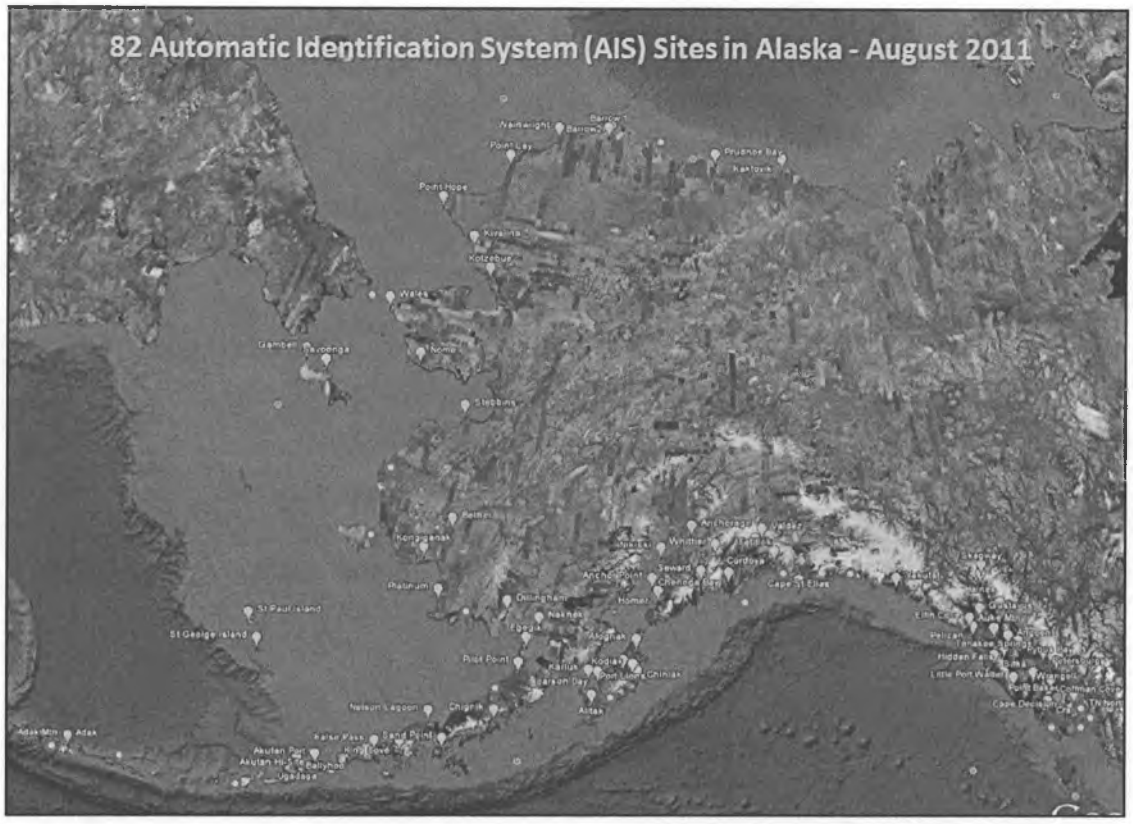

Figure 3. Proposed (yellow) and existing (blue) AIS stations in Alaska (courtesy of the Alaska Marine Exchange).

Issue 1.3: Spill response

Description of the issue: Under the National Contingency Plan the USCG serves as the Federal On Scene Coordinator for oil spill response and NOAA is designated to provide the Scientific Support Coordinator (SSC). NOAA's Office of Response and Restoration staffs the SSCs with oceanographers, modelers, chemists, and biologists available 24 hours a day. During a real oil spill, the primary Decision Support Tool for evaluating potential trajectories is the General NOAA Oil Modeling Environment (GNOME). GNOME forecasts spill trajectories based upon the best wind and ocean circulation forecasts available at the time of the response. Twice daily overflights of the spill are made to validate the real oil spill trajectory.

Importance to the region: NOAA does not officially respond to oil spills until formally requested by the U.S. Coast Guard. Therefore, the GNOME model as implemented by NOAA is generally not used in small oil spills, oil spill drills, or in pre-staging equipment in advance of an oil spill. This was demonstrated recently in Cook Inlet during the Mt. Redoubt volcanic eruption of 2009. The oil terminal at Drift River was in imminent danger of being overwhelmed by the ash flow, but the U.S. Coast Guard had not issued a request for spill trajectory scenarios from NOAA. Spill response organizations such as Alyeska Pipeline Service Company (Alyeska) in Prince William Sound and Alaska Clean Seas in the Beaufort Sea need oil spill trajectory forecasts for better planning scenarios, and to anticipate the placement of protection and response equipment.

Who are the impacted and targeted users: See 1.1

Geographic site selection: See 1.1: Areas Prince William Sound (2), Cook Inlet (3), Chukchi Sea (11), and Beaufort Sea (12).

1.3.1 PRODUCTS AND SERVICES: Real time surface currents used by NOAA HAZMAT, Coast Guard and others to track and forecast oil & chemical trajectories

See 1.2.1

TABLE 1.3.1 INFORMATION REQUIREMENTS (FOR REAL TIME SURFACE CURRENTS):

1.3.2 PRODUCTS AND SERVICES: Ocean circulation models & forecasts

See 1.1.2

INFORMATION REQUIREMENTS (FOR OCEAN CIRCULATION MODELS & FORECASTS):

See TABLE 1.1.2

Issue 1.4: Offshore Energy (includes oil and gas, wind, tidal, waves, etc.)

Description of the issue: Exploration for potential offshore energy has accelerated in Alaska in the last five years, and may be a primary source of energy for Alaska and the nation for many decades. Offshore energy is used here to describe all forms of energy derived from the sea including oil and gas (see 1.4.1), as well as marine renewable energy sources such waves, tides, currents, and winds (see 1.4.2). A tidal energy project is being planned for Upper Cook Inlet, with NOAA taking the lead in developing an ocean circulation model as an aid in siting this and other area projects. There are several sites in Southeast Alaska that also have potential for ocean current development. Oil and gas development is on-going in Cook Inlet and exploration is progressing in the Chukchi and Beaufort Seas.

Importance to the region: In Alaska, the Bureau of Ocean Energy Management (BOEM) is the primary federal agency administrating ocean energy development in offshore waters. The environmental issues of greatest concern to BOEM include monitoring the marine environment for changes attributable to offshore energy development, conducting research on oil spill fate and effects especially in ice environments, and minimizing impacts of seismic and acoustic operations. Issues relevant to AOOS and IOOS include quantifying change in the marine and coastal environment due to offshore activity, determining the role of currents in the distribution of anthropogenic pollutants, and the fate of pollutants, particularly in broken ice.

Who are the impacted and targeted users: See 1.1. In addition, users include statewide Alaska Native Villages that are aggressively pursuing wind energy sources to offset the high cost of petroleum energy products.

Geographic site selection: See 1.1: All Areas

1.4.1 PRODUCTS AND SERVICES*:* Atmospheric and oceanographic information to assist with offshore oil and gas operations

See 1.1.2

INFORMATION REQUIREMENTS (FOR WEATHER, WAVE, OCEAN CIRCULATION OBSERVATIONS AND NOWCASTS/FORECASTS):

See TABLE 1.1.2

1.4.2 PRODUCTS AND SERVICES: Atmospheric and oceanographic information to assist with alternative energy development such as wind, waves, and currents.

See 1.1.2

INFORMATION REQUIREMENTS (FOR WEATHER, WAVE, OCEAN CIRCULATION OBSERVATIONS AND NOWCASTS/FORECASTS):

See TABLE 1.1.2

2. Climate Variability and Change

Issue 2.1: Changes in ocean conditions over time

Description of the issue: The ocean is a fundamental part of the climate system. Short-term fluctuations (years to a few decades) such as the El Niño-Southern Oscillation, the Pacific decadal oscillation, the North Atlantic oscillation, and the Arctic oscillation, represent climate variability rather than climate change. On longer time scales, alterations to ocean processes such as thermohaline circulation, play a key role in redistributing heat by carrying out a very slow and extremely deep movement of water. These processes drive the long-term redistribution of heat in the world's oceans.

Importance to the region: The goal of this section is to provide data characterizing the response of Alaska's oceans to oscillations in climate. Quantitative information acquired includes mixed layer depth, vertical stratification, timing of the spring phytoplankton bloom, zooplankton species abundance, and summer mixing that results in production. AOOS hosted a workshop in May 2010 to discuss the important climate variability and change issues for Alaska. A summary and report of this workshop can be found at www.aoos.org/workshops-and-reports/.

Who are the impacted and targeted users: Resource managers, policy makers, commercial and recreational fishing, coastal communities, and subsistence users.

Geographic site selection: Gulf of Alaska, Bering Sea, Arctic Ocean (Chukchi Sea)

2.1.1 PRODUCTS AND SERVICES: Coastal climate records on key parameters over time. Regional contributions to climate indices and national climate assessments.

Issue 2.2: Ocean acidification

Description of the issue: Ocean acidification is the term used to describe increasing acidity, or decreasing pH, in the world's oceans. As carbon dioxide levels rise in the atmosphere, the ocean absorbs this gas, resulting in more acidic seawater. Scientists estimate that the ocean is 25 percent more acidic today than it was 300 years ago.

Importance to the region: Because cold water can absorb more carbon dioxide than warm water, the polar regions are most affected by ocean acidification. Increasing acidification can now be measured throughout these regions, and biological responses are detectable. The coastal seas around Alaska are more susceptible to ocean acidification because of unique circulation patterns and colder temperatures. These factors increase the transport of carbon dioxide from the atmosphere into surface waters. As the pH in the ocean decreases, it reduces the availability of carbonate ions, which play an important role in shell formation for a number of marine organisms such as corals, marine plankton, and shellfish. Some of the smaller calcifying organisms, such as Pteropods and other planktonic calcifiers, may be particularly susceptible to increases in acidity with potentially negative cascading effects on predator organisms such as salmon. Commercially important shellfish like crabs and oysters, and coraline marine habitats may all decline as a result of increased ocean acidification.

Who are the impacted and targeted users: Resource managers, policy makers, commercial and recreational fishing, shellfish growers, coastal communities

Geographic site selection: (Fig 4) Gulf of Alaska, Bering Sea, and Arctic Ocean

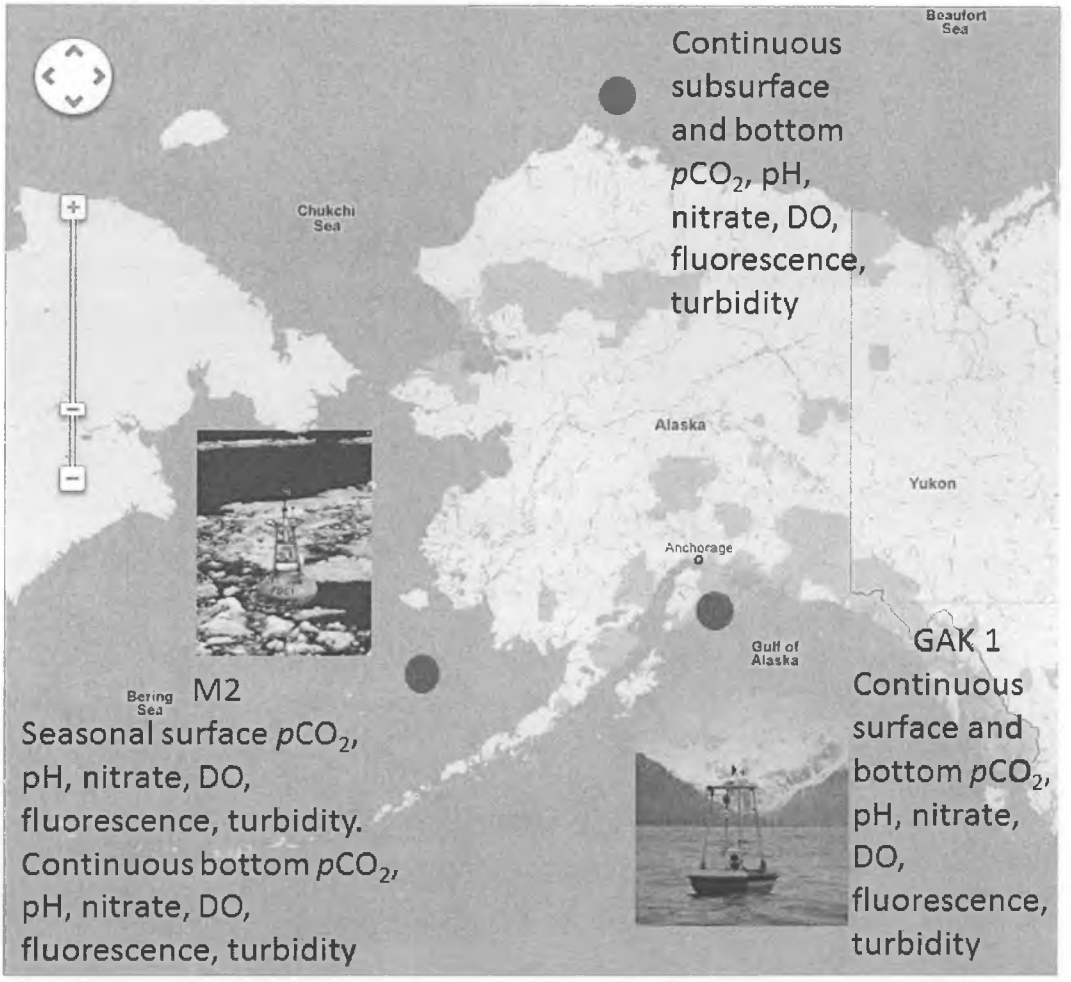

Figure 4. Location of ocean acidification moorings funded by NOAA, NSF, NPRB, and AOOS in the Arctic, Bering, and Gulf of Alaska in 2011 (from http://www.sfos.uaf.edu/oarc/).

2.2.1 PRODUCT AND SERVICES: Status and trends in ocean acidification as well as warnings sent to interested parties such as shellfish growers when ocean conditions may become unfavorable due to extreme changes.

Issue 2.3: Sea Level Change

Description of the issue: There is a widespread consensus that substantial long-term sea level rise across the globe will continue for centuries to come. For this century, one meter of sea level rise is well within the range of recent projections, although for Alaska this will be confounded somewhat by subsidence or uplift events. There are two main factors that have contributed to observed sea level rise. The first is thermal expansion: as ocean water warms, it expands in volume. The second is from the contribution of land-based ice due to increased melting. The major store of water on land is found in glaciers and ice sheets that are now rapidly decreasing in size.

Importance to the region: On the timescale of centuries to millennia, the melting of ice sheets could result in even higher sea level rise. Partial deglaciation of the Greenland and West Antarctic Ice Sheets could result in sea level rise of 4–6 meters or more. Such an increase in sea level would imply major changes in coastlines and ecosystems, and inundation of low-lying areas, with greatest effects in estuaries.

Who are the impacted and targeted users: Resource managers, policy makers, and coastal communities. Current sea level rise potentially impacts all human populations living in coastal regions and on islands.

Geographic site selection: Statewide

2.3.1 PRODUCT AND SERVICES: Improved forecasts for communities in areas affected by sea level rise, land subsidence, and coastal inundation.

3. Ecosystems, Fisheries and Water Quality

Issue 3.1 Healthy and Productive Ecosystems

Description of the issue: Alaska's coastal waters support a rich and diverse ecosystem, and are home to the nation's largest fisheries, as well as abundant populations of seabirds and marine mammals. Many economically important fisheries are now declining and conflicts exist between threatened and endangered species and development industries over critical marine habitats. The health of ecosystems in Alaska has direct social and economic implications that are likely to be more profound as the effects of climate change are manifested by large-scale ecosystem adjustments. In addition, as human activities increase in Alaska waters, management challenges increase and will require new sources of information and decision support tools. The relationship between changing ocean conditions and fish and shellfish populations is now better understood but decision support tools will require better data integration

Importance to the region: The Alaska region continues to demonstrate susceptibility to climate variability and change. Additional threats include oil spills, mineral extraction industries, overfishing, noise and pollution. The loss of sea ice is affecting marine mammal migrations, and potentially expanding the northern range of fishes and invertebrate species through the Bering Strait. Socioeconomic changes are likely to follow as in the mid-1970s when the relative dominance of the commercially important fish species changed. These ecosystem adjustments were linked to decadal-scale changes in the atmosphere and ocean of the North Pacific. As a consequence, the commercial fishing industry had to invest heavily in new infrastructure to remain economically viable. AOOS hosted a workshop in May 2010 to discuss the important ecosystem health and fisheries issues for Alaska. A summary and report of this workshop can be found at www.aoos.org.

Who are the impacted and targeted users: Representative stakeholders include resource managers, policy makers, the fishing industry, subsistence-based communities, academic and agency researchers, and everyone who depends on healthy and productive marine ecosystems.

Geographic site selection: Statewide

3.1.1 PRODUCTS AND SERVICES: Integrated datasets and displays linking habitats with physical oceanographic properties (Habitat GIS/seabird data portals).

TABLE 3.1.1 INFORMATION REQUIREMENTS (FOR COMPILING DATASETS FOR THE SPATIAL ANALYSIS OF HABITATS):

3.1.4 PRODUCTS AND SERVICES: Distributed Biological Observations (DBO) using vessels of opportunity. A marine Distributed Biological Observatory (DBO) in the U.S. Arctic is envisioned for consistent monitoring of biophysical responses in four pivotal oceanographic areas along a north-south latitudinal gradient. Each area exhibits high biological productivity, biodiversity, and gradients in ecosystem properties and direct linkages to subsistence-based coastal communities. All areas are projected to experience increased commercial use with the loss of sea ice. The Bering Strait region represents potential conflicts between commercial shipping and resource exploration, subsistence hunting, and management of biological resources. As sea ice retreats, the DBO will track the rate of ecosystem change and sample currently unknown impacts. The DBO integrates biological and physical sampling, including both mooring and dedicated repeat ship occupations using a collaborative international network of logistical support.

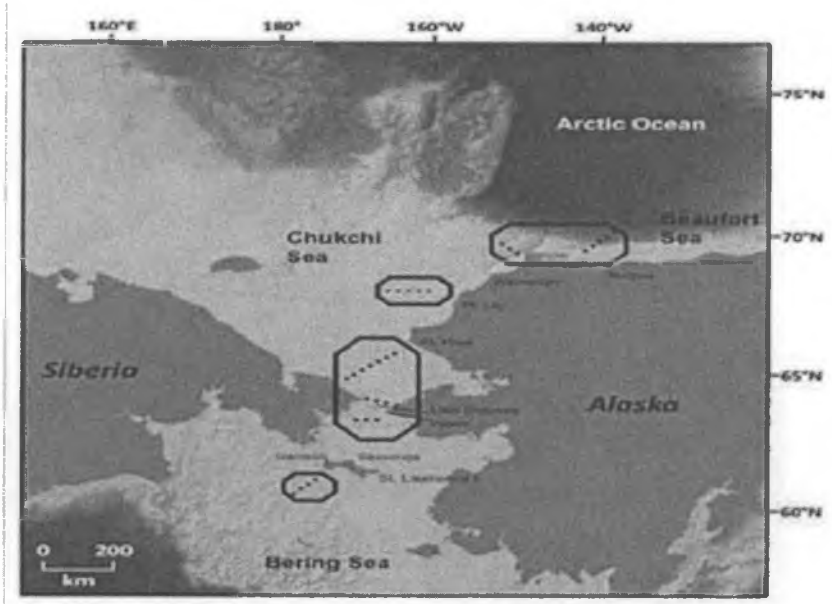

Figure 5. Four possible regional locations of Distributed Biological Observatory transect lines and stations for standard hydrological and biological measurements in the Pacific Arctic sector, including acoustics for marine mammal detection. These stations would include Canadian, Chinese, Japanese, Korean, Russian, and U.S. research vessels, coordinated through the international Pacific Arctic Group, and land-based research from coastal communities using helicopters, small ships, and long-term moorings.

TABLE 3.1.4 INFORMATION REQUIREMENTS (FOR A DBO USING VESSELS OF OPPORTUNITY):

Geographic Focus			Observations and models

Issue 3.2 Sustainable Fisheries

Description of the issue: One of the major impediments to the rational control or management of marine resources is inadequate or poor data. Fisheries management

decisions are often based on population models, but the models need quality data to be accurate. Scientists and fishery managers need simpler models, better population estimates, and better estimates of population and oceanographic baselines.

Importance to the region: Fishing is a mainstay of the Alaska economy, second only to the oil industry and wholly reliant on a healthy marine ecosystem and high quality data relevant to fishery managers.

Who are the impacted and targeted users: Resource managers, policy makers, commercial and recreational fishing industry, subsistence users, and Alaska coastal communities.

Geographic site selection: Statewide

3.2.1 PRODUCT AND SERVICES: Seasonal and annual climatologies and ecosystem syntheses of fundamental parameters and derived information products important for fisheries and ecosystem-based management.

INFORMATION REQUIREMENTS (FOR PRODUCING DERIVED SEASONAL AND ANNUAL OCEAN CLIMATOLOGIES AND ECOSYSTEM SYNTHESIS PUBLICATIONS):

See 3.1.2

3.2.2 PRODUCTS AND SERVICES: Surface current mapping for larval fish transport

INFORMATION REQUIREMENTS (FOR SURFACE CURRENT MAPPING):

See 1.2.1

3.2.3 PRODUCTS AND SERVICES: Participate in coordination of interagency monitoring programs and data collections for potential use in 3.2.1 (above). There is an extensive array of seabird, marine mammal, and fish surveys conducted in Alaska, and many of these programs have developed a time series useful to the synthesis in Section 3.2.1. See Appendix A.

	Beaufort Sea	12					

Issue 3.3 Harmful algal blooms

Description of the issue: Toxic or Harmful Algal Blooms (HABs) are becoming an increasing public health concern on a global scale. HAB events are generally attributed to anthropogenic nutrient enrichment of coastal waters. In Alaska, of most concern is Paralytic Shellfish Poisoning (PSP), caused by several species of dinoflagellates in the genus *Alexandrium*. Shellfish become toxic when environmental conditions such as changes in salinity and temperature enable toxic dinoflagellate cells to rapidly reproduce causing a toxic bloom. PSP episodes in Alaska tend to be seasonal, occurring most often during late spring and summer. Off-season occurrences of PSP are most likely caused by tissue retention of toxins from summer bioaccumulation.

Another HAB of concern in Alaska is caused by the marine bacteria *Vibrio parahaemolyticus*. This is the leading cause of seafood-associated gastroenteritis in the United States, and typically is associated with the consumption of raw oysters gathered from warm-water estuaries. Oysters associated with a 2004 outbreak on a cruise ship in Alaska were harvested from an oyster farm when mean daily water temperatures exceeded 15.0 degrees C. In this case, rising temperatures of ocean water seem to have contributed to one of the largest known outbreaks of *V. parahaemolyticus* in the United States.

Importance to the region: The economic consequences of the HABs has drastically impacted the commercial oyster farms and clam fisheries in Alaska., as well as recreational and subsistence users.

Who are the impacted and targeted users: Resource managers, policy makers, coastal communities, Alaska Natives, commercial farms, consumers

Geographic site selection: Gulf of Alaska and Western Aleutians

3.3.1 PRODUCTS AND SERVICES: Early information to coastal managers for when conditions are conducive for harmful algal blooms (includes alerts for shellfish consumers, growers and others)

TABLE 3.3.1 INFORMATION REQUIREMENTS (FOR HABS DETECTION AND MONITORING):

	Alaska Peninsula	5	Mooring	Turbidity	1 hr	Point	Site
Bering Sea	Adak	6					

*Areas in bold have some AOOS infrastructure

Issue 3.4 Hypoxia

Description of the issue: Ocean hypoxia (low-oxygen) areas or "dead zones" in the world's oceans have been increasing in number and size since oceanographers began noting them in the 1970s. These are generally attributed to regional eutrophication (such as the Gulf of Mexico) or areas of anthropogenic nutrient enrichment. There are no known areas of ocean hypoxia or ocean deoxygenation in Alaska and the nearest occurrence is off the Oregon coast.

Importance to the region: Not a critical concern at this time in Alaska.

Who are the impacted and targeted users: Resource managers, policy makers

Geographic site selection: None in Alaska at this time.

3.4.1 PRODUCTS AND SERVICES: Ocean monitoring of temperature, nutrients and phytoplankton blooms, and dissolved oxygen

INFORMATION REQUIREMENTS (FOR EARLY DETECTION OF DEOXYGENATION):

Geographic Focus			Observations** and models				
Regions	Areas		Platform	Parameters	Time step	Resolution	Spatial

Issue 3.5 Minimizing the Impact from Polluted Waters

Description of the issue: Alaska has a reputation of being a pristine wilderness despite well publicized pollution events such as the Exxon Valdez oil spill and the Selendang Ayu shipwreck in the Aleutian Islands. Less well publicized are smaller scale events such as cruise ship polluters, oil and other industry discharges, and sewage discharges from coastal communities.

Importance to the region: Economic mainstays of Alaska are the fishing and commercial cruise ship industries and both are based on a healthy marine environment. Many of Alaska's coastal communities and Alaska native villages depend on the ocean for food. Even minor pollution events could easily disrupt this fragile economy and subsistence lifestyle.

Who are the impacted and targeted users: Resource managers, commercial fisheries, cruise ships, coastal communities, Alaska Natives

Geographic site selection: Statewide

3.5.1 PRODUCTS AND SERVICES: Early warnings for when large spatial scale pollution events may be present or forecasted.

TABLE 3.5.1 INFORMATION REQUIREMENTS (FOR INFORMING THE PUBLIC ON PRESENT OR IMMINENT EVENTS):

Geographic Focus			Observations** and models				
Regions	Areas		Platform	Parameters*	Time step	Resolution	Spatial

3.5.2 PRODUCTS AND SERVICES: Assist public health officials and resource managers with ready access to multiple sources of information on regional water quality

INFORMATION REQUIREMENTS (FOR PUBLIC DISSEMINATION OF EVENT SPECIFIC POLLUTION RELATED DATA AND INFORMATION):

See 3.5.1

4. Coastal Hazards

Issue 4.1 Providing hazard and disaster information when and where it is needed

Description of the issue: The goal of the AOOS coastal hazards program is to improve forecasts of extreme weather events and sea ice conditions and the likely effects on coastal communities. The effects of climate change in Alaska are dramatically manifested by the loss of sea ice. As a direct result, the Bering Sea and Arctic Ocean coasts are experiencing significantly increased wave heights, coastal erosion, storm surge and subsequent coastal inundation, and thawing coastal permafrost. AOOS will focus on water level and coastal inundation, wave observations and coastal erosion, and sea ice trends and drift trajectory data products.

Importance to the region: With the rapid loss of sea ice, Arctic weather and ocean conditions are increasingly endangering Alaska Native coastal communities. In a statewide assessment, flooding and erosion affects 184 out of 213 Native villages (GAO 2003). While some villages may need to be permanently moved, relocation is prohibitively expensive. Meanwhile, better forecasting and communication of storm surge events and coastal inundation is needed to help communities prepare for threatening storm events. AOOS hosted a workshop in May 2010 to discuss the important coastal hazards issues for Alaska. A summary and report of this workshop can be found at www.aoos.org.

Who are the impacted and targeted users: See Section 1.1: Alaska coastal communities.

Geographic site selection: Arctic Ocean and Bering Sea areas (see Fig. 1)

4.1.1 PRODUCTS AND SERVICES: Improved forecasts for coastal communities of extreme weather events, storm surges, and erosion events

See 1.1.1

TABLE 4.1.1 INFORMATION REQUIREMENTS (FOR IMPROVED FORECASTS FOR COASTAL COMMUNITIES):

Geographic Focus			Observations and models				
Regions	Areas		Platform	Parameters	Time step	Resolution	Spatial
Bering Sea	Bristol Bay	7	Land	Wind speed	15 min	Point	Site*
	Norton Sound	8	Land	Wind direction	15 min	Point	Site*
	Bering Strait	9	Land	Temperature air	15 min	Point	Site*
Arctic Ocean	Kotzebue Sound	10	Land	Pressure air	15 min	Point	Site*
	Chukchi Sea	11	Model	Weather Nowcast/Forecast	6hr/48hr	3 km	Area
	Beaufort Sea	12	Satellite	Various	24 hr	Various	Region

*** minimum or 3 sites (TBD)/area**

4.1.2 PRODUCTS AND SERVICES: Increase water level observations and coastal inundation forecasts (See also Sea Level Change Section 2.3.1)

There are presently only three permanent water level gauges north of the Aleutians at Nome, Red Dog, and Prudhoe Bay. This area covers about half of Alaska's considerable coastline and dozens of Alaska Native villages. AOOS will facilitate the deployment of water level sensors at new village sites, likely using a bottom mount and a shore-based bubbler system at each site. Data from the bottom mount will be retrieved bi-annually while the bubbler will stream real-time data seasonally during ice-free seasons. These data will be used by the NWS for forecasting, and by the USACE for wave and inundation models to help inform safe development and community relocation plans.

TABLE 4.1.2 INFORMATION REQUIREMENTS (FOR WATER LEVEL OBSERVATIONS AND COASTAL INUNDATION MODELING):

Geographic Focus			Observations and models				
Regions	Areas		Platform	Parameters	Time step	Resolution	Spatial
Bering Sea	Bristol Bay	7	Land	Water level	15 min	Point	Site
	Norton Sound	8	Model	Coastal inundation	0.5 hr	0.5 km	Area
	Bering Strait	9					
Arctic Ocean	Kotzebue Sound	10					
	Chukchi Sea	11					
	Beaufort Sea	12					

4.1.3 PRODUCTS AND SERVICES: Increased wave observations and forecasts

AOOS will facilitate the deployment of additional wave buoys and develop wave forecast models for areas with coastal communities in need of additional wave information. These area locations cover missing gaps for NWS forecasters as well as USACE modelers, and will help implement the IOOS National Operational Waves Observation Plan in Alaska. The buoys will measure wave height, period, and direction. Real-time data from the buoys will be communicated and made available through the AOOS web portal, as well as pushed to the NWS for ocean forecasting center.

TABLE 4.1.3 INFORMATION REQUIREMENTS (FOR WAVE OBSERVATIONS AND FORECASTS):

Geographic Focus			Observations and models				
Regions	Areas		Platform	Parameters	Time step	Resolution	Spatial
Bering Sea	Bristol Bay	7	Buoy	Wave height	1 hr	Point	Area
	Norton Sound	8	Buoy	Wave period	1 hr	Point	Area
	Bering Strait	9	Buoy	Wave direction	1 hr	Point	Area
Arctic Ocean	Kotzebue Sound	10	Buoy	Water temperature	1 hr	Point	Area
	Chukchi Sea	11	Model	Wave Nowcast/Forecast	6hr/48hr	1 km	Area
	Beaufort Sea	12					

4.1.3 PRODUCTS AND SERVICES: Improved Sea Ice thickness, extent and trajectory nowcast/forecasts

See 1.1.3

INFORMATION REQUIREMENTS (FOR IMPROVED SEA ICE EXTENT AND TRAJECTORY NOWCAST/FORECASTS):

See TABLE 1.1.3

5. INTEGRATED PRODUCTS

This section is for products that apply to many users and don't fall into one of the above categories.

Issue 5.1

Description: The National Ocean Policy Task Force defines coastal and marine spatial planning as a comprehensive, adaptive, integrated, ecosystem-based, and transparent spatial planning process, based on sound science, for analyzing current and anticipated uses of ocean, coastal, and Great Lakes areas. Coastal and marine spatial planning identifies areas most suitable for various types or classes of activities in order to reduce conflicts among uses, reduce environmental impacts, facilitate compatible uses, and preserve critical ecosystem services to meet economic, environmental, security, and social objectives.

5.1.1 PRODUCTS AND SERVICES: Integrated regional maps in support of coastal and marine spatial planning.

INFORMATION REQUIREMENTS (FOR DEVELOPING DATA VISUALIZATION TOOLS TO AID IN CMSP):

See 3.1.1 and 3.1.2

5.1.2 OTHER PRODUCT AND SERVICES: Visualizations of observing information that serve multiple purposes, including coastal and marine spatial planning. AOOS will focus on developing data visualization tools for the spatial analysis of coastal ecosystems in response to the new National Ocean Policy recommendation for Coastal and Marine Spatial Planning (CMSP).

INFORMATION REQUIREMENTS (FOR DEVELOPING DATA VISUALIZATION TOOLS TO AID IN CMSP):

See 3.1.1 and 3.1.2

Executive Summary

The coast is a key interface in the Arctic environment. It is a locus of human activity, a rich band of biodiversity, critical habitat, and high productivity, and among the most dynamic components of the circumpolar landscape. The Arctic coastal interface is a sensitive and important zone of interaction between land and sea, a region that provides essential ecosystem services and supports indigenous human lifestyles; a zone of expanding infrastructure investment and growing security concerns; and an area in which climate warming is expected to trigger landscape instability, rapid responses to change, and increased hazard exposure. A high proportion of Arctic residents live on the coast and many derive their livelihood from marine resources.

This report addresses a recognized need for a more detailed assessment of the impacts of environmental and social change in the Arctic coastal zone. The Arctic Climate Impact Assessment (ACIA, 2005) provided an overall synthesis of observed and anticipated impacts on social and ecological systems in the Arctic, but did not attempt a focused treatment of the coastal zone. Five years on, the circumpolar Arctic coast is arguably one of the most critical zones in terms of the rapidity and the severity of environmental change and the implications for human communities dependent on coastal resources.

Rapid environmental, social, economic, political and institutional changes are defining characteristics of the past decade in the Arctic basin. In the physical environment, the prospect of a seasonally ice-free Arctic Ocean appears more likely and imminent, as previous records for annual minimum sea ice extent have been broken successively in recent years and the trajectory of ice loss is more rapid than the most extreme model projections in the Fourth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC, 2007a). The past decade has also been the warmest on record for global surface air temperature and some Arctic regions have grown warmer at an even faster pace than the global mean, validating projections in earlier assessment reports that foresaw earlier and more severe climate change at high latitudes. In the face of unprecedented and jarring changes in the local environment on which traditional livelihoods and cultures depend, Arctic coastal communities are coping with rapid population growth, technological change, economic transformation, confounding social and health challenges and, in much of the Arctic, rapid political and institutional change.

It is evident that the coast is a critical component of the Arctic system requiring explicit attention. As a focus of human activity with attendant hazards, the circumpolar Arctic coast is clearly a priority for monitoring and change detection to support proactive adaptation and sustainable development.

This report is organized in four parts. Chapter 1 provides an introduction. Chapter 2 assesses the state of the Arctic coast under three broad disciplinary themes – physical, ecological, and human systems. Chapter 3 considers the need for and progress toward integrative approaches to monitoring, understanding, and managing change in Arctic coastal systems. Chapter 4 provides a synthesis and identifies data gaps and research priorities over the coming decade.

Key Findings

Physical State of the Circum-Arctic Coast

- The evolution of Arctic coasts over the coming decades will be strongly influenced by changes in the natural environment caused by the effects of climate warming.
- Surface air temperatures have reached record levels over the past decade. Record warm air temperatures in 2010 extended across Greenland and the Canadian Arctic.
- The past decade has seen successive new record minima in Arctic sea-ice extent and 2010 had the third smallest summer minimum extent of the past 30 years. At the same time, the mean ice thickness has been decreasing, driven primarily by export of perennial ice.
- Less extensive sea ice creates more open water, allowing stronger wave generation by winds. This, combined with warmer sea-surface and ground temperatures, has the potential to increase erosion along Arctic coasts. Record warm sea-surface temperatures in 2007 contributed to rapid coastal erosion in Alaska.
- Sea-level rise in the Arctic coastal zone is very responsive to freshening and warming of the coastal ocean (leading to increased sea level at the coast) and is highly susceptible to changing large-scale air pressure patterns.
- Relative sea-level change depends on vertical land motion (uplift or subsidence), the patterns of which are predominantly a legacy of former glaciation. The rate of uplift in some regions exceeds the rate of sea-level rise, leading to falling relative sea level.
- Sea-level rise in much of the Arctic is moderated by gravitational effects (fingerprinting) associated with ice loss from regional glaciers and ice caps and especially from the Greenland Ice Sheet.
- Arctic ice shelves will continue the recent rapid pace of collapse due to climate warming and the decrease in multi-year sea ice.
- Carbon entering the coastal system from terrestrial sources appears to be more labile than in the past. Because this organic matter is a direct source of energy for secondary production and a potentially important indirect source once remineralized, the higher lability may have far-reaching, yet unknown consequences for Arctic coastal marine productivity.
- Despite increasing annual freshwater discharge, some Arctic deltas are being progressively flooded, with most of the Mackenzie Delta front (the second largest Arctic delta) retreating at 1-10 m/year or more.
- Storm-surge inundation of low coastal areas and deltas affects coastal communities and can have profound impacts on delta ecology through salinization of freshwater environments. Early-season surges can disrupt waterfowl breeding and winter surges may flood or break up winter ice roads, a critical form of transportation for many northern activities.
- Decadal-scale mean rates of coastal retreat are typically in the 1-2 m/year range, but vary up to 10-30 m/year in some locations. The highest mean erosion rates are in the Beaufort Sea, the East Siberian Sea, and the Laptev Sea.
- Recent results on erosion of ice-rich bluffs point to the importance of interaction between high sea-surface temperatures, which drive thermal

abrasion and undercutting, and the timing of ice break-up and freeze-up in combination with storm dynamics.

- The distribution and stability of gas hydrates in the Arctic coastal zone is poorly documented, but there is concern that climate change and other effects such as coastal erosion may destabilize some hydrate deposits.
- Rocky shorelines comprise 35% of the Arctic coastline and most are effectively stable on timescales relevant to adaptation planning and management.

Ecological State of the Circum-Arctic Coast

- Arctic coastal habitats are the prime lifeline for Arctic communities and provide a wide range of ecosystem services.
- They support very large populations of fish, mammals and birds that are harvested by Arctic and non-Arctic communities.
- The Arctic coastal zone provides habitat to an estimated 500 million seabirds alone.
- Arctic coastal habitats are highly vulnerable to changing environment conditions, including climate change and growing human activities such as oil and gas exploration and development.
- Arctic river deltas are biological hotspots on the circumpolar Arctic coast. They have high biodiversity and are extremely productive in relation to adjacent landscapes. The high biodiversity remains poorly understood, but may be related to the complex natural patterns of water level fluctuation that occur in these vast lake-rich systems.
- Arctic ice shelf microbial mat cryo-ecosystems are severely threatened by ice shelf collapse, with some of the richest examples already lost.

Social, Economic and Institutional State of the Circum-Arctic Coast

- Social, cultural, health and demographic conditions, economic systems, industrial structure and the relative importance of subsistence activities vary across the spectrum of communities on the circumpolar Arctic coast.
- The Arctic economy as a whole is dominated by four major characteristics: the continuing importance of traditional subsistence activities and local living resources in most regions, the lack of manufacturing industries, the local and regional impacts of large-scale natural resource extraction or exploitation projects, and the major importance of the public sector for service provision and transfer payments from the south.
- Disposable household income (DHI) is largest in the Arctic regions where large-scale resource extraction occurs. These are, however, also the regions where the discrepancy is largest between DHI and gross regional product, demonstrating that actors outside of the region reap a large portion of the benefits from the economic activities there.
- Even though the Arctic has a relatively large proportion of people living in a near-traditional manner, close to nature and utilizing the resources there for food and subsistence, it is also well linked to the global economy, in particular as a large supplier of natural resources. The same processes we see in the advanced industrialized regions, of a knowledge-based economy with a focus

on innovations, are also taking place in the Arctic.

- Although climate change and other processes affecting natural resources and environmental conditions impose large impacts on quality of life and economic activity for communities on the Arctic coast, other factors and processes will often be more important, especially in the short run. Where communities are already stressed, even small changes in the availability or quality of natural resources may be critical.
- Recently established integrated marine regional plans, as for example in the Barents Sea, are milestones in the implementation of ecosystem-based management. Laudable as these efforts are, however, it is clear that more work needs to be done, particularly on societal impacts of industrial activities and on the socio-economic impacts of ecosystem changes in the Arctic coastal zone. In each case, a multifactor perspective is essential.
- The Arctic Human Development Report found that, for people in the Arctic, fate control, cultural integrity and contact with nature are central for well-being and should be included in future statistical data collection efforts. The Arctic Social Indicators project has proposed a suite of indicators for these factors, in addition to aspects considered in the United Nations Human Development Index, and is working toward the implementation of these indicators in the Arctic.
- Statistical data specific to coastal regions are difficult to obtain, at least for circumpolar comparisons. Economic, social and demographic connections between coastal and inland areas hinder a clear delineation of what should be included, or excluded, in a coastal-based study such as this.
- At a time of incipient rapid changes in the Arctic coastal zone resulting from climate change and other factors, there are growing health challenges in Arctic communities. Monitoring of the human health situation across the Arctic is critically important, especially for indigenous people in rural areas and remote communities.

Integrated Approaches to Coastal Change in the Arctic

- Arctic coasts may be usefully viewed as complex social-ecological or social-biophysical systems. A social-ecological system is an ecological system intricately linked with and affected by one or more social systems and vice versa.
- The health of Arctic coastal and marine ecosystems is increasingly under pressure, putting at risk ecosystem goods and services that support coastal communities.
- There are major feedback loops in the Arctic system associated with rapid changes in the regional climate. For this reason, the impacts of climate change in the Arctic may extend to a global scale.
- There are two general approaches to more integrated understanding considered in this report:
  - Indigenous communities in general embrace holistic perspectives on the environment and culture.
  - The traditional scientific approach can be applied within a system science framework, with the application of integrated assessments to analyze the interactions in social-ecological systems, as outlined in the risk-based management approach.

- The holistic perspective of indigenous culture suggests that efforts to understand, manage, and respond to change in Arctic coastal systems may benefit from the integration and complementarity of both approaches. Recognizing the value of traditional ecological knowledge may contribute to enhanced resilience and adaptive capacity in coastal communities.

Monitoring, Detecting and Modelling Coastal Change

- Reduction of negative impacts through adaptation to climate change requires new approaches in monitoring strategies to detect and track changes in the Arctic coastal environment. Understanding and prognosis of change is an essential component of resilience in Arctic coastal communities.
- Biophysical and human monitoring both clearly demonstrate that the Arctic environment is changing rapidly – sustained observation and monitoring is essential to document change and validate projections.
- Field-based monitoring in the Arctic coastal zone is challenged by remoteness, accessibility, communications, and instrument performance in extreme cold, but new survey technologies, instrumentation, and higher resolution of remotely sensed data are revolutionizing monitoring capabilities.
- These new techniques, decreasing costs, and higher resolution are enabling better spatial and temporal coverage of coastal change.
- Models represent key tools for understanding current changes and projecting future changes and associated impacts on Arctic coastal ecosystems and human communities.
- Models provide a means of interpolating between periods or locations of observation, a valuable capacity in times of reduced research and monitoring budgets.

Vulnerability, Adaptation, Adaptive Capacity and Resilience

- Increasingly governments, communities, and industry stakeholders are exploring ways to reduce the negative impacts of climate change and take advantage of new opportunities through adaptation.
- Many Arctic coastal communities are experiencing vulnerabilities to decreased or less reliable sea ice, greater wave energy, rising sea levels, changes in winds and storm patterns, storm-surge flooding or coastal erosion, with impacts on travel (on ice or water), subsistence hunting, cultural resources (e.g. archaeological remains, burial sites) and housing and infrastructure in communities.
- In some places, this has necessitated community relocation, which in some cases increased vulnerability.
- In places, coastal erosion is threatening critical infrastructure or contaminated sites, with potential for spreading of pollutants.
- There has been great progress in recent years in the understanding of exposures and identification of elements of adaptive capacity that may enhance resilience, but other challenges including social, technical, financial, and institutional barriers may be inhibiting successful adaptation.
- There is a wide range of adaptive capacity among coastal communities of the circumpolar Arctic. A community with a greater resource base, including physical resources, financial capacity, knowledge (of all kinds), and social cohesion, is in

a better position to successfully adapt than one that lacks resources and options.

- Arctic indigenous peoples are traditionally resilient. This has allowed them to adapt to a harsh climate and changing environmental conditions over multi-century time-scales.
- With a faster pace of change and numerous compounding challenges, the indigenous peoples of the Arctic are generally less resilient today, although developments in regional governance and cultural initiatives, as well as growing familiarity with climate change, may be improving the situation to some extent.
- Quantitative scientific research concerning past, present, and future environmental changes and impacts is a key component informing policy and decision-making.
- Adaptation strategies perceived as imposed from outside will not be incorporated into the community's reservoir of mechanisms for coping with change, will not form a component of its adaptive capacity, and will thus not contribute to its resilience and ultimate sustainability.

Governance and Adaptation

- National agencies are the main actors in regional governance. In some areas such as northern Canada, regional (or in this case, territorial) agencies may play an equally important part. At national and international scales, almost all international land boundaries are settled, meaning that national jurisdiction at the coast is generally clear.
- There are enormous differences across the circumpolar Arctic in population size and distribution, economy, culture, institutional framework, and other factors.
- There are few Arctic-specific international regimes: the 1973 Polar Bear Treaty is the only legally binding regime.
- The Arctic Council, based on soft law (1996 Declaration), works primarily through assessment programs and projects to develop consensual knowledge and understanding on the status of the Arctic environment and related issues among the eight Arctic countries.
- Integrated coastal area management and integrated ecosystem-based oceans management are desirable strategies for coastal area governance and may embody a number of best practices which have emerged from recent reviews.
- Conclusions from consideration of integrated ecosystem-based management include the following:
  - Management needs to be flexible;
  - Decision-making must be integrated and science-based;
  - National commitment is required for effective management;
  - Area-based approaches and trans-boundary perspectives are necessary;
  - Stakeholder and Arctic resident participation is a key element;
- Adaptive management is critical.
- It has been recommended that future research should focus on increasing support, opportunity, and capacity for local decision-making or effective resident input to decisions on broader institutional policies with local impacts.

POLICY RECOMMENDATIONS

Oil Spill Prevention and Response in the U.S. Arctic Ocean

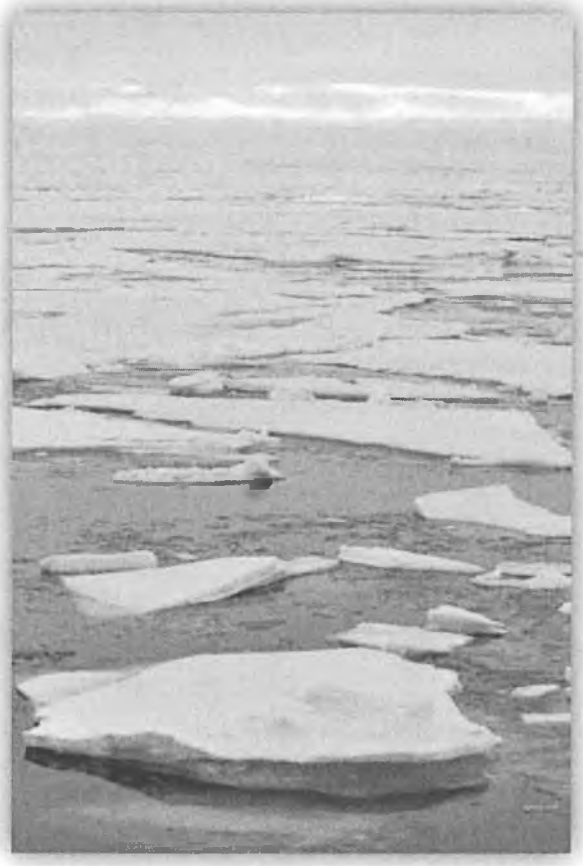
THE PEW ENVIRONMENT GROUP

OIL SPILL PREVENTION AND RESPONSE IN THE U.S. ARCTIC OCEAN:

Unexamined Risks, Unacceptable Consequences

Policy Recommendations by the Pew Environment Group[1]

The BP Deepwater Horizon oil spill in the Gulf of Mexico graphically illustrated the risks of offshore oil and gas drilling and the need for better prevention and response systems. The largest blowout and spill in U.S. history, which began with an explosion and fire April 20, 2010, released at least 50,000 barrels a day for three months for a total of at least 205 million gallons (4.9 million barrels). This disaster clearly exceeded the limits of existing technologies for stopping a well blowout, as well as the strategies to contain and clean up marine oil spills. The Gulf of Mexico—with its temperate waters, proximity to large population centers and ready access to necessary infrastructure and response resources—has some of the best conditions in the United States for offshore oil spill response. Yet even with these advantages, the spill response proved to be woefully inadequate. This was in large part due to lax oversight and inadequate environmental analysis, spill containment, response preparedness and assessment of risks.



Offshore oil and gas drilling plans are being considered for perhaps the most remote and extreme part of the U.S. outer continental shelf (OCS): the Arctic Ocean. The northernmost portion of the OCS, the Arctic Ocean is characterized by a demanding and challenging physical environment. Sea ice is present most of the year, and the sun does not rise for two months in winter. Extended periods of heavy fog, freezing temperatures and weeklong storms approaching hurricane strength are not uncommon. These harsh and icy conditions have, until now, been a barrier to industrial activity.

Figure 1. Arctic Sea Ice *(Photo: Patrick Kelley/USCG)*— Arctic Sea Ice is characterized by the presence of sea ice for much of the year and is important in structuring Arctic marine ecosystems.

1 This document provides policy recommendations and a summary of the findings of the accompanying technical report. Factual statements herein are taken from the technical report, which provides further details as well as full citations for all sources of information. Although the recommendations included herein are directed toward offshore oil and gas drilling in the Arctic Ocean, some of the recommendations address issues that arise throughout the U.S. outer continental shelf. For the accompanying technical report, *Oil Spill Prevention and Response in the U.S. Arctic Ocean: Unexamined Risks, Unacceptable Consequences,* scientific peer review was conducted by three experts in oil spill response, oceanography and Arctic marine ecology. This review informed the development of these policy recommendations.

The Arctic Ocean's coastal villages are remote, with no connecting roads. No airports or ports along the coast are capable of supporting the influx of equipment and personnel that would be required to respond to a catastrophic oil spill.

Although it is defined by its extreme conditions and remote location, the Arctic Ocean is ecologically important, with phytoplankton, ice algae and copepods underpinning the region's marine food web. It supports a variety of iconic marine mammals such as bowhead whales, walrus, polar bears and ice seals, which are well adapted to the area's conditions and are found nowhere else in the United States. Millions of birds and various species of whales migrate great distances to the Arctic each year. More than 100 species of fish—including Arctic cod, capelin, herring and saffron cod—are found there. Indigenous communities along the coastline depend upon a healthy Arctic marine ecosystem to support the many species at the heart of their subsistence way of life.

Figure 2. *(Photo: Stephanie Sell)*—Ringed seals live in Arctic waters and are generally found with drifting sea ice. Scientists are concerned about how the loss of sea ice will impact them.

Although we know that the Arctic Ocean's ecosystems are unique, we have incomplete scientific information on many of its species and little understanding of how its ecosystems function. Compounding that lack of information is the unprecedented change that the Arctic Ocean's climate is undergoing. The loss of sea ice during summer is fundamentally altering the way Arctic ecosystems function in ways that are unknown and unpredictable. Climate change is warming the Arctic at twice the rate of the rest of the planet, decreasing ice coverage and opening up the possibility for offshore drilling at the same time that marine fish and wildlife are undergoing a great deal of stress from these rapid changes.

Figure 3. *(Photo: Henry Huntington)*—The North Slope in February. Its extreme environment could make oil spill response much more challenging.

The extreme physical environment and remote location and the unpredictable effects of climate change mean that the risks, difficulties and unknowns of oil exploration and development are far greater in the Arctic than in any other U.S. ocean area.

Industry and government plans for oil and gas exploration and development in the Arctic Ocean have been rushed, relying on a cursory environmental analysis of the potential impacts of a catastrophic oil spill. They also rely on inadequate and unproven oil spill response plans and techniques. These plans have been pushed forward despite the lack of information on Arctic marine ecosystems and the effects of climate change and a lack of understanding of the impacts that oil and gas drilling would have on the Arctic Ocean's unique species. Government officials have not fully analyzed the risks of a catastrophic oil spill in the Arctic or the existing capacity to respond to such a spill, nor have they enacted requirements focused solely on spill prevention and response in the Arctic.

To shed light on these unique challenges, the Pew Environment Group commissioned a technical report, prepared by the Nuka Research and Planning Group and Pearson Consulting, to examine the risks and potential consequences of an oil spill in the Arctic Ocean. "Oil Spill Prevention and Response in the U.S. Arctic Ocean: Unexamined Risks, Unacceptable Consequences" identifies the need for additional research on Arctic marine ecosystems and oil spill response techniques, risk assessments and prevention measures that reflect Arctic conditions. Based on the report's technical analysis, the Pew Environment Group recommends reform of the federal government's approval and oversight of Arctic Ocean oil and gas activities in four areas:

1 ***Federal resource management agencies must complete a comprehensive science plan, including research and data collection on the Arctic marine environment, before oil and gas exploration and development proceed.***

2 ***Oil spill risk assessments and spill prevention technologies must reflect Arctic conditions.***

3 ***Spill response must be tailored to Arctic conditions, and response planning standards must be strengthened.***

4 ***Review and oversight of oil and gas drilling must be enhanced.***

Implementing recommendations across these four areas would provide the government with a basis for determining whether, when, where and how to responsibly conduct oil and gas activities in the Arctic Ocean. These reforms would go a long way toward ensuring that oil and gas activities have the least possible impact on the Arctic marine environment and the region's subsistence-based indigenous communities.

Significant time and resources will be necessary to effectively address the issues identified in these recommendations and the technical report. But with so much at stake in one of the world's most

iconic and fragile ocean environments, it is responsible to adopt a precautionary approach to oil and gas drilling.

We must heed the lessons of the Deepwater Horizon blowout and proceed with careful, inclusive planning and decisions based on sound science. At present, offshore oil and gas drilling in the Arctic Ocean cannot be undertaken with any level of assurance that the marine environment can be protected from a spill or that industry can respond effectively. All proposed oil and gas activity should be suspended until the issues identified in the recommendations below are addressed through regulations or legislation.

RECOMMENDATIONS

1 Federal resource management agencies must complete a comprehensive science plan, including research and data collection on the Arctic marine environment, before oil and gas exploration and development proceed.

The Arctic Ocean is among the least understood places on Earth. We have limited information on some Arctic marine species, but much is not known or understood about the larger ecosystem. For example, we know very little about how the Arctic marine food webs work, and we have an incomplete understanding of most of the species that inhabit the Arctic Ocean. Complicating this lack of basic information about species and ecosystems is the rapid and profound environmental transformation that is occurring in the Arctic as a result of climate change. The loss of sea ice during the summer is fundamentally altering the way the Arctic marine ecosystems function. Without a thorough understanding of Arctic marine species and ecosystems, and of the shifts that are occurring because of climate change, it is impossible to accurately assess the impacts of offshore oil and gas drilling or to develop a viable plan to respond effectively to a major oil spill.

To prevent and prepare for oil spills in the Arctic Ocean, decision makers need complete information on the physical environment and the unique challenges it poses to offshore oil and gas drilling. They also need to understand the effect of drilling and oil spills on marine ecosystems. A prediction of the impacts of spilled oil in Arctic waters must take into account the behavior of oil in an environment with sea ice, the varying characteristics of sea ice throughout the year, Arctic weather conditions, the long-term fate of oil in cold water and the specific vulnerabilities of Arctic marine species and ecosystems. A comprehensive science plan and ecosystem assessment are needed for the U.S. Arctic to improve our knowledge of the environmental conditions and marine ecosystem structure and function to help decision makers avoid irrevocable impacts on the Arctic environment and its people's subsistence way of life.

An independent science gap analysis should be completed for the Arctic Ocean. Before leaders can make informed decisions about oil and gas activities, an analysis must be completed to assess current scientific information, identify gaps in our understanding of Arctic marine ecosystems and define the research that will be necessary to fill those gaps. That assessment should, at a minimum, identify the specific research needs related to species, weather and ice conditions, and the behavior of oil in Arctic waters.

Figure 4. *(Photo: Brad Benter/USFWS)*—Walrus move seasonally, with the sea ice. The population size of many marine mammals remains unknown, and changing conditions make it even more difficult for researchers. Scientists are still working toward getting an estimate for walrus in the U.S. Arctic.

The U.S. Geological Survey (USGS), at the direction of Interior Secretary Ken Salazar, is conducting an evaluation of science gaps related to OCS oil and gas development in the Beaufort and Chukchi seas. The USGS report is a good first step toward assessing the scientific gaps in knowledge, but it should undergo review by the public and by an independent science panel or organization, such as the National Research Council, to ensure that the gap analysis is thorough and scientifically defensible.

Ecologically sensitive areas must be identified and protected. Areas within an ecosystem are not equal in biological and ecological terms; some areas are more important than others to the ecosystem or human populations. Identification of important ecological areas (IEAs), based on essential habitats and functions in the Arctic ecosystem, along with traditional cultural activities, can be an important step toward protecting traditional-use areas and critical habitats and ensuring ecosystem functionality. A comprehensive science plan for the Arctic Ocean should include identification of IEAs, which should be mapped and incorporated into decisions about where and when offshore drilling can occur. The most ecologically sensitive areas in the Arctic Ocean should be removed from the leasing process.

In addition, Arctic coastal areas require more detailed environmental sensitivity index (ESI) mapping. ESI maps are a critical component of oil spill contingency planning and response in that they identify the most biologically productive areas of coastal shoreline that are used by marine species and/or people where resources should be directed first. Existing ESI maps for the Arctic are outdated and at a scale that is too coarse. To be an effective planning tool, the maps must be updated to include more detailed information.

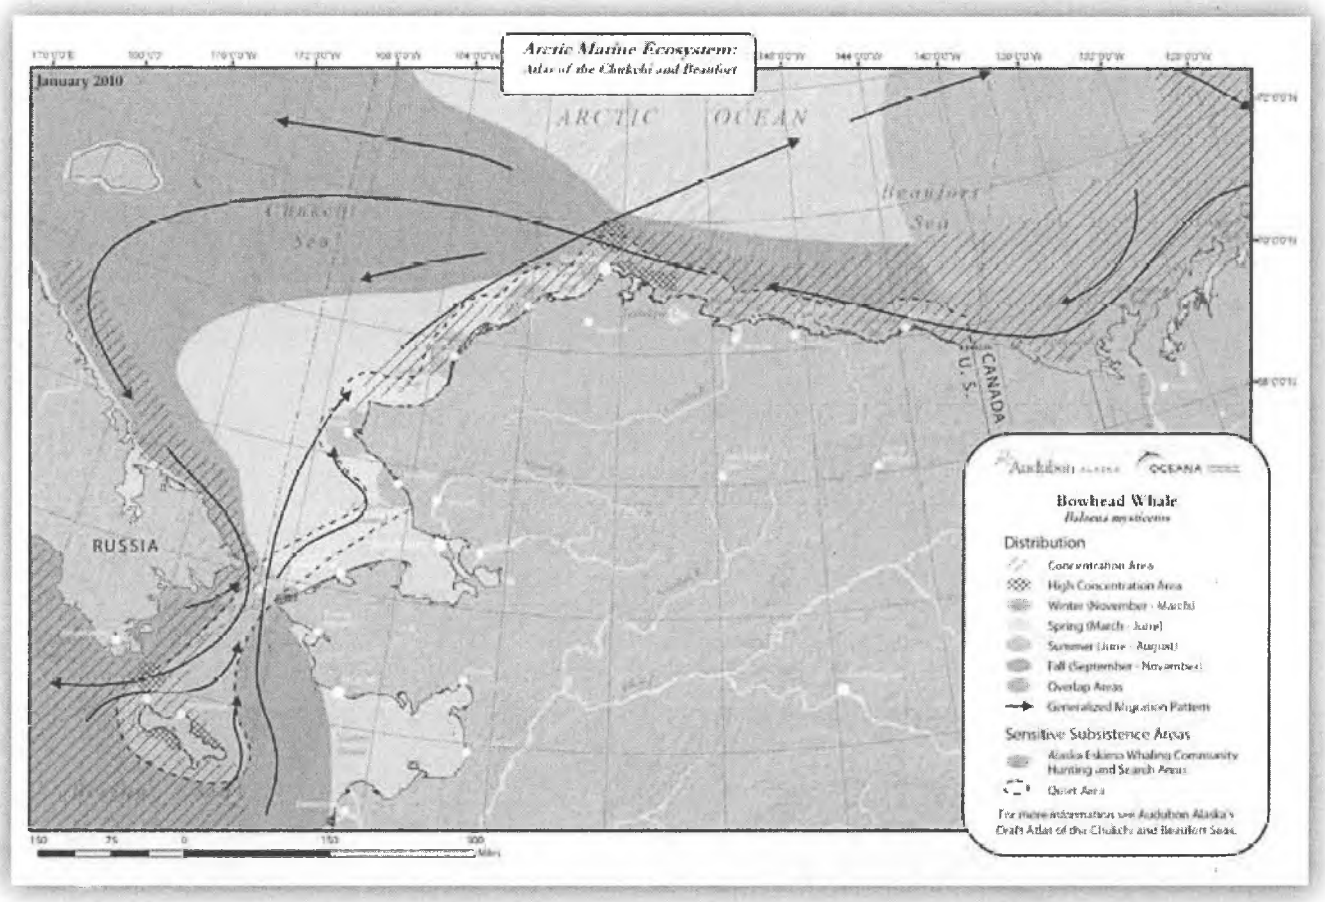


Figure 5. Bowhead Whale Migration Route *(Image: Audubon Alaska in coordination with Oceana)*—The bowhead whale is the only baleen whale that does not migrate to temperate waters and lives year-round near the sea ice.

Decision makers should incorporate traditional knowledge into Arctic research.
Communities along Alaska's Arctic coastline have followed a subsistence-based lifestyle in a physically challenging and ecologically rich region for millennia. To survive, residents have had to hone and share detailed knowledge about the region's species and conditions. This traditional knowledge should accompany research to aid the Western scientific understanding of the Arctic marine environment. Scientists' use of traditional knowledge has been rising, but a great deal more can and should be done to take advantage of and incorporate this information in research activities and management decisions. For example, a local observation and monitoring network could draw on the presence and expertise of the many hunters using the Arctic coastline who are likely to be the first to see new species, changes in existing species and other forms of ecosystem change. In the documentation of existing knowledge and the gathering of new information, those who have that knowledge should be involved throughout the research and management continuum to help analyze, interpret and apply that knowledge appropriately, in conjunction

with Western scientific findings and other relevant information. Key entities and agencies with experience in this area include the North Slope Borough Department of Wildlife Management, the Northwest Arctic Borough Planning Department, and the co-management marine mammal commissions.

Increase research funding and coordination. In addition to the need for a plan to identify ecosystem information gaps, there is also a need for a comprehensive approach to funding and oversight of science and research in the Arctic Ocean. Dedicated funding from the Oil Spill Liability Trust Fund could provide the resources needed to complete necessary research and also provide continuing funding for monitoring of species and the effects of climate change. Agencies must work together to share expertise and resources. They should also recognize and incorporate the wealth of knowledge from partners such as the North Slope Borough Department of Wildlife Management, the Alaska Ocean Observing System, the co-management marine mammal commissions and the University of Alaska, among others.

2 Oil spill risk assessments and spill prevention technologies must reflect Arctic conditions.

Risk is a product of probability and consequence. Understanding the oil spill risks associated with oil and gas drilling requires the ability to predict the probability of an oil spill and then anticipate its potential adverse consequences. Spill scenarios may range from a catastrophic well blowout to smaller spills from a pipeline, tank or vessel. Very large oil spills and well blowouts are low-probability events, but the consequences can be disastrous. Most of the planning in the Arctic Ocean has assumed that the probability of an oil spill is extremely low, based on data from other regions of United States. To reduce the potentially catastrophic impacts of oil spills from oil and gas drilling in the Arctic Ocean, a comprehensive risk assessment is needed that provides a complete picture of the types of spills that may occur and their potential impact on the Arctic environment. Specific measures must then be adopted to reduce the probability and impact of a spill. Useful risk assessments will require understanding of how and where spills might occur and how the timing, size and location of spills could affect the Arctic ecosystem in the short and long term.

An Arctic Ocean-specific risk assessment must be prepared. Because oil exploration and production in the Arctic Ocean have been limited, estimates of possible well blowouts in the Arctic have been based on data from temperate spills in the Gulf of Mexico (before the Deepwater Horizon spill). These estimates, however, have failed to adequately assess the extent to which the Arctic environment could change the equation. Arctic conditions, such as dynamic ice cover, freezing temperatures, reduced visibility (from fog or darkness), high winds and sea states, and extreme storms add to the probability of an accident or error that might cause a spill. These factors must be incorporated into estimates of future oil spill probability. Likewise, the potential consequences of an oil spill to the Arctic ecosystem can be estimated only after better baseline

science is developed. The area's sensitivity to oil spills, based on geography, season, ice conditions, and life stages of key organisms, must be better understood. To estimate how various spill scenarios might affect the Arctic ecosystem, trajectory models must have the capability to predict how oil spilled in ice-infested Arctic waters will behave. At this point, if a major oil spill were to occur in the Arctic Ocean, there would be no way to reliably estimate where the oil would travel or what the short- and long-term impacts would be.

Figure 6. *(Photo: NOAA/ESRL)*—A storm brews in the Arctic, top. *(Photo: Patrick Kelley/USCG)*—Low-lying clouds.

A sound risk assessment will require a realistic estimate of the frequency of oil spills in the offshore Arctic and a complete understanding of ecological vulnerabilities and environmental sensitivities. It must also include realistic assessments of the potential impacts from catastrophic blowout scenarios in a range of seasons and conditions.

There are several established methodologies for conducting oil spill risk assessments. One instructive example is a project on shipping being conducted by the state of Alaska and the U.S. Coast Guard in the Aleutian Islands using a methodology suggested by the National Academy of Sciences. A similar process should be conducted in the Arctic Ocean for oil and gas operations.

Spill prevention technologies must address Arctic-specific risks. After an analysis of how Arctic conditions affect the likelihood of oil spills and the impact of these spills on the environment, appropriate spill prevention measures should be identified. Measures should include restricting drilling in certain locations or imposing seasonal drilling restrictions. Prevention technologies should include redundant engineering controls such as multiple blowout prevention systems, on-site blowout containment structures and double-walled pipes or tanks. Finally, vessels and other equipment operating in the Arctic must meet appropriate engineering standards, carry additional equipment and adhere to precautionary procedures to reduce the probability of spills. To the extent that engineering standards and equipment designed for Arctic conditions do not exist, they must be developed before drilling is approved.

3 Spill response must be tailored to Arctic conditions, and response planning standards must be strengthened.

Even under ideal conditions in populated regions with temperate climates, cleaning up an oil spill in open water is challenging. It requires simultaneous efforts to stop the spill, contain the oil and remove as much of it as quickly as possible from the water. The Deepwater Horizon cleanup enlisted thousands of people, more than 3 million feet of containment boom, millions of gallons of dispersants and more than 6,500 vessels. An oil spill in Arctic waters would be considerably more challenging. Standard oil containment and recovery techniques may be constrained or ineffective because of ice or weather conditions. In addition, oil lasts longer in Arctic waters because it evaporates more slowly or may be trapped in or under ice. Moreover, the infrastructure to support an effective containment and removal response effort is limited. Consequently, an oil spill in the U.S. Arctic Ocean could be devastating to the environment and to the people who depend on it for their subsistence.

Oil spill response systems and technologies are unproved in the Arctic Ocean. Of the three response options available, all face limitations in Arctic conditions and may harm marine species. There are very narrow conditions in which mechanical recovery, in-situ burning and dispersants can be used in Arctic waters.

Mechanical recovery, the industry's primary response system, employs skimmers, booms, boats and personnel to collect and remove oil from the surface. The equipment is most effective in open water; in broken ice conditions, with ice concentration as low as 10 percent, the efficiency of mechanical recovery falls significantly. This method depends heavily on the ability of personnel to position boats, booms and skimmers and is susceptible to shutdown if any of these factors is affected by poor visibility, dense fog, high sea states and/or freezing temperatures.

In-situ burning is the industry's secondary response technique. Small-scale trials have shown that it may work in a variety of ice conditions; however, burning oil in sea ice requires that the slick be thick enough to ignite, and burning is not safe or feasible in high winds. In addition, in-situ burning creates toxic smoke and leaves behind oily residue that is difficult to recover and can harm marine species. Moreover, in higher ice concentrations, thick slicks are likely to occur in the open leads or polynyas between solid ice. These interfaces between ice and water are ecologically vital; the impact of an oil spill would be widespread on a range of species, from phytoplankton at the base of the food chain that live on the underside of the ice, to marine mammals that surface and breathe at these openings.

Chemical dispersants are still relatively untested in the Arctic Ocean, and many questions remain about their use in ice-infested waters. Dispersants become less effective in conditions such as those in the Arctic: reduced water temperatures, presence of sea ice and bad weather. Very little is known about the toxic effects of dispersants on marine organisms and communities. Furthermore,

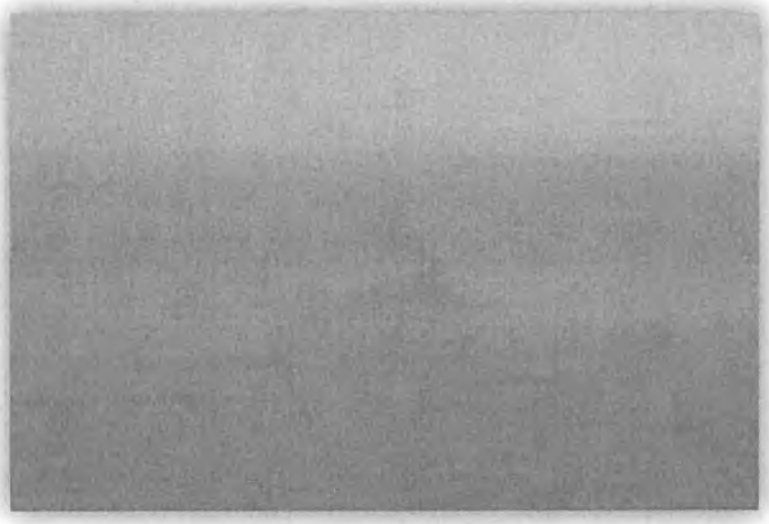
no studies have examined the effect of subsea dispersant application; the Deepwater Horizon spill was the first use of this tactic. In addition, dispersant application is limited by environmental conditions and weather, and aerial applications require low wind and good visibility. For these reasons, dispersants have not been preapproved for use in the Arctic Ocean.

Figure 7. *(Photo: SINTEF)*—SINTEF JIP controlled study with pre-positioned booms and response.

Current industry spill response plans are based on small-scale laboratory and field trials that have been extrapolated without large-scale verification. The Joint Industry Program (JIP) recently completed testing on oil spill response in broken ice conditions, but these tests, conducted in the Norwegian Barents Sea, did not include the logistical and operational constraints associated with day-to-day operations in the U.S. Arctic Ocean. A given technology may work well under controlled conditions in which preplanned tests eliminate real-world variables such as detection and containment of oil and mobilization of required equipment and personnel within the window of opportunity for effective treatment. These controlled trials provide critical information, but they do not demonstrate effectiveness or feasibility.

Response plans must include relief wells and other containment options. During an oil spill, stopping the flow of oil as quickly as possible is critical to minimizing environmental damage. For offshore drilling operations, the two methods for controlling a blowout are drilling a relief well and installing a containment structure. These options must be tested and ready for immediate deployment to avoid a blowout as long as the Deepwater Horizon incident, and they must be proved effective in Arctic conditions.

Spill response plans should require that industry is able to quickly deploy an alternative drill rig to immediately begin drilling a relief well, which must be completed before the end of drilling season, when sea ice forms. Canada has adopted such a policy, called same-season relief well capability. The policy requires companies to have the resources and personnel available in advance and to demonstrate that a relief well can be drilled within a specific time frame. In the Arctic, this might mean that exploration or production drilling should not occur late in the season if a relief well cannot be completed before ice precludes drilling activity.



Spill response plans should also include a requirement that companies have a prefabricated containment structure, demonstrated to work at the well location, before beginning exploration or production drilling. The structure and necessary resources or personnel would have to be available for immediate deployment.

Figure 8. *(Photo: Collection of Pablo Clemente-Colon, chief scientist, National Ice Center)*—Icebreaker navigates through heavy fog.

A response gap analysis must be prepared by responding agencies. In light of the questions regarding the effectiveness of oil spill response methods in Arctic conditions, a response gap analysis must be conducted. The purpose of this gap analysis (distinct from the research gap analysis) is to quantify the limit at which environmental conditions (temperature, wind, sea state, ice, visibility) preclude response and to calculate the frequency with which those conditions typically occur in the Arctic Ocean. This information will define the effectiveness of each spill response method in Arctic waters.

The analysis must be conducted by the agencies with responsibility for response: the U.S. Coast Guard (USCG), the Environmental Protection Agency (EPA) and the National Oceanic and Atmospheric Administration (NOAA). Such an analysis will help to define additional preventive measures, including seasonal drilling limits, which must be in place during times when an oil spill could not be contained or cleaned up.

Infrastructure gaps must be assessed and addressed. Because of its remote location and harsh environment, the Arctic Ocean's Alaskan coast has widely scattered communities and few year-round residents. Transportation, communication, equipment storage and deployment infrastructure are nonexistent or extremely limited. If a catastrophic oil spill were to occur, days or weeks could pass before response personnel and assets could be mobilized and deployed. The nearest USCG station is nearly 950 air miles away, and the closest major port is Dutch Harbor, 1,300 miles away.

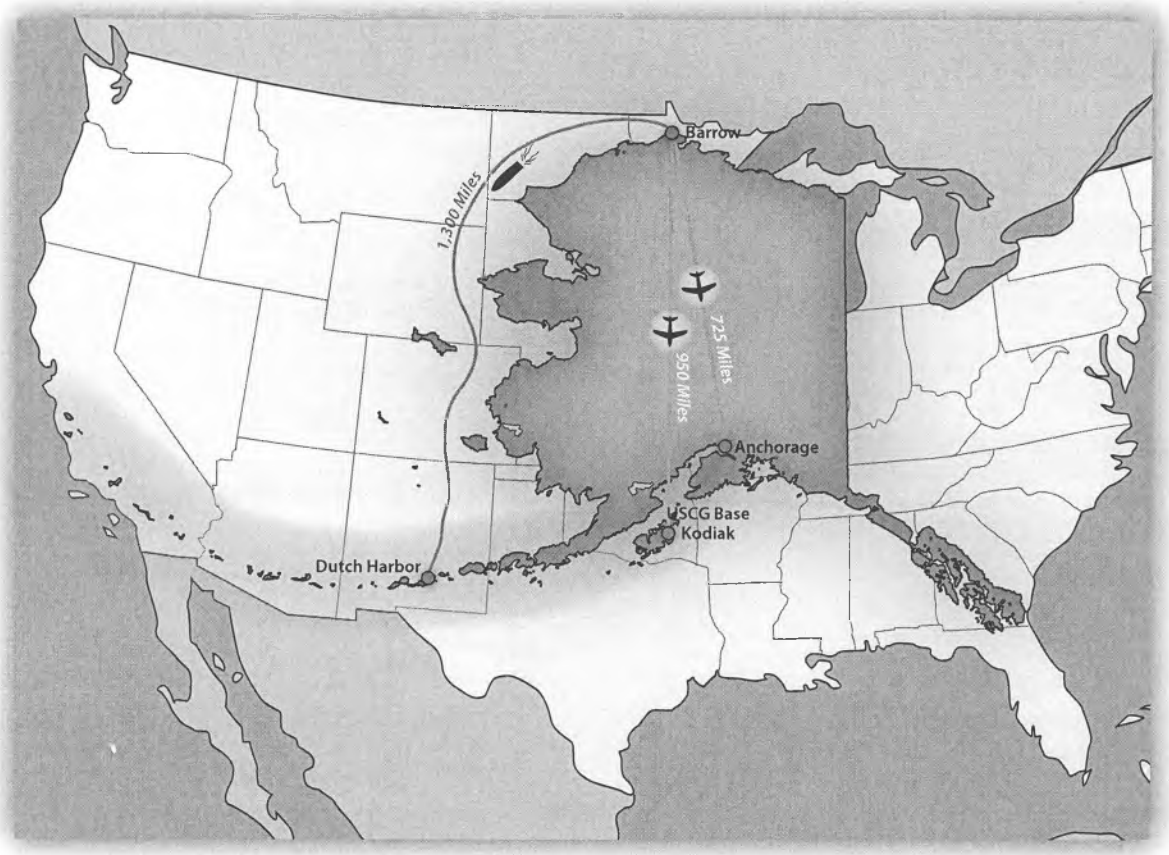


Figure 9. *(Image: Nuka Research and Planning)*—**Distance from Barrow, Alaska (in U.S. Arctic Ocean), to nearest major port (Dutch Harbor) and nearest Coast Guard air station (Kodiak)**

Limited air access makes quick transportation of response equipment impossible, and storage and housing to mount an adequate response effort do not exist, especially in the Chukchi Sea, where lease sites are up to 150 miles from shore. The lack of infrastructure for a major oil spill response is a limiting factor in the Arctic that has not been addressed effectively. A comprehensive assessment of infrastructure needs must be conducted by the Department of the Interior (DOI) in coordination with the USCG, NOAA, and state and borough governments. Strategies to address these infrastructure gaps must be put in place before oil and gas development in the Arctic Ocean can proceed. The USCG's pending high-altitude study should inform this effort.

Spill trajectory models based on Arctic conditions must be developed. Because accurate models of movement of oil in sea ice do not exist, it is impossible to accurately project oil spill trajectories for the U.S. Arctic Ocean. This information is critical to the development of an effective oil spill contingency plan.

Worst-case scenarios must be based on actual conditions. Oil spill contingency plans are based on worst-case discharge scenarios. To be effective planning tools, such scenarios should be based on actual well flow data. Currently, worst-case projections in the Arctic are based on unsupportable well flow assumptions that minimize the potential effects of an oil spill and skew decisions about whether and how to approve exploration or development activity. Moreover, using an inaccurate flow rate will lead to a response plan that may be insufficient to address an actual worst-case spill.

In areas such as the Chukchi Sea, where actual flow rates are unknown, spill plans assume a flow rate of 5,500 barrels of oil a day. This assumption, an average developed by the state of Alaska, is not based on well pressure information from wells in the surrounding region or on known geophysical data. A worst-case scenario based on this assumed flow rate can seriously underestimate the size of a spill and its impact. Rather than relying on an unsupported flow rate, the federal government should require that estimated flow rates be based on available information. Drillers must collect sufficient geophysical and offset well data to estimate subsurface well pressures before drilling can safely begin. Flow rates can be estimated using this and any other available data, and DOI must maintain the technical engineering expertise necessary to verify the accuracy of these rates. More accurate estimates of well flow rates will ensure that worst-case scenarios do, in fact, estimate a worst-case spill. Accurately predicting a worst-case spill is critical to determining whether and under what conditions drilling can occur, and to ensuring that adequate response capability is in place.

Worst-case discharge volume estimates should also factor in the time required to stop the blowout. The flow rate (in barrels per day) must be multiplied by the number of days required to stop a discharge. The Deepwater Horizon blowout continued for three months, and other blowouts have lasted longer. Yet most Arctic Ocean oil spill contingency plans consider a duration of only 30 days or less, severely underestimating the total volume of oil that could be spilled and the corresponding spill response resource needs and environmental impacts.

Response planning standards must be strengthened. Oil spill contingency plans must meet a number of statutory and regulatory planning standards for how a response would be conducted, but there is no performance standard requirement. Regulations do not require industry to demonstrate that its response plan will work in real-world Arctic conditions, that response equipment can be deployed immediately and that chosen equipment can in fact remove oil from the environment and meet an acceptable performance target. Instead, current plans are paper exercises with no process to verify that they will work. A response planning standard should be adopted requiring industry to define the amount of oil that could be released during a catastrophic oil spill. Additionally, industry must be required to demonstrate in detail that adequate equipment, personnel and resources—and contracts to immediately deploy them—are in place and ready to respond to a catastrophic spill.

Spill recovery and cleanup assumptions must be questioned, verified and amended as necessary before DOI approves a response plan. The approved spill response plan for Shell Oil's Arctic exploration drilling assumes 90 percent open-water recovery of oil under a worst-case spill scenario, despite the well-accepted fact that recovery under the most optimal conditions averages about 20 percent.

Response standards must clarify that removal of oil is the priority of spill response. The Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) defines the term "remove" to include actions to minimize or mitigate damage to public health or the environment. Mitigation, however, is a separate response method and should not be considered to be a means of removal. Merging mitigation into a definition of removal can lead to dependence on cheaper mitigation methods rather than employment and refinement of removal techniques.

Independent third-party review of contingency plans is perhaps the best way to ensure that effective planning standards are met. In addition, contingency plan requirements should be audited regularly for ongoing compliance during the period of exploration and/or production.

4 Review and oversight of oil development activities must be enhanced.

Historically, little offshore oil and gas activity has occurred in the U.S. Arctic Ocean. The Bush administration greatly expanded the area available for leasing, however, increasing it from 9 million to 69 million acres. This rapid expansion of activity occurred without a clear understanding of Arctic conditions and ecosystems, the region's subsistence-dependent communities and the effect of rapid climate change on the region.

Lax oversight of the oil and gas industry, a factor in the Deepwater Horizon catastrophe, has been repeatedly acknowledged in government reports issued before and after the Gulf spill. Included are reports from DOI (May 25 and Sept. 1, 2010) and its inspector general's office (Sept. 10, 2008); the House Committee on Oversight and Government Reform (Oct. 7, 2009); and the Government Accountability Office (April 8, 2010). Strong oversight of offshore oil and gas drilling is a critical measure for preventing oil spills and ensuring that the impact of any spill is minimized.

Review and oversight of oil development activities must be objective. Review of oil exploration and development plans and permits must be free of undue influence from industry. Federal employees must assess risks objectively and challenge unrealistic assumptions from industry to ensure protection of public resources. Considerable attention has focused on the decision-making culture within DOI and the extent of influence that industry has exerted over the agency charged with regulating its activities and protecting public resources. The culture and approach of the former Minerals Management Service (MMS)—now BOEMRE—must change.

Figure 10. Existing Production

Structural and regulatory changes DOI has undertaken to reform management and enhance oversight of industry are a step in the right direction. However, additional standards must be adopted, and the organizational changes and ethics reforms included in legislation proposed by Congress should be passed.

Review and oversight of oil development activities must involve all relevant agencies. BOEMRE cannot continue operating in a "silo," as MMS did for many years. In particular, NOAA, which has resource protection responsibilities for Arctic marine species under the Marine Mammal Protection Act, the Endangered Species Act and the Magnuson-Stevens Fishery Conservation and Management Act, should have a greater role in making initial decisions about whether, when, where and how oil and gas development activities can occur.

NOAA should have a substantive role in the preparation of five-year oil and gas leasing programs as well as oil spill response plans. Specifically, NOAA should conduct a comprehensive analysis on

the functioning of the Arctic ecosystem and species that could be affected by oil development. NOAA should also engage more fully in permitting and environmental analysis decisions under the National Environmental Policy Act.

The USCG, the on-scene coordinator and lead agency for response, should play a meaningful part in identifying how oil and gas drilling in the Arctic Ocean proceeds. The USCG should have joint authority (with BOEMRE) to review oil spill response plans. Currently, the USCG is responsible for reviewing oil spill response plans for vessels but has not been actively engaged in the review of plans for offshore facilities. It is illogical to treat vessels and facilities differently and to make the USCG responsible for spill response but not formally involved in response planning or spill prevention for facilities. The U.S. Fish and Wildlife Service (USFWS), the USGS and the EPA should also be involved in decisions affecting resources within their jurisdictions.

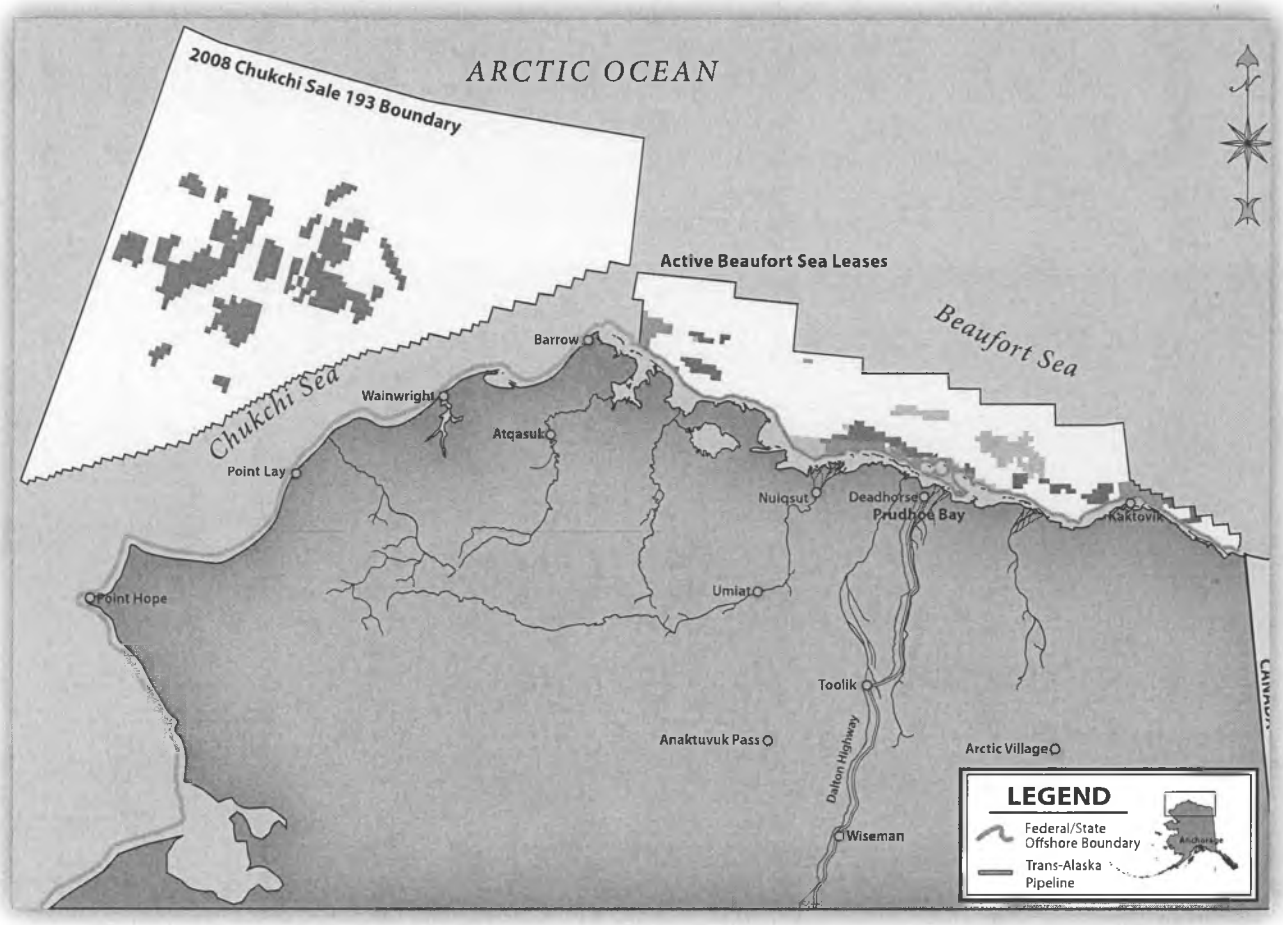

Figure 11. Map of Active Lease Areas in Arctic OCS (Chukchi and Beaufort Seas)

Figure 12. *(Photo: USGS)*—U.S. Coast Guard cutter Healy in the Arctic.

Oversight must include enhanced inspections and testing. The Deepwater Horizon spill highlighted the fact that industry inspections and emergency drills are not occurring at a level necessary to reduce the risk of spills. Inspections of facilities—including unannounced visits—should be conducted frequently to test the functioning of equipment and safety systems. In addition, regular and frequent test runs on emergency procedures and spill response should be required before drilling permits are issued, and operations should be halted if violations are found.

Equally important, BOEMRE must change the current management of inspection programs to ensure that inspectors have sufficient training and resources to undertake thorough and objective inspections and that their expertise is not undermined. The OCS Safety Oversight Board's Sept. 1, 2010, report documents a number of structural and management deficiencies in the existing inspection system, including a lack of bureauwide guidance on practices and inspector roles and responsibilities. Specifically, there is no standard bureauwide guidance for inspectors on applicable rules, regulations and policies as well as standard practices, roles and responsibilities. In addition, inspectors are not receiving the certification and training necessary to perform their jobs effectively and do not have sufficient resources, such as laptop computers. Equally disturbing, management routinely pressures inspectors to minimize reporting violations or undermines inspectors by rescinding citations. BOEMRE management's culture of supporting industry must change, and the inspection programs must be restructured and enhanced to ensure that inspectors have the training, resources and independence to perform their jobs.

Citizen input must be incorporated into oversight through regional citizens' advisory councils. Establishment of regional citizens' advisory councils (RCACs) could help prevent future oil spills. These councils should follow the model of the Prince William Sound RCAC, established by the Oil Pollution Act of 1990 after the Exxon Valdez oil spill. In Prince William Sound, citizen participation in the oversight of industry activities has prevented complacency and ensured vigilant review. The RCAC also performs an important independent oversight function by reviewing oil spill contingency plans. This has proved to be one of the most important methods for preventing oil spills in Prince William Sound and ensuring that tested, well-maintained response capability is in place.

Similar RCACs in the Arctic could provide advice and recommendations to DOI and the industry on development activity as well as associated pipelines and tankers in the region. They would also provide advice to DOI regarding the five-year leasing schedule, lease sales, exploration and production in the region, and oil spill contingency plans.

Adequate funding for oversight activities can be provided through statutorily established funding. Agencies with expertise on Arctic marine species and the environment and with responsibility for some aspect of spill response—including the USCG, NOAA, USFWS, USGS and EPA—should receive sufficient funding to undertake necessary monitoring and enforcement activities. Funding should be made available from the Oil Spill Liability Trust Fund for drills, inspections and contingency plan reviews, as well as review of five-year programs, lease sales and individual permits for offshore drilling. Funding for the Oil Spill Liability Trust Fund should be made permanent.

CONCLUSION

The Arctic Ocean presents unique challenges to oil and gas drilling that should not be underestimated. Before exploration and production drilling proceeds in Arctic waters, DOI and other agencies with relevant expertise must reassess the conditions under which future drilling might occur. The key issues that must be addressed include: (1) the need for research and data collection to provide an understanding of Arctic species, ecosystems and environmental conditions, and the impacts of oil spills in that environment; (2) the need for candid risk assessments and imposition of risk prevention measures; (3) identification of the response gap (shortfalls in spill response systems) and spill prevention measures such as drilling restrictions that must be in place to mitigate that response gap; and (4) vigilant oversight by government agencies and citizens to reduce the possibility of oil spills.

ARCTIC OIL SPILL REPORT

Oil Spill Prevention and Response in the U.S. Arctic Ocean: Unexamined Risks, Unacceptable Consequences details major gaps in response planning and Arctic marine ecosystem science. Government and industry oil spill response plans fail to account for the region's remoteness and harsh conditions and fail to protect the fragile Arctic marine ecosystems and food webs that support walrus, polar bears and other marine mammals found nowhere else in the United States.

Policy Recommendations Overview > (#policy)

REPORT DETAILS

This report provides a comprehensive analysis of the difficulties of drilling for oil in the Arctic Ocean. It identifies several major challenges to responding to and cleaning up oil spills in the Arctic. These challenges include remoteness (almost no roads or docks, minimal response manpower), extreme conditions (shifting sea ice, fog, 20 foot seas, hurricane force winds) and the reality that standards are not in place to ensure that a catastrophic spill can be contained and controlled or that fragile Arctic shorelines will be protected.

- The Arctic Ocean is a vital ecosystem for unique species found nowhere else in the US: polar bears, ice seal species, walrus, bowhead whales, and myriad fish and bird species. This ecosystem and its iconic species already are under strain from climate change. Even a moderate-sized spill that occurs in an area where sensitive or threatened species are concentrated could have devastating effects.
- Approximately 8,000 people live in this area, and depend on marine mammals and fish for as much as 60 percent of their diet. A reduction in the availability or safety of subsistence foods could have a profound impact on both the economy and culture of Arctic communities.
- Shifting sea ice, high seas, brutal winds and sub-zero temperatures could shut down spill response any time of the year. Even if drilling were limited to open-water season, a blowout that occurred late in the fall could continue for eight or nine months if a relief drill could not be completed before the ice pack moved in.

Nuka Research (http://www.nukaresearch.com/) and Pearson Consulting (mailto:pearson.consulting@mac.com) are consulting firms with internationally recognized expertise in oil spill prevention and response. Together they have 65 years experience in our field. Their clients include federal and state agencies, oil spill response organizations, oil companies, and non-governmental organizations. Nuka Research has published over 40 papers on oil spill prevention and response.

Tim Robertson, general manager of Nuka Research, has spent his professional career in Alaska, including past work as a fishery biologist, drilling mud engineer on the North Slope and in Cook Inlet; director of operations for Seldovia, Alaska during the 1989 *Exxon Valdez* oil spill; and delegate to the negotiated rulemaking committee for the U.S. vessel response plan regulations promulgated under the Oil Pollution Act of 1990. He has participated in the Incident Management Team for many oil spills since the *Exxon Valdez*, and has organized and facilitated dozens of oil spill response exercises, emergency management drills and equipment deployment trainings.Robertson holds a Master of Science degree in Fisheries Biology from the University of Alaska, Southeast.

Elise DeCola is the operations manager of Nuka Research. Her professional career began as a policy fellow in the Rhode Island Senate, where she organized hearings and drafted legislation to strengthen Rhode Island's oil spill prevention and response program in the wake of the 1996 *North Cape* oil spill. She has since worked on oil spill policy research and contingency plan development and review in Alaska, New England and several Gulf Coast states. She regularly conducts field preparedness exercises for oil spill responders in the Northeast. DeCola holds an M.A. in Marine Affairs from the University of Rhode Island.

Leslie Pearson is President of Pearson Consulting, LLC, which specializes in emergency management, planning, preparedness, policy research and regulatory compliance. Prior to starting a business, she spent 19 years with the Alaska Department of Environmental Conservation, including six year as the Oil Spill Response Program manager. She began her tenure with the ADEC in 1989 during the Exxon-Valdez oil spill. Her regulatory career focused specifically on issues associated with oil pollution planning, preparedness, response, damage assessment and response technology. Pearson earned a Master's of Science in Environmental Science from Alaska Pacific University.

Nuka Research (http://www.nukaresearch.com/) and Pearson Consulting (mailto:pearson.consulting@mac.com), are consulting firms with internationally recognized expertise in oil spill prevention and response. Together they have 65 years experience in our field. Their clients include federal and state agencies, oil spill response organizations, oil companies, and non-governmental organizations. Nuka Research has published over 40 papers on oil spill prevention and response.

Tim Robertson, general manager of Nuka Research, has spent his professional career in Alaska, including past work as a fishery biologist, drilling mud engineer on the North Slope and in Cook Inlet; director of operations for Seldovia, Alaska during the 1989 *Exxon Valdez* oil spill; and delegate to the negotiated rulemaking committee for the U.S. vessel response plan regulations promulgated under the Oil Pollution Act of 1990. He has participated in the Incident Management Team for many oil spills since the *Exxon Valdez*, and has organized and facilitated dozens of oil spill response exercises, emergency management drills and equipment deployment trainings.Robertson holds a Master of Science degree in Fisheries Biology from the University of Alaska, Southeast.

Elise DeCola is the operations manager of Nuka Research. Her professional career began as a policy fellow in the Rhode Island Senate, where she organized hearings and drafted legislation to strengthen Rhode Island's oil spill prevention and response program in the wake of the 1996 *North Cape* oil spill. She has since worked on oil spill policy research and contingency plan development and review in Alaska, New England and several Gulf Coast states. She regularly conducts field preparedness exercises for oil spill responders in the Northeast. DeCola holds an M.A. in Marine Affairs from the University of Rhode Island.

Leslie Pearson is President of Pearson Consulting, LLC, which specializes in emergency management, planning, preparedness, policy research and regulatory compliance. Prior to starting a business, she spent 19 years with the Alaska Department of Environmental Conservation, including six year as the Oil Spill Response Program manager. She began her tenure with the ADEC in 1989 during the Exxon-Valdez oil spill. Her regulatory career focused specifically on issues associated with oil pollution planning, preparedness, response, damage assessment and response technology. Pearson earned a Master's of Science in Environmental Science from Alaska Pacific University.

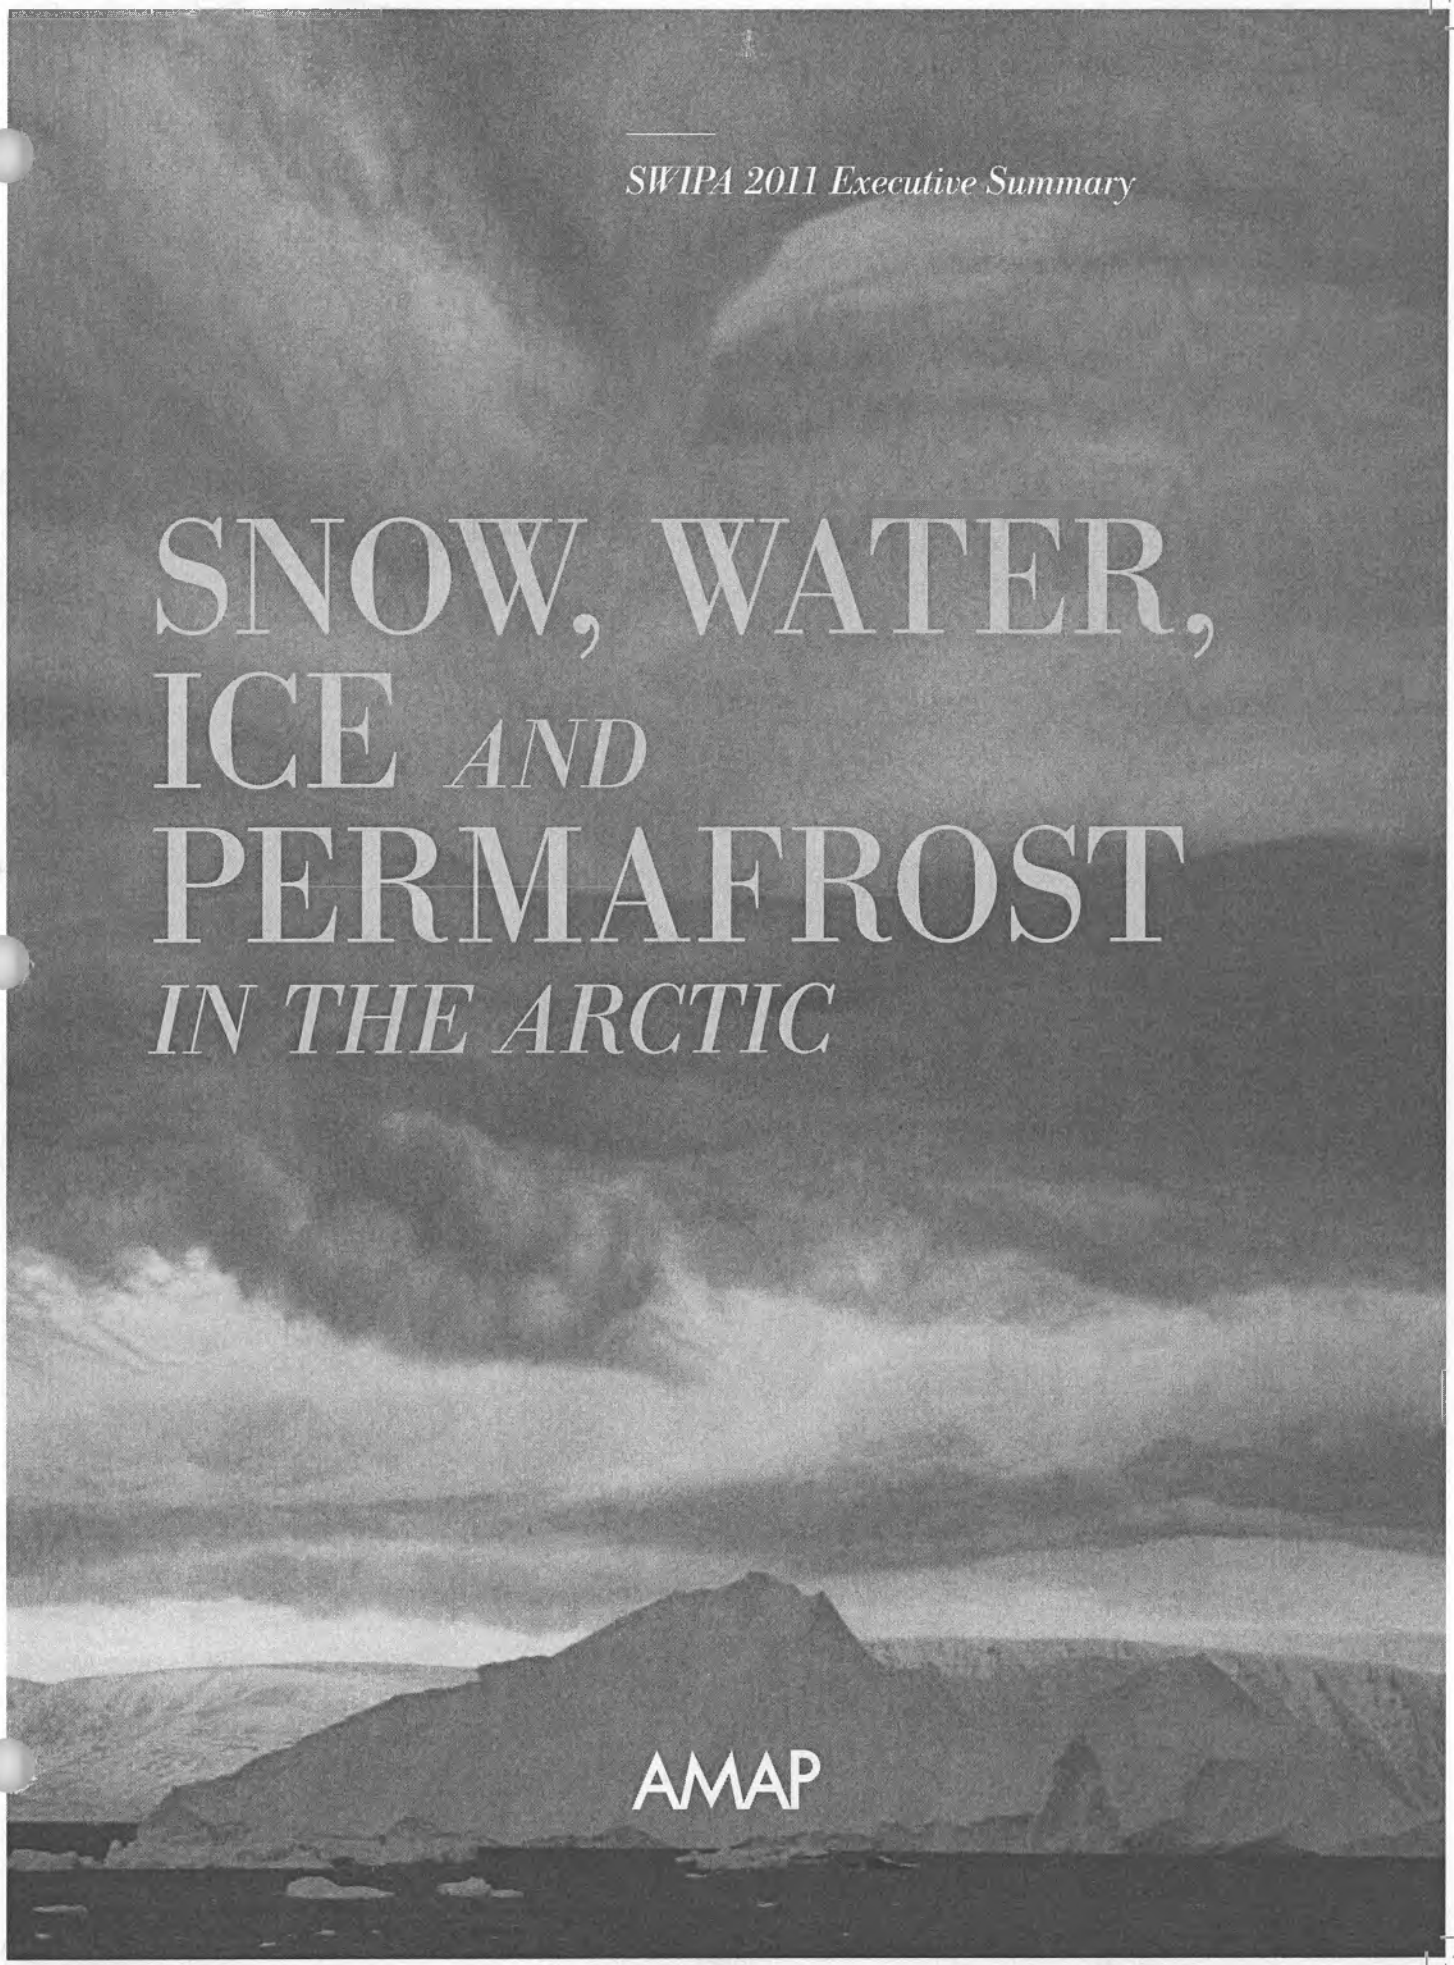
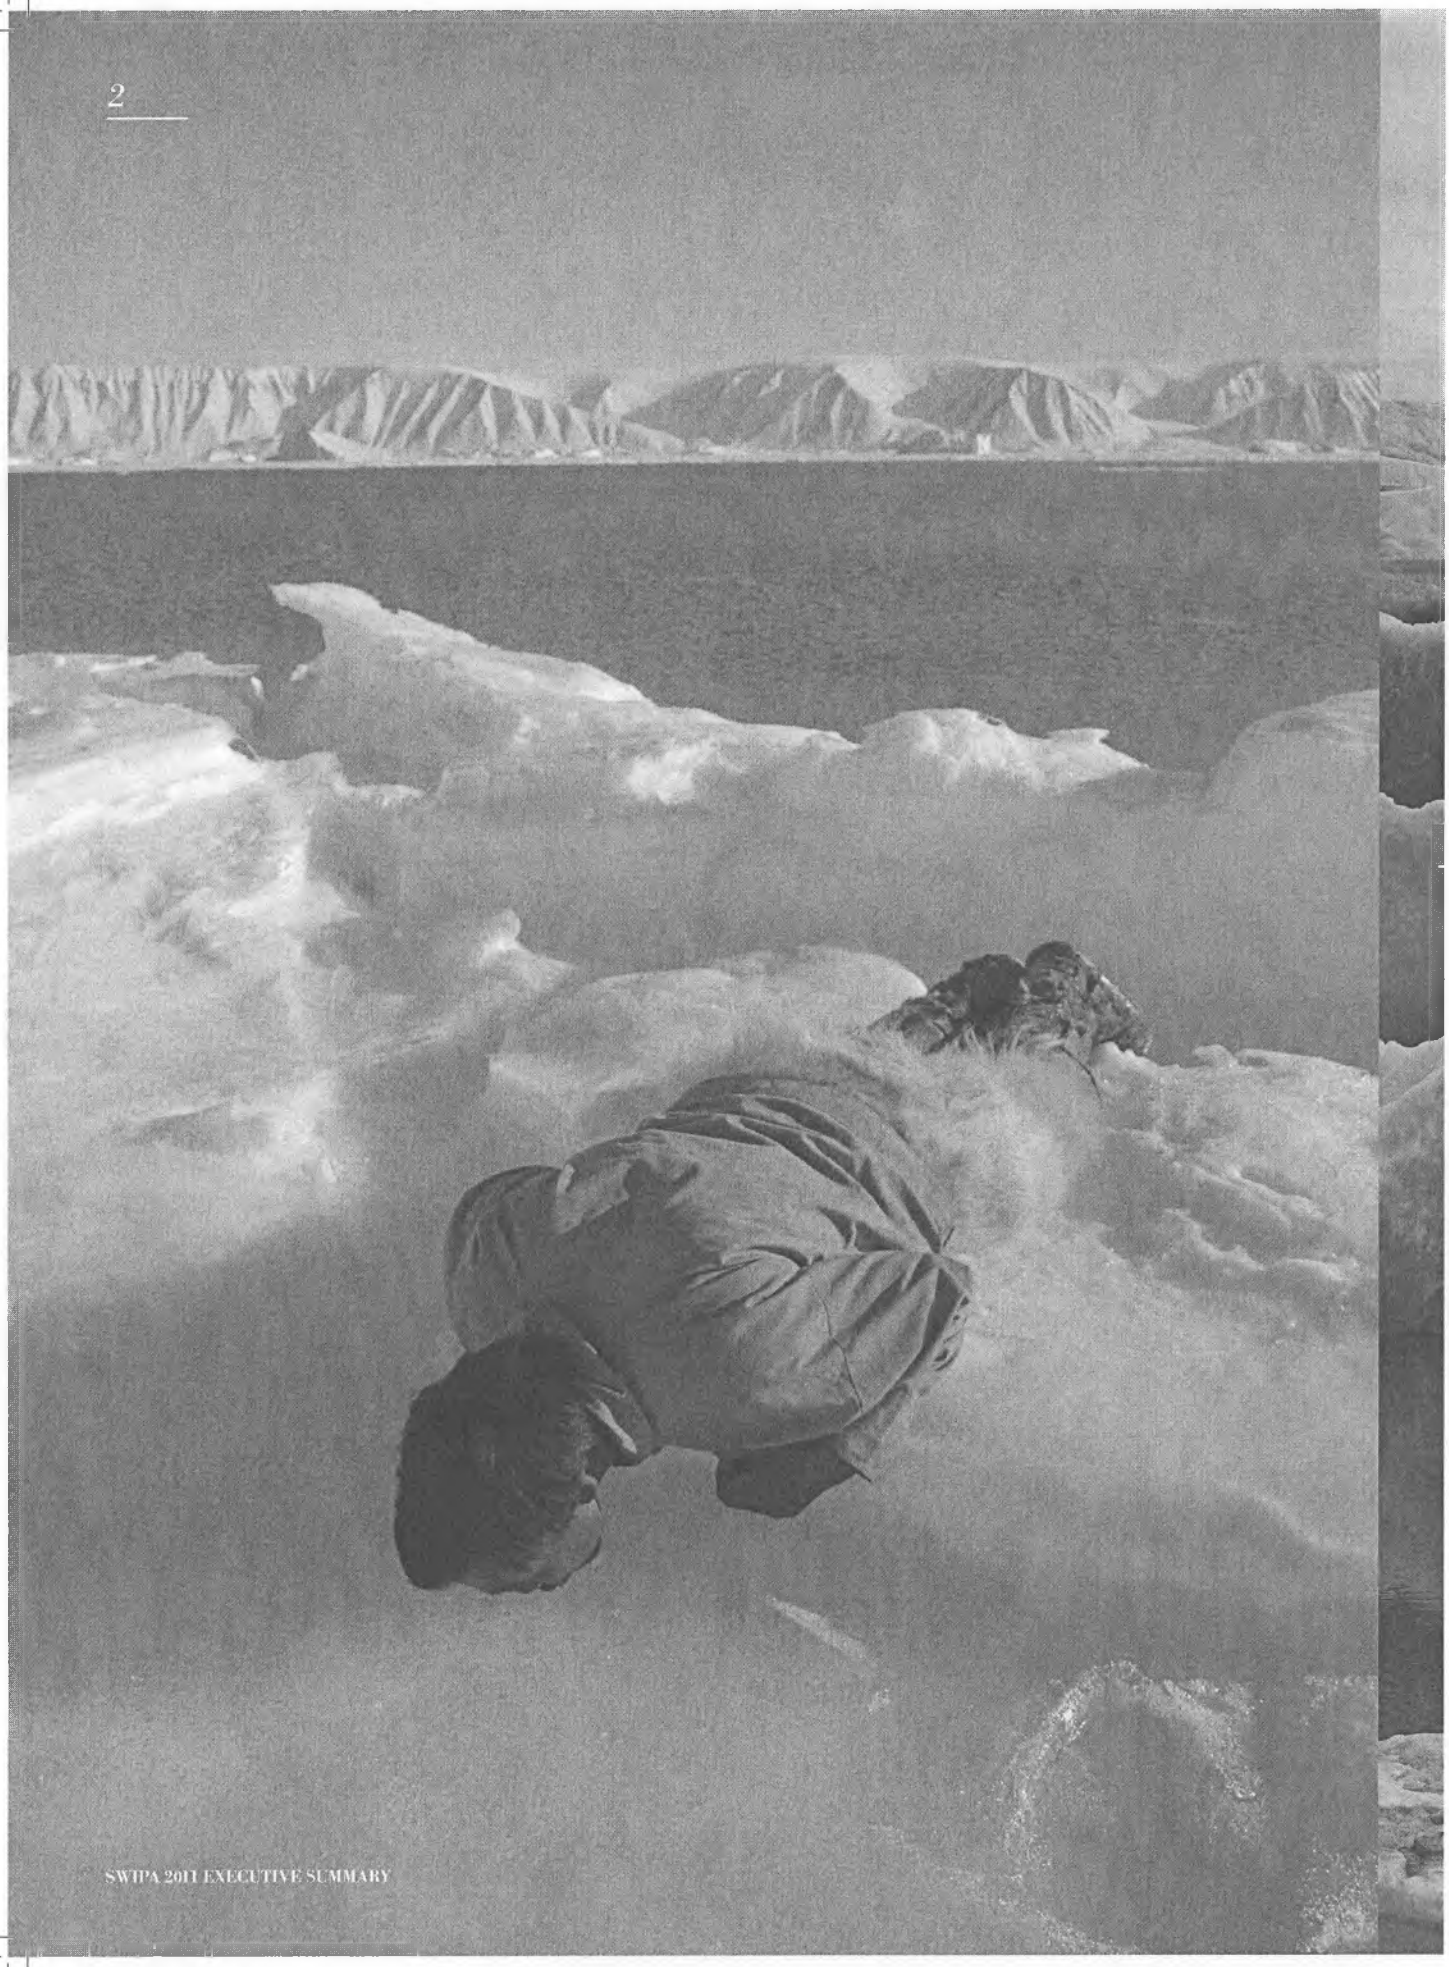
Snow, Water, Ice and Permafrost in the Arctic, SWIPA Executive Summary



SWIPA 2011 Executive Summary

SNOW, WATER, ICE *AND* PERMAFROST *IN THE ARCTIC*

AMAP



Bryan & Cherry Alexander / ArcticPhoto

EXECUTIVE SUMMARY AND KEY MESSAGES

SWIPA Summary for policymakers

AMAP's new assessment of the impacts of climate change on Snow, Water, Ice and Permafrost in the Arctic (SWIPA) brings together the latest scientific knowledge about the changing state of each component of the Arctic 'cryosphere'. It examines how these changes will impact both the Arctic as a whole and people living within the Arctic and elsewhere in the world.

'Cryosphere' is the scientific term for that part of the Earth's surface that is seasonally or perennially frozen. It includes snow, frozen ground, ice on rivers and lakes, glaciers, ice caps, ice sheets and sea ice. The cryosphere structures the physical environment of the Arctic. It provides services to humans such as freshwater supplies and transport routes. The cryosphere is an integral part of the climate system, and affects climate regionally and globally.

The SWIPA Assessment follows on from the Arctic Climate Impact Assessment (ACIA), published in 2005. It aims to update the findings from ACIA and to provide more in-depth coverage of issues related to the Arctic cryosphere.

The observed changes in sea ice on the Arctic Ocean and in the mass of the Greenland Ice Sheet and Arctic ice caps and glaciers over the past ten years are dramatic and represent an obvious departure from the long-term patterns.

Some elements of the cryosphere, such as the extent of snow, ice over water, and the dynamics of glaciers and ice streams vary greatly over short timescales (seasonally, or from year to year) and from place to place. Other aspects of the cryosphere, such as the extent of permafrost and large ice sheets, vary and change over decadal time scales and large areas. Distinguishing long-term change from natural variability requires data to be collected at many locations over many years and carefully analyzed. Detecting these cryospheric responses to changing climate presents different challenges and requires long term records as well as high frequency observations.

WHY THE ARCTIC CRYOSPHERE IS CHANGING

The past six years (2005–2010) have been the warmest period ever recorded in the Arctic. Higher surface air temperatures are driving changes in the cryosphere.

Key finding 1

There is evidence that two components of the Arctic cryosphere – snow and sea ice – are interacting with the climate system to accelerate warming.

Key finding 2

The Arctic is warming. Surface air temperatures in the Arctic since 2005 have been higher than for any five-year period since measurements began around 1880. The increase in annual average temperature since 1980 has been twice as high over the Arctic as it has been over the rest of the world. Evidence from lake sediments, tree rings and ice cores indicates that Arctic summer temperatures have been higher in the past few decades than at any time in the past 2000 years. Previously unseen weather patterns and ocean currents have been observed, including higher inflows of warm water entering the Arctic Ocean from the Pacific. These changes are the main drivers of change in the Arctic cryosphere.

In attributing the cause of warming in the Arctic, SWIPA refers to the findings of the Fourth Assessment Report from the Intergovernmental Panel on Climate Change (IPCC). This states that *"Most of the observed increase in global average temperatures since the mid-20th century is very likely* [> 90% probability] *due to the observed increase in anthropogenic GHG* [greenhouse gas] *concentrations".*

Climate-cryosphere interactions may now be accelerating warming

The greatest increase in surface air temperature has happened in autumn, in regions where sea ice has disappeared by the end of summer. This suggests that the sea is absorbing more of the sun's energy during the summer because of the loss of ice cover. The extra energy is being released as heat in autumn, further warming the Arctic lower atmosphere. Over land, the number of days with snow cover has changed mostly in spring. Early snow melt is accelerated by earlier and stronger warming of land surfaces that are no longer snow-covered.

These processes are termed 'feedbacks'. Snow feedbacks are well known. The sea ice feedback has been anticipated by climate scientists, but clear evidence for it has only been observed in the Arctic in the past five years.

A number of other potential feedback mechanisms at play in the Arctic have been identified. These mechanisms can alter the rate or even direction of climate change and associated changes in the cryosphere. Of those feedbacks expected to have strong effects, eight lead to further and/or accelerated warming, and just one leads to cooling. The intensity of feedbacks between the cryosphere and climate are not yet well quantified, either within the Arctic or globally. This lends considerable uncertainty to predictions of how much and how fast the cryosphere and the Arctic environment will change.

© Paul Souders / Corbis

HOW THE ARCTIC CRYOSPHERE IS CHANGING

The extent and duration of snow cover and sea ice have decreased across the Arctic. Temperatures in the permafrost have risen by up to 2 °C. The southern limit of permafrost has moved northward in Russia and Canada.

Key finding 3

The largest and most permanent bodies of ice in the Arctic – multi-year sea ice, mountain glaciers, ice caps and the Greenland Ice Sheet – have all been declining faster since 2000 than they did in the previous decade.

Key finding 4

Model projections reported by the Intergovernmental Panel on Climate Change (IPCC) in 2007 underestimated the rates of change now observed in sea ice.

Key finding 5

The extent and duration of snow cover have decreased throughout the Arctic. The Arctic land area covered by snow in early summer has reduced by 18% since 1966. Coastal areas of Alaska and northern Fennoscandia have seen the strongest decreases in the number of days with snow cover. The change is largely caused by snow melting earlier in the spring. Snow depth has decreased in some areas such as the North American Arctic, but has increased in others such as northern Russia.

Permafrost – permanently frozen ground – underlies most of the Arctic land area and extends under parts of the Arctic Ocean. Temperatures in the permafrost have risen by up to 2°C over the past two to three decades, particularly in colder sites (typical permafrost temperatures range from -16°C to just below 0°C, depending on the location). The depth of soil above the permafrost that seasonally thaws each year has increased in Scandinavia, Arctic Russia west of the Urals, and inland Alaska. The southern limit of the permafrost retreated northward by 30 to 80 km in Russia between 1970 and 2005, and by 130 km during the past 50 years in Quebec.

Ice cover on lakes and rivers in the Northern Hemisphere is breaking-up earlier than previously observed. Studies of sediments in High Arctic lakes indicate that the duration of ice cover on some lakes has declined significantly over the past 100 years. The rates of change in lake and river ice conditions vary across the Arctic, although there are few long-term systematic observations.

Large bodies of ice are melting faster

Net loss of mass from the Greenland Ice Sheet has increased from an estimated 50 Gt per year (50 000 000 000 metric tonnes per year) in the period 1995–2000 to ~200 Gt per year in the period 2004–2008. The current loss (~200 Gt per year) represents enough water to supply more than one billion city-dwellers.

Nearly all glaciers and ice caps in the Arctic have shrunk over the past 100 years. The rate of ice loss increased over the past decade in most regions, but especially in Arctic Canada and southern Alaska. Total loss of ice from glaciers and smaller ice caps in the Arctic probably exceeded 150 Gt per year in the past decade, similar to the estimated amount being lost from the Greenland Ice Sheet.

Arctic sea-ice decline has been faster during the past ten years than in the previous 20 years. This decline in sea-ice extent is faster than projected by the models used in the IPCC's Fourth Assessment Report in 2007. The area of sea ice persisting in summer (polar pack ice) has been at or near record low levels every year since 2001. It is now about one third smaller than the average summer sea-ice cover from 1979 to 2000. New observations reveal that average sea-ice thickness is decreasing and the sea-ice cover is now dominated by younger, thinner ice.

© Bryan & Cherry Alexander / ArcticPhoto

MORE CHANGE IS EXPECTED

Average Arctic autumn-winter temperatures are projected to increase by between 3 and 6 °C by 2080, even using scenarios in which greenhouse gas emissions are projected to be lower than they have been for the past ten years.

The climate models used for SWIPA do not include possible feedback effects within the cryosphere system that may release additional stores of greenhouse gases from Arctic environments.

Arctic snowfall and rain are projected to increase in all seasons, but mostly in winter. Despite this, Arctic landscapes are generally expected to dry out more during summer. This is because higher air temperatures mean that more water evaporates, snow melt finishes earlier, and water flow regimes are altered.

With increasing snowfall, all projections show maximum snow depth during winter increasing over many areas. The greatest increases (15–30% by 2050) are expected in Siberia. Even so, snow will tend to lie on the ground for 10–20% less time each year over most of the Arctic, due to earlier melting in spring.

Models project continued thawing of permafrost.

Projections show that sea-ice thickness and summer sea-ice extent will continue to decline in the coming decades, although considerable variation from year to year will remain. A nearly ice-free summer is now considered likely for the Arctic Ocean by mid-century. This means there will no longer be any thick multi-year ice consistently present.

Climate model projections show a 10–30% reduction in the mass of mountain glaciers and ice caps by the end of the century.

The Greenland Ice Sheet is expected to melt faster than it is melting now, but no current models can predict exactly how this and other land-based ice masses in the Arctic will respond to projected changes in the climate. This is because ice dynamics and complex interactions between ocean, snow, ice and the atmosphere are not fully understood.

Maximum snow depth is expected to increase over many areas by 2050, with greatest increases over Siberia. Despite this, average snow cover duration is projected to decline by up to 20% by 2050.

Key finding 6

The Arctic Ocean is projected to become nearly ice-free in summer within this century, likely within the next thirty to forty years.

Key finding 7

HOW THESE CHANGES AFFECT ARCTIC ECOSYSTEMS AND PEOPLE

Changes in the cryosphere cause fundamental changes in Arctic ecosystems

Changes in the amount of snow and the structure of the snowpack affect soils, plants and animals. Some species, such as pink-footed goose, benefit from less snow cover in spring. But animals grazing through snow, such as reindeer/caribou, suffer if winter rainfall creates an ice-crust over the snow. This is already happening more often in northern Canada and Scandinavia.

Less snow and faster melting are causing summer drought in forests, wetlands, and lakes supplied by snow melt. Thawing permafrost is also causing wetlands in some areas to drain and dry out, while creating new wetlands elsewhere.

The loss of ice cover over rivers, lakes and seas is changing animal and plant communities in the water.

The loss of large areas of sea ice represents devastating habitat loss for some ice-adapted species, including polar bear, seals, walrus, narwhal and some microbial communities. Many animals, including bowhead whales, depend on tiny crustaceans that thrive near the sea ice. This food source is changing as the ice edge recedes.

These changes to ecosystems directly affect supplies of water, fish, timber, traditional/local foods and grazing land used by Arctic people. For example, it has been suggested that stocks of some sub-Arctic and Arctic-adapted fish species, including commercially important species, could change as sea ice recedes. Uncertainty about changing supplies of living natural resources makes it difficult to plan for the future.

Forestry may benefit from thawing permafrost in areas where there is enough water for trees to grow, but insect pests are increasingly causing problems. Some hunted animals, such as seals and walruses, are declining in numbers as ice conditions change. Others are moving to new locations, so hunters have to travel further to reach them.

Cryospheric change affects Arctic livelihoods and living conditions

Access to northern areas via the sea is increasing during the summer as sea ice disappears; allowing increased shipping and industrial activity. Offshore oil and gas activities will benefit from a longer open water season, although threats from icebergs may increase due to increased iceberg production. The International Maritime Organization is devising new mandatory guidelines for ships operating in ice-covered waters. Sea-ice decline creates challenges for local residents who use the ice as a platform for travel and hunting; these challenges may include travelling farther over uncertain ice conditions and increased hazards.

On land, access to many areas is becoming more difficult as ice roads melt earlier and freeze later and as permafrost degrades. Industrial operations reliant on ice roads will need to concentrate heavy load transport into the coldest part of the year. Shorter seasons where ice and snow roads can be used severely impact communities

© Hulton-Deutsch Collection / Corbis

that rely on land transport of goods to maintain reasonable retail costs and ensure economic viability, particularly in northern Canada and Russia. Some land areas become more accessible for mining as glaciers and ice caps recede.

Thawing permafrost is causing increased deformation of buildings, roads, runways and other man-made structures in some areas, although poor design in the past is a contributing factor. New design methods are being developed that consider the likelihood of environmental change. Buildings and other infrastructure are at risk from heavier snow loads and floods caused by the release of ice jams in rivers or sudden emptying of glacial lakes.

Two-thirds of the Arctic coastline is held together and protected by ice. When land-fast sea ice melts earlier and permafrost thaws, rapid erosion can occur. Along the coasts bordering the Laptev and Beaufort seas, coastal retreat rates of more than two metres per year have been recorded. A number of Inuit villages in Alaska are preparing to relocate in response to the encroaching sea.

In the short term, increased glacier melt creates new opportunities for hydroelectricity generation. This has potential benefits for industry. In the longer term, the volume of meltwater will decrease as glaciers shrink, potentially affecting electricity production.

Melting ice and snow release contaminants that have been stored for many years, allowing the contaminants to re-enter the environment. Exposure of people and top predators to contaminants that accumulate in food chains could further increase.

Increased access to the Arctic creates new economic opportunities. Cruise ship tourism is increasing. More people are coming to witness the effects of climate change on Arctic glaciers, for example at the Ilulissat Icefjord in Greenland. Increased tourism may challenge lifestyles and services in local communities as well as increase the demand for effective infrastructure (e.g., air services, marine navigation aids, and other safety measures). Loss of Arctic wildlife and change of scenery may adversely affect the tourist industry in the long term.

Cryospheric change combined with rapid development creates opportunities and challenges for Arctic residents. Traditional knowledge can help to detect change and adapt to it. While traditional knowledge continues to evolve, it is a challenge to ensure that this knowledge is being passed on to younger generations as lifestyles change. Some aspects of traditional knowledge become less applicable as the cryosphere and other components of the Arctic system change even more rapidly and become less predictable.

Changes in the cryosphere cause fundamental changes to the characteristics of Arctic ecosystems and in some cases loss of entire habitats. This has consequences for people who receive benefits from Arctic ecosystems.

Key finding 8

The observed and expected future changes to the Arctic cryosphere impact Arctic society on many levels. There are challenges, particularly for local communities and traditional ways of life. There are also new opportunities.

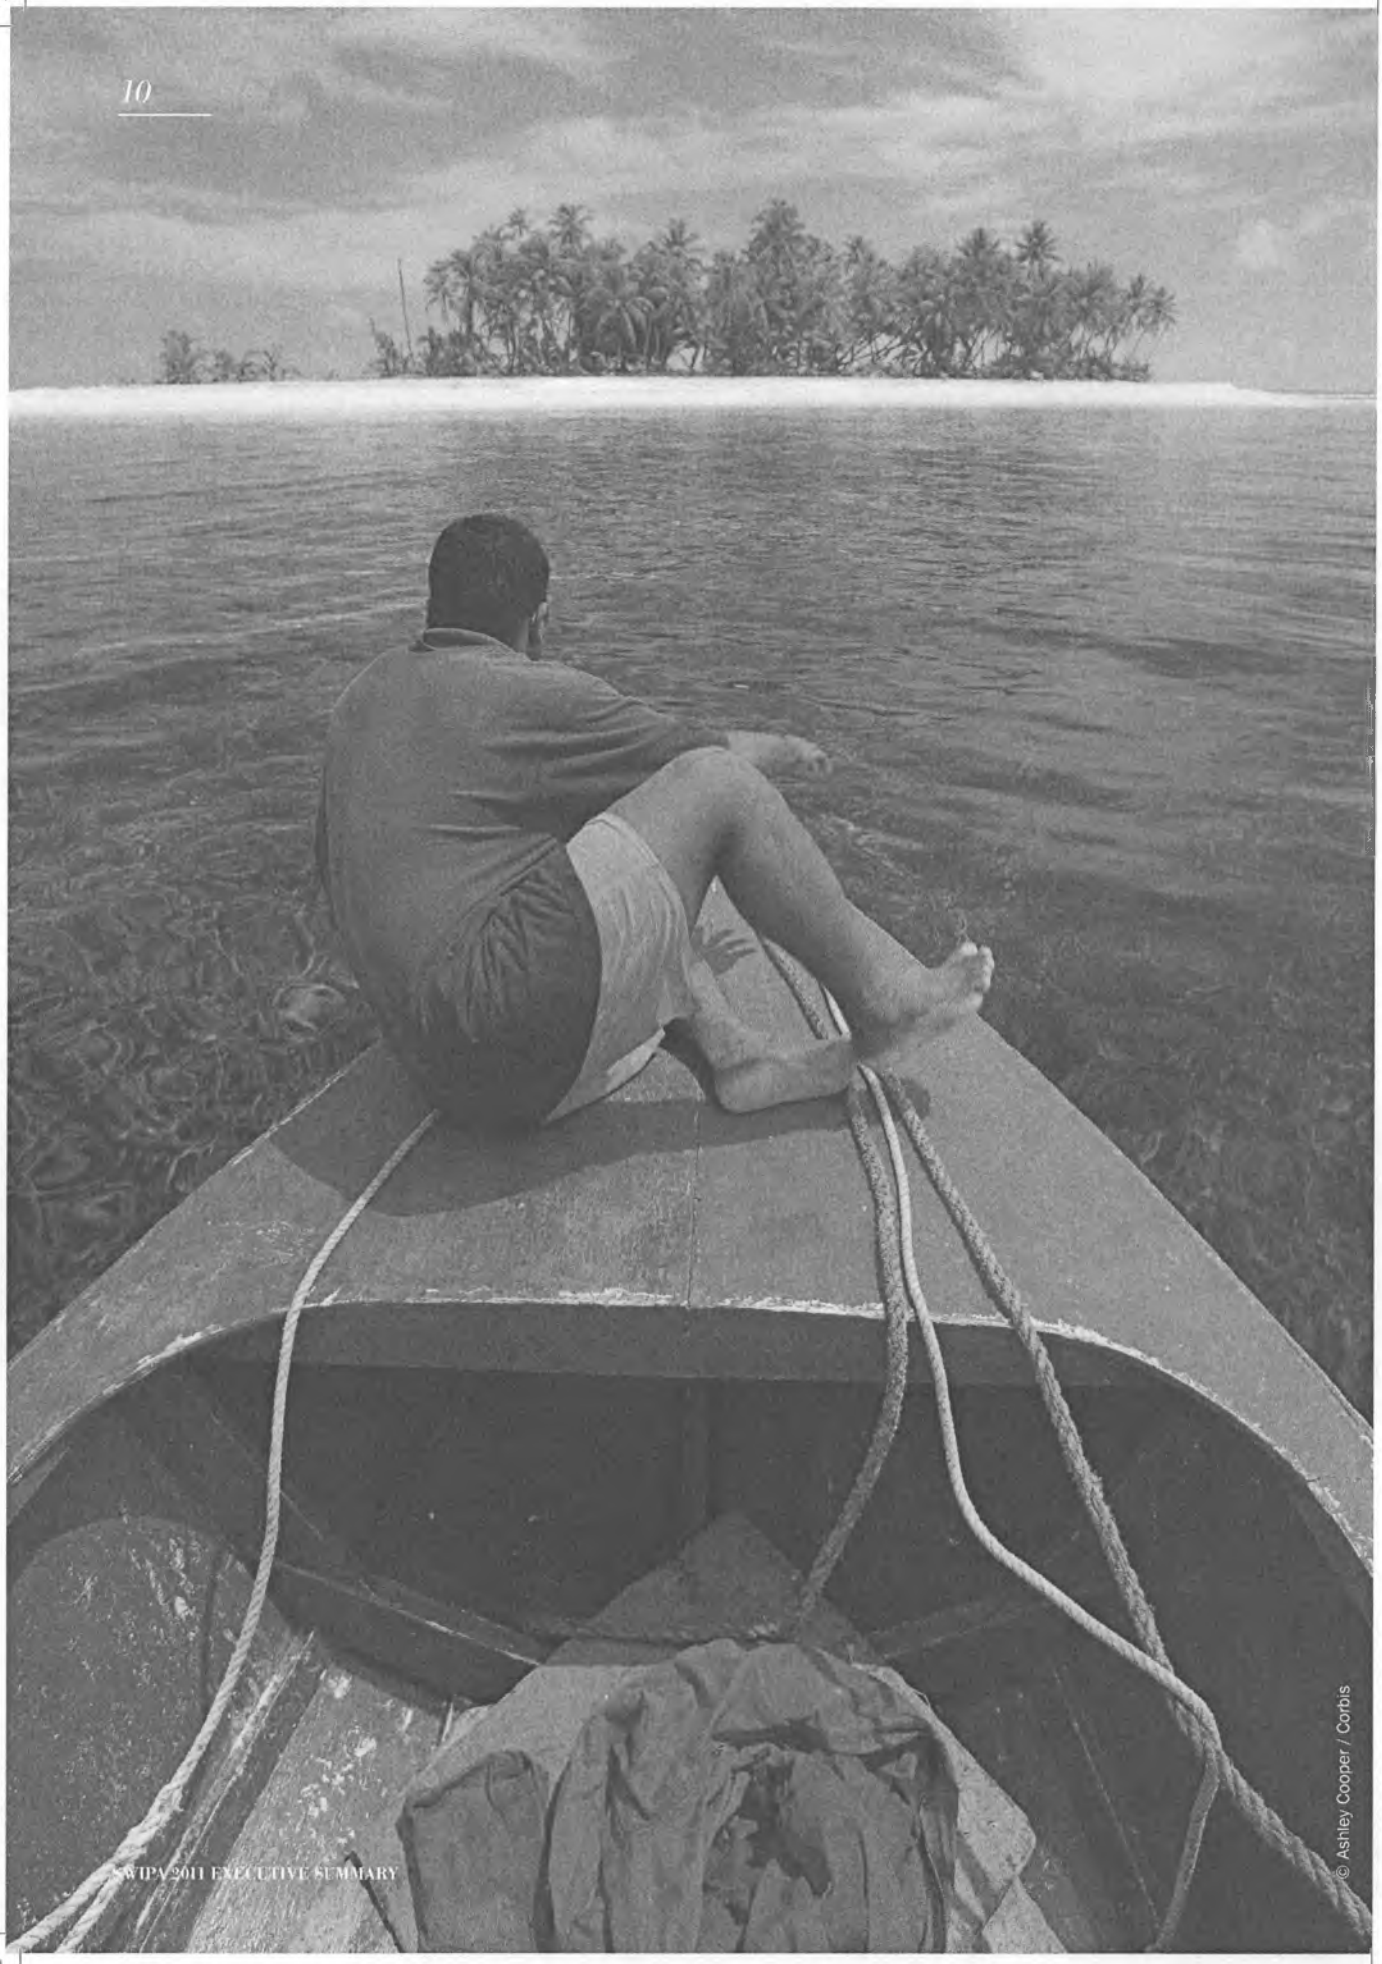
Key finding 9

Transport options and access to resources are radically changed by differences in the distribution and seasonal occurrence of snow, water, ice and permafrost in the Arctic. This affects both daily living and commercial activities.

Key finding 10

Arctic infrastructure faces increased risks of damage due to changes in the cryosphere, particularly the loss of permafrost and land-fast sea ice.

Key finding 11



© Ashley Cooper / Corbis

WHY CHANGES IN THE ARCTIC MATTER GLOBALLY

Changes in the Arctic cryosphere have impacts on global climate and sea level

When highly reflective snow and ice surfaces melt away, they reveal darker land or ocean surfaces that absorb more of the sun's energy. The result is enhanced warming of the Earth's surface and the air above it. There is evidence that this is happening over the Arctic Ocean as the sea ice retreats, as well as on land as snow melts earlier.

Overall emissions of methane and carbon dioxide from the Arctic could increase due to warming of soils and freshwater systems, and thawing of ancient frozen soil beneath the seabed.

The combined outcome of these effects on global climate is not yet known.

All the main sources of freshwater entering the Arctic Ocean are increasing – river discharge, rain/snow, and melting glaciers, ice caps, and the Greenland Ice Sheet. Recent calculations estimate that an extra 7700 km^3 of freshwater – equivalent to one metre of water over the entire land surface of Australia – has been added to the Arctic Ocean in recent years. There is a risk that this could alter large-scale ocean currents that affect climate on a continental scale.

Melting glaciers and ice sheets worldwide have become the biggest contributor to global sea level rise. Arctic glaciers, ice caps, and the Greenland Ice Sheet contributed 1.3 mm – over 40% – of the total 3.1 mm global sea level rise observed every year between 2003 and 2008. These contributions from the Arctic to global sea level rise are much greater than previously measured.

High uncertainty surrounds estimates of future global sea level. Latest models predict a rise of 0.9 to 1.6 m above the 1990 level by 2100, with Arctic ice making a significant contribution.

Changes in the Arctic cryosphere affect global society

Sea level rise is one of the most serious societal impacts of cryospheric change. Higher average sea level and more damaging storm surges will directly affect millions of people in low-lying coastal flood plains. Sea level rise increases the risk of inundation in coastal cities such as Shanghai and New York.

On the other hand, global economic activity may benefit from cryospheric changes in the Arctic. For example, opening transpolar sea routes across the Arctic Ocean will reduce the distance for ships travelling between Europe and the Pacific by 40% compared to current routes. This could reduce emissions and energy use.

Some unique Arctic species, such as the narwhal, face particular threats as the cryosphere changes. The decline of cryospheric habitats such as sea ice and wetlands over permafrost will impact on migratory species of mammals and birds from elsewhere in the world. These adverse effects on biodiversity are of global concern.

Loss of ice and snow in the Arctic enhances climate warming by increasing absorption of the sun's energy at the surface of the planet. It could also dramatically increase emissions of carbon dioxide and methane and change large-scale ocean currents. The combined outcome of these effects is not yet known.

Key finding 12

Arctic glaciers, ice caps and the Greenland Ice Sheet contributed over 40% of the global sea level rise of around 3 mm per year observed between 2003 and 2008. In the future, global sea level is projected to rise by 0.9–1.6 m by 2100 and Arctic ice loss will make a substantial contribution to this.

Key finding 13

WHAT SHOULD BE DONE

Everyone who lives, works or does business in the Arctic will need to adapt to changes in the cryosphere. Adaptation also requires leadership from governments and international bodies, and increased investment in infrastructure.

Key finding 14

There remains a great deal of uncertainty about how fast the Arctic cryosphere will change in the future and what the ultimate impacts of the changes will be. Interactions ('feedbacks') between elements of the cryosphere and climate system are particularly uncertain. Concerted monitoring and research is needed to reduce this uncertainty.

Key finding 15

Adaptation is urgent and needed at all levels

Cryospheric change affects people at the local level first, and local communities will need to devise strategies to cope with emerging risks.

At national and regional levels, adaptation requires leadership from governments and international bodies to establish new laws and regulations. For example, new fishing regulations will be required as fish stocks change. New standards will need to be developed for construction, particularly in areas affected by thawing permafrost.

Governments will need to invest in transport networks to cope with the shorter ice road season. Search and rescue operations will need to be enhanced to respond to increasing traffic and risks at sea, and accurate forecasts of weather and sea conditions are required to ensure travel safety.

Arctic communities are resilient and will actively respond to cryospheric change. However, rapid rates of change may outpace adaptation capacity. Knowledge and research are needed to foresee how living conditions are likely to change, and to evaluate possible adaptation options. Concerns of indigenous peoples need particular attention in this regard.

Changes in the cryosphere are not the only driver of change in the Arctic. Cryospheric change and climate change occur in the context of societal change, which may be even more challenging. The combined effects of societal, climatic and cryospheric change must be taken into account in adaptation strategies.

Cutting greenhouse gas emissions globally is urgent

Climate change represents an urgent and potentially irreversible threat to human societies. Global climate modeling studies show that deep and immediate cuts in global greenhouse gas emissions are required to hold the increase in global average temperatures below 2°C above pre-industrial levels. Combating human-induced climate change is an urgent common challenge for the international community, requiring immediate global action and international commitment.

Following the ACIA report, published in 2005, Ministers of the Arctic Council acknowledged that *"timely, measured and concerted action is needed to address global emissions."* They endorsed a number of policy recommendations for reducing greenhouse gas emissions, including to *"Adopt ... strategies ...* [to] *address net greenhouse gas emissions and limit them in the long term to levels consistent with the ultimate objective of the UNFCCC* [United Nations Framework Convention on Climate Change]."

The key findings of the SWIPA assessment, especially the rapid and accelerated rates of change in Arctic cryosphere conditions, emphasize the need for greater urgency in taking these actions.

Uncertainty can be reduced by further research

Current monitoring, research and model results provide high confidence that significant changes are occurring in the Arctic cryosphere and that these changes will continue in the future. Some of the observed changes align with expectations but one major component of the cryosphere (sea ice) has reacted faster than anticipated just five years ago. Even so, substantial uncertainty remains, particularly concerning the future timing of

changes, and the effects of interactions (feedbacks) between components of the cryosphere and climate system.

To reduce the uncertainty in future assessments, more robust observational networks are needed. Satellites and airborne measurements have improved the ability to observe some elements of the Arctic cryosphere such as sea-ice extent and snow cover. Monitoring of other key elements of the cryosphere, notably sea-ice thickness, snow depth, permafrost and glaciers, requires surface-based observations.

Many surface-based snow, freshwater ice, and precipitation gauge networks have diminished or have been completely lost, and sites for measuring sea ice, land ice, and physical properties of snow are sparse. Observational networks need to be expanded to provide a robust set of cryospheric data for monitoring, model improvement and satellite product validation.

The biggest unanswered questions identified by this report are:

- What will happen to the Arctic Ocean and its ecosystems as freshwater is added by melting ice and increased river flow?
- How quickly could the Greenland Ice Sheet melt?
- How will changes in the Arctic cryosphere affect the global climate?
- How will the changes affect Arctic societies and economies?

Answering some of these questions requires improved monitoring networks. A better understanding of the complex interactions between the physical, chemical and biological environments in the Arctic is needed. There is a lack of systematically collected information on the effects of cryospheric change on human society.

Communicating about cryospheric change and its effects

The SWIPA assessment documents the importance of climate-induced changes in Arctic snow, water and ice conditions and the profound implications for the local, regional, and global society.

Active communication of this new knowledge, to enhance global, national, and local awareness, will help to ensure that the SWIPA assessment generates benefits for people in the Arctic.

A co-ordinated response to cryospheric change

The combined effects of the changing cryosphere, climate change, and rapid development in the Arctic will create political challenges for Arctic societies, as well as the global community. Traditional livelihoods are most vulnerable to changes in the cryosphere. There is a need for co-operation and co-ordinated effort at all levels, to respond to change and increase the resilience of Arctic ecosystems and societies.

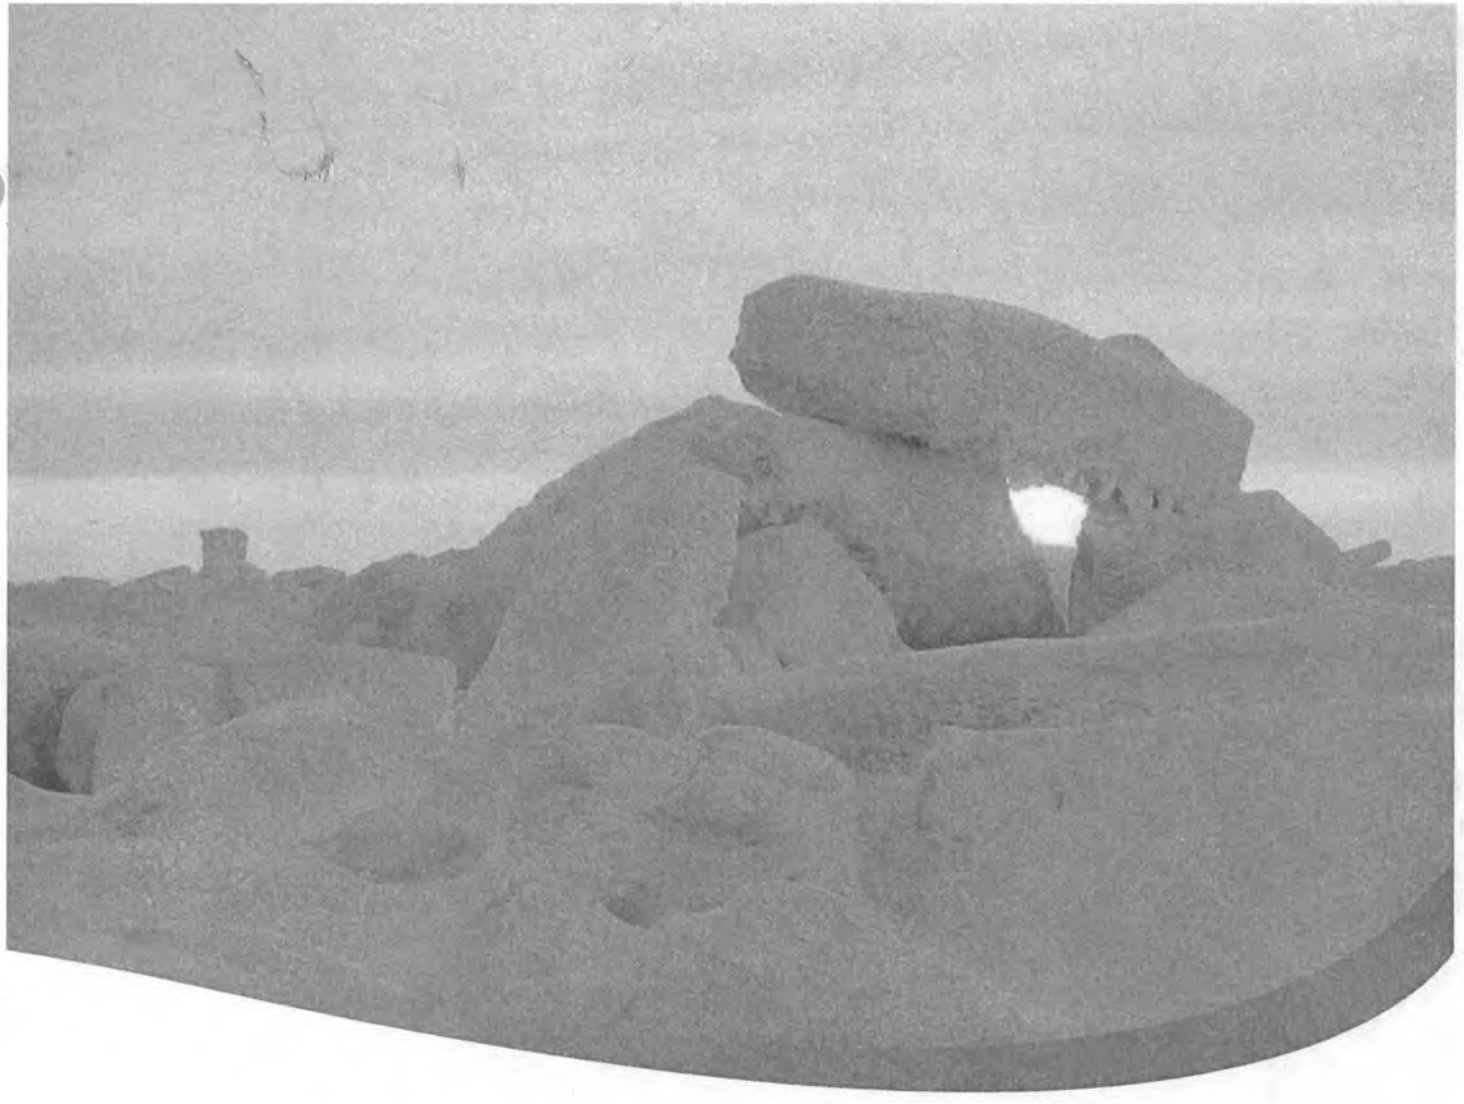
Arctic Council, Arctic Offshore Oil and Gas Guidelines, 2009



ARCTIC COUNCIL

ARCTIC OFFSHORE OIL AND GAS GUIDELINES

2009

The Arctic Council was established in 1996 and succeeded the Arctic Environmental Protection Strategy. It is a high-level intergovernmental forum that provides a mechanism to address the common concerns and challenges faced by the Arctic Governments and the Indigenous Peoples of the Arctic.
The members of the Arctic Council are Canada, Denmark (including the Faroe Islands and Greenland), Finland, Iceland, Norway, the Russian Federation, Sweden, and the United States of America.
The Permanent Participants of the Arctic Council are:

- Aleut International Association (AIA)
- Arctic Athabaskan Council (AAC)
- Gwich'in Council International (GCI)
- Inuit Circumpolar Council (ICC)
- Russian Association of Indigenous Peoples of the North (RAIPON)
- Saami Council

Observer status in the Arctic Council is open to Non-arctic states, inter-governmental and inter-parliamentary organizations, global and regional non-governmental organizations.

Preamble

The Ministers of the Arctic States—Canada, Denmark, Iceland, Finland, Russia, Sweden, Norway and the United States of America— originally adopted the Guidelines at the Fourth Ministerial Conference on the Protection of the Arctic Environment, 11-12 June, 1997 in Alta, Norway by declaring: "**We receive** with appreciation…the "Arctic Offshore Oil and Gas Guidelines" developed under AEPS, and **agree** that these Guidelines be applied."

The 2nd Ministerial Meeting of the Arctic Council 9-10 October 2002 in Inari, Finland recognized the updated version of these Guidelines by the following statement: *"We... endorse the updated Offshore Oil and Gas Guidelines and encourage the concerned stakeholders to apply them."*

The endorsement of these Guidelines recognizes a uniform understanding of the minimum actions needed to protect the Arctic marine environment from unwanted environmental effects caused by offshore oil and gas activities. The Ministers, however, acknowledge that further steps can be taken nationally as a part of the environmental and natural resource management policies of the Arctic States.

The users of these Guidelines will find that all stages of offshore oil and gas activity, are included, with the exception of transportation of oil and gas. The Introduction sets forth the background for the Guidelines and important general concerns. The chapters that follow set forth the specific suggested operational steps to follow when planning for Arctic offshore oil and gas activities.

Neither PAME nor the full Arctic Council has established a single geographic definition of the Arctic. This is left for Arctic states to determine. For the purposes of these Guidelines, the definition of the Arctic is contained in Annex A.

1 Introduction

1.1 Background

The Guidelines were originally written in response to the Report of the Third Ministerial Conference on the Protection of the Arctic Environment (Inuvik, Canada, March 20-21, 1996) which expressed concern regarding the potential impacts related to future increases in offshore petroleum activity in the Arctic. The Report requested PAME *...(to develop) "guidelines for offshore petroleum activities in the Arctic, in particular guidelines for timely and effective measures for protection of the Arctic environment. In this regard, the Ministers welcomed the initiative of the United States to conduct a government designated expert meeting to develop such guidelines, in cooperation, as appropriate, with other AEPS Working Groups"* (Paragraph 2.3.5(ii)).

In addition, the Inuvik Report requests AMAP (Arctic Monitoring and Assessment Program Working Group) to "*...review the feasibility of developing sub-regional cooperative oil- related monitoring and assessment activities, as appropriate.*" (Paragraph 2.1.2.1).

Finally, the Report requests EPPR (Emergency Preparedness, Prevention and Response Working Group) to "*...continue their work on contributing to development of preventative, mitigating and response measures for oil and gas accidental releases in the Arctic*" (Paragraph 2.4.5).

Although PAME had the overall responsibility for developing the 1997 guidelines, they were the result of a group effort and reflect coordination within the Arctic Council working groups that the ministers emphasized in the 1996 Inuvik Report.

The 1997 Guidelines stated in Section 1.7 Periodic Review, "*These Guidelines should undergo periodic review and amendment, as necessary, to take into consideration experiences in the management and control of offshore oil and gas operations. The Guidelines must remain current if they are to support timely and effective measures for protection of the Arctic environment. An Experts Meeting should be held after the third anniversary of the adoption of the Guidelines to review and update them.*"

In 2002 the Guidelines were updated and improved by PAME with the help of EPPR, AMAP, and CAFF (Conservation of Arctic Fauna and Flora Working Group) and with an attempt to incorporate the principles of sustainable development. The 2002 update was greatly assisted by the involvement and comments received from representatives of Arctic, regional and other governments, non-governmental organizations, industry, indigenous people, and the scientific community to provide agreed guidelines for offshore oil and gas activities in the Arctic.

It is acknowledged that a number of legal instruments related to offshore oil and gas activities exist, *e.g.* United Nations Convention on Law of the Sea; the International Convention for the Prevention of Pollution from Ships (MARPOL 73/78); the London Convention 1972; and regional conventions such as OSPAR. Arctic petroleum activities must be conducted in compliance with applicable international law.

Additional guidance and information resources that have relevance to the Arctic Offshore Oil and Gas Guidelines, have been provided by the Arctic Council since 2002, including the Human Health in the Arctic Report (2003), the Arctic Marine Strategic Plan (2004), the Transfer of Refined Oil and Oil Products in the Arctic (TROOP) Guidelines (2004), the Arctic Shoreline

Clean-up Assessment Technique (SCAT) Manual (2004), the Arctic Guide for Emergency Prevention, Preparedness and Response (2008), the Arctic Climate Impact Assessment (2004), the assessment, Oil and Gas Activities in the Arctic—Effects and Potential Effects (OGA, 2009).

1.2 Goals

Purpose of the Guidelines

These Guidelines are intended to be of use to the Arctic nations for offshore oil and gas activities during planning, exploration, development, production and decommissioning

Recommendations on the transportation of oil and gas are found in the OGA, 2008. The Guidelines should be used to help secure common policy and practices. The target group for the Guidelines is thus primarily the authorities, but the Guidelines may also be of help to the industry when planning for oil and gas activities and to the public in understanding environmental concerns and practices of Arctic offshore oil and gas activities. While recognizing the non-binding nature of these Guidelines, they are intended to encourage the highest standards currently available. They are not intended to prevent States from setting equivalent or stricter standards, where appropriate.

Policy development should take into account the domestic situation with respect to political, economic, legal, and administrative conditions. Consideration should be given to macro-economic effects, regional effects, and potential environmental impacts. Such consideration should result in a staged opening plan, and ensure protection of areas of special environmental concern. While these guidelines do not address socio-economic aspects in any detail, nor do they set standards for assessment of potential socio-economic effects of offshore oil and gas activities, these are nonetheless important to consider and integrate into the planning and conduct of exploration and development.

The Guidelines are intended to define a set of recommended practices and outline strategic actions for consideration by those responsible for regulation of offshore oil and gas activities (including transportation and related onshore activities) in the Arctic (see Figure 1 and Annex A). It is hoped that regulators will identify the key aspects related to protection of human health and safety and protection of the environment for the management of offshore activities, while at the same time remaining sufficiently flexible in the application of these management regimes to permit alternative regulatory approaches. It should be recognized that the eight Arctic nations have different systems with different emphases on the division of responsibility between the operator and the regulator. The goal is to assist regulators in developing standards, which are applied and enforced consistently for all offshore Arctic oil and gas operators. Sensible regulation will vary to some degree based upon local circumstances. Thus, it is expected that, based on the outcome of environmental impact assessment procedures, regulators will establish policies such that offshore oil and gas activities are conducted so as to provide for human health and safety and protection of the environment.

Offshore Arctic oil and gas operations may result in a variety of related onshore activities. Individual governments should determine the extent to which these Guidelines apply when evaluating these activities.

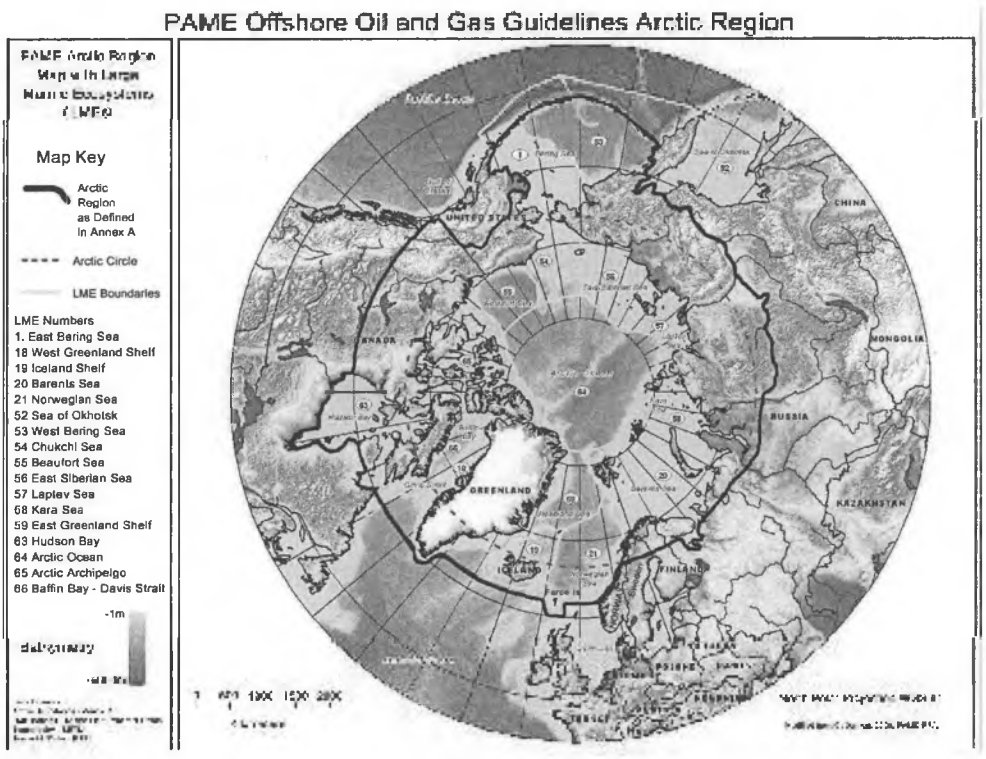

Figure 1 - Arctic Region (the area of application of the Guidelines is described in Annex A)

Goals for Environmental Protection during Oil and Gas Activities in the Arctic Area

Offshore oil and gas activities in the Arctic should be planned and conducted so as to avoid:

- adverse effects on air and water quality that exceed national or applicable international standards or regulations;
- changes in the atmospheric, terrestrial (including aquatic), glacial or marine environments that exceed national or applicable international standards or regulations;
- detrimental changes in the distribution, abundance or productivity of species or populations of species;
- further jeopardy to endangered or threatened species or populations of such species;
- degradation of, or substantial risk to, areas of biological, cultural, scientific, historic, aesthetic or wilderness significance;
- adverse effects on livelihoods, societies, cultures and traditional lifestyles for northern and indigenous peoples; and
- adverse effects to subsistence hunting, fishing and gathering.

1.3 General Principles

Arctic offshore oil and gas activities should be based on the following principles:

Principle of the Precautionary Approach

In order to protect the environment, the precautionary approach as reflected in Principle 15 of the Rio Declaration shall be widely applied by States to oil and gas activities according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

Polluter Pays Principle

National authorities should endeavor to promote the internalization of the application of the polluter pays approach as reflected in Principle 16 of the Rio Declaration. The polluter should, in principle, bear the cost of pollution, with due regard to the public interest and without distorting international trade and investment.

Continuous improvement

All parties should continually strive to improve health, environment and safety by identifying the processes, activities and products that need improvement, and implement necessary improvement measures. The process of identifying what can be improved may be based on mappings and results of analyses, investigation of situations of hazard and accident, or near hazards and accidents, handling of non-conformities, experience from internal follow-up or auditing, or experience gained by others.

Sustainable Development

In permitting offshore oil and gas activities Arctic governments should be mindful of their commitment to sustainable development, including, *inter alia*:

- protection of biological diversity;
- the duty not to transfer, directly or indirectly, damage or hazards from one area of the marine environment to another or transform one type of pollution into another;
- promotion of the use of best available technology/techniques and best environmental practices (See some examples in Annex B);
- the duty to cooperate on a regional basis for protection and preservation of the marine environment, taking into account characteristic regional features and global climate change effects;
- the need to maintain hydrocarbon production rates in keeping with sound conservation practices as a means of minimizing environmental impacts;
- development which meets the needs of the present without compromising the ability to meet the needs of the future;
- integration of environmental and social concerns into all development processes; and
- broad public participation in decision making.

1.4 Existing Effects of Oil and Gas Activities on Environment and Society

Impacts to marine Arctic areas from all human activities within Arctic countries at present mainly affect coastal areas. Effects in offshore areas are mainly due to long-range transport of contaminants by wind and sea currents, and rivers, but also include sediment transport in sea ice.

Some coastal areas of the Arctic may be contaminated by direct runoff from cities, villages, industry or mining, through river discharges, from dumping and from nuclear tests. Hot spots have been identified by the Arctic Council, but few of these are relevant in the context of these guidelines. Based on the results of the Arctic Council assessment AMAP 2002 persistent organic pollutants (POPs) and mercury represent the greatest contaminant related threat to the Arctic environment. While levels of most POPs appear to be declining in response to global restrictions on production and use, a group of new chemicals that includes brominated flame retardants and fluorinated surfactants are being measured at increasing concentrations in the Arctic marine environment. Levels of mercury in the marine environment from long range transport appear to be increasing, particularly in the North American Arctic. At higher trophic levels, both POPs and mercury are found at levels that pose a potential toxicological risk to wildlife. Artificial radionuclide seem to pose only a minimal threat to the environment.

Currently, the vast majority of the Arctic marine environment, away from local natural or anthropogenic sources, is largely pristine with regard to oil hydrocarbons. Physical disturbance due to exploration activities has declined over the last 2 decades due both to a reduction in activities and due to improvements in technology and use of best practices

Climate change presents numerous challenges to arctic marine environments and ecosystems, which are thoroughly discussed in the Arctic Climate Impact Assessment (ACIA 2004). Climate

change will also influence contaminant pathways and processes resulting in changes to current levels in the marine environment. Increased offshore activities may disturb marine life with their presence, noise, and discharges.

1.5 Potential Effects of Oil and Gas Activities on Environment and Society

Natural environment

The Arctic Council Oil and Gas Assessment in 2008 found that a significant threat from offshore oil and gas activities was the risk and potential impact of oil spills in an area of vulnerability to crucial habitats or threatened species However, concentration levels are elevated in some areas from natural sources such as oil seeps and erosion of coal-bearing rock. According to the AC, 2008, the Arctic has high sensitivity to oil spill impacts and the least capacity for natural recovery. During much of the year and under many conditions, response capabilities and methods are limited by environmental conditions, lack of resources capable of responding in a timely manner, and limited technologies for responding to oil spills in ice conditions.

Offshore oil and gas activities may entail considerable inputs of gases to the air from power generation, flaring, venting, well testing, leakage of volatile petroleum components, supply activities and shuttle transportation. These emissions contribute greenhouse gases to the atmosphere and increase the amount of pollutants emitted to the Arctic thus potentially affecting the climate and possibly causing acidification on nearby land. Although not currently widely practiced in the Arctic, discharges of drill cuttings with associated oil and chemicals and discharge of produced water may have acute effects on sea floor flora and fauna and reduce both their abundance and diversity in the immediate vicinity of the installations.

Arctic Council 2008 indicates that Arctic offshore operations currently contribute a very small part of atmospheric or marine contaminants, but an anticipated increase in activity has the potential to increase these.

Discharges of produced water and chemicals to the water column have the potential for acute effects on marine life only in the immediate vicinity of the installations However, according to the AC, 2008, discharge of produced water is not currently routinely practiced the Arctic offshore and if necessary is done in accordance with the guidance of Section 6.1 and Section 6.2.

Good and transparent governance, comprehensive but responsive regulatory regimes, and the use of international standards and practices coupled with evolving advances in technology and best practices have lessened the effects of oil and gas activities over time, including those in the offshore. But risks may arise as conditions change or new areas are explored and developed and evidence also shows that accidents will happen and best practices will not always be followed. Governments should continue to ensure that best practices, including oil spill response mechanisms, are in place before activities begin.

The accelerating loss of polar sea ice has drawn the attention of nations and industry for the possibility of increased oil and gas and shipping activities in their arctic waters. Therefore, all stakeholders share a concern about future oil and gas development in this changing and fragile environment and in dealing with the impacts and stresses both from direct environmental risks and those posed by climate change.

Human environment

Oil and gas activities may have pronounced positive effects on a nation's employment and economy. They also have socio-economic effects, both negative and positive, on local communities and indigenous people. The Arctic Council Oil and Gas Assessment also found that social effects of oil and gas activities, including those offshore, are often greatest at the local level, whereas the economic effects are often shared more widely. The economic value of oil and gas reserves developed will influence the scale of the activities and the magnitude and type of positive and negative effects at the national, regional and local level. Socio-economic effects also vary according to the 'life-cycle' stage of oil and gas activity and tend to be higher and more local at the exploration and construction phase, and stabilize and be more regional in the production stage. Expansion of oil and gas activities across the Arctic has increased the overlap and potential conflict between the industry and traditional land use and ways of life of indigenous people. Industry activity such as seismic surveying, exploratory drilling with associated vessel traffic, facility emplacement, subsequent development drilling, and production and transportation of oil or gas all have some potential for interfering with traditional marine subsistence hunting and fishing activities.

At the same time, in many Arctic countries, indigenous people are becoming active participants in oil and gas activities as decision makers, business owners, and employees. Project planning, environmental assessments and regulations should take into account indigenous and traditional knowledge when addressing local concerns and developing ways to mitigate possible environmental damage and negative socioeconomic effects.

In addition to direct effect of oil and gas activities on indigenous communities, provision should be considered to address secondary and cumulative impacts from oil and gas activities and the possible role of additive effects from other social stressors to the arctic peoples. These could include impacts on human health from changes in diet resulting in an increased risk of diabetes, obesity, hypertension, and cardio vascular disease, or social strain and potential for increased access to drugs and alcohol from contact with outsiders leading to higher risk of social pathologies

1.6 Institutional Strengthening in the Regional Context

Management of Arctic oil and gas activities and their effects on the Arctic offshore and near shore areas requires participation of governments, the public, non-governmental organizations and operators. In order to implement these Guidelines, institutional mechanisms or capabilities are required at the local, national and regional levels to:

- encourage the open, transparent and consistent application of regulatory regimes;
- facilitate strict enforcement of regulatory regimes;
- enable government agencies, local communities and non-governmental organizations to participate as appropriate in environmental management;
- make sure that scientific, technical and indigenous traditional knowledge are available to the processes and are effectively used;
- promote communication between operators, government bodies and communities that is conducted in culturally appropriate ways and in local languages;

- facilitate regional activities and mechanisms that best suit the regional physical, biological and socioeconomic environments, and potential regional impacts;

Efforts to establish effective communication with local residents for all processes involved in oil and gas activities should make sure that:

- technical terms and ideas are clearly presented and are not lost in translation to another language;
- terminology is consistent;
- summaries as well as the complete documents are available in advance of public review and comment meetings; and
- adequate advance notice is given of public consultation meetings that take into account local communities harvesting, hunting and fishing annual schedules

To address the above needs, Arctic States should:

- review their own needs, and regional needs, for institutional strengthening and capacity-building in these areas, and identify priority needs with schedules for addressing them; and
- cooperate in and facilitate bilateral and multilateral initiatives to address the needs, in concert with the public and with oil and gas industry operators.
- develop regional oil spill contingency plans that clearly delineate: response authorities and capabilities; acceptable response actions through pre-approvals and agreements; agreements for sharing expertise and resources

2 Arctic Communities, Indigenous Peoples, Sustainability and Conservation of Flora and Fauna

Offshore oil and gas activities should be conducted so as to protect, and avoid adverse impacts on, living resources and the ecosystems on which they depend; to avoid adverse impacts on the traditional ways of life, resource uses and cultural values of Arctic indigenous communities; and to coordinate with other human activities in the region.

2.1 Living Resources

Measures should be taken as necessary to ensure that Arctic flora and fauna and the ecosystems on which they depend are protected during all phases of offshore oil and gas activities. Special attention - particularly with regard to intrusive activities - is required for species (e.g. fish, birds, whales, seals, polar bears, and other marine mammals), which are resources for human use, particularly by indigenous people, and for special habitats (such as ice-edge zones, coastal lagoons and barrier islands, wetlands, estuaries, bays, and river deltas). Onshore features that should be considered for protection and/or avoidance during offshore exploration and production activities include areas used significantly by waterfowl (such as high-density nesting, brood-rearing, molting and staging areas), caribou (such as major calving and insect relief areas), and by musk oxen. Consistent with the interests of human safety and well-being, a primary governing policy in the Arctic should be the conservation of resources for sustainable use. This includes protection of subsistence hunting, fishing, and gathering.

2.2 Cultural Values

In planning and executing offshore oil and gas operations, necessary measures should be taken, in consultation with neighboring indigenous communities, to recognize and accommodate the cultural heritage, values, practices, rights and resource use of indigenous residents. Arctic States, in cooperation with the oil and gas industry, should address the economic, social, health and educational needs based on equal partnership with indigenous people. All phases of oil and gas activity should avoid disturbance of historic or prehistoric resources including archeological and sacred sites, historic shipwrecks and other potentially important cultural sites.

2.3 Other Human Activity

Offshore oil and gas activities should be conducted in coordination with other human activities in the region, such as tourism, fishing, shipping, and scientific research. There should be a solid understanding of other human uses in the area to forecast potential areas of conflict both annually and seasonally. Advanced information collection and analysis may permit improved consultation and dialogue to proactively avoid conflicts as well as target enhanced socio-economic impact analysis where required. Arctic governments should consider the use of integrated management schemes.

2.4 Arctic States should:

- incorporate local and traditional knowledge into the decision-making process including the initial siting studies and disposition of resource use rights. For example, ethnological expert studies are being used in Russia in which scientific and local knowledge are combined;

- pursue regulatory and political structures that allow for participation of indigenous people and other local residents in the decision making process as well as the public at large;

- urge and, where appropriate, require industry to integrate cultural and environmental protection considerations into planning, design, construction and operational phases of oil and gas activities;

- improve cross-cultural communication methods to ensure full and meaningful participation of indigenous residents including procedures to incorporate local knowledge;

- identify and appropriately manage oil and gas activities in ecologically and culturally sensitive areas; and

- for use in planning and decisions, identify species, which are resources for human use and their ecological requirements, and identify patterns of their use as resources.

3 Environmental Impact Assessment

Environmental impact assessment (EIA) procedures should be used to determine the potential impacts of offshore oil and gas exploration, development, transportation and infrastructure on the environment and human communities so as to inform decision-making. Arctic countries use a variety of methods and approaches. Annex D gives examples of the EIA process in several Arctic countries. Assessments may have a broad scope or be project specific. The responsibility for conducting the EIA or preliminary impact assessments (PEIA) varies from country to country (See Annex D)

Several approaches may be used for environmental assessments with a broad scope.

Examples of these approaches follow:

- regional assessments for oil and gas activities;
- ecosystem based approach;
- integrated oceans and coastal management;
- Strategic Environmental Assessment (SEA);
- regional cumulative impact assessment and studies; and
- land use or spatial planning.

Many of these approaches address common elements. They assess potential environmental impacts on the ecosystem and potential social and economic effects. They include a long-term focus that addresses both effects and planning. They include a discussion of the potential cumulative effects of oil and gas activities with the effects of other activities. They address competing interests.

Assessments should consider alternative development options and any impacts that alternative activities may have, including potential cumulative impacts from other existing and known planned activities.

PEIAs and EIAs should consider, in particular, the following effects (for example contamination, habitat disturbance and alteration) on:

- human society including indigenous ways of life;
- cultural heritage;
- socio-economic systems;
- other human activities (e.g., tourism, scientific research, fishing, and shipping);
- overall landscape (e.g., fragmentation);
- subsistence ways of life (e.g. harvest practices and availability of food supply);
- oil spill preparedness and response in sea ice conditions;

- permafrost and transition zones;
- climate;
- sustainability of renewable resources;
- flora and fauna including marine mammals;
- air, water and sediment quality;
- ports and shore reception facilities;
- Arctic shipping routes;
- ice dynamics;
- human health; and
- the interaction among any of the above.

(See the table showing an overview of offshore activities and potential environmental effects in Annex E.)

Baseline environmental studies should be done on a regional basis to provide information for the EIA process. Regional baseline and monitoring programs should be established prior to activities and may be done as part of the SEA. This is in addition to project specific monitoring as further described in Section 4 (**Monitoring**).

When monitoring biodiversity the best available knowledge, including indigenous and traditional knowledge should be employed. Independent scientific peer review and public input should be used to assure program quality.

Since project impacts may have international effects, it is important that environmental monitoring programs are adequate and intercompatible so that results may be compared from one year to another and from one place to another allowing changes to be measured and trans-boundary effects considered.

3.1 Purpose

A main purpose of the EIA process is to integrate environmental considerations in the overall planning from the beginning. Environmental impact assessment aims at determining potential impacts of offshore oil and gas activities to the Arctic environment, its flora and fauna, abiotic components, and human health, security and well being, and assessing their probability and potential consequences. It does this to help inform decision making authorities at all stages of project review.

3.2 Technique and Process

The EIA process

The EIA process is a series of interactive steps, including feedback mechanisms and quality assurance procedures. Some of the main features are:

Organization:

Responsibility for coordination of the EIA process, including arrangements for logistical and financial support should be with a single organization or harmonized between appropriate entities. A first task of this group should be to define the boundaries of the assessment area and reach agreement on the timetable to be followed.

Scope:

The scope of the assessment should be comprehensive. However, it may be decided that initial assessments should give priority to environmental sectors considered to be most at risk from the planned activities. In the context of offshore petroleum activities this may be for instance particularly sensitive nesting or feeding habitats for seabirds, or spawning grounds for important fish species which may determine whether and how development takes place.

Roles and Responsibilities:

There should be a clear and accepted understanding of roles and responsibilities regarding the EIA process to ensure efficiency and avoid misunderstanding of work to be performed and associated cost requirements in keeping with the scope of the assessment.

Data Quality Assurance:

A system of quality assurance for data and their collection should be in place.

Timetable:

It is essential that the EIA process is performed according to a realistic time table agreed upon at an early stage of the process. The timeframe will vary depending on the extent and type of assessment to be carried out.

Sources of Information:

Data for EIA purposes may be gathered from existing sources (scientific literature, databases, registers, indigenous and traditional knowledge, public hearings and comments, etc.) and necessary additional information may be obtained through baseline investigations or monitoring programs.

Decision/Implementation/Project monitoring/Modification:

There should be a description of monitoring programs to determine effects, assess the effectiveness of mitigation measures and provide any early warning of adverse effects. The programs should be designed with flexibility so they can be modified to respond to unforeseen effects. These programs should be elaborated in a manner consistent with Section 4 **Monitoring**. They should also provide for the possibility of modification of an activity, where warranted. And there should be adequate time to properly conduct studies and digest and assess the scientific content of the resulting reports.

Risk Assessment and Environmental Risk Analysis:

The reason for a risk assessment or analysis is to determine if an action has an acceptable level of risk. Both regulators and industry use the information gathered through an EIA and risk analysis to make decisions on whether a proposed activity or development should go forward as planned, to institute preventative and mitigating measures to reduce risk, or to chose another alternative action.

Prior to carrying out an environmental risk analysis, risk criteria should be defined. The risk criteria should be documented and the regulator and/or operator should update the criteria during the course of operations as appropriate and necessary for enhancing the safety level and as an effort to achieve the objectives defined for the activities. Risk or acceptance criteria must at a minimum incorporate national and international laws and standards. Consultation should also include input from local communities and interested parties for risk criteria analysis. If data is insufficient to define risk criteria, then the risk assessment should also incorporate the precautionary principle as reflected in Principle 15 of the Rio Declaration.

The environmental risk analysis should be initiated as soon as practical to allow time if needed for public consultation. The analysis should be valid for the period of the year the operations will be carried out. If there is uncertainty of the timing of operations, the analysis should be valid for a longer period.

Risk associated with offshore oil and gas activities has two main elements--the risk that an event might happen, such as an oil spill, and the risk that something will be impacted, such as ecologically sensitive areas. A risk assessment should be carried out in order to estimate the risk of an acute oil spill or other event. An environmental risk analysis should be conducted to identify impact sensitivities from an acute spill or event, as well as, spills that result from routine operations, including approved discharge of drilling fluids or cuttings. The analysis of each potentially affected environmental resource should clearly distinguish between the risk of oil spills or other accident and impact severity. The risk of contact in an acute spill does not influence the impact severity. Probabilities related to acute oil spills should be estimated or modeled based on geological studies on resource estimates and distribution, development scenarios, site-specific and regional considerations, exploration and production plans, and historical data. An analysis of response strategies, techniques, and capabilities should be conducted to determine the efficacy and feasibility of oil spill response throughout the year.

The analysis also should identify the need for risk reducing and contingency measures. Requirements stipulated by or in law or regulations, including requirements for risk reducing measures and the operator's safety objectives, should form the basis for defining an acceptable level of risk.

A flow-chart depicting an environmental risk analysis scheme is represented in Annex F.

3.3 Strategic Environmental Assessment (SEA)

A Strategic Environmental Assessment (SEA) is a systematic process for evaluating the environmental consequences of a proposed policy, plan or program initiative in order to ensure they are included and appropriately addressed at the earliest appropriate stage of decision-making. An SEA involves an integrated approach.

An SEA provides decision-makers with information, strategies, and actual and projected environmental effects on a larger scale than an Environmental Impact Assessment (EIA). SEA's wider frame enables policy-makers to anticipate effects on species, habitats and ecological processes that site-specific studies do not necessarily capture. SEA also fits well with current scientific understanding in ecology and biodiversity conservation, which emphasizes the importance of ecosystems, their processes, and a multi-factor, broader analysis over a single-species or single-threat analysis.

The use of SEA is recommended on a regional basis to determine the potential environmental impacts of human activity including opening areas for oil and gas. As part of an SEA it is recommended that all available regional baseline monitoring information be used, as well as meaningful stakeholder and public involvement, and incorporation of indigenous traditional ecological knowledge.

The SEA is an ongoing process and initial analyses should be revised periodically to take into account new information and new developments. One important component of the SEA process is the analysis and tracking of cumulative impacts on a regional basis. This information in turn should be used to adjust polices, and development, accordingly.

A final function of SEA is to identify existing and potential protected areas in the region, as well as sensitive areas of biodiversity and cultural importance. This may include identification of areas where petroleum activities may be modified or prohibited. Some of these areas may already be protected; others are not. In the marine environment, any area with both sea ice and important biodiversity significance should be afforded appropriate levels of protection. This will involve regional spatial planning.

3.4 Preliminary Environment Impact Assessment (PEIA)

A PEIA (or similar process) is a screening level review that should contain sufficient detail to permit assessment of whether a proposed activity may have a significant impact and should include:

- a description of the proposed activity, including its purpose, location, duration, and intensity;
- consideration of alternatives to the proposed activity and any impacts that the activity and its alternatives may have, including consideration of cumulative impacts in the light of other existing and known planned activities;
- a determination whether significant impacts, that would require further assessment, are likely to occur; and
- consideration of input from early engagement with local communities potentially impacted from the development

3.5 Environmental Impact Assessment (EIA)

An EIA should be based on the best available information and include:

- a description of the reference/initial state of the area where the activity is to take place and identification of baseline data needs;
- an environmental risk analysis of potential impacts and a risk analysis of potential spills from

the activity. This should delineate pollution sources, transport mechanisms (including trajectories), routes and duration of exposure to species or habitats of concern;

- identification of oil spill response methods, and their respective limits of operation and tradeoff evaluations under varying environmental conditions (oil type, seasonality, ice conditions, etc.);
- the best available time series data;
- a description of the proposed activity, including its purpose, location, duration, and intensity. This includes the physical characteristics of the proposed activity and its land use requirements during construction and operation phases. It should state the main characteristics of the development process proposed, including type and quantity of materials to be used;
- the estimated type and quantity of expected residues and emission (including air, water, soil, vibration, light, heat and radiation pollution);
- the forecasting methods used to assess effects on the environment and any limitations
- on models due to lack of data, in undertaking the assessment;
- based on the above, an identification of the area of potential impact;
- the likely significant effects, direct or indirect and an evaluation of their spatial and temporal scales;
- the likelihood of transboundary impacts;
- potential socio-economic effects and the effects on traditional ways of life of indigenous people;
- a description of the measures proposed to avoid, reduce or rectify identified potential significant adverse effects, taking into consideration the recovery and regenerative capacity of the Arctic;
- an accounting with the principles of conservation biology, including disturbance and cumulative effects;
- other development options, and where authorities prepare the analysis, this may include the alternative of no action. This discussion should include an evaluation of the different alternatives and the reasons for choosing the selected activity;
- a summary in non-technical language, assisted with figures and diagrams, of the information specified above. If need be, other means of displaying this information, based on cultural heritage of the local and indigenous residents should be prepared;
- an assessment of all associated sources of noise, including seismic or other testing equipment, vessels, aircraft, drillships, drilling operations, and ice-breaking equipment and their potential effects on fish, marine mammals, and other wildlife including cumulative effects;
- an assessment of human health effects involving a systematic consideration of public health status baseline and analysis of oil and gas activity; and

- integrate the results of the Arctic Climate Impact Assessment and other research into the evaluation of possible impacts of oil and gas activities and infrastructure in the Arctic Ocean.

3.6 Consultations and Hearings

Consultation is an effective dialogue between and amongst regulators, potential operators and stakeholders. In general, consultation should commence at the planning stage and continue throughout the lifetime of a project. It ensures transparent interaction and minimises potential risks for all parties. Consultation also provides a mechanism to resolve disagreements and provide appeal rights to all parties. Consultation is generally thought of in terms of public hearings, but it can also work effectively through informal discussions, focus group and key interviews and questionnaires. There is no single, standard approach to consultation, however some guiding principles promote effective consultation. These include:

- effective consultation is two-way;
- identifying and building relationships with potential consultees can take considerable time;
- consultation programmes are integral to project planning and decisions making;
- there are limits to the consultation process; and
- consultation should be open and transparent

Collection and review of information from publicly available sources and stakeholders is important and continuous through the life of a project. Such information, including vital indigenous and traditional knowledge can enhance the understanding of the project on all sides, including its social setting, the stakeholder community and the issue and values that are important to those stakeholders.

To ensure that various deliberative processes protect social and environmental values, timely release and dissemination of critical information to potentially affected parties is essential. In order to ensure that local communities are informed and involved in all appropriate phases, alternative methods for communicating information such as translation into indigenous languages, multimedia, radio, TV, public meetings, etc. should be explored.

States should consult and cooperate with the indigenous peoples concerned through their own representative institutions in order to understand and integrate their needs and concerns with any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources, such as oil and gas.

4 Environmental monitoring

4.1 Aims and Objectives

The operator should carry out environmental monitoring to ensure that the basis for decision-making and the knowledge about the marine environment are sufficient to maintain acceptable environment conditions as a result of petroleum activities. Sufficient information should be obtained to see that all pollution and disturbance caused by the activities is detected, mapped, assessed and alerted so that necessary measures can be implemented.

Environmental monitoring implies systematic and regular examinations to document the state of environmental resources, describe the risk of pollution and disturbance and keep a check on their effects on marine resources.

Marine environment means sea, coast, shore, seabed, water column and environmental resources.

Environmental resource means naturally occurring or natural biotic and abiotic components which may include one or more species, biotopes and/or types of nature in a marine environment.

Environmental monitoring entails:

- establishing a basis for identifying environmental responses and trends;
- mapping of critical conditions and parameters for risk, transportation and spreading of pollution;
- measuring possible effects of disturbance and noise on marine habitats and organisms
- mapping of impact on environmental resources;
- helping to identify and assess geological and engineering hazards;
- assessing whether the observed environmental impacts are in line with the forecasted and accepted environmental impacts identified in the EIA; and
- compiling information to aid future decisions about where, when, how and if oil and gas activities should be allowed to occur.

Environmental monitoring should measure physical, chemical, and biological conditions that may impact or be impacted by the activities being conducted. Before activities commence, environmental monitoring should begin with a comprehensive baseline investigation, which should incorporate existing information, and comprise as a minimum all monitoring sites and variables planned to be used in the long term monitoring program. The environmental monitoring program should continue through the decommissioning and reclamation phases.

Environmental monitoring should preferably be conducted so as to distinguish impacts due to oil and gas activities from other relevant sources. Environmental monitoring should be carried out regionally and be integrated so that interactions between multiple activities may be more easily detected. The type of monitoring conducted depends on the specific type of activity anticipated and the nature of the environment that could be affected.

Priority monitoring should comprise the following areas during all phases of oil and gas activities to assess and minimize or mitigate adverse effects:

- environmental accounting of emissions to air, discharges to water and sea floor and emissions of noise;
- natural and industrial hazards in the region of activities including seismic and extreme weather and ice events;
- physical disturbance to sea floor, benthic communities, fish, ice edge communities and the sea shore, and effects on species populations, distribution and migration routes;
- levels of contaminants such as heavy metals, total hydrocarbons, polyaromatic hydrocarbons, phenol, barium, and POP's in bottom sediments and the water column;
- and their effects on living marine resources, seabirds and other wildlife, with particular attention to vulnerable life stages and areas of critical habitat;
- effects of petroleum activities on local human populations, subsistence access and harvest and other human activities;
- environmental effects on the integrity of the infrastructure;
- subsistence hunting and fishing activities such as the timing, position of harvest, search areas, and species, to aid in conflict avoidance; and
- acoustic monitoring of marine mammals in case of potential significant impact.

The type and content of environmental monitoring will vary depending on the phase of the activity. Exploratory drilling and production activities will demand different monitoring emphasis.

Environmental monitoring programs should be reviewed on a regular basis to determine whether the results they are yielding indicate a need for changes in operational practices (for example, as a result of failing to achieve the initial hypotheses set out in the EIA or because of unforeseen impacts). Programs should also be reviewed to determine whether they should continue, be modified or terminated. Ultimately, the length and breadth of environmental monitoring programs will be determined by the scale and duration of offshore oil and gas activities and the immediate or longer-term impacts.

The main emphasis of the baseline survey and/or EIA should be to make a complete inventory of environmental resources that may be affected by the planned petroleum activity and identify resources, areas or uses particularly sensitive to the various phases of the petroleum activities. Some resources may be sensitive to acute or continuing discharges/emissions even at sub-lethal concentrations. Both types may have effects on local biological communities, directly or indirectly through effects on the ecosystems.

Programs for identification and understanding of spatial and temporal distribution of biota particularly sensitive to pollution/discharges and emissions from petroleum activities should not only include adult stages and established communities (e.g. seabird feeding grounds, shoreline communities) but also early stages in the life cycle of plants and animals including larval stages, which may be more vulnerable to oil and chemicals than adult stages, if they are spatially or temporally relevant. Such programs should also consider acute and long-term chronic exposures. Therefore, not only vulnerable species should be identified prior to setting up a monitoring

program, but particularly sensitive life stages should also be identified.

4.2 Environmental monitoring methods

Environmental monitoring of trends in levels of contaminants in sediment, water, ice/snow and biota has been the traditional way of monitoring impacts of pollutants on environment. This is still the backbone of most monitoring programs, since reliable trend data are needed both to document changes in the environment as the result of the activities and as a basis for the prediction of future changes.

Monitoring should not only measure the level of potential pollutants in environmental compartments, but also the potential effects these might have on living resources. These effects may be monitored by recording changes in biodiversity over time or by measuring effects on single indicator species. Such methods, including the use of biological indicators, could give early warning of negative changes in the environment. Methods for monitoring effects should be an integrated part of monitoring programs.

The monitoring programs should not only be centered around field monitoring, but also include laboratory experiments and combinations of laboratory experiments and field studies whenever relevant.

4.3 Standards and Practices for Environmental Monitoring

Monitoring standards and practices for environmental monitoring should be established for all phases of offshore petroleum activities, including offshore seismic operations and marine transportation. Environmental monitoring activities should occur before any activity in the area, during drilling, development, production, decommissioning, and reclamation, as well as during transportation of oil, gas, supplies and personnel.

Most monitoring should have a long-term perspective showing developmental trends, and should form the basis for predicting what impacts to expect in the years to come. Monitoring surveys should be more frequent during the first years of investigation until the main impacts and trends are clarified and then as frequent as necessary in subsequent years. Environmental accounting and budgeting should be part of the monitoring system, showing the type and quantity of chemicals and substances that are used and discharged, what environmental impacts have been monitored, and what might be expected in subsequent years.

Requirements for monitoring should be defined in each country's legal and regulatory framework.

Environmental monitoring should start with a baseline survey establishing pre-activity population structure, distribution and size; habitat status; and existing level of contamination in the environment and biota. This information is essential if previous introductions of the contaminant in question have already taken place either naturally or from human activity. Usually, environmental monitoring will be the chemical measurement of the level of the contaminant in the air, water, ice/snow, sediments, or biological tissue. The levels found are then compared to applicable criteria such as baseline data or appropriate standards. The ultimate goal, however, must be to measure the effects of contaminants on organisms.

Monitoring of contamination levels related to petroleum activities should take into account the source of the contaminant, the potential routes of transport (e.g., aqueous, particulate, or air borne) and the potential pathways for bioaccumulation. Besides the contaminant in question and the particular processes that might be involved, other considerations may include: wind strength

and gustiness; ocean currents; relevant river flow; precipitation; air temperature; ocean temperature; sea ice conditions and movement; water depth; sea surface state; subsurface geology; and other resources affected.

Data from environmental monitoring should be harmonized in collaboration with AMAP and could be collected and stored in Arctic database repository, such as Circumpolar Biodiversity Network and GINA (Geographical Information Network Alaska), Arctic Ocean Observatory, and others, where it would be available freely to all national environmental protection and monitoring authorities and to other users.

Whenever appropriate, operators should consider local indigenous populations for contractual monitoring activities as well as drawing upon indigenous and traditional knowledge for the identification of historical environmental extremes and trends. Establishment of cooperative relationships with resident indigenous communities for biological sample collection, environmental observation and monitoring, should be pursued.

Results have shown that air emissions from the offshore installations may have an impact on nearby land areas and the results of any monitoring of these impacts should be included in updated monitoring guidelines.

For an example of guidelines for environmental monitoring of oil and gas activities refer to the OSPAR Convention (see references).

Air quality monitoring should include identification and reporting of all air pollution sources, emissions of priority air pollutants including nitrogen oxides, carbon monoxide, volatile organic compounds, PAHs, ozone, etc. and hazardous and toxic substances.

4.4 Following up environmental monitoring

Results of environmental monitoring should also be utilized by regulators in compliance audits and on-site regulatory supervision as the basis for requiring any modification, postponement, or shut-down of operations or specific components of an operation and also as a basis of revising legislation when necessary. Monitoring activities can be conducted in conjunction with environmental audits to verify that the equipment and procedures associated with an operation are functioning within design parameters and will not lead to any significant impact on the environment.

Authorities should use environmental audits to verify that the results of monitoring are used by the petroleum companies and reflected in their environmental strategy (see Annex H, Examples of Generalized Monitoring Plans).

Results from environmental monitoring should be used by regulators in evaluating whether the legislation and specific requirements that apply is adequate and sufficient, and take action to change this if needed.

5 Safety and Environmental Management

Two basic regulatory approaches are available for dealing with the safety and environmental aspects of offshore Arctic oil and gas operations. They are: (A) a performance-based system and (B) a prescriptive approach.

(A) In the performance based approach, the regulator sets specific quantifiable goals but does not specify how the operator must meet these goals. This system allows the operator the flexibility to specify how they intend to comply with a regulatory body's mandate that operations be conducted safely and in an environmentally sound manner. There are a variety of approaches available to the operator to meet the intent of this alternative, including the use of technical standards, company guidelines, "safety case" initiatives, or combinations of the above.

(B) The prescriptive approach to regulation is based on a series of specific regulatory requirements, which typically represent minimal expectations on behalf of the regulatory body. This approach can be complemented by a performance-based program. Under the prescriptive system, a regulatory body normally develops requirements addressing all phases of offshore operations. The requirements are typically developed from a series of existing standards, practices, guidelines, and procedures. Compliance with these requirements are normally evaluated by a regulatory body through review and evaluation of a series of plans, permits, and related documents and through a system of field based inspections and evaluations.

Either regulatory approach, performance or prescriptive, can be modified to form a 'hybrid" system of regulation, composed of appropriate elements from both regimes. Such a system of regulation may represent a viable alternative for a regulatory body to consider adopting due to the systems' ease of operation and flexibility.

Today, there has been significant interest by both the offshore oil and gas industry and the various regulatory bodies to adopt, when applicable, appropriate international standards as a component of a regulatory system (performance, prescriptive, or hybrid). Use of these international standards addresses the fact that more often than not, regulators are regulating a global industry and there is value in using global standards wherever practical.

In either approach, before oil and gas activities are approved, regulatory bodies should require the operator to demonstrate financial capacity to carry out all aspects of the operation, including responding to environmental emergencies and decommissioning of facilities. This should also include the proven ability to adequately clean up oil spills.

There are many similarities between the two systems of regulation. An important management tool to assist the operator in meeting the regulatory objectives of either system, eliminating unsafe behavior, and achieving continual improvement in safety and pollution prevention practices is defining and communicating a culture focus on safety and environmental performance to the workforce and ensuring that they are fully motivated to implement it through a management system. This philosophy can also be applied to a hybrid regulatory program. See Annex G.

Management Systems

Proper planning to address the environmental sensitivities of a project and to ensure safety of the work force is essential. Whether required by the regulator or conducted voluntarily within industry, environmental and safety planning should be contained in a formal management system. Often referred to as EMS (Environmental Management System), HSEMS (Health and Safety and Health Environmental Management System) or SEMP (Safety and Environmental Management Program) these systems focus attention on the influences that human behaviour and organization have on accidents. Various types of management system documents have been developed around the world with applicability to the offshore oil and gas industry. These include; American Petroleum Institute (Recommended Practice 75), the International Organization for Standardization (ISO 14000 and 9001 series) and Oil and Gas Producers (OGP) and UNEP/OGP publications.

These systems all have as a common and central feature a cyclic process involving sequential consideration of:

- policy and strategic objectives;
- organization, resources and documentation;
- risk evaluation and risk management;
- planning;
- implementation and monitoring; and
- auditing and review

Each step of the cyclic process requires leadership and commitment by the implementing body and the principal aim of the system is to deliver continual environmental, safety and health performance. This is assessed by periodic audit or review of a management system's performance to ensure that necessary components are in place and that they are effective.

The key elements of a management system can be described as follows:

5.1.1 Policy and Strategic Objectives

The operator's management should define and document its safety and environmental policies and strategic objectives and ensure that these:

- have equal importance with the operator's other policies and objectives;
- are implemented and maintained at all organizational levels;
- are publicly available;
- commit the operator to meet or exceed all relevant regulatory and legislative requirements;
- commit the operator to reduce the risks and hazards to health, safety and the environment (HSE) of its activities, products and services; and

- provide for the setting of safety and environmental objectives that commit the operator to continuous efforts to improve performance.

The operator should also take steps to ensure that all contractors engaged in operations are also able to meet the requirements of the operator management system and applicable laws and regulations.

A more detailed and specific list of possible objectives is set out in Annex G.

5.1.2 Organization, Resources and Documentation

Successful management of safety and environmental matters is a line responsibility, requiring the active participation of all levels of management and supervision. This should be reflected in the organizational structure and allocation of resources. The operator should define, document and communicate - with the aid of organizational diagrams where appropriate - the roles, responsibilities, authorities, accountabilities and interrelations necessary to implement the HSEMS and meet regulatory responsibilities. The operator should also stress and encourage individual and collective responsibility for safety and environmental performance to all employees. It should ensure that personnel are properly trained, competent, and have necessary authority and resources to perform their duties effectively.

5.1.3 Evaluation and risk management

The operator should maintain and implement procedures to identify systematically the hazards and potential effects, which may affect or arise from project inception through to decommissioning and disposal. Procedures should be maintained to evaluate (assess) risk and potential effects from identified hazards against screening criteria, taking into account probabilities of occurrence and severity of consequences for:

- People;
- Environment; and
- Assets.

The operator should maintain procedures to select, evaluate and implement measures to reduce risks and effects throughout the project. Risk reduction measures should include both those to prevent incidents (*i.e.* reducing the probability of occurrence) and to mitigate chronic and acute effects (*i.e.* reducing the consequences). In all cases, risks should be reduced to a level deemed as low as reasonably practicable, reflecting amongst other factors, local conditions and circumstances, the balance of costs and benefits and the current state of scientific and technical knowledge.

5.1.4 Planning

The operator should maintain, within its overall work program, plans for achieving environmental objectives and performance criteria. These plans should include:

- a clear description of the objectives;
- designation of responsibility for setting and achieving objectives and performance criteria at each relevant function and level of the organisation;
- the means by which they are to be achieved;

- time scales for implementation;
- programs for motivating and encouraging personnel towards a suitable HSE culture;
- mechanisms to provide feedback to personnel on environmental performance;
- processes to recognise good individual and team environmental performance; and
- mechanisms for evaluation and follow-up.

The operator should develop, document and maintain and review plans and procedures for responding to emergencies. These plans and procedures should reflect site-specific characteristics. In order to assess effectiveness of response plans, the operator should maintain procedures to test emergency plans by scenario drills and other suitable means at appropriate intervals. Plans should be revised and updated as necessary in light of experience gained. Plans should be available to the affected communities and the public at large.

5.2 Compliance Monitoring, auditing and verification

Compliance monitoring, which include carrying out audits, inspections and verifications, are key activities for the authorities when it comes to following up the petroleum activities in the Arctic.

Compliance monitoring may be carried out within a variety of organizational frameworks. For example, the recommendations of the European Parliament and Council provides for minimum criteria for environmental inspections in the European Union (EU).

The regulatory supervision should cover all stages of design, fabrication, installation, operations and removal of offshore installations. It should address all relevant parts of the operating company's management systems, such as procedures for ensuring compliance with legislation, licences, permits, and approved plans, as well as how the carrying out of activities are documented and reported. The regulatory supervision should also encompass the company's systems for pollution control and environmental monitoring, drilling and well operations techniques, production, and pipeline operations.

Representatives of the regulatory agencies should have the legal base to take appropriate action in case of violations, noncompliance, or if the operator fails to react adequately to dangerous situations. These actions can include issuing warnings, injunctions, shutting down specific operation, a complete shut-down of the installation, withdrawal of environmental licence or permit, or initiating prosecution by the relevant authority.

Authorized and qualified representatives from the regulatory agencies should have the legal base to access the installations and to see all relevant documentation and equipment at any time. The operating company shall provide for, as far as practical, the accommodation and necessary transportation.

Compliance monitoring may be carried out regularly as a part of a programme, or unscheduled in response to complaints, in connection with the issuing, renewal or modification of an authorisation, permit or licence, or in the investigation of accidents, incidents and occurrences of non-compliance. The frequency and extent of such activities should be decided by the regulatory agencies.

The regulatory agencies should establish plans for these supervisory activities. The extent and the issues to be covered should be based on the relevant regulatory requirements, the previous

experience with the operators' compliance, environmental and geologic conditions, the type of activity carried out by the operator, the type of technology applied, reported accidents and incidents, and general knowledge regarding the operator and its ongoing activities. The plans should be available to the public.

Procedures should be maintained for compliance monitoring to:

- determine whether environmental management system elements and activities conform to requirements in the legislation, and are implemented effectively;
- examine line management systems and procedures, field operations, internal compliance monitoring practices, and data to see if they fulfill the company's environmental policy, objectives, and performance criteria;
- review incident reporting and remedy schemes in relation to incidents that have occurred;
- find out how identified current and potential environmental problems have been dealt with by the operator and how this is reflected in the environmental management system;
- determine compliance with relevant legislative and regulative requirements;
- identify areas for improvement, leading to progressively better environmental performance; and
- formulate the conclusions in a report, which must be well documented.

Reporting and evaluation of compliance monitoring activities

The reports from compliance monitoring activities should include the following information:

(a) legal basis for carrying out compliance monitoring;

(b) background for carrying out the specific monitoring activity;

(c) issues covered during the inspections or audits;

(d) non-compliances or deviations found, as well as other observations;

(e) requirements regarding correcting non-compliances or deviations, including time lines and needs for reporting back to the authorities; and

(f) listing parties taking part in the inspections or audits.

The reports should be available to the public.

To prevent illegal cross-border environmental practices, the coordination of inspections with regard to installations and activities which might have transboundary impact should be encouraged.

6 Operating Practices

6.1 Waste Management

Offshore oil and gas activities produce a variety of wastes in the form of aqueous and solid discharges and atmospheric emissions that need to be managed to avoid air and water pollution, smothering of benthic communities, and contamination of materials and food sources. Waste management should be included in the overall planning from the beginning and combined with pollution prevention measures. Prevention and elimination of these discharges and emissions, which pose pollution threats to the Arctic environment, should be a targeted goal of regulatory activity. New technology makes this goal achievable in some situations. Arctic governments should set discharge standards.

The operator should to the extent possible avoid generation of waste. Any waste generated should be handled in an environmentally and hygienically adequate manner. Solid waste should not be discharged into the sea.

The operator should prepare a plan connected to waste, including possibilities for waste reduction, waste segregation, reuse, recycling, energy recovery or treatment. The need for enhanced onshore infrastructure should be looked into.

Transfer of pollutant from one media to another should be avoided, based on risk assessment.

Examples of Recommended Preventative Management Techniques:

- consider no discharge of the main waste streams at the planning and construction stage, in particular drilling waste and produced water;
- reduce waste at the source by process modification, material elimination, material substitution, inventory control and management, improved housekeeping, and water recovery;
- reuse of materials or products such as chemical containers, and oil-based or synthetic-based drilling fluids;
- recycle/recovery by the conversion of wastes into usable materials and/or extraction of energy or materials from wastes such as recycling scrap metal, recovery of hydrocarbons from tank bottoms and other oily sludge, burning waste oil for energy, and the use of produced water for enhanced recovery;
- reduce toxicity of effluents through the careful selection of drilling fluids and chemical products used in separation equipment and wastewater treatment systems;
- perform radiation surveys of equipment and sites to prevent or minimize the spread of Naturally Occurring Radioactive Materials (NORM); and
- where NORM-scale formation is anticipated, use scale inhibitors to minimize or prevent the buildup of radioactive scale in tubulars.

Management Techniques for Drilling Wastes and Production Effluents

Waste from Drilling Activities

Drilling wastes in the form of residual drilling fluids and cuttings comprise the principal wastes generated during well drilling. Initially, a determination needs to be made on whether or not to prohibit discharge based on the nature/volume of the discharge and its effect on the environment. In certain areas, due to identification of environmentally sensitive areas drilling fluids and cuttings may need to be managed in a manner that will prevent discharge. In areas where discharge is permitted, the method of disposal should be based upon careful consideration of drilling fluid formulation and specific environmental conditions at the site.

Where water-based drilling fluids are employed, additives containing oil, heavy metals, or other substances with negative ecotoxicological properties should be avoided or removed prior to discharge. Persistent and toxic substances should be avoided. Criteria for the maximum allowable concentration of harmful or hazardous substances should be established. If the option of land disposal is used, then both the properties of the drilling fluid and the environmental conditions at the proposed disposal site should be carefully considered to determine acceptability of the disposal site. This is particularly important in the arctic where creation of a disposal site on land may lead to greater environmental damage.

Environmental considerations favor the use of non oil-based drilling fluids for drilling. In shallow portions of a well, saltwater and saltwater with clay are often used as the primary drilling fluid and the cuttings and residual fluids can generally be safely discharged into the marine environment.

Discharge to the marine environment should be considered only where zero discharge technologies or reinjection are not feasible. Based upon site-specific biological, oceanographic and sea ice conditions, risk assessment methods should be used to determine whether the discharges should be at or near the sea floor or at a suitable depth in the water columns to keep impact on marine life as low as possible. These discharges should be considered on a case-by-case basis.

Where the use of non-aqueous fluids is required, for example in highly deviated wells or in certain geological formations, operators should ensure that the content of harmful or hazardous components is as low as possible, and that fluids are recycled as far as practicable. Disposal of cuttings contaminated with such fluids should be assessed on the basis of a comparative assessment of alternatives, including re-use of the material, injection into geological formations and discharge on to the sea bed taking into account possible impacts on the sea and other environmental compartments.

Spent oil-based or synthetic-based drilling fluids can often be reconditioned and recycled. Injection into disposal wells or encapsulation of reserve fluid pits containing drilling fluids and cuttings, including those with acceptable levels of NORMs, and other pumpable wastes, are potential disposal techniques. Where geological conditions permit, reinjection of wastes into the reservoir achieves a significant reduction of discharges to the marine environment of cuttings and drilling fluids. Management of down-hole disposal will require diligence to ensure that wastes do not migrate into unsealed or undesirable stratigraphic zones and that well integrity is maintained. Stabilized burial at approved onshore disposal sites is another alternative.

Production Waste Discharges

During production, produced water can be properly treated and discharged or may be reinjected. Other fluids, which are brought to the surface in connection with completion, work over, well

treatment or production, may be mixed with waste waters, unless those waters are identified as hazardous waste at the time of injection. In most cases they can be commingled with produced water for treatment and discharged within acceptable limits or reinjected.

Produced water treatment should be taken into account in the design phase and when significant modifications in operations are carried out. As characteristics of production water differ from one platform to another, there is no single system that can be applied successfully to all offshore platforms. Therefore, a site-specific combination of technologies should be employed based on the characteristics of produced water such as droplet size, stability of emulsion, ratio of droplets/dissolved hydrocarbons, and the presence of other substances such as corrosion inhibitors, solids, and naturally occurring substances.

Regulators and the industry should give consideration to the options for reduction and possible elimination of produced water discharged to the sea through the application of BAT, for example, injection, down hole separation or water shut-off. The focus should be on reducing the volume of discharges of produced water with the highest loads of oil and other substances.

Regulators and industry should ensure that BAT and BEP are implemented on each platform and that BAT and BEP are regularly reviewed. In addition, regulators and industry should ensure that new offshore platforms or major modifications to existing platforms should consider design changes that minimize discharges, and preferably aspire to produced water not being discharged at all.

Produced sand containing elevated levels of naturally occurring radioactive material should be re-injected, encapsulated, or removed from the site and stored in a safe and environmentally sound manner that is carefully controlled and whose risks and circumstances have been properly evaluated. Management of these wastes will require diligence to ensure that radioactive wastes taken to shore are handled and disposed of in accordance with applicable international law and in an appropriate and approved manner. Radioactive materials should be transported in approved containers with proper labeling, which identify the substance and its special transport and handling requirements. Appropriate record keeping and proper notification for shippers should be maintained.

Deck wash and chemical/fluid releases are another concern to the marine environment, especially where oil-based drilling fluids are in use. A facility plan should be developed to address these potential conditions and methods of spill control and leak minimization should be incorporated into facility design and maintenance procedures. These plans, minimization efforts and controls shall be applied to, but not limited to, material storage areas, loading and unloading operations, oil/water separation equipment, wastewater treatment, waste storage areas, and facility runoff management systems.

All washdown waters, hydrocarbon contaminated rainwater and deck wash, and machinery drainage space fluids should be either processed through an oil-water separator prior to overboard discharge, meeting MARPOL 73/78 requirements, or equivalent, or injected where possible.

Fluid Waste from Well-Testing

There may be oil or water containing oil which will not be completely incinerated when flaring during well testing. The regulators must determine whether this may be discharged into the sea, and if so, the quality of the fluid which is allowed discharged. One possibility is to allow discharge after treatment, if the quality of the water is similar to the discharges from produced water or drainage water.

Solids and Domestic Wastes

Disposal of solid and domestic wastes should be done in conformity with international law, such as MARPOL 73/78, and national legislation.

Sanitary Waste

Sanitary wastes such as sewage and gray waters should be processed according to international or local government standards prior to discharge into the marine environment. Processing in an acceptable sanitary waste treatment unit will generally properly treat waste streams prior to discharge.

Hazardous Waste Handling and Disposal

The most effective way of protecting human health and the environment from the dangers posed by hazardous wastes is to ensure the reduction of their generation to a minimum in terms of quantity and/or hazard potential. Minimizing the generation of hazardous wastes requires the implementation of environmentally sound low-waste technologies, recycling options, good housekeeping and management systems. Necessary measures should be taken to ensure that management of hazardous wastes is protective of human health and the Arctic environment.

The availability of adequate disposal facilities should be ensured prior to allowing an activity to generate hazardous wastes. Hazardous wastes requiring transport to a disposal site should be packaged, labeled, and transported in conformity with generally accepted and recognized international rules and standards in the field of packaging, labeling, and transport. Due account should be taken of relevant internationally recognized practices. Transported hazardous wastes should be accompanied by a movement document from the point at which movement commences to the point of disposal.

6.2 The use and discharge of chemicals

The use and discharge of chemicals from the oil and gas industry should be strictly regulated to avoid or reduce possible negative effects on the marine environment.

The amounts of chemicals used and discharged should be as low as possible.

All substances in chemical preparations should be tested for their ecotoxicological properties such as potential for bioaccumulation, biodegradation rate and acute toxicity. The tests should be performed by laboratories that are approved in accordance with established international standards, for example, OECD's principles for good laboratory practice (GLP) or equivalent.

Biodegradability

The substance should if possible be tested in accordance with established standards, for example, the seawater test OECD 306 "Biodegradability in Seawater" or equivalent.

Bioaccumulation

Chemicals that consist of several substances should be tested for the individual organic substance's bioaccumulation potential. The substances should be tested according to established standards, for example, OECD standards or equivalent. For substances where standardised tests are not applicable, as for surfactants, a calculation or a scientific evaluation of the bioaccumulation potential may be performed.

Acute toxicity

Inorganic and organic chemicals should be tested for acute toxicity. Toxicity tests specified in the OSPAR *Protocols on methods for testing of chemicals used in the offshore industry* may be used.

Assessing chemical risk

The operators should ensure that risk evaluations are done based on the chemicals' intrinsic properties, time, place and amounts of discharge, and also other conditions of significance for the risk. The operator should choose the chemicals which according to environmental risk evaluations poses the lowest risk of harming the marine environment.

The operator should have plans to ensure that hazardous chemicals are substituted with substances which pose less risk of harm to the environment. The plans shall give a description of which chemicals are prioritized to replace, and when this can take place.

Chemicals should be stored in a safe and prudent way.

6.3 Emissions to air

Air emissions associated with oil and gas exploration and production activities can be generally categorized as arising from three activities: (1) the combustion of fuels for power generation; (2) emissions arising directly from the production, treatment, storage or transportation of produced oil and gas, and (3) flaring of gas.

Energy efficiency

Overall emissions reductions can best be achieved through programs that emphasize energy efficiency and conservation in all activities, exploration (survey and exploratory drilling), development (construction and drilling), production, and transportation. Such programs can also encourage the use of energy effective technology (turbines with high power efficiency, waste heat recovery units when heat demand, dry low emission turbines etc.)

Policy instruments to reduce emissions/discharges from petroleum activities

The regulators can apply terms and conditions when awarding licenses, as requirements connected to EIAs, in emission or discharge permits, and/or in production permits. Such terms may include taxes on emissions of CO_2 and NOx.

Using such economic measures may be used to enhance power generation efficiency and reduce emissions.

Emissions from flaring

If associated gas is flared, this may be a significant source of emissions to air. To reduce the amount of gas flared from an offshore installation is beneficial both from and environmental point of view, but also can help avoid potential waste of resources and reservoir energy.

There may be a need for specific licenses or permits covering flaring of gas. Flaring permits can be issued after a thorough assessment of environmental considerations and evaluations in accordance with technology, economy, resources, safety, infrastructure, jurisprudence etc. The regulators should early in the process of awarding licenses specify what the operators must expect with regard to limiting flaring of associated gas. Some gas may be utilized for power production

at the installation, but if a large amount of gas is produced, possible solutions may be injection into the reservoir or export through pipelines. Every effort should be made to flare only where necessary for safety purposes.

The planning and execution of activities regarding flaring reduction is extremely time consuming and cost intensive. This has to be taken into account in the early phases of deciding on the production strategy of the field. Technologies that could be used for reducing emissions from flaring may be *closed flare* technology and/or *flare gas recovery* systems.

VOC emissions

Offloading and storage of oil is an emitting source of volatile organic compounds. Emissions of such non methane volatile organic components (nmVOC) can be significantly reduced by applying technologies for nmVOC recovery. These can be condensation, absorption or adsorption technologies, and can be installed at storage ships and shuttle tankers.

Best Available Techniques (BAT)

All large combustion plants offshore (both existing and new) should apply integrated prevention and reduction of pollution. This implies application of Best Available Techniques (BAT). Regulators should refer to BAT when discharge limits are set in the discharge permits, and reflect what levels of reduction can be achieved without a definite resolution on what technology to use. Instructive reference documents (see reference) for guidance on what to consider as BAT has been developed. These reference documents will inform the relevant decision makers about what may be technically and economically available in order to improve the industry's environmental performance and consequently lead to environmental improvements. The reference documents can be considered as guidelines for considerations regarding BAT.

When making plans for development of new fields, it is important to take into consideration the need to reduce emissions to air. It is important that operators inform the regulators on BAT considerations at an early stage in the development. The operator should as early as possible, for example in the EIA document that BAT has been considered (e.g Dry Low Emission turbines, power co-ordination, and waste heat recovery if heat is needed).

6.4 Design and Operations

Offshore oil and gas activities should make use of the best available and safest technologies as appropriate and be conducted in a manner to minimize impact on the environment. Operators should identify technologies and procedures to be employed for each step of the process from prospecting to exploration, development, production, platform decommissioning, and site clearance. Regulators should examine technologies and procedures proposed for use by operators and their adequacy to ensure that they are appropriate for the Arctic.

Of primary importance is the need to ensure that wells remain under control at all times during drilling, well-completion, production, and well-workover operations. This capability must be maintained even while operating under extreme conditions.

When planning an offshore oil and gas operation, a risk analysis may be used as a tool to identify potential hazards and prevent personal injuries, loss of human lives, and pollution of the environment. Criteria used for conducting such an analysis should be based on local regulatory requirements, local environmental conditions in the area of operation, and the planned operational activity.

A risk analyses should:

- address prevention of injuries, loss of human life, and pollution of the environment;
- include risk criteria that has been defined prior to conducting the analysis and document the evaluations forming the basis of the acceptance criteria;
- be used to follow the progress of activities in planning and implementation;
- identify risk that has been assessed with reference to the acceptance criteria, form the basis of systematic selection of technical operational and organizational risk to be implemented;
- be updated on a continuous basis and included as part of the decision making process; and
- systematically follow-up implemented risk reducing measures and assumptions made in the analysis to ensure safety within the defined criteria.

Technology

Offshore platforms and other structures used for oil and gas activities in the Arctic should be designed, built, installed, maintained, and inspected to ensure their structural integrity taking into account the site-specific environmental conditions. Standards exist for the construction of fixed offshore platforms, including those constructed of steel and concrete; mobile offshore drilling units; and floating production, storage and offloading units (FPSOs). (FPSOs should be double hulled). Standards, such as those under the International Organization for Standardization (ISO), are under development for offshore artificial islands including those constructed of sand, gravel and ice. In iceberg-prone areas, provision should be made for the emergency removal of removable installations.

Employment of effective well control technology and practices including incident drills and exercises will lower the risk of blowouts and unintended release of other hazardous substances. Blowout preventers and related equipment should be suitable for operation in subfreezing conditions. Drilling fluids, well casing programs, cements, emergency well shut-in procedures and well safety programs should also be suited to Arctic conditions including moving ice and possible subsurface permafrost.

Pipelines should be installed, operated, and maintained in a manner that minimizes disturbance of sea floor habitat and does not unreasonably interfere with other uses of the sea floor in the area. Pipelines should be installed only after a thorough survey of the seafloor for hazards or cultural resources. Design of offshore Arctic pipelines should follow recommended practices such as those from Det Norske Veritas or the American Petroleum Institute and take into account factors such as thaw settlement, near shore strudel scouring, and ice keel gouging. Pipe properties, instrumented internal inspection techniques, leak detection systems and techniques, cathodic protection, and preventive maintenance must also be considered in the design of Arctic pipelines.

Procedures

Procedures relevant to the special conditions in arctic areas should be worked out as a part of the operator's management system.

Operators should submit a summary of the proposed project at the outset, followed by more detailed information prior to the initiation of each major activity, such as the drilling of a well. The application should describe all procedures to be employed, including those necessary to prevent harm to life and the marine environment. Special attention should be paid to operations in

offshore areas underlain by permafrost.

Safe work procedures should be developed for all phases of the proposed operations, including construction activities, transportation, equipment operation and maintenance, safety tests and drills. For example, well-control exercises should be conducted regularly for each crew to develop an adequate level of response proficiency to conditions threatening a blowout. Exercises should cover a wide range of situations. As appropriate, procedures should also be developed to ensure that hot work, welding, burning, cutting, and other operations with the potential to cause ignition of flammable vapors are conducted safely. Safe work procedures may also be developed for cold work such as use of radioactive material, trenching and excavating, and work on fire suppression, gas detection or emergency shutdown devices. These procedures may include issuance of a work permit.

Procedures should be developed to protect personnel from the toxic effects of hydrogen sulfide, if it is encountered during drilling and production.

Decommissioning, and site clearance are discussed in Section 8 (**Site Clearance and Decommissioning**). Operators shall incorporate into the design of an installation needed measures to ensure that removal of the installation can be accomplished without causing significant impacts on the environment.

6.5 Human Health and Safety

Threats to human health and safety including unsafe working conditions are factors contributing to accidents that could lead to environmental pollution. Possible threats or hazards affecting the health and safety of personnel in Arctic offshore oil and gas activities take many forms and comes from multiple sources. Principal sources include, but are not limited to, the harsh Arctic environment, the structural integrity of the installation, blowouts, fire and explosions, equipment failure, the transfer of personnel and supplies, and drilling, production, well completion, and workover operations.

All offshore activities should be conducted in a safe and skillful manner and equipment maintained in a safe condition for the health and safety of all persons and the protection of the associated facilities. All necessary precautions should be taken to control, remove, or otherwise manage any potential health, safety or fire hazards.

Management System and Work Procedures

One way to manage potential risks is through the use of an appropriate management system. A management system or plan should address the identification of potential hazards, the evaluation of risks to the health and safety of personnel and procedures to eliminate or reduce health and safety risks (See 5.1 **Management Systems**). Management plans should:

- identify and recognize significant health and safety risks;
- evaluate significant health and safety risks;
- plan and implement actions/procedures to manage risks;
- review and test preparedness and effectiveness on a regular basis;
- establish clear lines of communication with personnel;

- provide training to personnel;
- identify appropriate personnel protection equipment; and
- communicate contents of the management plan to all personnel.

Operators should ensure that all contractors pursue established safe working environment objectives. Safe working procedures should be established for all persons, including contractors, to ensure safe working conditions for all offshore activities. In addition work permits may be required for specific work activities including hot work, cutting, and welding (see 6.4 **Design and Operations**).

Another useful tool to consider in the management or elimination of risks is through the use of a Health, Safety and Environment (HSE) Committee. HSE Committee meetings could be held to ensure that critical safety and environmental control information is communicated to all parties throughout offshore operations. HSE meetings would coordinate among the operator, contractors, and employees to ensure a mutual understanding of potential hazards in working environment. Meetings would allow employees an opportunity to express safety concerns to be addressed by the operator.

Control of Materials

Materials specifications, inventories, separation, confinement, and handling of toxic or hazardous materials that can affect human health and safety should be determined, documented, labeled, and communicated to appropriate person and addressed (see 6.1 **Waste Management**).

6.6 Transportation of supplies and transportation infrastructure

Offshore transportation by air and water should be planned and carried out in a manner to eliminate or minimize adverse impact on the environment. The sections in these guidelines on management systems, monitoring programs and planning for emergencies should be applied, with adaptations where necessary, to transportation activities. Information gathering and mitigation measures identified at the environmental assessment stage of project planning should be fully utilized for minimizing the environmental impacts associated with transportation of supplies and people to and from offshore operations. For example, it may be necessary to select routes, frequency, flight altitudes and/or the time of voyages to avoid impact on wildlife or the harvesting of wildlife by area residents.

The planning and implementation of supply routes involves many considerations beyond environmental impacts. The system of transportation consists of supply bases, routes and mode. Procedures involved are the safe handling of cargo and safe navigation. All these elements must be carefully evaluated and accounted for prior to the field development. Transportation of supplies, infrastructure and crude oil, shall therefore be an integrated part of the environmental impact assessment outlined in these Guidelines.

Where roads are required, ice roads, which create seasonal rather than permanent physical barriers to animal movements, may be preferable to permanent roads.

Planning and environmental studies should be done to ensure the use of water from lakes or rivers to make ice roads will not significantly affect important freshwater habitat, including habitat for migratory birds.

Ship-based transportation of supplies to offshore oil and gas installation are to be carried out

under the administration of those requirements and guidelines laid down in the Safety of Life at Sea Convention, including in particular Chapter IX pertaining to the International Safety Management (ISM) Code, The International Convention on Oil Pollution Preparedness, Response and Co-operation (OPRC), and the International Convention on the Prevention of Pollution from Ships (MARPOL 73/78), among others. The basis of the ship owners management system should include guidelines, codes and relevant international conventions to safeguard those additional requirements of the harsh environment of the Arctic such as those established by the Marine Environment Protection Committee (MEPC) and Maritime Safety Committee (MSC) of the International Maritime Organization.

Supplies

In maintaining the activity of an oil or gas installation in every aspect, supplies of many categories are involved:

- supplies for maintaining production;
- supplies for installation maintenance and safe operation; and
- supplies of domestic use.

Storage, packaging and operational procedures of handling are to be as in accordance with general rules of safe practice and to recommendations of the product manufacturer.

Supply base, routing and installations

Prior to field development, it is necessary to plan infrastructure required to serve the needs of the installation. In addition to systems for handling the production, a system is also required to secure sufficient and safe supply. Beside the installation itself, the main elements of such infrastructure are the supply bases and sea-routes. The location of such bases is often decided on the basis of compromises in which the requirements for safe transportation must compete with other possibly conflicting alternatives. This calls for an even closer focusing on safe routing. An Arctic land-offshore transport routing system might cover more than one field and therefore must be reliable. To assure safe operations, sufficient care must be taken regarding both climatic and environmental seasonal variations. In order to account for these factors, one should evaluate the possible need for ice handling and management procedures (integrated in the field operational plans if feasible) covering the installation, and the route as well as the supply base.

6.7 Training

Trained operator and contract personnel are the key to safe and environmentally sound oil and gas activities. Appropriate training plans, programs, and practices addressing offshore Arctic oil and gas activities should be established and implemented for these personnel in accordance with their duties and job responsibilities. (Refer to Section 7, **Emergencies**, for information concerning response training).

All personnel should be provided with training on basic safety and environmental issues and procedures specific to the offshore environment prior to assuming their duties. This training should provide personnel with the necessary skills and knowledge needed to conduct their jobs in a safe manner, provide for health and safety of all persons, and protect the environment.

Training programs should provide instruction on the operation of equipment, offshore operating practices, offshore emergency survival and fire fighting, local or regional regulatory

requirements. It should include Arctic cultural, social, and environmental concerns including marine mammal interactions as dictated by an individuals' job responsibilities. Where appropriate, indigenous and traditional knowledge should be used in training programs.

Supervisory personnel should have a thorough knowledge of the operations and the operating procedures for which they are responsible. Individuals responsible for drilling, well completion, or workover operations should be properly trained in well control. Individuals responsible for production operations should be properly trained in production safety system operations.

A person designated by the operator to be in charge of the offshore operation should have a thorough knowledge of the operations and the operating procedures they are responsible for, and training in the following areas as appropriate:

- leadership and command ability;
- communication skills;
- team building;
- crisis management; and
- installation specific emergency training.

Periodic refresher training should be provided to personnel as appropriate. As required, procedures should be developed to monitor the effectiveness of training programs.

7 Emergencies

Arctic States that are party to the International Convention on Oil Pollution Preparedness, Response and Cooperation (OPRC 1990) and/or the International Convention for the Prevention of Pollution from Ships (MARPOL 1973/1978, Annex I – regulations for the prevention of pollution by oil), are required to ensure that operators have oil pollution emergency plans and that these plans are carried on board installations.

7.1 Preparedness

Operators should establish and maintain emergency preparedness so that the mitigation of an incident will be carried out without delay in a controlled, organized, and safe manner. Risk analyses should be carried out in order to identify the accidental events that may occur and the consequences of such accidental events. Hazardous situations and accidents should be defined for the operations in question. An analysis should be carried out to design the emergency preparedness requirements so as to meet the specific circumstances of the operation. Such an analysis should include oil spill response strategies, techniques, and capabilities. The emergency preparedness required for the operation should be incorporated in the design and modification of the oil and gas installation, and for the selection of equipment. The performance requirements expected of both standby vessel and ice roads in emergencies should also be defined. This should include design criteria, equipment and manning requirements for standby vessels and design criteria and construction and maintenance requirements for roads. Emergency preparedness should be part of the safety and environmental program to ensure its integration into all phases of the operation in question.

Preparedness relating to oil pollution should ensure that the source of any oil pollution is first secured, and any release is effectively contained and collected near the source of the discharge as quickly as possible. Particular attention should be paid to response contingencies in ice conditions, where oil spill response, including containment, may require a range of techniques depending on the condition of the ice. The preparedness should also address protection of public health, environmental resources including shorelines, ice and water interfaces, and economic and cultural resources. The health and safety of all persons who may be involved in an incident (e.g., local populations and their representatives, responders, volunteers, etc.) should be a predominant consideration, and should be integrated into the overall emergency preparedness regime.

The communication within the emergency preparedness organization should ensure effective administration and control of all response resources when abnormal conditions and emergencies occur. The means of communication and their use should ensure unambiguous and effective transmission of information.

A key factor in preparedness is ensuring that personnel involved in the response are trained and instructed in their roles and duties.

Preparedness planning of the operator should include co-ordination with any relevant municipal, local, state or federal emergency response plan.

Governments are responsible for oversight including national emergency contingency planning. Governments should also make appropriate arrangements that facilitate international coordination and cooperation.

7.2 Response

Contingency Planning

The contingency planning process is one of the key best management practices for evaluating the environmental effects of the response operation. Through the planning process, response options (e.g., no response, dispersant use, in situ burning, or mechanical recovery) can be fully evaluated under varying weather and ice conditions to decide ahead of time which options may be most successful in minimizing the effects of a spill and subsequent clean-up operations. By conducting this risk assessment through a multilateral contingency planning process such issues as disturbance to marine mammal migration from response, including ice-breaking activities can be evaluated in the context of each response measure and/or a combination of response measures. Through a multilaterally developed plan, response options would be vetted through the countries in preparation for an incident. The plan should establish training schedules so that response organizations are exercised periodically, and communicate on a regular schedule.

A multilateral Arctic response plan would delineate regional response zones, clearly identify the lead response group for each region and identify response groups to cascade in to help with the response. The plan would identify roles and responsibilities, would be maintained so contacts could be made effectively given an incident, and would identify response capabilities (personnel, equipment, platforms, communication, infrastructure, etc.) for each region.

Emergency Response Plans

Refer to the EPPR Field Guide for Oil Spill Response in Arctic Waters for a practical introduction to oil spill response. Emergency response plans should address abnormal conditions and emergencies that can be anticipated during the oil and gas operation being carried out, including:

- personnel injury or loss of life;
- loss of well control, or release of flammable or toxic gas;
- fire, explosion or other emergencies that may occur;
- damage to the oil and gas installation;
- loss of support craft including aircraft;
- spills of oil or other pollutants; and
- hazards unique to the operation including ice encroachment; uncontrolled flooding of the installation; loss of ballast control or stability; pipeline leaks or ruptures; vessel collision; and heavy weather and difficulties with support facilities such as ice roads, aircraft or shuttle tankers.

Contents of Emergency Response Plans

An emergency response plan should contain at least the following elements:

- a description of the response organization, clearly stating its structure, roles, responsibilities and decision-making authorities;

- policies and procedures for responding, including a summary of equipment to combat the particular condition or emergency situation, clearly stating the make and type of equipment, its capacity, location, type of transport, field of operation and operational procedures and training for operating staff. The procedures should include each key person's duties, when and how the emergency equipment is to be employed, and the action to be carried out. Policies should state measures for limiting or stopping the event in question and conditions for terminating the action. The procedures should be designed so as to be expedient to use for the emergency;

- a description of the alarm and communication systems, including notification criteria, reporting procedures and policies regarding government notification. Primary and secondary communication facilities among operational components should also be identified;

- Alert Criteria, whose procedures should list precautionary measures to secure the well and evacuate personnel in the event of damage from severe weather, sea, ice, erosion or other event;

- On-Site First Aid - List available backup medical support, medevac facilities and other emergency facilities, such as emergency fueling sites. Also describe required survival equipment, including extreme weather survival gear, alternate accommodation facilities, and emergency power sources; and

- Relief Well Arrangements - The operator should outline his immediate response to a well control incident or blowout. Also, the operator should demonstrate the availability of the necessary equipment, and support systems to be utilized.

- Designated response operation center to coordinate response actions; and

- "Emergency response contact list" in order to identify who and how key responders to an emergency are to be contacted.

Oil Spill Response Plan

Operators should be required to have site-specific or operator-specific plans. An oil spill response plan addresses an oil spill volume based on relevant well data, catastrophic loss of a tank ship or barge, or damage to a pipeline. The Plan should be supplemented by resource sensitivity maps arranged sequentially by month for those areas identified by spill trajectories as being potentially exposed to oil pollution. The plan should also describe the process for its development, which should include involvement by response entities, both government and private, health officials, scientists, local populations that may be affected, wildlife experts, trustees of resources, and anyone else who may be affected or who may have a role in the response. Operators should allow the opportunity for public review and comment of the Plan.

The oil spill response plan should include, in addition to the items described above, the following:

- a brief description of the operation;

- a description of remote sensing systems in order to detect and monitor oil spills;

- a description of the site, water depth, seasonal constraints, and logistical support;

- references to all environmental support material that would be relevant to establish cleanup priorities;

- details of the operator's capability in using real time wind and current data to implement an oil spill trajectory model both for open sea and for ice-infested areas;
- a map depicting sensitive areas to be protected;
- a description of cleanup and containment strategies required for shoreline and ice-covered areas;
- a description of alternative cleanup strategies such as the use of dispersants, in situ burning, and no response;
- a strategy to respond to small spills from the installation, shore base or loading operations;
- provisions for transport, storage, and disposal of recovered oil and oil contaminated materials;
- spill response crew relief & logistics; and
- a list or inventory of spill response equipment and their measured efficiency when used as expected in the plan.

Operators should have access to oil spill countermeasures equipment. The oil spill response plan should itemize equipment on-site for immediate containment purposes. The plan should also provide details of oil spill equipment and resources that are not onsite but will be mobilized in the event of a spill; the details should include type of equipment, required resources, logistics and timing of mobilizing the equipment to the site.

The oil spill response plan should include the qualifications and training of personnel responsible for the management of oil spill responses. It should clearly define their authority to take actions to respond to such emergencies.

A national preparedness and response system should be developed on the basis of protecting the health and safety, the environment, and the socio-economic interests of the nation's citizens.

Oil spill response plans must take the existence of ice conditions into account. Broken ice conditions make it difficult to respond to oil spills with conventional mechanical response equipment because oil can be trapped in melting or freezing ice and require the coordinated application of a suite of response strategies. Through ice movement and drift, oil can be carried a long distance from the original site of the spill. Deployment of oil tracking buoys in the ice can aid in maintaining knowledge of the position of the oil. Where ice conditions exist, oil spill response plans must outline the strategies to be used, list the equipment to be deployed, and techniques to be implemented including for tracking oil in ice and for alternative response measures.

Exercises and Drills

To enhance response capabilities, response organizations should conduct regular safety and emergency response drills during which trained workers and emergency responders carry out regular exercises. Drills include desk-top exercises and actual equipment and operational deployment exercises. Such drills should be conducted by operators as well as by relevant government authorities in their areas of responsibility, such as coast guards for marine spills.

Ice Management Plan

Where there may be pack ice, drifting icebergs or ice islands at the operational site, the operator should develop an ice management plan that provides for the protection of the installation.

The Plan should include details regarding ice detection, ice surveillance, data collection, forecasting and reporting of ice encroachment, multiyear ice hazards, ice loading, and structural loading. If required, the Plan should also include details of ice avoidance or ice deflection, including forecasting oil-in-ice drift.

The Plan should include alert criteria and alert procedures to ensure a totally effective mobilization of all relevant emergency preparedness resources, including procedures for moving the installation. Measures for danger limitation should be implemented when a hazardous situation occurs in order to prevent its developing into an accident situation.

Emergency Preparedness Maintenance

All the established technical, operational and organizational measures that make up the emergency preparedness of the individual activity, as well as, the actual equipment should be maintained in order to keep up a state of effective emergency preparedness.

Oil spill response exercises should be carried out on a scheduled basis allowing responders to use actual equipment. In addition, a communication exercise in response to an emergency should be conducted on a scheduled basis. Exercises should be reviewed to ensure compliance with all requirements relating to emergency preparedness. Any deviation should be identified and corrected immediately; the causes of such deviation should be identified. In accordance with the safety and environmental program, emergency preparedness work should be verified and documented.

Measures should be taken to update the established emergency preparedness based on continuous evaluation of experience, technological development and new knowledge.

8 Decommissioning and Site Clearance

Decommissioning is an integral part of the life cycle of an offshore project. Plans for decommissioning should be incorporated at the design phase of a development and reviewed again when the facility is no longer needed for its current purpose. These plans should involve both technical considerations and financial provisions required to undertake the activity and any post-abandonment clearance and/or monitoring work.

A decommissioning plan should be site- and condition-specific and should take into account sound science and field experience and balance environmental, safety, health, economic and technological factors as well as any constraints imposed by intergovernmental agreements. It is noted that those Arctic States that are Contracting Parties to the OSPAR Convention have agreed to a binding package of measures (via OSPAR Decision 98/3) which generally prohibits disposal of installations at sea, but which allows for derogation from this prohibition in a limited number of instances. These include leaving in place the footings of a large steel jacket platform (with a jacket weight in excess of 10,000 tons) as well as a broad exemption for gravity-based concrete structures for which leaving in place and/or disposal at a designated site may be considered.

Other Arctic States will need to take into account the provisions of the London Convention (1972) or the 1996 Protocol to that agreement where full or partial disposal at sea (including toppling and leaving in place) is considered. For both the 1972 and 1996 agreements, Contracting Parties to the London Convention (1972) have adopted specific guidelines for disposal of platforms.

In addition to these agreements dealing with the special case of disposal of platforms, the International Maritime Organization has adopted "Guidelines and standards for the removal of offshore installations and structures on the continental shelf and in the Exclusive Economic Zone" (Resolution A.672(16))" which govern safety of navigation. Amongst other things, the guidelines state that for structures placed on the seabed after 1998, complete removal should be feasible.

Decommissioning plans should be developed in consultation with the competent authorities and stakeholders, including indigenous residents, fishing groups and other interested parties. The decommissioning plan should address both the facilities and the environment. (The London Convention (1972) Waste Assessment guidance is a useful reference in this regard.) Abandoned wells should be plugged and sealed. Pipelines may be removed, or cleaned flushed and left in space either on the seabed, if they will not interfere with other uses of the sea, or trenched. Removal of facilities should consider potential impacts on the site, including noise (as from the use of explosives), physical disturbance of communities established during the life of the facility and demobilization routes.

Site clearance and post decommissioning monitoring programs are important aspects. These will ensure that with the exception of facilities purposely left in place that the site is clear of debris and that no obstacles are left that might interfere with other uses of the site. Post decommissioning monitoring can also be used to assess the recovery of the production site. Where an artificial island has been constructed as a platform for drilling or construction, it may be appropriate to allow natural processes to return the site to its former configuration.

Development of a trust fund that can be used to decommission the infrastructure when its production life is over should be considered.

9 Abbreviations and Definitions

Accident: A sudden, unplanned, unintentional and undesired event or series of events that causes physical harm to a person or damage to property, or which has negative effects on the environment.

ADD: International Arctic Environmental Data Directory http://www.grida.no/add/

AEPS: Arctic Environmental Protection Strategy

AMAP: Arctic Monitoring and Assessment Program, a working group under the Arctic Council. http://www.amap.no/

API: American Petroleum Institute http://www.api.org

Arctic Ocean Observatory (AON) is an integral part of the SEARCH (Study of Environmental Arctic Change) program, as an initiative for the United States National Science Foundation International Polar Year (IPY) to improve observational capabilities in the Arctic. The Cooperative Arctic Data and Information Service (CADIS) supports AON by providing portal for data discovery, provide near-real-time data delivery, a repository for data storage, and tools to manipulate data. http://www.arcus.org/search/aon.html

BAT: Best Available Technology/Techniques

BEP: Best Environmental Practice

BOP: Blowout Preventor--Safety system that quickly closes a well in the course drilling to avoid blowouts.

CAFF: Conservation of Arctic Flora and Fauna-- a working group under the Arctic Council. http://www.caff.is/

Circumpolar Biodiversity Network: An initiative of the Circumpolar Biodiversity Monitoring Program by the Conservation of Arctic Fauna and Flora (CAFF) Working Group of the Arctic Council providing data-management structures and a Web-based data portal for the synthesis, analysis, and dissemination of biodiversity information. http://arctic-council.org/working_group/caff

Chemicals: A generic term for both chemical substance and/or mixture of substances (see definition for 'mixture of substances').

Chemical Substance: A chemical element and chemical compound of several elements, naturally or industrially produced.

Chemical waste: Oil/fuel residues, empty chemical and paint packaging, all kinds of chemical waste (solid and liquid) and all kinds of paint and solvents.

Contamination: concentrations of naturally occurring substances enhanced by man's activities or the occurrence of synthetic substances in the environment at concentrations that do not give rise to adverse effects;

DNV: Det Norske Veritas, Classification, Consulting and Certification Society. http://www.dnv.com/

EIA: Environmental Impact Assessment

EMS: Environmental Management System

Emergency: An unplanned event which has caused injury, loss or damage or which is an actual or potential threat to human life, the environment or the installation and has made it necessary to deviate from the planned operation or suspend the use of standard operating procedures.

EPPR: Emergency Preparedness, Prevention and Response a working group and program of the Arctic Council. http://eppr.arctic-council.org/

FPSOs: Floating production, storage and offloading units.

GINA: The Geographical Information Network Alaska, run by the University of Alaska Fairbanks provides a framework for organizing and sharing geographic data and technology among Alaska, the arctic and world communities. http://www.gina.alaska.edu/

GLP: Good laboratory practice as defined in the Organisation for Economic Co-operation and Development

Hazard: A physical situation with a potential for causing human injury, damage to property, negative effects on the environment or a combination of these. British Standards BS 8800 definition--A source or a situation with a potential for harm in terms of human injury or ill-health, damage to property, damage to the environment, or a combination of these.

Hazard Analysis: The identification of undesired events that lead to the materialisation of a hazard, the analysis of the mechanisms by which these undesired events could occur and usually the estimation of the extent, magnitude and likelihood of any harmful effects.

Hazard Identification: (British Standards BS 8800) The process of recognising that a hazard exists and defining its characteristics.

HSEMS: Health, Safety, and Environmental Management System

HSE: Health, Safety and Environment

ISM: International Safety Management Code in Chapter IX of the Safety of Life at Sea Convention. http://www.imo.org/

ISO: International Organization for Standardization. http://www.iso.ch/

IMO: International Maritime Organization. http://www.imo.org/

Impact: an alteration to the natural environment arising from the activity in question

Incident: A sudden, unplanned, unintentional and undesired event or series of events having the potential of causing physical harm to a person or damage to property, or which has negative effects on the environment. British Standards BS 8800 definition—An unplanned event which has the potential to lead to accident.

London Convention 1972: The International Maritime Organization Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter 1972. http://www.imo.org/

London Protocol 1996: The International Maritime Organization Proticol to modernize and replace the London Convention of 1972. http://www.imo.org/

MARPOL: International Convention for the Prevention of Marine Pollution. 1973, 1978. MARPOL-Annex I, IV, V and Annex VI. International Maritime Organization http://www.imo.org/

MMS: United States Department of the Interior, Minerals Management Service. http://www.mms.gov/

MSC: Maritime Safety Committee of the International Maritime Organization. http://www.imo.org/

MEPC: Marine Environment Protection Committee of the International Maritime Organization http://www.imo.org/

nmVOC: Non methane volatile organic components.

NORM: Naturally Occurring Radioactive Materials

OECD: Organisation for Economic Co-operation and Development. http://www.oecd.org/home/

OGP: International Association of Oil and Gas Producers http://www.ogp.org.uk/

OPRC: International Convention on Oil Pollution Preparedness, Response and Cooperation (1990) http://www.imo.org/

OSPAR: Oslo Paris

PAME: Protection of the Arctic Marine Environment http://www.pame.is/

PEIA: Preliminary Environmental Impact Assessment

Performance Standard: A statement, which can be expressed in qualitative or quantitative terms, of the performance required of a system, item of equipment, person or procedure, and which is used as the basis for managing the hazard e.g. planning, measuring, control or audit - through the life cycle of the installation.

Petroleum activity: is in this context used for all activities being an integrated part of oil and gas activities, including shuttle transportation of petroleum, supply transportation etc.

Pollution: the introduction by man, directly or indirectly of substances or energy into the marine environment which results, or is likely to result in hazards to human health, harm to living resources and marine ecosystems, damage to amenities or interference with other legitimate uses of the sea.

POP: persistent organic pollutants

Risk: The probability that physical harm to persons will be suffered or negative effects on the environment or that damage to property will occur as a consequence of exposure to a hazard.

Risk Analysis: (United Kingdom Health and Safety Executive, Offshore Research Issue 134/DEC01) The estimation of risk from the basic activity "as is"

Risk Assessment: (Lloyds Register Definition) The quantitative evaluation of the likelihood of undesired events and the likelihood of harm or damage being caused together with the value judgments made concerning the significance of the results. (British Standard BS 8800 Definition) The overall process of estimating the magnitude of risk and deciding whether or not the risk is tolerable or acceptable. (United Kingdom Health Safety Executive (HSE), Offshore Research Issue 134/DEC01) A review as to acceptability of risk based on comparison with risk standards or criteria, and the trial of various risk reduction measures.

Risk Management: (United Kingdom Health Safety Executive (HSE), Offshore Research Issue 134/DEC01) The process of selecting appropriate risk reduction measures and implementing them in the on-going management of the activity.

Safety: freedom from unacceptable risks to, personal harm, damage to property, or environmental pollution.

Safety of Life at Sea Convention: International Convention for the Safety of Life at Sea (SOLAS), 1974. http://www.imo.org/Conventions/

Safe Job Analysis: A review of the work situation, in which the job is broken down into sub-activities. Possible elements of danger associated with each sub-activity are considered as well as how/which risk reducing measuring should be established.

SEA: Strategic Environmental Assessment--a systematic process for evaluating the environmental consequences of a proposed policy, plan or program initiative in order to ensure they are fully included and appropriately addressed at the earliest appropriate stage of decision-making on par with economic and social considerations.

ANNEX A - Definition of the Arctic

Canada:

Canada has defined its Arctic area to include the drainage area of the Yukon Territory, all lands north of 60 degrees North latitude and the coastal zone area of Hudson Bay and James Bay.

Kingdom of Denmark

The Arctic area within the Kingdom of Denmark is the Faroe Islands and Greenland, which is the world's largest island on which stands 9% of the World's ice cap.

Finland:

In Finland the Arctic Area is defined as the territory north from the Polar Circle.

Iceland:

Iceland has defined the whole of Iceland to be within the Arctic area.

Norway:

Norway does not have any formal definition of the Arctic. For the purposes of the Arctic Oil and Gas Guidelines, 62 degrees North in the Norwegian Sea areas north shall be used as the southern delimitation of 62 degrees North form the Arcticthe Arctic area. This is in line with the AMAP Assessment delimitation.

Sweden:

Sweden does not have any formal delimitation of the Arctic but has, for the purpose of the Arctic Council, accepted the Arctic Circle as the southern delimitation of the Arctic area.

Russian Federation:

In accordance with the draft Law of the Russian Federation "On Zoning of North Russia", the Arctic areas of North Russia include:

- All lands and islands of the Arctic Ocean and its seas;
- Within the Murmansk region: Pechenga district (coastal areas of the Barents Sea including populated centers located on Sredniy and Rybachiy Peninsulas, as well as Liynakhamareye populated center, and the town-type settlement of Pechenga) Kolsk district (territories administered by the Tyuman and Ura-Guba rural government bodies), Lovozersk district (territory under the Sosnovsk rural government body), territory administered by the Severomorsk municipal government, and closed administrative-territorial entities of Zaozersk, Skalistiy, Snezhnogorsk, Ostrovnoy, and the city of Polyarniy with populated centers administratively Attached to it;
- Nenets autonomous national area – all territory;
- Within the Komi Republic – city of Vorkuta, within areas managed by it;
- Within the Yamal-Nenets autonomous national area; Priural, Tazov, and Yamal District, and territories and administered by the Salekhard and Labytnang Municipal governments;
- Taimyr (Dolgan-Nenets autonomous area) – all territory;

- Within the Krasnoyarsk territory – areas administered by the Norilsk municipal government;
- Within Sakha Republic (former Yakutia): Allaikhov, Anabar, Bulun, Nizhnekolym, Olenek and Ust-Yan district;
- Chuckchi autonomous national area – all territory;
- Within the Koryak autonomous area -- Olutor district.

United States of America:

All United States territory north of the Arctic Circle and all United States territory north and west of the boundary of formed by the Porcupine, Yukon and Kuskokwim Rivers; all contiguous seas, including the Arctic Ocean and the Beaufort, Bering and Chukchi Seas; and the Aleutian chain.

ANNEX B - Definition of Practices and Techniques

Criteria for the Definition of Practices and Techniques mentioned in Paragraph 3(b)(i) of Article 2 of the OSPAR Convention

BEST AVAILABLE TECHNIQUES (BAT)

1. The use of the best available techniques shall emphasise the use of non-waste technology, if available.

2. The term "best available techniques" means the latest stage of development (state of the art) of processes, of facilities or of methods of operation which indicate the practical suitability of a particular measure for limiting discharges, emissions and waste. In determining whether a set of processes, facilities and methods of operation constitute the best available techniques in general or individual cases, special consideration shall be given to:

   (a) comparable processes, facilities or methods of operation which have recently been successfully tried out;

   (b) technological advances and changes in scientific knowledge and understanding;

   (c) the economic feasibility of such techniques;

   (d) time limits for installation in both new and existing plants;

   (e) the nature and volume of the discharges and emissions concerned.

3. It therefore follows that what is "best available techniques" for a particular process will change with time in the light of technological advances, economic and social factors, as well as changes in scientific knowledge and understanding.

4. If the reduction of discharges and emissions resulting from the use of best available techniques does not lead to environmentally acceptable results, additional measures have to be applied.

5. "Techniques" include both the technology used and the way in which the installation is designed, built, maintained, operated and dismantled.

BEST ENVIRONMENTAL PRACTICE (BEP)

6. The term "best environmental practice" means the application of the most appropriate combination of environmental control measures and strategies. In making a selection for individual cases, at least the following graduated range of measures should be considered:

   (a) the provision of information and education to the public and to users about the environmental consequences of choice of particular activities and choice of products, their use and ultimate disposal;

   (b) the development and application of codes of good environmental practice which covers all aspect of the activity in the product's life;

   (c) the mandatory application of labels informing users of environmental risks related to a product, its use and ultimate disposal;

   (d) saving resources, including energy;

(e) making collection and disposal systems available to the public;

(f) avoiding the use of hazardous substances or products and the generation of hazardous waste;

(g) recycling, recovery and re-use;

(h) the application of economic instruments to activities, products or groups of products;

(i) establishing a system of licensing, involving a range of restrictions or a ban.

7. In determining what combination of measures constitute best environmental practice, in general or individual cases, particular consideration should be given to:

(a) the environmental hazard of the product and its production, use and ultimate disposal;

(b) the substitution by less polluting activities or substances;

(c) the scale of use;

(d) the potential environmental benefit or penalty of substitute materials or activities;

(e) advances and changes in scientific knowledge and understanding;

(f) time limits for implementation;

(g) social and economic implications.

8. It therefore follows that best environmental practice for a particular source will change with time in the light of technological advances, economic and social factors, as well as changes in scientific knowledge and understanding.

9. If the reduction of inputs resulting from the use of best environmental practice does not lead to environmentally acceptable results, additional measures have to be applied and best environmental practice redefined.

ANNEX C-Environmental Assessment Flowchart

Phase	Procedure	Activity	Responsible
Opening of new area for petroleum activities	***PEIA*** ⇓ hearing ⇓ ***EIA*** ⇓ hearing ⇓ opening ⇓ Baseline survey	Environmental survey Impact assessment Regulations	Authorities
Exploration	***EIA*** in Particularly Sensitive Areas Risk assessment Contingency planning and emergency response	Seismic Drilling	Operator/Authorities
Development	***EIA*** ⇓ Permission for discharge ⇓ Risk assessment Contingency planning and emergency response	Construction activities Transportation Drilling	Operator/Authorities
Production	***Monitoring*** Risk assessment Contingency planning and emergency response	Drilling Discharges to water Air emissions Transportation	Operator/Authorities/ Third Party
Decommissioning	***PEIA/EIA*** ***Monitoring***		Operator/Authorities

ANNEX D-Examples of the EIA Process from some Arctic Countries

The EIA process for the Faroe Islands:

Prior to inviting applications for exploration and production licences, the possible impact on navigation, fishing and other commercial activities, and on nature, environment and any other effects on the community from the exploration and production activities shall be assessed.

Regional Environmental Impact Assessments have been carried out for the areas covered by the first and second Faroese licensing rounds. The Regional EIAs were funded by the oil companies involved in the Faroese area.

Before approval for any drilling operations, the operator, as part of the drilling application, must submit a site specific Environmental Impact Assessment (EIA).

The EIA Process for Greenland Offshore Oil and Gas Activities:

Opening of new areas for exploration

In connection with the opening of frontier areas with technologically challenging conditions the Greenland Home Rule's Bureau of Minerals and Petroleum develops a strategic environmental impact assessment (SEIA) as part of the basis of decision in relation to granting licences to the international oil and gas industry. The SEIA identifies knowledge and data gaps, highlights issues of concern, makes recommendations for mitigation and planning and identifies restrictive and mitigative measures and monitoring requirements that must be dealt with by the companies applying for oil and gas licences in Greenland.

However it is the responsibility of the license holding companies to prepare environment impact assessment's (EIA) for their specific activities. This company initiated EIA must include the full life cycle of activities: exploration, field development, production transport as well as decommissioning. The EIA must be updated and further developed when needed e.g. when going from exploration to production phase, or if there is a change in the plans presented in the initial EIA.

An important source of information to the license holding companies when preparing their EIA's is the strategic environmental impact assessment developed by the Greenland Bureau of Minerals and Petroleum.

The Bureau of Minerals and Petroleum has developed a guideline how to prepare an environment impact assessment directed towards the international oil industry. In developing this guideline, information on the requirements to EIA's related to oil and gas exploration and exploitation in other Arctic countries has been studies. Furthermore, the guideline is based on the 'Arctic Offshore Oil & Gas Guidelines' issued by the Arctic Council and on the 'OSPAR Guidelines for Monitoring the Environmental Impacts of Offshore Oil and Gas Activities.

The EIA process for Norwegian offshore oil and gas activities:

Before areas are opened for licensing, an extensive EIA must be carried out. This EIA is similar to a Strategic Environmental Assessment (SEA). The process is initiated and funded by the authorities. The SEA, in addition to results from projects carried out as background for the assessment, may lead to an integrated management plan being issued.

Integrated management plans should take into account activities in all sectors in the relevant area, like the fishing sector, oil and gas sector and transportation sector. In Norway, a large number of governmental institutions, consultants and research institutes, NGOs and other stakeholders are involved. The intention is to be aware of any potential conflicts between different users of the area, and to ascertain sustainable development and protection of sensitive resources.

The Ministry of the Environment is responsible for the administration and coordination of integrated management plans.

According to the Norwegian Petroleum Act, EIAs have to be carried out for each new development. The work is carried out and funded by the operators. The responsible authority is the Ministry of Oil and Energy.

EIAs has been carried out regionally in two regions, the North Sea and the Norwegian Sea. Awarding new licences within these areas lead to updating of the regional EIA.

All EIAs/SEAs in Norwegian waters have a stepwise development similar to the one shown in the flowchart in Annex C.

The EIA Process for U.S. Offshore Oil and Gas Activities:

United States law requires an environmental review process for major actions that are proposed, approved, regulated, or funded by federal agencies under the National Environmental Policy Act of 1969. In the United States an EIA is called an Environmental Impact Statement (EIS). Federal regulations implementing this law require that the EIS be integrated early with the planning for proposed activities. For the offshore oil and gas program, the Minerals Management Service (MMS) initiates the EIS process early in the planning for proposed Five-Year Oil and Gas Leasing programs, proposed lease sales, and requests from industry to approve oil and gas plans or permits. The MMS assumes full responsibility for funding and development of the EIS.

The EIS for the proposed Five-Year OCS Oil and Gas Leasing Program analyzes alternative leasing configurations in all regions of the U.S. Outer Continental Shelf. This EIS is broader in scope and has less detailed analysis than the subsequent EISs that are prepared for lease sales in particular regions. An EIS may also be prepared to provide site-specific analyses for individual development proposals. The scope, level of detail, and issues of concern for each EIS are tailored to the actual proposal. The programmatic EIS examines issues broadly, while a development plan EIS focuses on more immediate, geographically focused concerns. In all cases, EIS analyses are intended to address only those issues that have a bearing on the decision at hand. For example, only the Five-Year Oil and Gas Leasing Program EIS discusses alternative energy sources, while a development plan EIS would analyze alternative pipeline routes within a particular area.

The EIA Process for Canadian Offshore Oil and Gas Activities:

Environmental assessment

Primary authorization for an oil and gas industry activity in Canada's Arctic offshore is by the National Energy Board (NEB) under the *Canada Oil and Gas Operations Act* (COGOA), while Indian and Northern Affairs Canada is responsible for the issuing exploration, significant discovery and development licenses under the *Canadian Petroleum Resources Act*. Efforts are underway to design a pilot, multistakeholder regional environmental assessment process for the Beaufort Basin. This study is being considered in anticipation of renewed investment in hydrocarbon exploration in the Beaufort over the next decade and is expected to inform and simplify downstream project-level assessments and regulatory decision while also contributing critical information to support integrated management for the Beaufort region.

Prior to issuing an authorization under COGOA, the project must undergo an environmental assessment conducted in accordance with the provisions of the applicable environmental assessment regime(s). Due to the settlement of land claim agreements, different environmental assessment processes apply in various regions of the northern Canada. For example, in the Inuvialuit Settlement Region which encompasses a large portion of the offshore area, the environmental assessment processes under the Western Arctic Claim (Inuvialuit Final Agreement) and the *Canadian Environmental Assessment* Act, apply. To the east in the Nunavut Settlement Area, Article 12 of the Nunavut Land Claims Agreement outlines the sole environmental assessment process applicable to the area.

Under the *Canadian Environmental Assessment* there are three types of environmental assessment - screening, comprehensive study, and review by a mediator or independent panel. Environmental assessments of hydrocarbon exploration activities are normally carried out as screenings. Where the responsible authority, after reviewing a screening report, determines that a project is likely to cause significant adverse environmental effects that cannot be mitigated and justified in the circumstances or where there is uncertainty about the environmental effects or public concern so warrants, the responsible authority must refer the project to the Minister of the Environment for subsequent referral to a mediator or review panel. Certain activities known to have a high likelihood of generating significant adverse environmental effects are identified in the *Comprehensive Study List Regulations* under CEAA. Once a decision is made to continue the environmental assessment of a project listed in the regulations as a comprehensive study, the project cannot be later referred to a mediator or panel. Certain offshore hydrocarbon production projects are listed in the *Comprehensive Study List Regulations*.

In the Inuvialuit Settlement Region there are two levels of environmental assessment.

The Environmental Impact Screening Committee is responsible for screening all proposed developments which may negatively impact the environment and/or Inuvialuit wildlife harvesting. If the Environmental Impact Screening Committee determines that significant negative environmental impacts or significant negative impacts to present or future Inuvialuit wildlife harvesting may result from the proposed development, the committee will refer the proposed development to the Environmental Impact Review Board. The Environmental Impact Review Board will establish a review panel to carry out a public review of the developer's environmental impact statement in accordance with their procedural guidelines. The Environmental Impact Screening Committee also has the ability to refer the proposed development to another review body for further assessment if it determines that another review process will adequately encompass the requirements of the process established under the Inuvialuit Final Agreement. The *Canadian Environmental Assessment Act* also applies in the Inuvialuit Settlement Region, and opportunities to ensure cooperative or harmonized EA processes are exercised on a case-by-case basis.

In the Nunavut Settlement Area, there are two levels of assessment; screenings and reviews. The Nunavut Impact Review Board is responsible for conducting screenings and reviews of proposed physical works or activities. During a screening, the Nunavut Impact Review Board evaluates a proposal to determine whether it may have significant adverse effects on the ecosystem, wildlife habitat or Inuit harvesting activities; or whether it may have significant socio-economic effects or cause significant public concern. If the Board determines further review is required, the project is either referred back to the Board or to a Federal Environmental Assessment Panel for a detailed public review of the project proposal. A Nunavut Impact Review Board review under Part 5 of the Nunavut Land Claims Agreement involves a more thorough evaluation of the proponent's project proposal and environmental impact statement taking into account any potential ecosystem and socio-economic impacts. A review under Part 6 of the Agreement is conducted by a federal environmental assessment panel appointed by the Minister of the Environment and is reserved for projects that are transboundary in nature, or involve matters of important national interest.

Russian Environmental Impact Assessment:

According to regulations on the assessment of impacts of planned economic and other activities, an environmental impact assessment (EIA) report must be prepared by the proponent of a planned project. Under the Federal Law on Ecological Expertise, the EIA report and any other relevant materials must be reviewed by an ecological expert commission under a relevant State organization and approved before a license or other permit may be issued for the project or activity.

An EIA is conducted in three main steps:

1. A preliminary EIA, in which the developer must prepare and submit to State authorities a document containing a general description of the planned activity and its purposes, possible alternatives, and other required information. The developer must also inform the public, carry out a preliminary consultation with interested parties, and conduct an initial assessment after the collection of basic environmental information.

2. The developer undertakes the EIA, considering alternatives for achieving the purposes of the activity, and prepares a draft EIA report. The developer must also provide the public with the opportunity to become familiar with the draft EIA report and to comment on it, and must subsequently inform the public of the decisions made, accounting for the comments and proposals submitted.

3. Public review of the EIA report. The developer is required to conduct public consultations on the planned activity and to keep a record of the issues on which possible disagreements between the public and the developer arise. There are specific rules concerning the period over which the draft EIA report must be available for public consultation.

The next stage comprises review of the EIA, as part of the project materials for the proposed activity, by an expert commission under the authorized State environmental agency; this includes determination of compliance with environmental, technological, and legal requirements. There is also a possibility for public environmental review by appropriate public organizations.

State environmental review is required before approval of the development may be given. The review is based on a presumption of potential environmental hazard of the planned activity. It is conducted by a commission of independent experts who review the composite nature of the EIA of the planned activity and its implications, as well as the reliability and completeness of the information presented for review. There are requirements for openness and responsiveness to public opinion in the conduct of this review. Materials reflecting public opinion must be forwarded to the expert review commission during the process of preparing their conclusions.

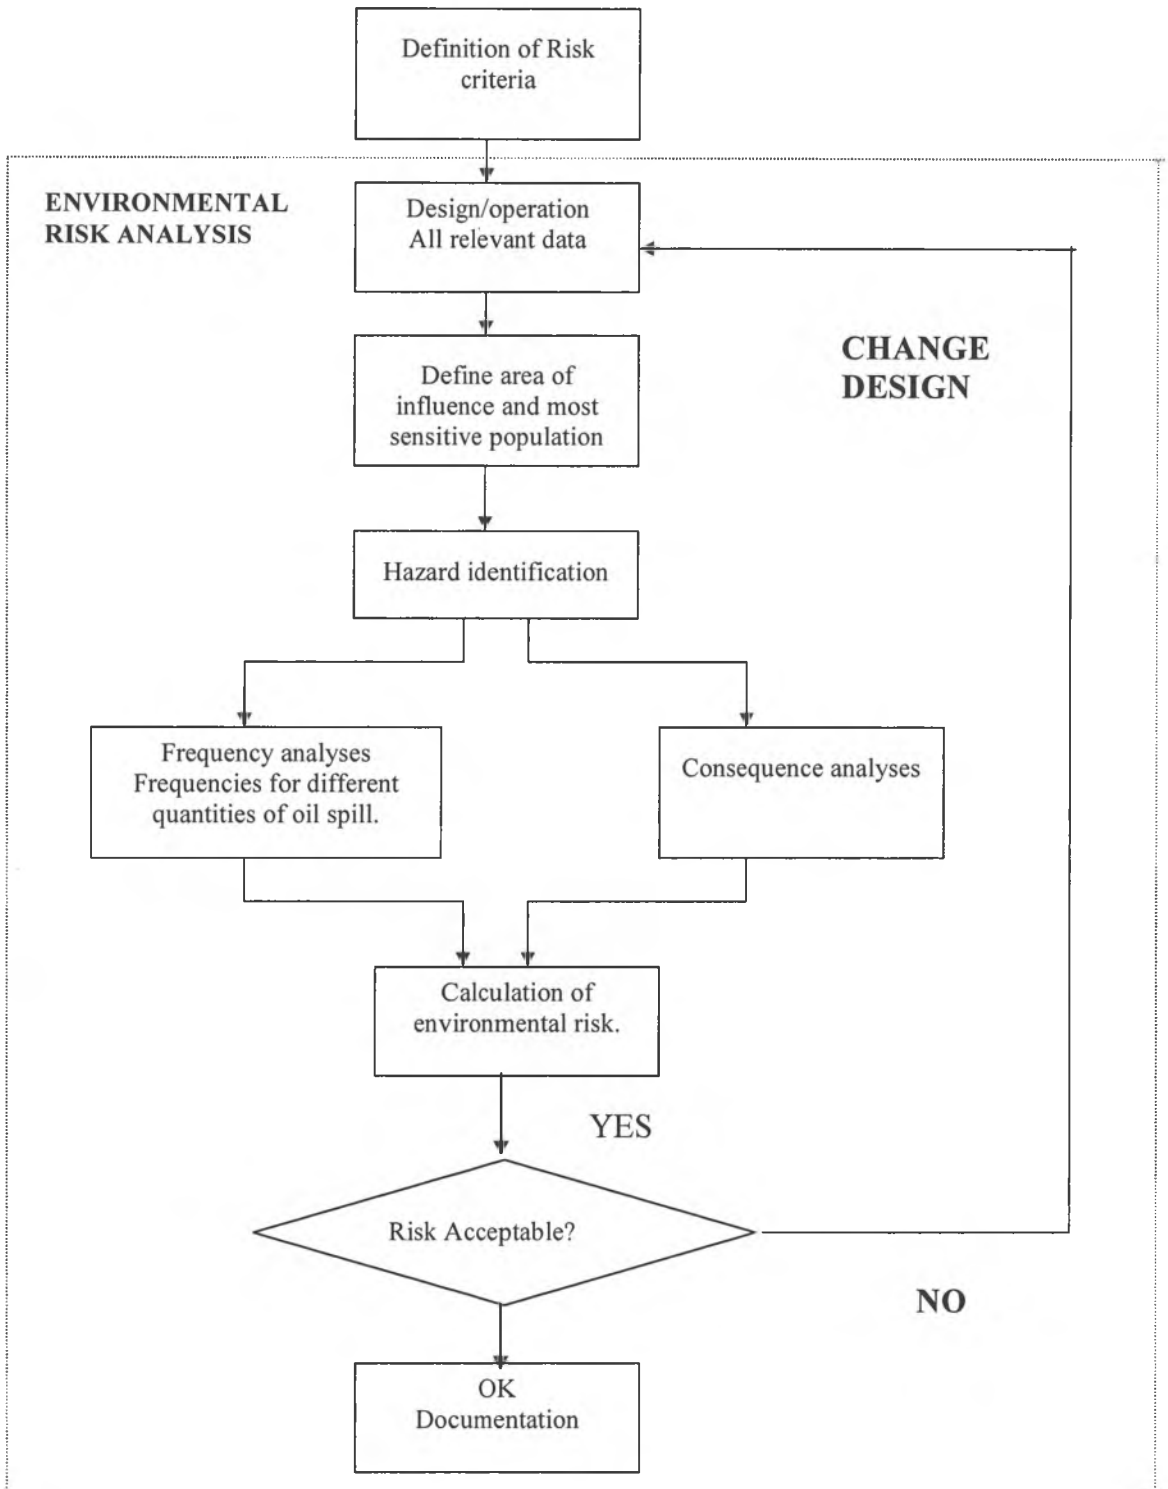
The proponent of a project must pay in advance for the State environmental review according to procedures provided for by the authorized State body conducting the review.

A positive conclusion of the environmental expert review is a necessary pre-condition for constructing or re-constructing any industrial site and is, in a sense, a building permit from environmental authorities.

ANNEX E-Overview of offshore activities and potential environmental effects

Activity	Possible Causes	Potential environmental effects
Evaluation		
Seismic activity	Noise	Effects on fish, sea birds and marine mammals such as avoidance behavior.
Exploration		
Rig emplacement	Dredging, filling, anchoring, and/or rig set-down.	Seabed disturbance.
Drilling	Discharges of drill cuttings, drill fluids, excess cement, platform drainage, household discharges and emissions of exhaust gases. Discharges from supply vessels, helicopter transportation, etc.	Predominantly local effects on living resources.
	Risk of blowouts.	Potential effects on living resources such as birds and marine mammals, as well as susceptible areas of the coastal zone.
Development and production		
Facility and pipeline installation	Potentially more dredging, filling and anchoring.	Long and short-term seabed disturbances.
	Extended risk of blowouts and oil spills.	As under exploration, but more extensive in both the water column and air.
Drilling	Discharges of produced water. Emissions of gases.	Potential effects on the reproduction of fish and possible contribution to climate effects, acidifying effects, etc.
Production	Spills, discharges and emissions connected to transportation (tankers, supply vessels, pipelines etc.).	Additional risks of effects on the marine environment and atmosphere.
Decommissioning and reclamation		
Removal of installations	Cutting piles containing oil and chemicals, dredging, air emissions, noise, etc.	Seabed disturbance, possible effects on fish, sea birds and marine mammals.
Leaving artificial islands or partial installations in-place	Exposed Biophilic substrate or surfaces.	Development of habitat for fish, mammals and/or birds.

ANNEX F - Environmental Risk Analysis Flow Diagram



ANNEX G - Company Safety, Environmental Policies and Objective

Detailed elements that may be incorporated in to company safety and environmental policies and objectives

- Competent personnel are used during planning and implementation of the separate phases, including design, fabrication and installation and operation
- The operator's personnel and those of any Contractors are provided with necessary training
- Lines of responsibility, authority and communication are clearly defined and understood;
- Risk evaluation should be a part of the project management strategy in order to establish and maintain an acceptable level of health Safety and Environmental protection for the personnel and the environment;
- No activity should be performed unless and acceptable level of HSE protection can be maintained;
- Management of discharges should be achieved through the application of Best Available [Techniques/Technology]
- Experiences from arctic operations should be integrated into specifications, functional requirements, standards and procedures;
- Safety evaluations should be undertaken both prior to start-up and in subsequent phases of the operation;
- Administrative systems are established for the control of all documentation in all phases of the operation;
- Purchase documents and specifications should contain Quality Assurance requirements;
- Contractor's Quality Assurance systems should be evaluated and assessed and be the subject of regular audits;
- The quality of supplied and materials should be documented;
- Quality Assurance and Quality Control during operations should function effectively and corrective action should be taken when quality control indications deviation from specification;
- Operational programmes should be prepared and compiled with relevant regulations and their functional capability should be subject to verification;
- Specifications for repairs should be established and specifications provide sufficient basis and requirements for their execution;
- Temporary equipment may be installed and operated in a secure way and in accordance with established specifications;
- Modifications should not reduce the degree of safety originally specified;
- An emergency preparedness system should be established and maintained so hat necessary measures can be activated effectively and authorities involved notified;
- Administrative decisions made be the supervisory personnel are communicated effectively to the personnel and contractors;
- There should be continuous control and monitoring of all aspects of the working environment with regard to health safety and environmental risks and that necessary actions are implemented
- There should be continuous control and monitoring of the danger of pollution of the external environment and that personnel at all times will perform their tasks in such a way that pollution is avoided ;
- Both operator and contractor personnel should be made aware of the potential danger of accidents and inherent health and pollution aspects and they are given necessary information, training and exercises.

ANNEX H-Example of a Generalized Monitoring Plan

Region	Installation	Phase	Type of investigation	Part of environment	Elements to be included	Frequency
		planning for development				
		development	baseline	Seabottom and other as relevant	inventory of biota, contaminants	every year and as frequent as necessary, depending on the type of activity
		production	monitoring	Seabottom and other as relevant	physical disturbance, biota, contaminants	every year and as frequent as necessary
		Decommissioning	monitoring	Seabottom Water column, as relevant	levels of contaminants and effects on biota, as relevant	during operations and once at reclamation phase
Region II						
	Inst. 1					
	Etc					
	Etc					
	Etc					
Etc	National shelves should be divided into regions where monitoring of the individual installations is coordinated. Regional monitoring of the water column is coordinated for the entire shelf of each country.

Subject: INFO: Naval Studies Board releases

Dear TFCC Colleagues,

On March 10, the National Research Council's Naval Studies Board released a report "National Security Implications of Climate Change for U.S. Naval Forces." We are pleased that Task Force Climate Change was consulted in the development of this report and it will be an essential tool as we continue our efforts. Below please find a press release with more details. The report may be accessed from this website: http://www.nap.edu/catalog.php?record_id=12914.

All the best,
Courtney St. John

Courtney St. John.

New Report Focuses On Climate Challenges To Naval Forces (NAVY NEWS SERVICE 10 MAR 11) ...
Bob Freeman, Office of the Oceanographer of the Navy Public Affairs

WASHINGTON -- The National Research Council of the National Academies released the "National Security Implications of Climate Change for U.S.
Naval Forces" report, March 10.

The newly-released study was commissioned by Chief of Naval Operations Adm. Gary Roughead in 2008, and indicates that the most moderate trends in climate change, if continued, will present new national security challenges for the U.S. Navy, Marine Corps, and Coast Guard. "This report represents the most detailed and analytical look at the impact of climate change on naval forces to date," said Rear Adm. David Titley, the Navy's senior oceanographer and

director of Task Force Climate Change. "It provides superb guidance for long-term strategic planning and investment considerations."

Acknowledging that the timing and severity of climate change impacts are not fully understood, the report recommends that naval leadership "adopt a risk analysis approach for dealing with climate change uncertainties."

The study addresses both long-term and short-term implications, and identifies areas for action for naval leadership, providing findings and recommendations for each area.

The first recommendation of the report is for naval leadership to continue their advocacy for accession to the United Nations Convention on the Law of the Sea, an international agreement that codifies the rights and responsibilities of nations in their use of the seas.

Although the U.S. helped draft the convention, signed the 1994 Agreement on Implementation, and adheres to the provisions of the law, it has not yet ratified the convention. The Navy and the Department of Defense have been long-time advocates for ratification.

Another recommendation of the study is that naval forces prepare for new mission requirements due to the opening of international and territorial waters in the Arctic Ocean as the sea ice continues to decrease. It identifies the Arctic as a place where "recent climate change may have the most immediate and obvious implications for maritime operations."

The recommendations include increasing Arctic operations and training for the Navy and Marine Corps; engaging the Joint Chiefs of Staff to ensure the most effective command structure with respect to the Arctic; and supporting U.S. Coast Guard initiatives to define future icebreaker requirements.

Recognizing that the opening of the Arctic Ocean will present increased technical challenges to naval forces, the report recommends increasing research and development efforts to address operational shortfalls and "increase priority for extending modern navigation, communications, and charting coverage to include the Arctic region."

In regards to global climate change, the study also highlights the probability of increased humanitarian assistance and disaster response missions related to the changing environment. It cites amplified stress on vulnerable nations due to "more severe or frequent droughts, floods, storms, and other events with negative consequences for food and water supplies, possibly leading to even greater stress on the expanded human population."

These same challenges will impact U.S. allies and their militaries.

Since no single nation can be fully prepared to respond to all climate contingencies, the report recommends fostering enhanced partnerships with "long-standing allies and non-traditional partners alike."

The report singles out NATO, saying "developing climate change response capabilities within the NATO alliance could strengthen global climate change response capabilities and the alliance itself."

Rising sea levels and increased storm surges will present significant challenges to naval coastal installations, and the report suggests naval forces should carefully assess facility vulnerabilities and consider potential risks when renovating existing or planning future infrastructure.

Finally, the study supports investment for additional research and development that will have implications for future naval force operations and capabilities. It specifically recommends investment in contributions to a global ocean observing system and the development of climate forecasting models that incorporate data from land, ocean, atmosphere and ice, to provide reliable predictions decades out.

The authors of the report expressed the opinion that both the Navy's Task Force Climate Change and Task Force Energy were providing strong leadership on these issues across the Navy and the Department of Defense, adding that "both task forces are well positioned in capability and credibility to continue their strong contributions."

"The findings and recommendations of this study will help ensure that U.S. naval forces are able to adapt to a changing climate and fulfill any mission assigned by the president throughout this century," said Titley. "It's all about being ready in tomorrow's world."

The Shared Future: A Report of the Aspen Institute Commission on Arctic Climate Change

The Shared Future:
A Report of the Aspen Institute
Commission On Arctic Climate Change

THE ASPEN INSTITUTE

Energy and Environment Program

THE ASPEN INSTITUTE

2011

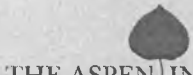
THE SHARED FUTURE:
A REPORT OF THE ASPEN INSTITUTE COMMISSION ON ARCTIC CLIMATE CHANGE

THE ASPEN INSTITUTE

This report, while taking a hard and new look at climate change in the Arctic, does not exhaust the dialogue needed to address many of the important issues raised. Undoubtedly, more discussion beyond this report is warranted. Participants in the Aspen Dialogue and Commission on Arctic Climate Change participated as experts in their field and not in their professional capacity or organizational affiliation. As with all policy dialogues in the Aspen Institute's Energy and Environment program, the format followed the Institute's time-honored approach to intentional, values-based dialogue, and adhered to a strict not-for-attribution rule throughout the duration of the dialogue. The names and affiliations of participants are listed for identification purposes only and do not indicate individual or organizational responsibility for this report or recommendations. This report is issued under the auspices of the Aspen Institute and the members of the Aspen Institute Commission on Arctic Climate Change, with generous support from the Prince Albert II of Monaco Foundation and the Shell Oil Company.

The Prince Albert II of Monaco Foundation strives to act as an accelerator of projects and solutions for the environment. It promotes sustainable and equitable management of natural resources and places the individual at the centre of its projects. It encourages the implementation of innovative and ethical solutions in three main areas: climate change, biodiversity and water.

www.fpa2.mc



The Aspen Institute Energy and Environment Program provides nonpartisan leadership and a neutral forum for constructive dialogue on complex policy issues in the areas of energy and environmental policy.

How Can Marine Spatial Planning in the Arctic Be Advanced? 77

ENDNOTES 80

Preface

People the world over think of the vast ice-covered polar Arctic as a symbol of our shared natural heritage. The Arctic is a constant reminder of nature's wild beauty – the world is amazed that people live there and call it home. Our vision of the Arctic, though, is changing.

As reported by the National Snow and Ice Data Center on January 5, 2011, "Arctic sea ice extent for December 2010 was the lowest in the satellite record for that month." The rate of global warming in the Arctic, which is twice as fast as the global mean average, raises new challenges for governing and managing its many human uses in balance with protecting this unusual natural environment. While the loss of sea ice and thawing permafrost over time will likely create new access to natural resources and to shipping routes, further retreat of the ice extent will lead to new challenges (and opportunities) for the coordination and management of the Arctic marine environment by its regional governments.

Climate change raises important new questions about ecosystem resilience, adaptation readiness, sustainable development and social change in the Arctic. Just as the Arctic marine environment is not one ecosystem, neither is it one society or one people governed by a single political system. Although climate change and the impacts it will have on the Arctic are a shared global responsibility, much of the Arctic marine environment is governed by sovereign states (and international law), each with its own national priorities, regulatory and management systems, and needs. It is the sovereignty of Arctic governments, nonetheless, that affords the strongest foundation and greatest opportunity for international cooperation and shared responsibility for sustainably protecting the Arctic marine environment.

In recognition of the scientific forecast of significant changes in the Arctic caused by global climate change, the Aspen Institute convened a civil society Dialogue and Commission on Arctic Climate Change. The Commission began its deliberations by identifying a set of dialogue principles as the foundation by which governance and sustainable management should proceed in the Arctic marine environment. The Aspen Principles of Arctic Governance (see page 3) set the backdrop for the Commission's dialogue and the formulation of its recommendations.

Due to its composition, the intensity and longevity of its deliberations, and the scope of concerns it addressed, this Aspen effort is distinct. Whereas other Arctic governance projects may have focused on specific questions such as how to improve regulation of certain sectors or activities, or how to strengthen Indigenous peoples' participation in the Arctic Council, the Aspen process has been focused on the climate adaptation challenges facing the Arctic marine environment and its human communities, as well as the regional and global governance implications of these issues. As these challenges were identified and discussed, the Commission's working group strived in a dialogue process to develop a shared understanding of the potential consequences of climate change in the Arctic marine environment, and the intensifying pressure of global economic forces anticipated for the region in the future. The working group and invited experts sought to identify strategies and approaches to help conserve the critical biological resources of the Arctic Ocean and to assure sustainable livelihoods of the communities that depend on these resources for their survival. (A full description of Commission-related meetings can be found in Appendix 2).

This report presents the Commission's recommendations, foremost of which is that governance in the Arctic marine environment, which is determined by domestic and international laws and agreements, including the Law of the Sea, should be sustained and strengthen by a new conservation and sustainable development plan using an ecosystem-based management approach. The

Commission believes marine spatial planning provides a workable method or approach to begin implementation of ecosystem-based management. According to the Commission, Arctic governance can and should be strengthened through an inclusive and cooperative international approach that allows greater participation in information gathering and sharing, and decision-making, leading to better informed policy choices and outcomes.

The Commission recommends that Arctic governments, in partnership with universities and other civil society and scientific entities, develop an open-source network (or series of networks) focused on supporting a plan for conservation and sustainable development in the Arctic marine environment. These networks should be developed and used as a means to connect communities and civil society sectors with each other as well as with governments. Such networks should be created and implemented to identify, record and track existing and newly emerging transnational ecological priorities in the Arctic marine environment.

The Commission recognizes that this Aspen Dialogue has been a preliminary step toward a fuller discussion on the future of the Arctic marine environment. Its major discovery is that a more modern, holistic and integrating international plan is needed to sustainably steward and govern the Arctic marine environment. The Commission has made significant progress in understanding the needs and requirements for action to sustain the Arctic and realizes that in order to implement its recommendations the entire Arctic community must be engaged.

The dedicated participation by Members of the Commission, their working group delegates, and the invited experts, some who agreed to have their name listed in this report, was essential to defining the scope of the dialogue, guiding the direction of the project, and creating a final report. Charles N. Ehler is the principal author of the marine spatial planning section in Part Two. We thank him for applying his extensive experience and expertise in marine spatial planning to the Arctic.

The Aspen Institute would also like to thank Brooks Yeager for his prolific role as Special Advisor to the Commission. This report and its recommendations owe much to his considerable experience and his thoughtful contributions to the dialogue. Francesca Cava and Regan Nelson both served as Project Managers for this dialogue, skillfully extracting the important themes and illustrative points from a wealth of excellent presentations and complicated discussions. Timothy Olson admirably coordinated the administrative preparations and extensive dialogue support, and Ray Bolger added his invaluable drafting and editing skills, synthesizing the major themes of this report.

We are profoundly grateful to H.S.H. The Prince of Monaco and The Prince Albert II of Monaco Foundation, our partner in creating and generously supporting this timely dialogue.

David Monsma
EXECUTIVE DIRECTOR
ENERGY AND ENVIRONMENT PROGRAM
THE ASPEN INSTITUTE

Foreword

In July 2008, my wife Rosalynn and I joined over one hundred distinguished scholars, political and religious leaders, journalists, and business executives for a weeklong tour of the high Norwegian Arctic aboard the *National Geographic Endeavor*, a vessel operated by Lindblad Explorations. Of all the places in the world I have visited as a naval officer or during and after my time as president of the United States, this voyage to the Arctic stands out in memory as one of the most enlightening journeys I have taken.

One afternoon that I will never forget, Rosalynn and I ventured out from the ship on a small boat with Larry and Lucy Page, Tom Daschle, and the undersea specialist David Cothran to launch a remotely operated vehicle in about 240 feet of remarkably clear water. We photographed many animals that day (many looked like plants) growing on the sea bottom and feeding in the current.

If you have never paddled a kayak up close to a bearded seal resting on a glacier, we can attest that it is an unforgettable, wonderful experience. We stepped ashore for a walk along a fjord near the southern tip of Spitsbergen, beneath a very high cliff that was almost completely blanketed with nesting birds. As avid birdwatchers, we enjoyed the many birds we saw each day of our voyage, including rare Ivory Gulls.

The next morning, back on board the *Endeavor*, we got up early to view two large polar bears feeding on a ringed seal, while a smaller one swam around them, then climbed out on a nearby floe. The largest bear then swam over to a nearby sheet of ice and bathed and dried itself while its mate slept nearby. Although we got very close, they never seemed disturbed.

The Arctic is a world of inherent silence and stark beauty, populated by majestic animals above and below the sea, and in the air. It is a place of great natural mystery, where so much about its ecology remains unknown.

At that point in the voyage we were close to Edgeoya Island, where we went ashore on the west coast for a long hike, with reindeer roaming all around. Later that night, we steamed through the Freemanssundet Strait, moving northwest toward Nordaustlandet Island, whose ice cap is the third largest in the world, after the Antarctic and Greenland.

The Arctic is a world of inherent silence and stark beauty, populated by majestic animals above and below the sea, and in the air. It is a place of great natural mystery, where so much about its ecology remains unknown.

Yet, despite its remoteness, the Arctic is an integral part of the entire global climate system, functioning as a natural source of cooling for the planet. Alarmingly, its ability to regulate Earth's climate is being diminished as the ice and snow cover, which reflect solar heat back into the atmosphere, retreat dramatically amid rising temperatures. Global temperatures are expected to increase, and the sea level, as a result of warming oceans and melting glaciers, is expected to rise 20 inches in the next century. Already, storms in low-lying regions of the world such as Burma and Bangladesh are far more devastating than before, while coastal villagers in Alaska are being forced to move their homes en masse as the sea level increases and protective ice disappears.

Meanwhile, the greatest international interests in the Arctic appear to be fixated not on how to minimize the pervasive damage there, but how to define territory and exercise national dominion over the rich natural resources in terms of oil and gas, fishing, and minerals. The United States has yet to ratify the Law of the Sea Treaty, while Russia and other Arctic nations are making territorial claims.

Given the prevailing circumstances, many of us on board the *Endeavor* understandably began the trip in a pessimistic mood—bemoaning climate change and blaming the state of affairs on the oil producing nations, our own governments, and competition from India, China, and others for scarce energy supplies.

…profound change is in store for the region's inhabitants, including its proud Indigenous Peoples, who have existed for several thousand years in harmony with their environment.

Over the course of the journey, though, a surprising thing happened: The general mood among the ship's passengers seemed to turn more positive as we focused on the possibility of courageous leaders tapping mankind's great potential for science, innovation, efficiency, and strength when united by a challenging goal. In striving to mitigate impacts on the Arctic from climate change, we can create millions of new jobs, working harmoniously with other nations and giving special care to the poor who have least caused global warming, but who will suffer most from it.

After our enlightening journey aboard the *Endeavor* the Aspen Dialogue and Commission on Arctic Climate Change inquired into the economic and political forces affecting the region and the limited scope of scientific knowledge about its ecosystems. Their findings lead to the conclusion that profound change is in store for the region's inhabitants, including its proud Indigenous Peoples, who have existed for several thousand years in harmony with their environment.

It is our duty to help them in whatever ways possible to adapt to the changing future as we strive to minimize the scale and rate of that change. Ultimately, their interests and those of the rest of us are aligned, for we share one planet with a contiguous climate. That unavoidable reality underpins the observations and recommendations contained in this report, which are the result of the Commission's efforts to understand what is happening in the Arctic and to determine how we can best respond as an international community.

Commission Vision Statement

The Commission envisions a future Arctic as a healthy ecosystem with management and governance that is responsive to the needs of its residents, that supports conservation of its sensitive habitats, and that ensures sustainable development of its resources. To optimize economic fairness and environmental sustainability in the Arctic marine environment, the Commission envisions a regional conservation and sustainable development planning process utilizing an ecosystem-based management approach and an Arctic marine network linking all interested and affected constituencies, including Indigenous Peoples, Arctic communities, governments and the business sector. Anticipating continued, dramatic impacts in the Arctic marine environment due to climate change, the Commission envisions the development of a highly adaptive management approach to its ecosystems, based on close and consistent monitoring of environmental conditions and a constantly evolving plan that seeks to maximize the resilience of ecological and human systems in the region. To that end, the Commission envisions a far-reaching commitment by Arctic governments to cooperate more fully and broadly among themselves and with the broader international community in an effort to mitigate the damaging effects of climate change in the Arctic and to support optimal adaptation of its inhabitants.

The Commission envisions a future Arctic as a healthy ecosystem with management and governance that is responsive to the needs of its residents, that supports conservation of its sensitive habitats, and that ensures sustainable development of its resources.

Building on this vision, the Commission proposes active engagement of civil society by governments to support the rapid synthesis of scientific knowledge and effective policy making. Such governmental and non-governmental networks can help identify policy gaps and develop innovative solutions to the complex challenges facing the Arctic marine environment. These partnerships among all levels of civil society, governments and commercial institutions, when connected in an open-source network of information sharing, activity reporting, and decision making, will work together toward enhancing the capacity of Arctic governments to sustainably preserve what is unique and valuable in the Arctic marine environment—promoting adaptation to the inevitable environmental changes to come.

The Aspen Commission on Arctic Climate Change has identified the following initial Principles of Arctic Governance as forming the guiding foundation of its recommendations and the standards by which future governance and sustainable management of human activities in the Arctic marine environment should be measured. Specifically, governance and sustainable management of human activities in the Arctic marine environment should seek to:

Aspen Principles of Arctic Governance

1. Optimize ecosystem resilience, integrity and productivity by maintaining food-web (trophic) structure and protecting and restoring biodiversity and available habitat.
2. Maintain the full suite of Arctic ecosystem services to support human well-being on a continuing basis.
3. Promote investment in scientific research and related infrastructure necessary to ensure sustainable development and environmental protection.
4. Avoid exacerbating changes that may be difficult or impossible to reverse in temperature, sea-ice extent, pH, and other key physical, chemical and biological ecosystem parameters.
5. Assess, monitor and manage multiple human activities using an integrated, adaptive, ecosystem-based management system that takes into account risks and cumulative and interacting effects.
6. Apply ecosystem-based management processes based on science and traditional knowledge, particularly to new and expanded human activities which are subject to prior evaluation and analysis. Prudent measures to reduce or eliminate impacts are to be taken when there are reasonable grounds for concern that such activities, directly or indirectly, will bring about hazards to human health, harm living resources and ecosystems, damage amenities or interfere with other legitimate uses.
7. Fully respect the rights, including human rights, of Arctic residents and Arctic indigenous peoples, and maximize participation in and transparency of decision-making for all interested stakeholders.
8. Link global policy discussions to the need to conserve and manage Arctic ecosystems and dependent communities.
9. Promote cooperation among Arctic states to arrive at appropriate standards for managing activities in the Arctic to meet the special conditions of the Arctic region, while promoting sustainable development.
10. Inform, in a timely manner, national and international decision-makers as well as the public of the consequences of climate change impacts in the Arctic, and needed actions required to meet the above noted principles.

The Aspen Institute Commission on Arctic Climate Change believes that existing frameworks can be enhanced and new frameworks can be established to improve governance and strengthen resilience in the Arctic marine environment in response to climate change impacts and the need for adaptation readiness. The Commission developed its recommendations against the backdrop of at least three observable strategies currently discussed internationally: strengthen the Arctic Council; expand and strengthen the existing system of bilateral and multilateral agreements; and/or establish a new Framework Convention for Arctic governance.

Aspen Commission Recommendations

This report focuses on several major Commission recommendations as follows:

1. Arctic governments should take immediate steps to begin developing an Arctic Marine Conservation and Sustainable Development Plan by 2012, in collaboration with civil society and other interested parties.

An Arctic Marine Conservation and Sustainable Development Plan should integrate ecosystem-based management to preserve ecosystem resilience and support sustainable development in the Arctic. The key features of this approach should include a consideration of multiple scales (e.g., temporal and spatial, sectors and activities, etc.), a long-term perspective, the recognition that humans are an integral part of ecosystems, an adaptive management perspective, and a concern for sustaining natural goods and services. The Plan should articulate shared objectives within and across multiple sovereign territories and national boundaries, and be implemented by a combination of civil society actors, the private sector, and governments. This Plan should provide the umbrella that coordinates national and international planning and stewardship to balance competing economic interests, while maximizing the resilience of natural ecosystems in the region. Once the plan is initiated, it should be reviewed at sufficiently regular intervals by the Arctic Council, civil society entities, affected constituencies, government agencies, and/or other international bodies.

An Arctic Marine Conservation and Sustainable Development plan should:

- **a.** Develop a coordinated approach that emphasizes science-based management; integrated marine spatial planning covering all relevant sectors of activity; participation of and benefits to Indigenous Peoples, local communities and civil society; and application of the precautionary[1] and ecosystem-based approaches;
- **b.** Identify, within each nation's jurisdiction, sensitive marine areas (including areas of high productivity and fragile or vulnerable areas, etc.), protect such areas through appropriate national means, and share information regarding these areas to enable coordinated networks of inter-territorial marine protection; and,
- **c.** Designate the high seas of the Central Arctic Ocean as a zone of international scientific cooperation. The lack of basic scientific information regarding the ecological characteristics of the high Arctic Ocean means that informed, science based decisions on whether and where extractive and polluting activities can take place is virtually impossible. The Aspen Commission recommendations therefore call for an agreement to protect the waters of the High Arctic, beyond the Arctic coastal nations' respective exclusive economic zones, as a zone of international scientific cooperation.

[1] As per the *Final Report of the US Commission on Ocean Policy*, a balanced precautionary approach applies "judicious and responsible" management practices, based on the best available science and on "proactive, rather than reactive, policies." *See* ENDNOTE 19

2. Arctic governments, independently and collectively, should implement an integrated ecosystem-based management approach in the Arctic marine environment utilizing appropriate marine spatial planning, as well as regulatory rules and standards, that address the special conditions of the Arctic region.

Ecosystem-based management is an integrated approach to management that considers the entire ecosystem. The approach differs from current management procedures that usually focus on a single sector, activity or concern. Rather, it considers the cumulative impacts of different sectors. Marine spatial planning is an innovative tool to implement and measure the success of ecosystem-based management across sectors. It is a public process that collects, analyzes, and identifies where human activities occur in time and space to achieve agreed upon ecological, economic and social goals.

Although several marine spatial planning efforts are underway in the Arctic, there are areas where marine spatial planning has not begun. Both marine spatial planning and regulatory standards should be used to achieve sustainable economic development, along with environmental conservation and marine area protection. Part II of this report introduces many of the preliminary steps and activities that should be considered as part of a cooperative regional initiative to develop a conservation and sustainable development plan for the Arctic marine environment.

3. In addition to an Arctic marine conservation and sustainable development plan, a number of specific actions should be initiated through the development of agreements or standards that foster consistent implementation among and across Arctic governments.

- **Fisheries:** In accordance with a precautionary approach to new or expanded commercial fishing in the Arctic, the Commission calls on all countries to refrain from authorizing their vessels to take fish in the high seas of the central Arctic Ocean where no cross-border regional fishing management organization or agreements exist, until sufficient scientific information is available on the impacts of potential new fisheries on target and non-target species, habitats, ecological relationships, and human communities. Regional Fishing Management Organization agreements should be developed for those areas of the Arctic where none currently exist.
- **Uniform Offshore Oil and Gas Standards and Spill Response:** The Commission calls for the development of a framework for the staged implementation of performance-based standards governing Arctic offshore oil and gas exploration, development, production, and transportation (including oil spill response), which take into consideration the special nature and challenges of the Arctic environment, and enable compliance integrated with regulatory arrangements.
- **Environmental Impact Assessments:** Pursuant to Article 206 of the Law of the Sea Convention, the Commission recommends conducting environmental impact assessments of individual and cumulative environmental impacts of human activities in the Arctic marine environment, including those that may have trans-boundary effects.[2] The Arctic Council should be encouraged to review the assessments and make recommendations.
- **Marine Shipping:** The Commission supports the development of a mandatory polar shipping code and recommends its swift adoption and implementation.
- **Marine Tourism:** As tourism is likely to grow with new waters opening up as ice cover diminishes, there is a clear need

[2]UNCLOS Article 206: Assessment of potential effects of activities: "When States have reasonable grounds for believing that planned activities under their jurisdiction or control may cause substantial pollution of or significant and harmful changes to the marine environment, they shall, as far as practicable, assess the potential effects of such activities on the marine environment and shall communicate reports of the results of such assessments in the manner provided in article 205."

to establish protocols that take safety, environmental protection and quality of experience issues into consideration. Participatory discussions that include international regulatory bodies and industry need to begin as soon as possible in order to limit accidents going forward.

4. An open-source Arctic network, focused on ecosystem-based management, should be developed through the Arctic Council and used to complement the existing system of national and international governance mechanisms in the Arctic.

Any new governance strategy and plan for Arctic marine conservation and sustainable development should recognize the region's challenges are not limited to national concerns. Given the complex economic and ecological forces affecting the Arctic marine environment, and the interwoven fabric of communities and public and private interests at stake, international cooperation, innovative ideas, and greater inclusion of interested stakeholders should be mobilized to supplement national governmental action.

As noted above, the Commission advocates development of a Conservation and Sustainable Development Plan for the Arctic marine environment. This plan would optimize the use of linked policy and community networks and the development of an open, electronic information environment through which stakeholders and institutions can exchange information needed for Arctic management and effective long-term governance. Well-structured and dynamic reporting and information-sharing networks involving public and private institutions and stakeholder groups, can be a critical element of strengthening management in the Arctic, provided that it is guided by a defined set of economic, ecological and scientific and cultural objectives, with a recognized monitoring, evaluation and reporting process to monitor ecosystem resilience, climate-induced ecological changes, and human activity as well as planning goals and conservation objectives.

A prototypical model of an open-source Arctic network should be created and implemented to identify, record, and track existing and newly emerging transnational ecological priorities in the Arctic marine environment. An Arctic marine network (or system of networks) should be based on existing structures (such as the University of the Arctic), provide opportunities for involvement by all parties who have an interest in governance and management in the Arctic, and should be designed to provide appropriate civil society access to influence governmental decisions.

The development of an open-source network should be led by the Arctic Council and Arctic governments in partnership with industry, universities and other civil society and scientific entities (as well other international bodies such as the IMO and the UNEP). It should be developed as an inclusive and cooperative international undertaking to allow open participation in information gathering and sharing, leading to better governance choices and management decisions in the Arctic. Participation in Arctic networks should be structured in a way that maximizes the use of information technologies for collection and distribution of information and data analysis, as well as embody a communication strategy that includes the implications for public policy decisions.

5. Arctic governments should call for a special diplomatic conference in 2012, which includes participation by Indigenous Peoples and the eight Arctic nations, to establish a timetable for designing and implementing the preceding recommendations.

Diplomatic conferences have historically played a key role in Arctic governance. In 1996, for example, the Ottawa Declaration established the Arctic Council as a high intergovernmental level forum focused on environmental protection of the Arctic. Since 1996, climate change and world economic forces have presented new challenges in the Arctic and led many Arctic policy-makers to begin rethinking the direction of governance in the region. The Commission envisions that a new diplomatic conference can both promote the importance of the Arctic and seek ways to strengthen the safeguards needed to protect sensitive ecosystems and highly productive marine habitats.

6. All Arctic residents, including Indigenous Peoples, should play a pivotal role in planning the future of the Arctic and should share in the benefits of its resources as well as responsibility for its sustainable future.

Arctic governance decision-making should build upon the Permanent Participants' strong engagement in the Arctic Council through a networked structure that: 1) recognizes the existing complex institutional arrangements at local, national and international levels; 2) brings the diverse and traditional knowledge and expertise of Arctic residents, including indigenous peoples, to the forefront where their perspectives can inform and advise Arctic-wide ecosystems-based management; and 3) works to alleviate the procedural and resource constraints that limit indigenous organizations' full and effective participation.

All states should therefore recognize the unique rights of Indigenous Peoples over development of their traditional lands and waters, and provide them with the necessary technical and financial support they need to participate in key policy venues affecting their futures, as avowed in the United Nations Declaration on the Rights of Indigenous Peoples, adopted by General Assembly Resolution 61/295 on 13 September 2007, Article 32, 2 says the following:

> *"States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources."*[3]

In building the capacity for Arctic residents to participate in Arctic governance, communication protocols and technological infrastructure must be expanded and improved to effectively share information to and from Arctic communities. The benefits of economic development in Arctic marine environment should also be invested in organizations and communities to sustainably support the engagement of Arctic communities and develop leadership among their youth.

7. An Arctic science program should be implemented and integrated as part of the Arctic Marine Conservation and Sustainable Development Plan using an open-source information network.

The program should contain the following minimum areas of focus:

- Designating the high seas of the Central Arctic Ocean as a zone of international scientific cooperation.
- The Sustaining Arctic Observation Networks (SAON) should be expanded to maintain observing systems in the Arctic, improve coordination between multidisciplinary networks, and facilitate data acquisition, access and dissemination.
- The effects of climate change on the Arctic marine and terrestrial environments, including the potential release of

[3]United Nations Declaration on the Rights of Indigenous Peoples Adopted by General Assembly Resolution 61/295 on 13 September 2007, Article 32. UNDRIP is a Declaration adopted by the General Assembly of the United Nations; a Declaration adopted by the General Assembly reflects the collective views of the United Nations but is not subject to ratification and does not have legally binding status.

methane and other greenhouse gases due to melting permafrost.

- Access to research data and data sharing should be improved, and issuance of research permits should be expanded in Arctic countries.
- Environmental and development challenges facing the Arctic should drive the development of scientific questions and the collection of scientific data that inform the decisions of policy makers.
- Education, recruitment and retention of key personnel at educational facilities, such as the University of the Arctic and others, should be supported in order to encourage a culture of understanding across boundaries and disciplines.
- The International Polar Year's scientific data and information should contribute to future assessments by the Intergovernmental Panel on Climate Change, as well as other efforts to address climate change. In particular, there is a need to utilize local and traditional knowledge and observation as part of the scientific process. Arctic residents should also be kept abreast of the results of Arctic scientific findings and conclusions.
- Encourage a series of bilateral memoranda of understanding (MOUs) among Arctic nations to support common scientific research. These MOUs would provide a predetermined means of transferring or sharing resources such as scientific instruments, personnel and data, and would perform services like contracting mechanisms to facilitate execution of scientific support activities. Scientific MOUs would likely be between corresponding agencies of each country (i.e., NOAA-to-NOAA counterparts).

8. The Commission urges that the Arctic Council be reinforced as an effective, multilateral organization for the region and that it be given the resources and a revised architecture to ensure that the planning, participation, management and accountability recommendations put forward in this report are implemented.

The short-term and practical way to successfully implement the Commission's proposed recommendations is to build on the existing framework and activities of the Arctic Council, which provides a forum for effective, cooperative management of the circumpolar region with due recognition of the rights of its people. In the interest of good stewardship in the Arctic the Commission recommends:

- Member states should commit to full cooperation in the development of a new conservation and sustainable development plan, similar in purpose to the level of coordination around search and rescue.
- The Arctic Council should be given a full-time secretariat and sufficient funds to produce strong results from its working groups. A sustainable source of funding is provided for the participation of Indigenous Peoples' Organizations.
- Governments should recommit to the spirit of the Arctic Council as a true partnership between Arctic states and Indigenous Peoples. Six Indigenous Peoples[4] are considered "permanent participants" at the Council. Their active inclusion in all future deliberations on Arctic governance is paramount.
- Arctic nations should participate in the Arctic Council through senior or ministerial-level officials who are empowered to make significant commitments and decisions for their governments.

[4]The six permanent participants of the Arctic Council are: the Aleut International Association, Arctic Athabascan Council, Gwich'in Council International, Inuit Circumpolar Council, Russian Association of Indigenous Peoples of the North (RAIPON), and the Sami Council.

Introduction

In the fall of 2007, the drastic melting of Arctic sea ice as viewed from space satellites offered the most dramatic evidence to date of global climate change and provided a sharp image that was easily understood by observers around the world. Meanwhile, at ground level across Arctic Canada, Inuit hunters reported that their traditional means of weather monitoring were no longer accurately predicting dangerous weather, often exposing hunters to treacherous travel conditions at times they would otherwise have thought safe. [1]

Glaciers are melting, sea level is rising and Indigenous coastal villages are becoming increasingly vulnerable to erosion and storms that were previously buffered by shorefast ice. Meanwhile, the seas of the Arctic continue to warm, mainly as a result of wide-scale ice melt, which allows more solar energy to be absorbed by the darker ocean. On land, trees and shrubs are advancing further into the tundra and foreign species of insects are being observed in the region.

The Arctic is the first region in which human-induced climate change impacts are being seen and it will—in all probability—be the first region where climate change will lead to transformative ecological, economic, and social change.

The Arctic is among the first regions in which human-induced climate change impacts are being seen and it will—in all probability—be the first region where climate change will lead to transformative ecological, economic, and social change. The rapid and profound transformation underway in the Arctic as a result of climate change may well trigger other global changes and climate shifts: The Arctic's ability to contribute to the cooling function of the planet could be altered; Arctic atmospheric warming and the potential release of greenhouse gases from land and the seabed could impede global efforts to mitigate greenhouse gas emissions; The stability of ocean circulation systems and biological productivity in the region and globally could change inexorably. These changes will almost certainly manifest themselves in terms of rising sea levels, increased contribution to global climate change, and increased demand for exploitation of new energy and food sources from the Arctic Ocean.

"The Arctic's warmer temperatures and decreases in permafrost, snow cover, glaciers and sea ice also have wide-ranging consequences for the physical and biological systems in other parts of the world."

Jane Lubchenco, PhD
Under Secretary of Commerce
for Oceans and Atmosphere
and NOAA Administrator

Further complicating the situation, although the Arctic is a definable marine environment it is not a single ecological or political system. It is governed by several sovereign states, each with its own priorities and regulatory and management systems. National efforts by Arctic governments, as well as the international agreements, laws and institutional arrangements that presently guide the management of the Arctic marine environment, may or may not contend well with new levels or new forms of economic activity, unparalleled changes in the function of natural ecosystem services, or further negative impacts to human and natural habitats, if the Arctic continues to warm at an unprecedented rate.[2] The anticipated further recession of the Arctic ice pack will, over time, impel new levels of economic activity, including expanded oil and gas development, new commercial-scale fisheries, and increased bulk and trans-

continental shipping. These activities are reasonably expected to have impacts on the region's ecology and economy and will pose serious management challenges to the Arctic nations.

The deep basin of the Arctic Ocean is surrounded by the continental shelves of Eurasia and North America. In the modern era, the legal and regulatory framework for managing resources in the Arctic has largely been defined by international law and the United Nations Convention on the Law of the Sea, as well as the laws of individual Arctic nations within their territorial waters and exclusive economic zones.[3] The Arctic Council, formed in 1997, is constituted as an international forum for the discussion of environmental and development issues in the region—not as a regulatory body—and has strict constraints on its ability to address the scale of emerging challenges.[4]

It is the sovereignty of Arctic governments... that affords the strongest foundation and greatest opportunity for international cooperation and shared responsibility for sustainably protecting the Arctic marine environment.

The eight Arctic nations have addressed challenges in the region with a substantial number of multilateral agreements. However, these agreements have not been uniformly adopted and the stronghold of beliefs in national sovereignty has caused some governments to overlook the benefits and necessity of greater multilateral cooperation – particularly in view of climate change. In addition to national management efforts within territorial waters, and international agreements such as the Law of the Sea, Arctic governments need to respond to the call for enhanced regional cooperation and innovative transnational stewardship approaches with greater involvement of new and existing actors. There is an obvious need for greater international cooperation and collaboration between states, which includes participation from all levels of civil society and interested stakeholders, to support effective management of the Arctic ecosystem as it undergoes dramatic change and economic activity there expands.

First, all options must be consistent with the fundamental framework for governance of the Arctic marine environment, the UN Convention on the Law of the Sea (UNCLOS).

Early on, the Aspen Arctic Commission recognized that Arctic residents are already beginning to adapt to significant physical and ecological shifts as a result of climate change. Because several nations have contiguous territories bordering on the Arctic Ocean and share the ocean's living resources, adaptation to an environment significantly altered by climate change will require both clear national policies, multinational cooperation and local implementation. Although changes will result in the Arctic, they will have significant implications for the global community as well, and the challenges of adaptation to climate change for communities and living resources in this remote region may provide important lessons for the future of other regions.

Thus, regulation, management, and governance in the Arctic must respond to the transformation already taking place in the region. This led the Commission to discussions leading to the *Principles of Arctic Governance* (see page 3), which became the first public product of its thinking. The principles are specific to the unique conditions of the Arctic. However, in considering institutional and governance developments that respond to climate change in the Arctic, some universal considerations also

were taken into account: First, all options must be consistent with the fundamental framework for governance of the Arctic marine environment, the UN Convention on the Law of the Sea (UNCLOS). Second, governance reform proposals need to be responsive to the rate of change occurring in the Arctic and should be appropriately matched to the scale of the issue. Third, governance options should seek to build on the strengths of existing institutions. Finally, they must seek every means to address issues cooperatively and diplomatically, and without destabilizing peace, security, and stability in the region.

In reviewing various approaches to the management of marine systems over the past half century, the Commission became convinced that industry sector-based regulation as traditionally practiced has not been successful in protecting the integrity of marine ecosystems, and will likely not prevent the degradation of the Arctic. The Commission recognized that most of the new economic activity projected in the Arctic marine environment will take place in the coastal zones surrounding the high Arctic, and that the resources of these coastal areas are increasingly fragile and stressed by the direct impacts of climate change. Thus, they focused on the potential for ecosystem-based management and integrated marine spatial planning as strategies for ensuring the rational and sustainable use of this fragile resource base.

Second, governance reform proposals need to be responsive to the rate of change occurring in the Arctic and should be appropriately matched to the scale of the issue.

One particular feature of the ecosystem-based management and integrated marine spatial planning approaches heightened their attractiveness for the Commission, namely their accessibility to and reliance on the contribution of local communities and stakeholders. The Commission believes strongly that the conservation and sustainable use of the resources of the Arctic marine environment should be conducted in a manner that benefits the local communities of the Arctic, and most particularly the traditional communities that have co-existed in the region's environment for thousands of years. There is a clear need for traditional and indigenous communities to have a role in decisions affecting their future, and it is hoped that an integrated planning approach such as the one outlined in this paper will contribute a useful framework for their increased participation in the future.

Third, governance options should seek to build on the strengths of existing institutions.

Ultimately, it is clear to all on the Commission that global climate change, if not effectively addressed by the international community, could result in serious degradation of the Arctic's ecosystems and massively transform the region, making incremental efforts at adaptation futile. The reality of this threat resulted in the Commission Statement on Arctic Climate Change, which many commissioners endorsed.

Definitions Of The Arctic

Offshore Oil and Gas Guidelines (2009 version; ANNEX A - Definition of the Arctic)

Canada:
Canada has defined its Arctic area to include the drainage area of the Yukon Territory, all lands north of 60 degrees North latitude and the coastal zone area of Hudson Bay and James Bay.

Kingdom of Denmark
The Arctic area within the Kingdom of Denmark is the Faroe Islands and Greenland, which is the world's largest island on which stands 9% of the World's ice cap.

Finland:
In Finland the Arctic Area is defined as the territory north from the Polar Circle.

Iceland:
Iceland has defined the whole of Iceland to be within the Arctic area.

Norway:
Norway does not have any formal definition of the Arctic. For the purposes of the Arctic Oil and Gas Guidelines, 62 degrees North in the Norwegian Sea areas north shall be used as the southern delimitation of 62 degrees North form the Arcticthe Arctic area. This is in line with the AMAP Assessment delimitation.

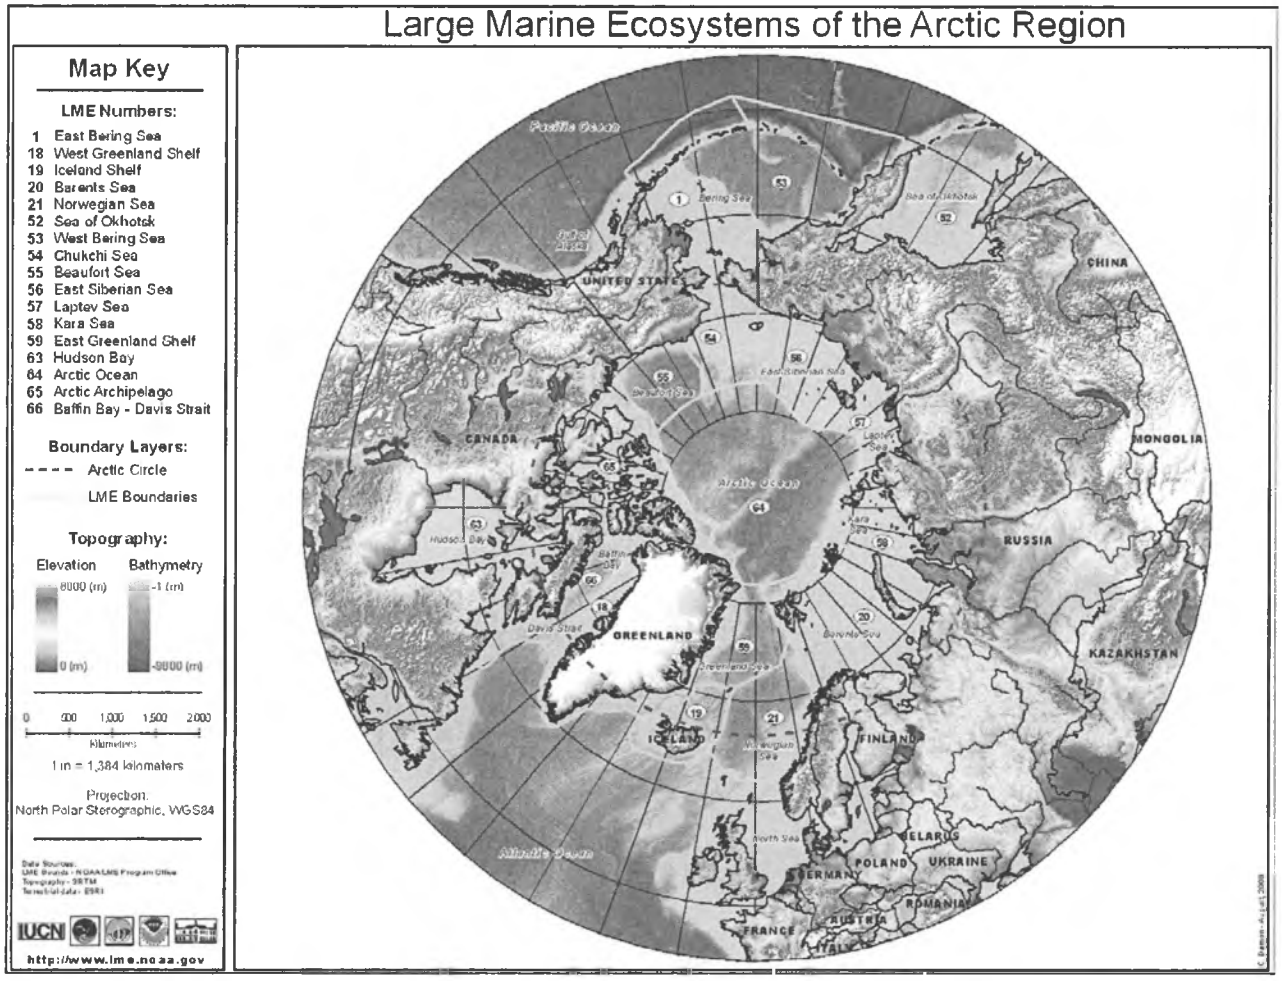
Sweden:
Sweden does not have any formal delimitation of the Arctic but has, for the purpose of the Arctic Council, accepted the Arctic Circle as the southern delimitation of the Arctic area.

Russian Federation:
In accordance with the draft Law of the Russian Federation "On Zoning of North Russia", the Arctic areas of North Russia include:

- All lands and islands of the Arctic Ocean and its seas;
- Within the Murmansk region: Pechenga district (coastal areas of the Barents Sea including populated centers located on Sredniy and Rybachiy Peninsulas, as well as Liynakhamareye populated center, and the town-type settlement of Pechenga) Kolsk district (territories administered by the Tyuman and Ura-Guba rural government bodies), Lovozersk district (territory under the Sosnovsk rural government body), territory administered by the Severomorsk municipal government, and closed administrative-territorial entities of Zaozersk, Skalistiy, Snezhnogorsk, Ostrovnoy, and the city of Polyarniy with populated centers administratively Attached to it;
- Nenets autonomous national area – all territory;
- Within the Komi Republic – city of Vorkuta, within areas managed by it;
- Within the Yamal-Nenets autonomous national area; Priural, Tazov, and Yamal District, and territories and administered by the Salekhard and Labytnang Municipal governments;
- Taimyr (Dolgan-Nenets autonomous area) – all territory;
- Within the Krasnoyarsk territory – areas administered by the Norilsk municipal government;
- Within Sakha Republic (former Yakutia): Allaikhov, Anabar, Bulun, Nizhnekolym, Olenek and Ust-Yan district;
- Chuckchi autonomous national area – all territory;
- Within the Koryak autonomous area – Olutor district.

United States of America:
All United States territory north of the Arctic Circle and all United States territory north and west of the boundary formed by the Porcupine, Yukon and Kuskokwim Rivers; all contiguous seas, including the Arctic Ocean and the Beaufort, Bering and Chukchi Seas; and the Aleutian chain.

Figure 1. Commonly Used Reference Map of the Arctic



The eight Arctic nations have addressed challenges in the region with a substantial number of multilateral agreements. However, these agreements have not been uniformly adopted and the stronghold of beliefs in national sovereignty has caused some governments to overlook the benefits and necessity of greater multilateral cooperation – particularly in view of climate change. Thus, there is an obvious need for greater international cooperation and collaboration between states, which includes participation from all levels of civil society and interested stakeholders, to support effective management of the Arctic ecosystem as it undergoes dramatic change and economic activity there expands.

I. A CONSERVATION AND SUSTAINABLE DEVELOPMENT PLAN FOR THE ARCTIC

Considering the scale and complexity of ecological and social impacts that are occurring in the Arctic due to climate change, some of which are beyond the capacity of governments acting alone to address, the Commission urges that a comprehensive Arctic Marine Conservation and Sustainable Development Plan be developed as rapidly as possible. Given the many layers of public and private interests at stake, as well as the dynamic economic and ecological forces at work in the region, the plan should encourage international cooperation, innovative ideas, and greater inclusion of all interested stakeholders, so as to complement official governmental policies and actions.

The Arctic Marine Conservation and Sustainable Development Plan should provide an umbrella that coordinates national and international planning to balance competing economic interests, while maximizing the resilience of natural ecosystems in the region. It should also open the door to a new model of natural resource governance in the Arctic that promotes an ethic of stewardship and multinational use of best management practices. Successful governance in the region will require a capacity to deal with human and natural systems that are complex, heterogeneous, dynamic, and prone to nonlinear and sometimes abrupt changes.

The Arctic Marine Conservation and Sustainable Development Plan. . . should also open the door to a new model of natural resource governance in the Arctic that promotes an ethic of stewardship and multinational use of best management practices.

This is not simply a matter of improving the management of fisheries, paying more attention to the effects of vessel routing, or managing the effects of increased tourism. What is needed is a more holistic and integrated "systems approach" to planning that facilitates analysis of the interactions between multiple natural and human drivers, and directs attention to emergent and cumulative impacts. To be successful under these conditions, management systems must be able to monitor various types of change closely, adjust strategies to changing circumstances, and cope with a relatively high degree of uncertainty (i.e., engage in adaptive management).[5]

High Seas of the Central Arctic Ocean as a Zone of International Scientific Cooperation

Substantial onshore areas of the Arctic enjoy some kind of protected status. Unfortunately this is not the case with the Arctic marine environment, where only a tiny fraction of the ocean is off limits to industrial development. In addition, the Arctic marine environment remains one of the least understood regions of the planet.

The lack of basic scientific information regarding the ecological characteristics of the high seas of the central Arctic Ocean means that informed, science based decisions on whether and where extractive and polluting activities can take place is virtually impossible. The Aspen Commission recommendations therefore call for an agreement to protect the waters of the High Arctic, beyond the Arctic coastal nations' respective exclusive economic zones, as a zone of international scientific cooperation. Such protection could be achieved through establishment of a zone of international scientific cooperation in international waters of the Arctic high seas. For example, in the waters of an Arctic science reserve, new economic activities could be temporarily suspended

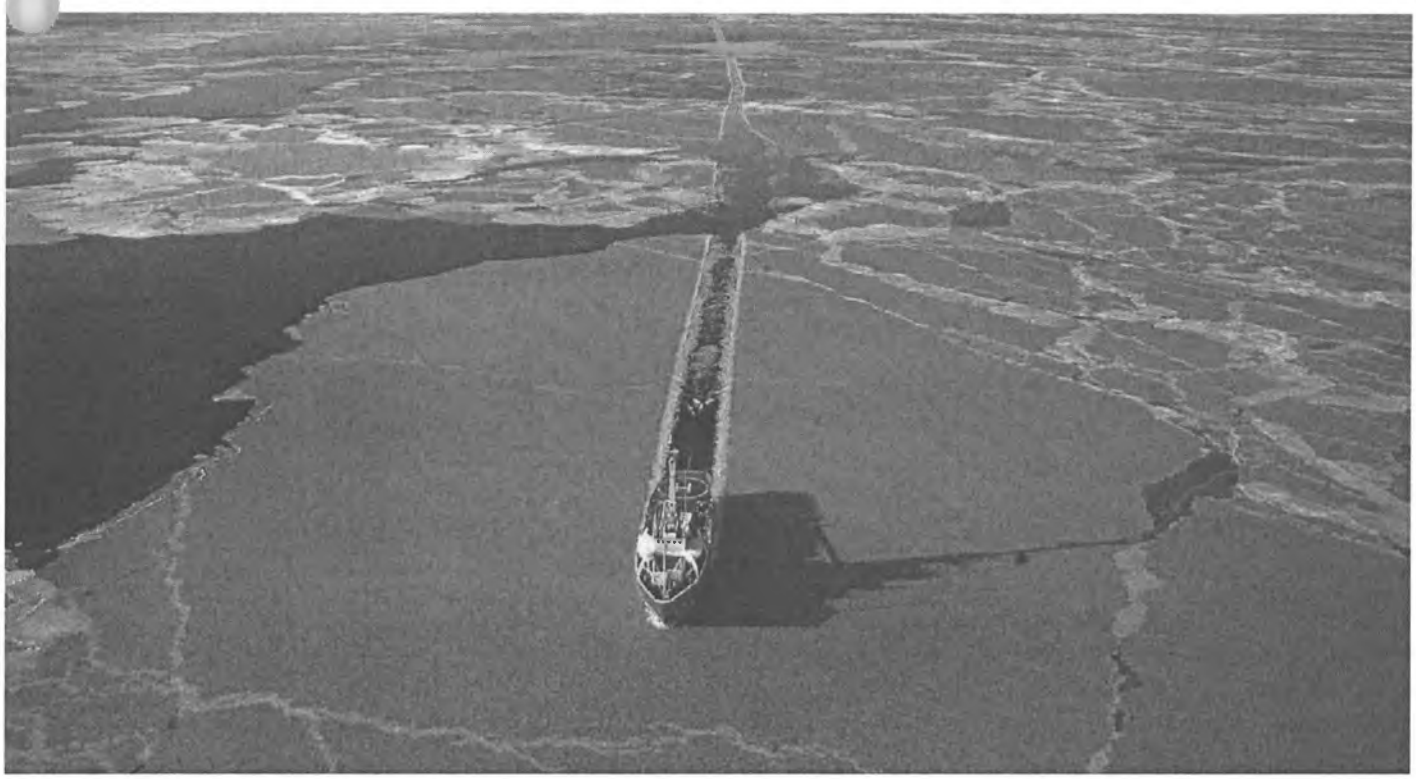
in order to allow scientific understanding of the ecology of the high Arctic and the changes it is undergoing to "catch up" with the pace of warming temperatures, melting summer sea ice and the extraordinary ecological changes underway as a result.

Establishment of an Arctic marine science reserve would encourage necessary international cooperation and development of a science plan to provide both protection and future sustainable use of this area.

Establishment of a zone of international scientific cooperation (i.e., Arctic marine science reserve) would encourage necessary international cooperation and development of a science plan to provide both protection and future sustainable use of this area. This reserve should encompass the water column beyond the jurisdiction of individual nations. It would not cover the seabed, which is subject to a variety of claims by neighboring coastal States that are currently being resolved.

II. ECOSYSTEM-BASED MANAGEMENT AND MARINE SPATIAL PLANNING

The ecosystem-based management (EBM) strategy is an integrated approach, with a goal of maintaining an ecosystem in a healthy, productive and resilient condition. As such, it differs from prevalent, place-based natural resource management strategies that focus on a single species, economic sector, activity or concern.



In fact, many recommendations for such an ecosystem-based approach to marine management in the Arctic already exist and most of the Arctic countries are working to one degree or another to implement EBM within their own marine areas. Norway, Canada and the United States have already embraced an ecosystem-based approach in the Arctic, as has the European Commission. The multilateral Arctic Council has repeatedly called for an ecosystem-based approach to marine management in the region, but as yet there is no truly integrated plan, and no plan yet conceived that speaks to the spatial and temporal scale necessary to understand and cooperatively manage large marine ecosystems and changing climate factors.

In order to overcome this as yet still fragmented management coordination, and to build on nascent attempts at EBM, the Commission calls for the development of a holistic plan that builds on efforts such as The Best Practices in Ecosystem-based Oceans Management in the Arctic[6] (BePOMAr) project of the Arctic Council, which has summarized the practices that Arctic countries have used to apply ecosystems-based management in marine environments, including:[7]

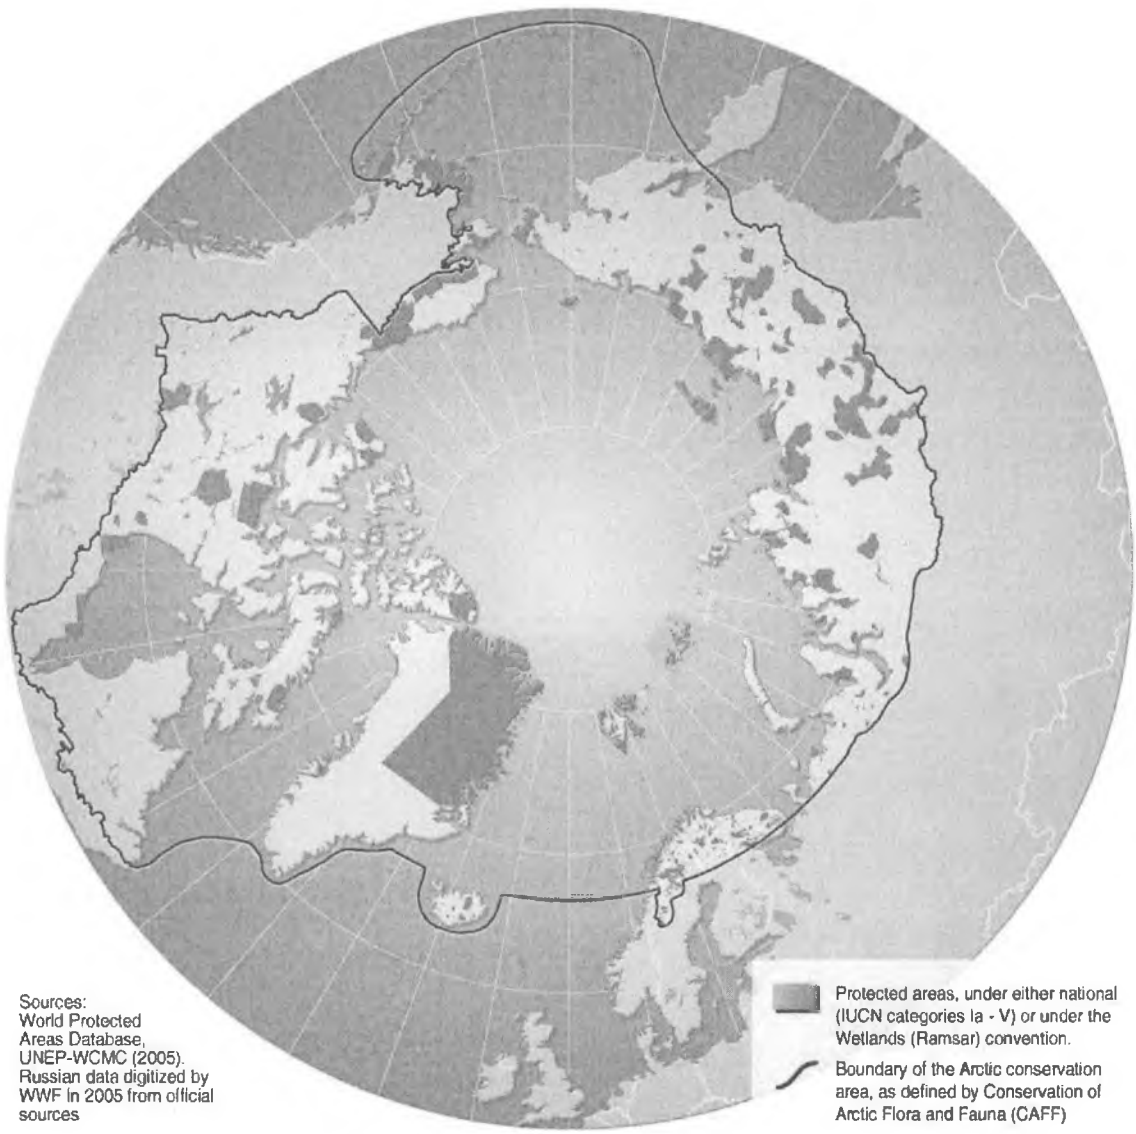
The plan envisioned by the Commission for the Arctic would set forth common objectives across multiple sovereign territories and national boundaries and be implemented by a combination of civil society actors, the private sector, Indigenous Peoples, and governments.

- Integrated and science-based decision-making;
- Flexible application of ecosystem-based oceans management;
- National commitment to effective management;
- Area-based approaches and trans-boundary perspectives;
- Stakeholder and Arctic resident participation;
- An adaptive management approach.

The plan envisioned by the Commission for the Arctic would set forth common objectives across multiple sovereign territories and national boundaries and be implemented by a combination of civil society actors, the private sector, Indigenous Peoples, and governments. It should consider the specific challenges presented by new and expanding economic development of the Arctic in the areas of fisheries; oil, gas and minerals extraction; shipping and tourism; and bio-prospecting. It should lay the groundwork for agreements and standards that foster uniform, international cooperation in regulating these expanding economic activities in a sustainable manner.

Once the Arctic Marine Conservation and Sustainable Development Plan is developed and implemented, its outcomes should be constantly evaluated, based on the identification and monitoring of key biophysical, social, economic and governance indicators. Outcomes of the plan should undergo constant review by all relevant stakeholders and the plan should be adjusted as necessary based on continual monitoring and analysis of changing ecosystem conditions.

Figure 3. *Protected Areas in the Arctic*



The Arctic is a unique region in the world, with very little human activity and vast expanses of tundra and taiga that presents ecological values. This graphic presents the areas that currently are protected for conservation, as recognized by the IUCN in the World Protected Areas Database at UNEP-WCMC, 2005. Some areas, like the Dehcho territory in Canada, have been placed under interim protection. The data for Russia has been updated from national sources, with the assistance of WWF Russia. Note the dearth of marine protected areas, despite their ecological significance and importance to indigenous peoples.[8]

Marine Spatial Planning in the Arctic

As sea ice coverage in the Arctic diminishes over time, the opportunity for various economic activities in the marine environment expands accordingly, most notably in fisheries, oil and gas extraction, shipping, and marine tourism. Failure to plan for holistic, ecosystems-based management of all the various expanding economic activities in the Arctic will almost assuredly lead to regrettable environmental impacts, as well as otherwise preventable disputes or conflicts in proposed uses.

The Arctic marine environment supports unique species and habitats found nowhere else on the planet and may be the basis of future commercialized pharmaceutical, agricultural, industrial or chemical products. An effective Arctic Marine Conservation and Sustainable Development Plan will integrate scientific information and ecosystem-based management principles, as well as identifying and protecting critically sensitive marine areas within all jurisdictions, including areas of high biological productivity and fragile or vulnerable ecosystems, while allocating space to permit sustainable economic development.

Failure to plan for holistic, ecosystems-based management of all the various expanding economic activities in the Arctic will almost assuredly lead to regrettable environmental impacts, as well as otherwise preventable disputes or conflicts in proposed uses.

The past failures of sector-by-sector management in marine areas around the world are well known and documented. Typically, fisheries have been managed separately from oil and gas development, which in turn has been managed separately from marine navigation, etc., despite real and potential conflicts among various uses. Single-sector management has generally failed to resolve incongruent policy goals, rarely dealing explicitly with the inherent trade-offs between various uses—and even more rarely dealing with the compound and cumulative effects of multiple uses on marine environments.

In response, the Arctic Council has repeatedly called for an ecosystem-based approach to marine management, but cooperative action so far has been limited. Most of the Arctic nations are working unilaterally to implement ecosystem-based management of their own marine areas to some degree,[9] but these are essentially disconnected efforts, whereas the Arctic's ecosystem spans across national boundaries (fish, whales and polar bears, for example, migrate without concern for territorial boundaries).

Marine Spatial Planning or "MSP" (more fully developed and applied in Part Two of this report) is an alternative, public process that collects, analyzes, and identifies where human activities occur, in order to achieve agreed upon ecological, economic and social goals. Key features of successful MSP programs include consideration of multiple scales; a long-term perspective; recognition that humans are an integral part of ecosystems; an adaptive management perspective; and concern for sustaining ecosystem goods and services.[10] Some of the potential conflicts that arise from competing uses can be (and have been) avoided or reduced in various ocean environments through MSP, which manages multiple human activities in space and time. [11]

Recently, MSP initiatives have been undertaken in highly used marine areas such as the North Sea, the Baltic Sea, the coastal seas of China, and in large ocean areas such as the exclusive economic zones of Canada, Australia and New Zealand. The new U.S. National Ocean Policy calls for the systematic development of marine spatial plans throughout its entire marine and Great Lakes regions. In the Arctic, Norway has served as an early leader in adopting MSP within its own territory, through its efforts to address environmental conservation and potentially conflicting uses in the Barents Sea. Some grassroots MSP efforts among indigenous communities in Canada also provide examples of a more holistic approach to ecosystems management.

What is needed to promote natural resilience and support sustainable development in the Arctic marine environment is a more coordinated, scientific system that reflects the actual temporal and spatial scales of the Arctic ecosystem and integrates MSP programs internationally, across the region.

What is needed to promote natural resilience and support sustainable development in the Arctic marine environment is a more coordinated, scientific system that reflects the actual temporal and spatial scales of the Arctic ecosystem and integrates MSP programs internationally, across the region. A detailed analysis of just how such a plan might be developed specifically for the Arctic, based on the current state of various ecosystem management programs in the region, is provided in Part II of this report, "Marine Spatial Planning in the Arctic," which was produced at the direction of the Commission. By its nature, the MSP process engenders interaction and cooperation between various economic sectors and the governing bodies that oversee and regulate them. Indeed, in order to be effective, the specific goals and objectives that arise from a cooperative MSP process must have sufficient governing authority backing them up—one of the key attributes of MSP programs that have proved successful thus far in various parts of the world.

Marine Spatial Planning can also be used to consider what appropriate protective measures should be in place. In the Arctic, less than 1% of large marine ecosystems[12] are currently protected, leaving vulnerable areas open to harmful impacts before their potential value is understood. Moreover, there is presently no international mechanism to establish a transboundary network of marine protected areas in the Arctic. While there have been efforts to identify and map ecologically significant marine sites and some important areas have been protected from certain activities[13], designation of protected areas in the ocean generally lags far behind the terrestrial areas of the Arctic, where substantial portions enjoy some type of protected status.[14]

By its nature, the MSP process engenders interaction and cooperation between various economic sectors and the governing bodies that oversee and regulate them.

The need to identify and protect critical Arctic marine habitats is urgent. Establishment of a network of marine protected areas can provide a tangible mechanism to implement the UN Convention of Biological Diversity. Marine protected areas can also provide a barometer for better understanding the impacts of increased human activities in the Arctic marine environment made possible by the accelerating retreat of sea ice. Once economic interests become entrenched, it will be very difficult to protect areas that are subsequently identified as biologically significant.

III. THE NEED FOR AGREEMENT ON COMMON STANDARDS

Although the Arctic is a definable marine environment, it is not a single ecological or political system. It is governed by several sovereign states, each with its own priorities and management systems. Further complicating the situation, the existing fabric of international hard and soft law governing the Arctic developed when ice and extreme cold severely constrained what economic activities people could feasibly pursue. Now, as fishing, shipping, and offshore oil and gas activity is expected to expand, along with advances in technology and diminishing sea ice, important regulatory gaps have been exposed.

In addition to an Arctic marine conservation and sustainable development plan, a number of specific actions should be initiated through the development of agreements or standards that foster consistent implementation among and across Arctic governments.

Most of the new economic activity projected in the Arctic will take place in the coastal zones surrounding the high Arctic, while the resources of these coastal areas are increasingly fragile and stressed by the direct impacts of climate change. The Commission has surveyed the main areas of economic activity occurring in the Arctic, which are likely to continue expanding as sea ice diminishes and new technologies are developed, and has arrived at the following, broadly considered observations and recommendations for each sector:

. . . there should be implementation of international standards governing all phases of new resource development such as offshore oil and gas exploration, development and production, with improved oil-spill prevention and response capabilities assuming first priority.

Oil and Gas

A report issued by the US Geological Survey in 2008 estimated that the Arctic contains as much as 13% of the world's remaining undiscovered oil and 30% of its undiscovered gas. Of these resources, most of the oil is expected to occur offshore.[15] Exploration and development of these resources will involve seismic surveys, drilling, platform construction, pipe laying and the building of processing facilities onshore, in addition to marine and air support, and tanker operations. The key sustainable development issues for the oil and gas industry in the Arctic are potential spills, impacts on biodiversity, and influences on Indigenous Peoples and traditional ways of life.

In order to adequately manage and govern oil and gas development together with other economic activities in the Arctic, the Commission proposes applying best-in-class practices for environmental impact assessment and associated science; comprehensive and inclusive stakeholder engagement; ecosystem-based management; the use of marine spatial planning; and a framework for harmonized offshore operating standards subject to compliance assessment. To that end, there should be implementation of international standards governing all phases of new resource development such as offshore oil and gas exploration, development and production, with improved oil-spill prevention and response capabilities assuming first priority.[16]

Fisheries

Some of the world's largest and most valuable fisheries such as cod, herring and pollock occur in the sub-Arctic and many experts predict these fisheries are likely to move north as the ocean warms and sea ice melts.[17] However, for areas north of the Bering Strait and Svalbard/East Greenland shelf no significant commercial fisheries have yet been established, and no international regimes exist to manage fishing other than in the small portion of the Central Arctic Ocean that lies within the North East Atlantic Fisheries Convention area.[18]

Marine species in the Arctic are also likely to be affected by CO2-related changes that include warming water temperatures, loss of sea ice, changes in salinity due to melting glaciers, and ocean acidification. Fish populations are likely to be affected by expanded economic activities, particularly by fish harvesting and to a lesser extent by offshore oil and gas development, shipping, and tourism—all made possible by receding sea ice. The ecological implications of climate-related impacts on marine species are difficult to assess, but are likely to reverberate in unpredictable ways throughout Arctic marine food webs.

The ecological implications of climate-related impacts on marine species are difficult to assess, but are likely to reverberate in unpredictable ways throughout Arctic marine food webs.

In accordance with a precautionary approach to new or expanded commercial fishing in the Arctic,[19] the Commission calls on all countries to refrain from authorizing their vessels to take fish where no international regional fishing management organizations exist, until sufficient scientific information is available about the impacts of potential new fisheries on target and non-target species, habitats, ecological relationships and human communities. The Commission also urges that the high Arctic, an area of great scientific uncertainty, be protected as a zone of international cooperative research until better understanding of its geophysical and biological systems can be attained.

Marine Shipping and Tourism

Diminishing sea ice cover is opening the Arctic to expanded intra- and trans-Arctic shipping of all kinds. According to the 2009 Arctic Marine Shipping Assessment, there are roughly 6,000 individual vessels that operate in the Arctic, many making multiple trips, of which a substantial number are fishing vessels. Marine-based tourism is expanding especially rapidly in the Arctic, from 1.2 million cruise ship passengers traveling to Arctic destinations in 2004 to more than double that number in 2007. In Greenland, the number of passengers calling at its ports (22,051) represented almost half the number of Greenland's total population in 2006.[20]

Figure 4. *Vulnerable Areas*

Alarmingly, most of these vessels are not designed to operate in the Arctic and are not ice-strengthened. Retreating summer sea ice is likely to result in increased trans-Arctic and intra-Arctic shipping traffic, bringing with it the risk of groundings, collisions, spills, invasive species, pollutant discharges and underwater noise. Like other types of shipping, marine vessel tourism can significantly affect the environment, but it is not currently subject to uniform, mandatory international environmental standards specific to the Arctic.

Environmental Impact Assessments

Environmental impact assessment of proposed economic activities *prior* to their approval is fundamental to preventing potentially harmful results, but there is currently no international mechanism to assess and mitigate the individual or cumulative effects of human activities affecting transboundary ecosystems or species in the Arctic. In addition, there is no Arctic-wide mechanism to assess activities within the zone of one country that can easily affect transboundary species or ecosystems that are important to others.

Article 206 of the United Nations Convention on the Law of the Sea (UNCLOS) requires, when there are reasonable grounds for believing that planned activities within the jurisdiction or control of a state may cause substantial pollution or significant harmful changes to the marine environment, that state must assess the potential effects of such activities. Thus, Arctic states should implement Article 206, elaborating requirements to conduct environmental impact assessments of individual and cumulative impacts, including those that may have transboundary effects. Such a framework could also incorporate guidance on marine environmental impact assessments beyond national jurisdiction under the auspices of the Convention on Biological Diversity.[21] Further, because impact assessments can vary considerably in their quality and level of detail, a uniform set of standards for conducting environmental impact assessments of activities throughout the Arctic should be adopted.

IV. ARCTIC NETWORKS

There is an obvious demand for more effective means of international teamwork and goal-setting to meet the challenges of Arctic governance brought about by global climate change. In recent years, information, community and "policy networks" have emerged as a means to address governance issues globally. These networks have been possible because of advances in communication information technology—in particular the Internet, "cloud" computing,[22] and social networking applications—and the recognized need and benefits of collaboration across sectors and borders.[23] They have demonstrated promise in addressing some of the world's most complex, intractable political and ecological challenges by promoting use of best management practices and adoption of successful protocols developed by the world's best experts.

The creation of the Landmines Treaty[24] in 1997 and the International Criminal Court (ICC) in 2002 via the Rome Statute were early expressions of this line of thinking. Coalitions of like-minded states combined with NGOs and international organizations such as the Red Cross to overcome the resistance of unresponsive powers in order to create both new norms and new institutions to advance human security objectives. These groups have displayed an impressive ability to mobilize public opinion and put sustained pressure on relevant institutions.

Global environmental governance questions are not limited to the Arctic marine environment or "who" governs according to which national policies, or international laws, but how "governance" is changing and evolves.[25] For example, "Netpolitik"[26]—a nascent reference akin to the concept of "networked governance"—is emerging around the world, wherein diplomacy and international politics are being altered by the power of new actors working together to share ideas and resources in innovative ways.[27] Change on a variety of shared global problems can be mobilized more efficiently as governments and government agencies, civil society groups, international bodies, and groups of individuals work together to effect change. By their nature, this collaborative approach can help narrow down complex issues and present new solutions that spring from fresh and unconventional views on otherwise deadlocked political positions.[28] As opposed to traditional "top-down," command-and-control systems, these new networks involve input from stakeholders at all levels through less formal channels.[29]

> ***"The management of the global issues in an era of growing interdependence, demands innovative governance on our part as the rapid pace of the change in the information flow alters the concept of what we consider information."***
>
> David Bollier
> The Rise of Netpolitik

In the Arctic, networks can be used to build consensus and long-term capacity by directly addressing the newly emerging priorities in the Arctic and seeking to reduce conflict among participants. Such a process should be encouraged through the Arctic Council which is already a model for collaboration. Use of networks would allow for the integration of various levels of government, NGOs, private sector, industry, and Indigenous peoples, and enable different groups to provide their input and

have a role in implementing management goals. Scientists and environmental NGOs, human rights organizations, academic and other relevant institutions can all play a vital role in a policy making for the Arctic. Not only are their areas of expertise key to developing effective policy solutions, they have been on the front lines of the creation of global issues based networks and using the Internet to mobilize change and monitor activities of the private sector and governments. For example, this is a fundamental tenant in applying Marine Spatial Planning throughout the region.

In the Arctic, networks can be used to build consensus and long-term capacity by directly addressing the newly emerging priorities in the Arctic and seeking to reduce conflict among participants. Such a process should be encouraged through the Arctic Council which is already a model for collaboration.

In addition to the use of networks of the world's experts to support cooperative, ecosystem-based management in the Arctic, the Commission urges the development of a dedicated prototypical "Arctic Conservation and Sustainable Development Network" designed around the principles of marine spatial planning, which will map and monitor the ecology and ongoing human activity in the region. The proposed Arctic Network should be organized as an inclusive and cooperative international undertaking so that participation in it—as well as access to its data and analysis—is maximized through an "open source" approach. Through the collection, tracking, linking and dissemination of information and analysis about environmental change and human activity in the Arctic, the long-term goal of the network will be to inhibit unplanned exploitation of natural resources and to identify opportunities for conservation and sustainable economic development in the region.

The prototype of an open-source Arctic observation and information-sharing network should be created and implemented to identify, record and track existing and newly emerging transnational ecological priorities in the Arctic marine environment.

The prototype of an open-source Arctic observation and information-sharing network should be created and implemented to identify, record and track existing and newly emerging transnational ecological priorities in the Arctic marine environment. This network (or networks) should be designed to stimulate policy discussions and help preempt potential use conflicts. The development of an Arctic-wide system of participatory networks should be led by Arctic governments in partnership with universities (i.e., the University of the Arctic) and other civil society and scientific entities. It should encourage equitable participation and employ a communications

strategy that makes clear the implications of its scientific data analysis for public policy decisions.

Scientists and environmental NGOs, academic and other relevant institutions, and human rights organizations will all have important roles to play in an Arctic network as it is envisioned by the Commission. Many of these sectors have already been employing global issues-based social networks to support their missions, using the Internet to mobilize change (e.g., Google Earth), as well as monitoring activities of the private sector and governments. This practical experience will be particularly useful in developing an information network that supports a marine spatial planning process throughout the Arctic.

When effectively instituted with cooperation between the states involved in the framework of the Arctic Council and other civil society entities, a dedicated communications and information regime will make the present governance system all the more holistic, integrated and effective across borders, sectors, and time.

In addition to modern scientific information, information and policy networks should also incorporate input from local communities, as well as the traditional knowledge of Indigenous Peoples, who are keenly aware of their natural environment and often best situated to detect changes in it. In order to fully access and contribute to the network, Indigenous communities should receive the necessary financial and technical support. Indeed, there is an opportunity here for governments and the private sector to support an information technology infrastructure that will allow all stakeholders to fully engage in Arctic governance.

Governments, the private sector and foundations should all commit to investing in an information-sharing network that ensures all stakeholders can effectively participate in the governance process. Support should include training in the use of hardware and software resources; providing equal access to all relevant data and analysis; and creating specific web-based communication and decision-making portals for carrying forward the policy setting, implementation, and course-correction actions called for in the Arctic, as determined by all the interested rights holders and stakeholders, together with government.

While ultimate responsibility for political decisions continues to lie with the executive authority (usually the government), it is also possible to construct incentives for ensuring compliance with a plan through heightened standards of accountability. Through stakeholder involvement increases each stakeholder group's responsibility for their own contributions and makes each one more likely to hold government and other stakeholders accountable for their respective commitments.

When effectively instituted with cooperation between the states involved in the framework of the Arctic Council and other civil society entities, a dedicated communications and information regime will make the present governance system all the more holistic, integrated and effective across borders, sectors, and time. Given the spatial expanse, multiple sovereign territories, and the dimensions of human activity in the Arctic now and in the future, an information-network-driven form of accountability for governance in the region is precisely what is needed to enhance the stewardship of newly emerging adaptation priorities in the Arctic due to climate change.

V. CALL FOR A SPECIAL DIPLOMATIC CONFERENCE ON THE ARCTIC

Achieving integrated, cross-sector ecosystem-based management on an international scale will require a political commitment at the highest levels. The Commission therefore recommends that, no later than 2012, heads of governments of the eight Arctic states convene an international diplomatic conference expressing clear agreement on a commitment to set in motion a ministerial level of action to develop an Arctic Marine Conservation and Sustainable Development Plan.

The Commission . . . recommends that, no later than 2012, heads of governments of the eight Arctic states convene an international diplomatic conference expressing clear agreement on a commitment to set in motion a ministerial level of action to develop an Arctic Marine Conservation and Sustainable Development Plan.

Recognizing the rapid and unpredictable changes that are occurring in the Arctic due to climate change and the fact that no adequate governance structure currently exists to address this change, the Commission proposes that the Arctic Governments authorize or otherwise engage the Arctic Council, with dedicated ministerial level and multi-stakeholder involvement, to initiate a five year planning process to develop an Arctic-wide Marine Conservation and Sustainable Development Plan based on integrated ecosystem-based management and a marine spatial planning process. This planning process should be used to define a set of common rules and standards for the Arctic marine environment based on ecosystem sciences, international law and the Law of the Sea, to effectively and sustainably manage human activities and natural resources across territorial boundaries and on the High Seas of the Arctic Ocean. The Commission believes a special diplomatic conference would both promote international cooperation and the importance of the Arctic, as well as seek ways to strengthen the safeguards needed to protect sensitive ecosystems and highly productive marine habitats.

Diplomatic conferences have historically played a key role in Arctic governance. The Ottawa Declaration in 1996, for example, established the Arctic Council as a high-level, intergovernmental forum focused on environmental protection in the region.[30] However, climate change impacts since the Council's founding have forced the need to rethink the direction of governance in the region. The Commission anticipates that a new diplomatic conference can promote the importance of the Arctic as a highly unique ecosystem, as a primary feature of global climate regulation, and as a focus of potentially competing international economic interests.

This high-level diplomatic conference proposed by the Commission will set in motion a more intentional form of multilateral cooperation between governments and civil society aimed at advancing an integrated plan, as well as information networks for conservation and sustainable development in the Arctic. The conference will also act as an international venue to raise global awareness of the importance of the Arctic and the ecological and social disruptions occurring there due to climate change.

VI. THE CRITICAL ROLE AND RIGHTS OF ARCTIC INDIGENOUS PEOPLES

Arctic Indigenous Peoples are not merely another group of stakeholders with an interest in the region; they are *rights-holders* under a number of formal international and domestic mechanisms.[31] Nevertheless, currently their interests are not fully represented in all the relevant governing bodies.

All states should therefore recognize the unique rights of Indigenous Peoples over development of their traditional lands and waters, and provide them with the necessary technical and financial support they need to participate in key policy venues affecting their futures, as avowed in the United Nations Declaration on the Rights of Indigenous Peoples, adopted by General Assembly Resolution 61/295 on 13 September 2007, Article 32, 2 says:

> *"States shall consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free and informed consent prior to the approval of any project affecting their lands or territories and other resources, particularly in connection with the development, utilization or exploitation of mineral, water or other resources."*[32]

New scientific findings should be communicated to Indigenous Peoples, as they are discovered, and economic benefits flowing from development in the Arctic should be shared equitably by the Indigenous Peoples.

All of the Permanent Participants (PPs) of the Arctic Council presently face thin staffing and a lack of scientific and technical capacity—a situation that will lead to growing difficulties as they participate in ever more demanding Arctic management processes, such as marine spatial planning or Arctic Ocean-wide fisheries management. To effectively engage in the processes affecting their future, these communities need the capacity to preserve their cultural heritage and richness which has made them such effective stewards of Arctic lands and waters for generations.

To effectively engage in the processes affecting their future, these communities need the capacity to preserve their cultural heritage and richness which has made them such effective stewards of Arctic lands and waters for generations.

In order to foster fuller civic participation among Northern indigenous communities and to ensure that those with the best knowledge of Indigenous Peoples' concerns are brought into the appropriate conversations and decision-making bodies, the capacity of these organizations and communities to participate

in such structures must be increased. Additional support must take the form of increased funding from member states and other sources (perhaps from civil society) as well as increased and/or pooled technical resources.

Some structures already in place may be able to serve the purpose of increased Indigenous participation in governance bodies, but they would require additional support. Linkages with NGOs, universities and other institutions should be explored to provide technical capacity to Indigenous Peoples. Universities in the region might serve as convening bodies, pools of expertise to support monitoring and decision-making, and centers with advanced telecommunications such as videoconferencing systems.

Formal institutions alone, however, will not be enough to ensure Arctic communities can effectively participate in new networked systems. Communications between communities and organizations at all levels must be improved.

The University of the Arctic, for example, was launched in 2001 with the goal of performing a social and cultural development and outreach role in Northern communities. Since then, it has evolved into a virtual network, with less focus on direct community development and more on providing post-secondary educational courses through a network of partner institutions. The university's original charter should be re-examined with a view toward how it can better support participation by Indigenous Peoples in Arctic governance. Its structure could be adapted to provide a long-term institutional communication network, including linguistic translation for non-English speakers and developing programs focused on building the next generation of young indigenous leaders with the skills and capacity to actively engage in future policy decision-making processes.

Some structures within the University of the Arctic could be revised or improved to very directly support networked processes. In particular, its Standing Committee on Ecosystem-Based Management, with its strong membership of indigenous organizations, might be well-placed to initiate Arctic-wide ecosystem-based management planning and activities, if reinvigorated. Formal institutions alone, however, will not be enough to ensure Arctic communities can effectively participate in new networked systems. Communications between communities and organizations at all levels must be improved.

As part of the capacity-building effort for Indigenous Peoples throughout the Arctic, it will be necessary to develop and encourage multiple means of communication, in multiple languages, whether informal channels like radio and TV announcements and web outreach or more formal channels including regular meetings, dialogues and reports. These methods should all be leveraged to complete the circle of information to and from communities.

VII. COLLABORATING ON ARCTIC SCIENCE

In view of the scale of global climate change and the lack of any international agreement on mitigation of its impacts, the need to better understand adaptation with respect to the geophysical and ecological dynamics of Arctic systems has only grown more urgent. But much about the natural ecosystems of the Arctic is still unknown. At the same time, the Arctic remains a remote and expensive place to conduct scientific research, placing a premium on cooperation, coordination of monitoring

efforts, and the sharing of research platforms.

Scientific understanding of fish-population numbers, life history characteristics, spatial distribution, and predator-prey relationships over much of the Arctic is very limited, with the exception of the North East Atlantic fishery. Predicting how CO2-related changes will affect fish is even more difficult, but some experts predict that polar cod, capelin and Greenland halibut populations are likely to decline as their ranges contract, while others are likely to expand into the Arctic.

…the Arctic remains a remote and expensive place to conduct scientific research, placing a premium on cooperation, coordination of monitoring efforts, and the sharing of research platforms.

The major limitation to establishing marine protected areas in the Arctic is the relative scarcity of published scientific information on specific marine habitats in the regions that are biologically or ecologically important. In addition, there has never been a coordinated, Arctic-wide effort to tap the enormous reservoir of local knowledge about ecologically and biologically significant marine habitats. The United Nations Convention on the Law of the Sea provides a basic framework for conducting scientific research, but not for allowing access to territorial waters for that specific purpose. Several national policies support international cooperation in this area, yet no international agreement exists to respond to the effects of climate change. Meanwhile, satellites that have provided invaluable tools for scientists studying changes to Arctic glaciers are reaching the end of their useful life, leaving a real void in the ability to continue observing key geophysical phenomena in the region.

In general, funding of scientific research in the Arctic should be prioritized based on specific environmental and development challenges facing policymakers. The effects of climate change on Arctic marine and terrestrial environments should be a primary focus.

One successful model of cooperative scientific research in the region, the International Polar Year (IPY) was a particularly important effort in the development of polar science. Concluded in 2009, it represented a vast investment in science for enhanced understanding of the polar areas and their role in the global climate system in particular. However, with the conclusion of IPY, the level of effort in polar research (the larger share of which went to the Antarctic in any case) has been substantially reduced. A concerted effort is therefore required to maintain momentum in polar science and to build on the legacy of the IPY, whose Sustaining Arctic Observation Network (SAON) should be continued and developed further. Its data and analysis should also contribute to future assessments by IPCC.

Scientific education, recruitment, funding and exchanges are critical to encouraging a culture of understanding across borders and disciplines. Achieving mutual objectives for data sharing, unified monitoring, and access may be possible on the basis of existing technical working relationships, but it is also likely that some important scientific initiatives would benefit from broader, more formal agreements at the regional level.

THE NEW YORK TIMES

The Commission therefore urges the development of a series of multilateral memoranda of understanding (MOUs) among Arctic nations to support shared research infrastructure and access to areas of scientific interest in the Arctic. Access to research data and the issuance of research permits should be expanded, as should access to resulting scientific data and analysis. These MOUs will provide a predetermined means of sharing resources such as scientific instruments, personnel, and data, and perform additional services such as contracting mechanisms to facilitate execution of scientific support activities.

Perhaps one of the most obvious strategies for implementing the Commission's proposed recommendations in this report is to reinvigorate the Council as a forum that supports effective, cooperative governance of the circumpolar region with due recognition of the rights of its people.

Traditional knowledge has been a vital component to scientific understanding of Arctic ecosystems for centuries, and Indigenous peoples have been instrumental in a number of recent Arctic Council technical initiatives, such as Arctic Climate Impact Assessment.

In addition to enhancing the University of the Arctic's existing structure, reforms might also aim to create a "bricks and mortar" higher educational system directly in Northern communities. This system could focus on training a new generation of indigenous scientists to respond to the complex challenges of resource conservation, monitoring and management, and sustainable development that lie ahead for Arctic peoples.

In general, funding of scientific research in the Arctic should be prioritized based on specific environmental and development challenges facing policymakers. The effects of climate change on Arctic marine and terrestrial environments should be a primary focus.

VIII. STRENGTHENING THE ARCTIC COUNCIL

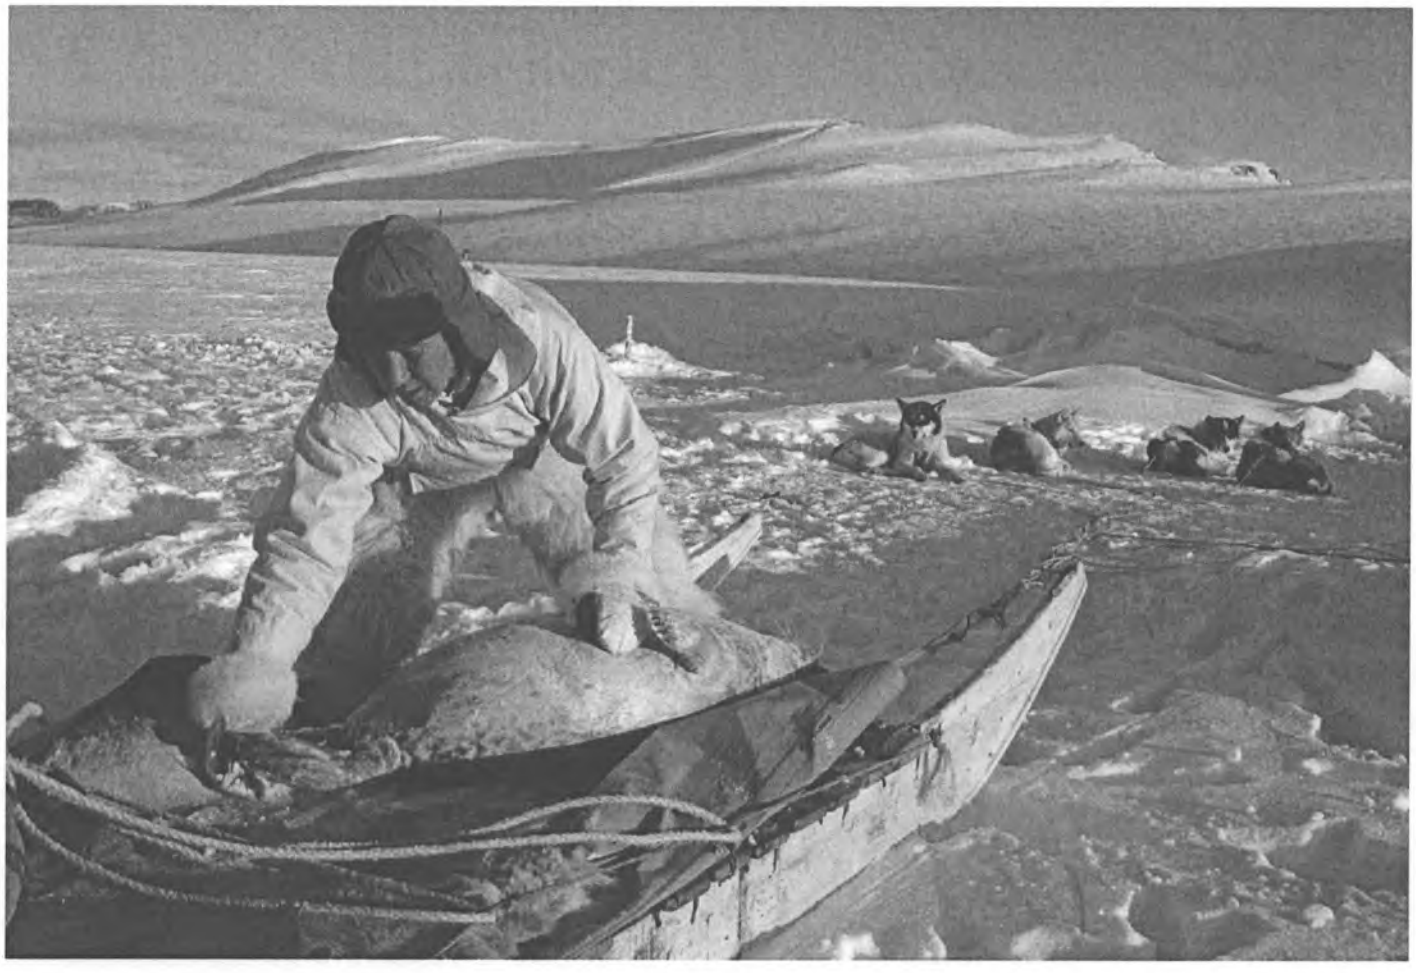
As a result of the fact that a number of Commission participants have worked extensively over the years with the Arctic Council, they were well aware that the Council, from its founding in 1996, represents an historic innovation, both in its structure and operations. The formal inclusion of the six permanent participant (PP) representatives of Indigenous Peoples in the Council, for example, remains a progressive benchmark.

The Arctic Council has embodied a commitment among the eight Arctic nations to cooperate on issues of environmental protection and sustainable development. As such, the spirit in which the Council was founded represents the type of cooperative, collegial, institutional thinking needed now to address new challenges arising from climate change in the Arctic.

The active inclusion of Permanent Participants (PPs) in all future deliberations on Artic governance is paramount, which means a sustainable source of funding must be available for the participation of Indigenous Peoples' Organizations.

Over the years, the Council has focused on critical issues such as widespread chemical contamination caused by persistent organic pollutants (POPs) in Arctic wildlife and human communities, with rigorous scientific assessments leading to recommendations for corrective action by the Arctic governments. Other priorities that have emerged from the Council's cooperative process include the remediation of abandoned hazardous and radioactive waste sites; the enhancement of habitat conservation through protected area strategies; the enhancement of capacity for emergency preparedness and response; improvement of post-secondary educational opportunity in the region; the strengthening of regulation of shipping; improvement of the consistency of regulation of offshore oil and gas activities; development of ecosystem-based management strategies for marine resources; and the improvement of understanding and response to threats related to climate change.

Moving forward, the Council will also need to reconsider how it interacts—both formally and informally—with interests beyond the eight Arctic nations.



The Council also recently conducted a thorough assessment of the impact and management of future shipping in the Arctic Ocean, and has recommended steps to address a number of regulatory gaps in this area. Its recommendations in this area will require the Arctic governments to work in concert with the recognized international shipping regulator, the International Maritime Organization (a coordination effort that inherently adds to the complexity and time needed to reform Arctic shipping regulations).

Despite its notable achievements, the Council is constituted as a forum, rather than a regulatory body in its own right, and therefore has no legal or policy-forming personality to address emerging governance challenges in the region. In recent years, the Council has faced a lack of resources and an increasing tendency among its member countries to bypass it as a forum for discussion and decision. While it remains an important body, issues of real geopolitical significance for the region are increasingly being debated among the Arctic Ocean states outside the purview of the Council. The Arctic nations now appear to be growingly concerned with mapping out their undersea shelves, planting flags at the bottom of the ocean, and arguing over the possession of tiny islands.

The Arctic Council should be reinforced as an effective, multilateral organization for the region by giving it the resources and a revised architecture to ensure that the planning, management and accountability expressed in this report's recommendations are realized. The Council should be given a full-time secretariat and sufficient funding to produce strong results from its working groups and non-Arctic states should be permitted to participate in the Council.

The Arctic Council should be reset as an effective, multilateral organization for the region and given the resources and a revised architecture to ensure that the planning, management and accountability expressed in this report's recommendations are realized. The Council's mandate should be expanded to include discussions of environmental security and it should be given a full-time secretariat and sufficient funding to produce strong results from its working groups. A permanent post of Ambassador for Circumpolar Affairs should be appointed to the Council by each member state (alternatively, Arctic nations should participate in the Arctic Council through senior ministerial-level officials who are empowered to make significant commitments and decisions for their governments) and non-Arctic states should be permitted to participate in the Council as permanent observers.

The active inclusion of Permanent Participants (PPs) in all future deliberations on Artic governance is paramount, which means a sustainable source of funding must be available for the participation of Indigenous Peoples' Organizations. Enhancing their capacity to participate in the Council's forum, by strengthening the PPs technically and financially, along with other indigenous organizations (such as the Indigenous Peoples' Secretariat) and other communities across the Arctic, may be the first, most effective step in this capacity-building process. Moving forward, the Council will also need to reconsider how it interacts—both formally and informally—with interests beyond the eight Arctic nations.

Conclusion: A Hopeful Future For The Arctic

Having extensively, although not entirely, analyzed some of the most difficult and complex challenges facing the Arctic, a unique and remote region that affects the entire globe, the Commission has formulated what it considers the most hopeful and flexible strategies for ensuring the highest degree of resilience and adaptation for the region's societies and ecosystems.

To optimize economic fairness and environmental sustainability in the Arctic, the Commission recommends an enhanced management system that includes linked information networks among all interested stakeholders. This entails a new model of ecosystems management in the Arctic, employing global and regional information networks that promote an ethic of stewardship and multinational use of best management practices, as well as adoption of successful management protocols developed by leading experts from around the world.

A model of transparent governance and open-source information sharing and decision making will complement the existing system of national and international governance mechanisms in the Arctic across traditional boundaries and sectors, enhancing ecological stewardship as new priorities emerge in the region. It will also help empower Indigenous Peoples in the Arctic to adapt socially and economically to the future impacts of climate change, with an appreciation for their ancient connection to the environment and the cultural values they derive from it.

A well-structured and dynamic network of public and private institutions and stakeholder groups will be critical to strengthening management and governance in the Arctic, guided by a defined set of economic, ecological and scientific and cultural objectives that allow for sustainable development. The proposed Arctic network will integrate monitoring, evaluation and reporting processes that consider ecosystem resilience, climate-induced ecological changes, and human activity, as well as a transparent process for establishing planning goals and setting conservation objectives.

It should be noted that stakeholders committed to an improved system of Arctic governance need not wait for governments to take the lead; like-minded groups could begin any time developing networks that strengthen and improve governance in the region. Indigenous Peoples, for example, already have the basis for a network of their own through organizations such as the Inuit Circumpolar Council (ICC) and the University of the Arctic. With sufficient resources and a clear strategy, such as a common approach for initiating large scale marine spatial planning, such existing networks could be interconnected and mobilized to begin playing an active, cooperative role in Arctic governance.

Essentially, what the Commission proposes is a civil society governance model that rapidly synthesizes scientific knowledge and supports effective political decision making through a marine spatial planning process. A network of non-governmental organizations—along with active engagement and support from governments—will help develop fresh and unconventional solutions to the complex scientific and governance challenges facing the Arctic. These creative new alliances will involve partnerships between a broad constellation of actors at all levels of civil society, governments and commercial institutions, not necessarily limited by the traditional concerns of nation states, but sharing ideas and resources in innovative ways, all directed toward preserving what is unique and valuable in the Arctic, and promoting adaptation to the inevitable environmental changes to come.

APPENDIX 1

NOTED ARCTIC EXPERTS INVITED TO SELECTED COMMISSION AND WORKING GROUP MEETINGS

Jack Belcher, PARTNER, **ENERGYNORTHAMERICA LLC**

Paul Berkman, HEAD, **ARCTIC OCEAN GEOPOLITICS PROGRAMME, SCOTT POLAR RESEARCH INSTITUTE, UNIVERSITY OF CAMBRIDGE**

Mike Boots, ASSOCIATE DIRECTOR, **LAND AND WATER ECOSYSTEMS, COUNCIL ON ENVIRONMENTAL QUALITY**

John Crump, POLAR ISSUES COORDINATOR, **UNEP/GRID-ARENDAL**

Hajo Eicken, PROFESSOR OF GEOPHYSICS, **UNIVERSITY OF ALASKA FAIRBANKS**

Chad English, DIRECTOR OF SCIENCE POLICY OUTREACH, **COMPASS**

Bernard Fautrier, VICE-PRESIDENT AND CEO, **PRINCE ALBERT II OF MONACO FOUNDATION**

Paul Gibbard, DIRECTOR, **ABORIGINAL AND CIRCUMPOLAR AFFAIRS, FOREIGN AFFAIRS AND INTERNATIONAL TRADE DEPARTMENT, CANADA**

David Gordon, EXECUTIVE DIRECTOR, **PACIFIC ENVIRONMENT**

Marika Holland, SCIENTIST, **NATIONAL CENTER FOR ATMOSPHERIC RESEARCH**

Maria Ivanova, DIRECTOR, **GLOBAL ENVIRONMENTAL GOVERNANCE PROJECT, CENTER FOR ENVIRONMENTAL LAW AND POLICY, YALE UNIVERSITY**

Brendan Kelly, RESEARCH BIOLOGIST, **NATIONAL MARINE MAMMAL LABORATORY**

Thomas Laughlin, DEPUTY HEAD OF THE GLOBAL MARINE PROGRAMME, **INTERNATIONAL UNION FOR CONSERVATION OF NATURE**

Michael Macrander, SCIENCE TEAM LEAD, ALASKA VENTURE, **SHELL EXPLORATION AND PRODUCTION COMPANY**

Dawn Martin, PRESIDENT, **SEAWEB**

Michael Mehling, PRESIDENT, **ECOLOGIC INSTITUTE**

Petter Meier, COUNSELOR FOR FISHERIES, **NORWEGIAN EMBASSY, WASHINGTON, D.C.**

Kent Satterlee, III, MANAGER REGULATORY POLICY –OFFSHORE UPSTREAM AMERICAS, **SHELL EXPLORATION & PRODUCTION COMPANY**

Rodion Sulyandziga, FIRST VICE-PRESIDENT, **RUSSIAN ASSOCIATION OF INDIGENOUS PEOPLES OF THE NORTH (RAIPON)**

Mead Treadwell, FORMER CHAIR, **U.S. ARCTIC RESEARCH COMMISSION, CURRENT LIEUTENANT GOVERNOR, ALASKA**

APPENDIX 2

COMMISSION MEETINGS AND EVENTS

The following is a list of the meetings convened by the Aspen Institute for the Commission:

- **May 4 - 7 2008:** Formal start of the Dialogue and Commission on Arctic Climate Change and Working Group Meeting - Session I, Aspen, CO
- **July 11 - 18, 2008:** Commission Expedition to the Arctic
- **August 11 – 14, 2008:** Dialogue and Commission on Arctic Climate Change Working Group Meetings with Arctic Parliamentarians; Barrow, AK, residents; and University of Alaska, Fairbanks, scientists to hear their findings and concerns firsthand
- **November 19 – 22, 2008:** Dialogue and Commission on Arctic Climate Change Working Group - Session II, Wye, MD
- **March 5 – 7, 2009:** Dialogue and Commission on Arctic Climate Change Working Group - Session III, Brussels, Belgium; the Commission also participated in the Arctic Transform Meeting entitled "Transatlantic Policy Options for the Marine Environment."
- **April 17 – 18, 2009:** Dialogue and Commission on Arctic Climate Change - Commissioner Meeting, Monaco
- **July 22 – 25, 2009:** Dialogue and Commission on Arctic Climate Change Commissioner Meeting and Working Group - Session IV, Winnipeg, Canada
- **September 22, 2009:** Commission United Nations General Assembly Press Conference featuring remarks by Prince Albert II and selected Commissioners
- **November 12 – 14, 2009:** Dialogue and Commission on Arctic Climate Change Working Group - Session V, Ft. Baker, CA
- **December 3, 2009:** Arctic Workshop, Antarctic Treaty Summit, Washington DC
- **December 11 – 15, 2009:** Informal press event with Prince Albert II and selected Commissioners, COP-15; participation in the WWF "Pole to Pole" Tent
- **February 21 – 24, 2010:** Dialogue and Commission on Arctic Climate Change Working Group - Session VI, Aspen, CO
- **May 17 – 18, 2010:** Dialogue and Commission on Arctic Climate Change Working Group - Session VII, Washington, DC
- **August 1 – 4, 2010:** Dialogue and Commission on Arctic Climate Change Working Group - Session VIII, Ft. Baker, CA
- **August 4 – 6, 2010:** Dialogue and Commission on Arctic Climate Change Working Group Meeting with Indigenous Leaders, Ft. Baker, CA
- **September 20 – 21, 2010:** Dialogue and Commission on Arctic Climate Change Meeting, New York City, NY
- **September 22 – 23, 2010:** International Forum: The Arctic: Territory of Dialogue, hosted by the Royal Geographic Society, Moscow, Russia
- **October 13 – 15, 2010:** NATO Advanced Research Workshop: Environmental Security in the Arctic Ocean, hosted by Scott Polar Research Institute, University of Cambridge
- **October 14 – 15, 2010:** Arctic Futures Symposium, Climate Change, Research and Developing Economic Opportunities, Implications for Policy in the Arctic, Brussels, Belgium

ENDNOTES

[1]The Arctic's Indigenous Peoples are already facing the need to adapt their ways of life as the summer ice pack retreats, resulting in profound implications for their economic and cultural traditions. These changes include impacts on subsistence hunts for marine mammals, with declines of ice-dependent species such as polar bear, walrus, and certain seal species.

[2]National Oceanic and Atmospheric Administration: "Arctic Report Card: Region Continues to Warm at Unprecedented Rate…Record temperatures in Greenland, thinning sea ice, record snow cover decreases and links to some Northern Hemisphere weather are among dramatic changes…" and pullout quote accompanying text: Jane Lubchenco, PhD, Under Secretary of Commerce for Oceans and Atmosphere and NOAA Administrator, "The Arctic is an important driver of climate and weather around the world and serves as a critical feeding and breeding ground that supports globally significant populations of birds, mammals and fish." October 21, 2010.

[4]As a result of the fact that a number of Aspen Commission participants have worked extensively over the years with the Arctic Council, the group was well aware that the council represented an historic innovation, both in its structure and its method of operation. In particular, the formal inclusion of the six "permanent participant" (PP) representatives of Indigenous Peoples in the Arctic region's premier intergovernmental forum remains a progressive benchmark.

[15]U.S. Geological Survey, 2008. Circum-Arctic Resource Appraisal: Estimates of Undiscovered Oil and Gas North of the Arctic Circle

[16]Other key operations subject to standards include the policy for relief wells, handling of solid and liquid discharges, marine sound emissions, air emissions and possible seasonal restrictions (e.g., with respect to marine mammal migration). There are different standards across the arctic for different jurisdictions and operating theatres and it is imperative that industry, regulators and key stakeholders share best practices based on science and prevailing local requirements

[17]On the other hand, polar cod, capelin and Greenland halibut will are likely to see their ranges contract and are expected to decline in abundance. The latter three species play an important role in Arctic ecosystems. Capelin is an important prey species for cod, seabirds and seals. Greenland halibut provides an important source of food for deep feeding marine mammals (narwhals and hooded seals), and sharks. Polar cod is considered a keystone species linking lower trophic levels to seals, whales and seabirds. The ecological implications of climate-related impacts on these species fish are difficult to assess but are likely to reverberate in unpredictable ways up the marine food chain.

[18]Fishing for species that occur solely within waters under the jurisdiction of an Arctic nation is subject to national regulation and control. Fishing for species that occur beyond the jurisdiction of one country typically requires international management. Many global soft and hard law agreements apply to fishing generally, including in the Arctic. These include the Law of the Sea, the UN Fish Stocks Agreement, and various voluntary guidelines and codes of conduct. In addition, there are a number of bilateral or regional fishery management organizations and arrangements (RFMO/As) that apply to fishing in the Arctic south of the Bering Sea and Svalbard.

[19]As per the Final Report of the US Commission on Ocean Policy, a balanced precautionary approach applies "judicious and responsible" management practices, based on the best available science and on "proactive, rather than reactive, policies." When the level of uncertainty is low and the likelihood of damage is also low, the decision to proceed with an activity is supported. At the other extreme, when the level of uncertainty is high and the potential for irreversible damage is also high, activities should not be allowed to proceed. (In actual practice, managers typically face decisions between these two extremes). After a decision to proceed with a certain activity is made, managers must continue to gather information needed to reduce uncertainty, periodically assess the situation, and modify activities as appropriate.

[24]Convention on the Prohibition of the Use, Stockpiling, Production and Transfer of Anti Personnel Mines and on Their Destruction. Ottawa 1997.

[25]Lloyd Axworthy and Dan Hurley, Networks and the Future of the Arctic. "A new strategy for Arctic governance must therefore encompass a shift in consciousness toward global networks, and recognize that the challenges of the region are not limited to national concerns – and, indeed, that these broader concerns cannot be addressed solely by the governments of nation-states. These are challenges that require broader awareness, international cooperation and innovative ideas…One idea gaining credence as an alternative to the state-centric approach is the notion of network governance."

[26]The Rise of Netpolitik, id at n23

[27]It is imperative at the onset of the consideration for how "networked governance" can be used in the context of Arctic stewardship to recognize the uncertainty and skepticism that this concept elicits. Contrary to what may be gainsaid about networked governance as a way to enhance international policy and regulatory objectives (i.e., networked governance builds accountability where none is present, or enhances governance where it is weak, but it does not displace government), an open source network of information sharing has great potential to complement the existing matrix of overlapping national and international governance mechanisms. Networked governance neither replaces nor substitutes the roles of government, which are based on national and international laws and regulations, including the Law of the Sea.

[28]Annette Heuser, "New Methods of Governance: Networked Governance will decide the competitiveness of states in the future," iPolitics, July/August 2009, pp. 26-31 [translation].

[29]In the case of the Landmines Treaty, Six nongovernmental organizations founded the International Campaign to Ban Landmines in 1992 using a powerful communications network that relied on the cutting-edge technology of the time. About 2,000 groups that were organized in a coordinated network successfully brought international attention to the dangers of abandoned landmines and forced governments to account for their use of the weapons. From that point on, this network focused on the treaty process and on effectively shifting international norms.

[30]The Arctic Council was established by the General Assembly of the United Nations as a high level forum to inter alia "provide a means for promoting cooperation, coordination and interaction among the Arctic states, with the involvement of the Arctic indigenous communities and other Arctic inhabitants on common arctic issues, in particular issues of sustainable development and environmental protection in the Arctic." Declaration on the Establishment of the Arctic Council (Ottawa, Canada, 1996).

PART TWO

MARINE SPATIAL PLANNING IN THE ARCTIC:

A first step toward ecosystem-based management

A technical report of the Aspen Institute
Dialogue and Commission on
Arctic Climate Change

Prepared by Charles N. Ehler, Ocean Visions

This technical report of the Aspen Institute's Dialogue and Commission on Arctic Climate Change was commissioned by the Aspen Institute on behalf of the Commission. The views expressed in this report are those of the author, Charles N. Ehler, and do not necessarily represent the views of the Aspen Institute or any individual member of the Commission. All efforts have been made to ensure accuracy of this report, but the author is ultimately responsible for all inaccuracies in this report.

Executive Summary

Driven by outside economic forces and the effects of climate change, the Arctic, its ecosystems, and its people are faced with substantial change ranging from the loss of ice-dependent species, more intense uses of the Arctic resources, including space, and the loss of natural services provides by Arctic ecosystems. International and national interests in mitigating and adapting to these changes has led to increased calls to manage human activities through an ecosystem-based approach. Marine spatial planning has emerged as an operational approach to translate this concept into management practice in many marine areas around the world.

Marine spatial planning is a public process of analyzing and allocating the spatial and temporal distribution of human activities to specific marine areas to achieve ecological, economic, and social goals and objectives that are specified through a political process. MSP is integrated, future-oriented, participatory, adaptive, ecosystem-based, and area-based. The process of MSP answers three simple questions: (1) where are we today?; (2) where do we want to be?; and (3) how do we get there?

Effective marine spatial planning is a continuous process, not a one-time "master plan", and can only be successful through a highly-participatory networked governance approach, i.e., all who have an interest in the governance of the Arctic are included in all stages throughout the process—from setting goals and specifying measurable objectives, through implementation, monitoring, and evaluation. Monitoring and evaluation of the performance of the MSP process is critical. The performance of management plans and their specific measures should be monitored, evaluated and reported to all stakeholders and rights-holders in a transparent manner.

MSP can provide a variety of environmental, economic and social benefits ranging from identifying biologically and ecologically important areas and identifying the cumulative effects of human activities on the environment, to creating certainty for business investment decisions and streamlining the process to creating new opportunities for local community and citizen participation, including indigenous peoples.

Marine spatial planning is already in place in one Arctic country—Norway has implemented an integrated management plan, including spatial and temporal management measures, for its part of the Barents Sea. The plan integrates previously separate management regimes for fisheries, shipping, oil and gas, and nature conservation. Canada has developed an integrated management plan for its part of the Beaufort Sea that will develop a marine spatial plan as one of its future actions. In the US, the federal government has developed a marine spatial planning framework for its entire exclusive economic zone, including its Arctic seas.

Alternatives for moving MSP forward in the Arctic are identified: (1) a "business as usual", incremental approach; (2) a "bilateral" approach between national governments; (3) a "hot spot" approach; (4) an Arctic-wide approach among national governments; and (5) an Arctic-wide approach beyond national governments.

Introduction

During the course of the deliberations of the Aspen Commission on Arctic Climate Change, marine spatial planning (MSP) assumed a prominent role as a potential tool for meeting natural resource management challenges in the Arctic in the face of growing pressure from various industries, notably energy, minerals and fisheries.

In some ways the Arctic is undoubtedly unique. Yet the changes taking place there will have significant implications for the global community, and the challenges of adaptation for communities and living resources in this remote region may provide important lessons for the future of other regions as well. It became clear to the Commission during their fact-finding missions and deliberations that the scale of change in the region, if not addressed in a suitably comprehensive manner as represented by the MSP approach, would so seriously degrade the Arctic's living systems and so transform the region as to make incremental efforts at adaptation futile.

In parallel with gathering information and views about the changes already underway in the Arctic, the Commission and its working group began a process of reviewing the current institutional framework for management of natural resources in the Arctic, and of exploring models of management approaches that have shown promise in other areas. In reviewing various approaches to the management of marine systems over the past half-century, the participants in the dialogue became convinced that sector-based regulation as traditionally practiced has not shown success in protecting the integrity of marine ecosystems, and would not likely prevent the degradation of the Arctic. With the able assistance of a number of experts, including Jane Lubchenco (now the Administrator of the U.S. National Oceanic and Atmospheric Administration (NOAA)) and Andy Rosenberg (Senior Vice-President for Science and Knowledge at Conservation International), the Commission explored models of integrated marine management that could be applied in the Arctic.

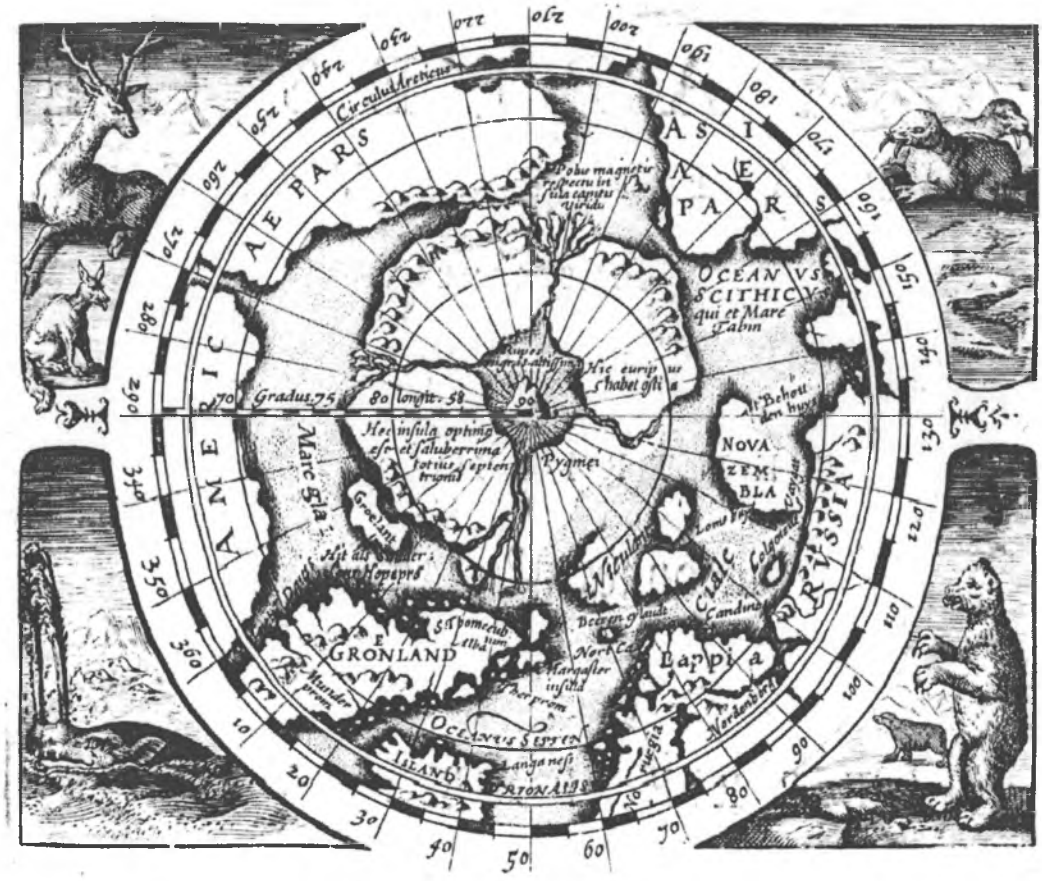
Dialogue participants recognized that most of the new economic activity projected in the Arctic maritime environment will take place in the coastal zones surrounding the high Arctic, and that the resources of these coastal areas are increasingly fragile and stressed by the direct impacts of climate change. They focused on the potential for ecosystem-based management, and integrated marine spatial planning, to ensure rational and sustainable use of this fragile resource base. A second feature of this planning approach further heightened its attractiveness—its accessibility to, and in fact, its reliance on the expert contribution of communities and local stakeholders. It is a premise of this report that the conservation and sustainable use of the resources of the Arctic marine environment should be conducted in a manner that benefits the local communities of the region, and most particularly the traditional communities that have co-existed in the Arctic environment for thousands of years. There is a clear need for traditional and indigenous communities to have a voice in decisions affecting their future, and it is hoped that an integrated planning approach such as the one outlined in this paper will contribute a useful framework for this participation in the future.

Context and Perspective

While parts of the Arctic have been inhabited for over 10,000 years, many parts have never been inhabited. If any of the early inhabitants drew maps, none have survived. Until 500 years ago, the Arctic was unknown to Western man—simply a white space on maps. Total open water, all land, land with rivers and magnetic mountains—all were conceptions of the Arctic.[1] A voyage by Sebastian Cabot to somewhere in the Davis Strait in 1508-09 was probably responsible for the first depiction of a Northwest Passage to the riches of China on a map. Cabot, in 1553 the Pilot Major of England, also recommended that the English search northeast for a passage to China. Over the next 450 years attempts in both directions by the English, Spanish, Portuguese, and Dutch failed. The Northwest Passage (Oslo, Norway, to Nome, Alaska) was finally achieved in 1905 by the Norwegian explorer Roald Amundsen in a refitted herring boat, the Gjoa. The first Northeast Passage (Vladivostok to Arkhangel'sk) was made by two Russian ice-breaking survey ships only in 1915.

Our knowledge of the Arctic has evolved rapidly in the last 100 years as technology has advanced. Theories of an ice-free open polar sea did not die until the 1870s, yet these were still as much guesswork as 16th century theories of an ice-free Arctic and a clear passage over the Pole. Now, because of climate change, the reality of an ice-free Arctic may not be so far away.

Figure 1. *Petrus Bertius, 1618. North Polar Regions (note that four rivers flow out from a polar mountain)*



The Need for an Ecosystem-based Approach to Marine Planning and Management in the Arctic

The Arctic—all 30 million square kilometers of it—is one of the most pristine, yet vulnerable, ecosystems in the world. [2] Protected by its historic inaccessibility, harsh environment, comparatively small human population, and slow rate of economic development, the Arctic has been relatively less affected by human activity than most other regions of the earth.

This is about to change. Driven by outside economic forces and the effects of climate change, the Arctic, its ecosystems, and its people are all faced with substantial change ranging from the loss of ice-dependent species, more intense human uses of the Arctic, and the loss of natural services provided by Arctic ecosystems. As the Arctic warms, its ice melts, and its ecosystems change, as technology improves, and as the demand for natural resources increases, opportunities open up for industry—shorter shipping routes, virgin fishing grounds, new areas of oil and gas exploration and development, and new places for commercial tourism. As well as business opportunities, these changes represent new risks to the Arctic's unique natural environment and to the people who now live and work in the Arctic. Once these activities begin in the Arctic, it will be difficult for policy makers and managers to put limits on them.

The failure of sectoral management in marine areas everywhere is long known and well documented. Before the last century, the oceans were used mainly for two purposes: navigation and fishing. Conflicts between uses were few and far between except around some ports. Traditionally marine management has been characterized as a sector-by-sector approach. Fisheries were managed separately from oil and gas development, which in turn was managed separately from marine navigation, despite real conflicts between uses. [3] Single-sector management has often failed to resolve these user-user conflicts, rarely dealing explicitly with trade-offs among uses, and even more rarely dealing with conflicts between the cumulative effects of multiple uses and the marine environment. New uses of marine areas including renewable energy, offshore aquaculture, and marine tourism, as well as the designation of new marine protected areas, have only exacerbated the situation. Single-sector management has also tended to reduce and dissipate the effect of enforcement at sea because of the scope and geographic coverage involved and the environmental conditions in which monitoring and enforcement have to operate. In sharp contrast to the land, little "public policing" of human activities takes place at sea.

As a consequence marine ecosystems around the world are in trouble. Both the severity and scale of impact on marine ecosystems—from climate change, biodiversity loss, pollution, development, habitat loss, and fragmentation—are increasing, with no corner of the world left untouched.[4,5] Awareness is growing that the ongoing degradation in marine ecosystems is in large part a failure of governance.[6,7] Many scientists and policy analysts have advo¬cated reforms centered on the idea of ecosystem-based management (EBM). [8] To date, however, a feasible method for translating this concept into an operational management practice has not emerged.

Many recommendations for an ecosystem-based approach to marine management in the Arctic already exist. In fact, in most Arctic countries are working to implement ecosystem-based management of their marine areas. The Arctic Council has repeatedly called for an ecosystem-based approach to marine management. For example, in its 2004 Arctic Marine Strategic Plan ecosystem-based management is defined as an approach that "...requires that development activities be coordinated in a way that minimizes their impact on the environment and integrates thinking across environmental, socio-economic, political

and sectoral realms." The key features of this approach includes a consideration of multiple scales, a long-term perspective, the recognition that humans are an integral part of ecosystems, an adaptive management perspective, and a concern for sustaining production and consumption potential for goods and services. [9]

The Best Practices in Ecosystem-based Oceans Management in the Arctic (BePOMAr) Project of the Arctic Council has summarized the practices that Arctic countries have used to apply an ecosystems-based management approach to marine management. [10] The conclusions of that project include:

- Flexible application of effective ecosystem-based oceans management;
- Decision-making must be integrated and science based;
- National commitment is required for effective management;
- Area-based approaches and trans-boundary perspectives are necessary;
- Stakeholder and Arctic resident participation is a key element; and
- Adaptive management is critical.

Successful ocean governance requires a capacity to deal with human and natural systems that are complex, heterogeneous, dynamic, and prone to nonlinear and often abrupt changes. This is not simply a matter of improving the management of fisheries, paying more attention to the effects of vessel routing, or managing the effects of increased tourism. What is needed is a "systems approach" that facilitates thinking about interactions among multiple natural and human drivers and directs attention to emergent and cumulative impacts from these interactions. To be successful under these conditions, governance systems must be able to monitor changes closely, adjust existing management action to changing circumstances, and cope with relatively high levels of uncertainty, i.e., they must engage in adaptive management. Feedback—in the form of monitoring information that informs management about the reactions of the managed systems to external influences and management measures—is critical to adaptation and success under these conditions. [11]

The thinking that underlies marine spatial planning is one that emphasizes spatially and temporally explicit activities and dynamic processes. It recognizes the heterogeneous distribution of marine species, habitats, and human activities in the sea; resources and resource uses occur in "places." Some are fixed in place, e.g., oil deposits; some are mobile, e.g., fish populations. Some places are more important than others. Relatively dense information about the direct effects of human actions upon the interacting elements of the system, whether measured or not, is likely to be found near the occurrence of those activities. Over time, the effect of any activity spreads and often dissipates and, consequently, becomes more difficult to isolate and measure. Management that operates at the scale where dense and direct information about the impact of a particular activity is available enhances the prospect of capturing useful and less costly feedback. If carried out at the same time the management agency is monitoring other elements of the system, such feedback becomes even more valuable. Such improvements can lead to more rapid adaptation and more effective learning about how to govern. [12]

Box 1. A Definition of Ecosystem-based Management

Offshore Oil and Gas Guidelines (2009 version; ANNEX A - Definition of the Arctic)

Ecosystem-based management is an integrated approach to management that considers the entire ecosystem, including humans. The goal of ecosystem-based management is to maintain an ecosystem in a healthy, productive and resilient condition so that it can provide the services humans want and need. Ecosystem-based management differs from current approaches that usually focus on a single species, sector, activity or concern; it considers the cumulative impacts of different sectors.

Specifically, ecosystem-based management:

- emphasizes the protection of ecosystem structure, functioning, and key processes;
- is place-based in focusing on a specific ecosystem and the range of activities affecting it;
- explicitly accounts for the interconnectedness within systems, recognizing the importance of interactions between many target species or key services and other non-target species;
- acknowledges interconnectedness among systems, such as between air, land and sea; and
- integrates ecological, social, economic, and institutional perspectives, recognizing their strong interdependences.

Scientific Consensus Statement on
Marine Ecosystem-Based Management, 2005 [13]

An integrated, ecosystem-based management approach has been identified in many marine places as an appropriate evolution to address problems caused by today's incremental, single-sector approach to marine management. However, examples of practical applications of an ecosystem-based approach are elusive. How to begin is the first challenge.

As mentioned, several Arctic nations have already begun to implement an ecosystem-based approach to their marine waters. [14] Both Norway in the Barents Sea and Canada in the Beaufort Sea have developed integrated management plans that employ an ecosystem-based approach (see later section of this report). A policy directive of the United States instructs appropriate federal departments to "pursue marine ecosystem-based management in the Arctic." [15] A more recent initiative by the U.S. to develop and implement an ocean policy and framework for marine spatial planning throughout its exclusive economic zone also supports adoption of "ecosystem-based management as a guiding principle, acknowledging regional differences, and practicing adaptive management." It also concludes that "human activities that may affect ocean, coastal, and Great Lakes ecosystems should be managed using ecosystem-based management and adaptive management, through an integrated framework that accounts for the interdependence of the land, air, water, ice, and the interconnectedness between human populations and these environments. Management should include monitoring and have the flexibility to adapt to evolving knowledge and understanding, changes in the global environment, and emerging uses." [16]

However, a large gap exists between the concepts of ecosystem-based management and its implementation. [17] Scientists characterize EBM differently than governmental agencies planning to manage coastal and marine ecosystems. In practice management objectives and measures tend to miss critical ecological and human factors emphasized in the academic

literature. While managers are beginning to put some EBM principles into practice, implementation needs to be much more thorough. The degree to which specific EBM criteria are translated from definitions to management actions is extremely variable in reality. In both science and management we lack a clear approach or toolkit for implementing EBM. Tools for traditional, single-species management are available and widely used, but explicit approaches are still needed to successfully conduct EBM. *Marine spatial planning is one important, practical approach to begin implementing EBM.*

What Is Marine Spatial Planning?

Marine spatial planning (MSP) is a practical way to create and establish a more rational approach to the human use of marine space and the interactions between its uses, to balance demands for development with the need to protect marine ecosystems, and to achieve social and economic objectives in an open and planned way.

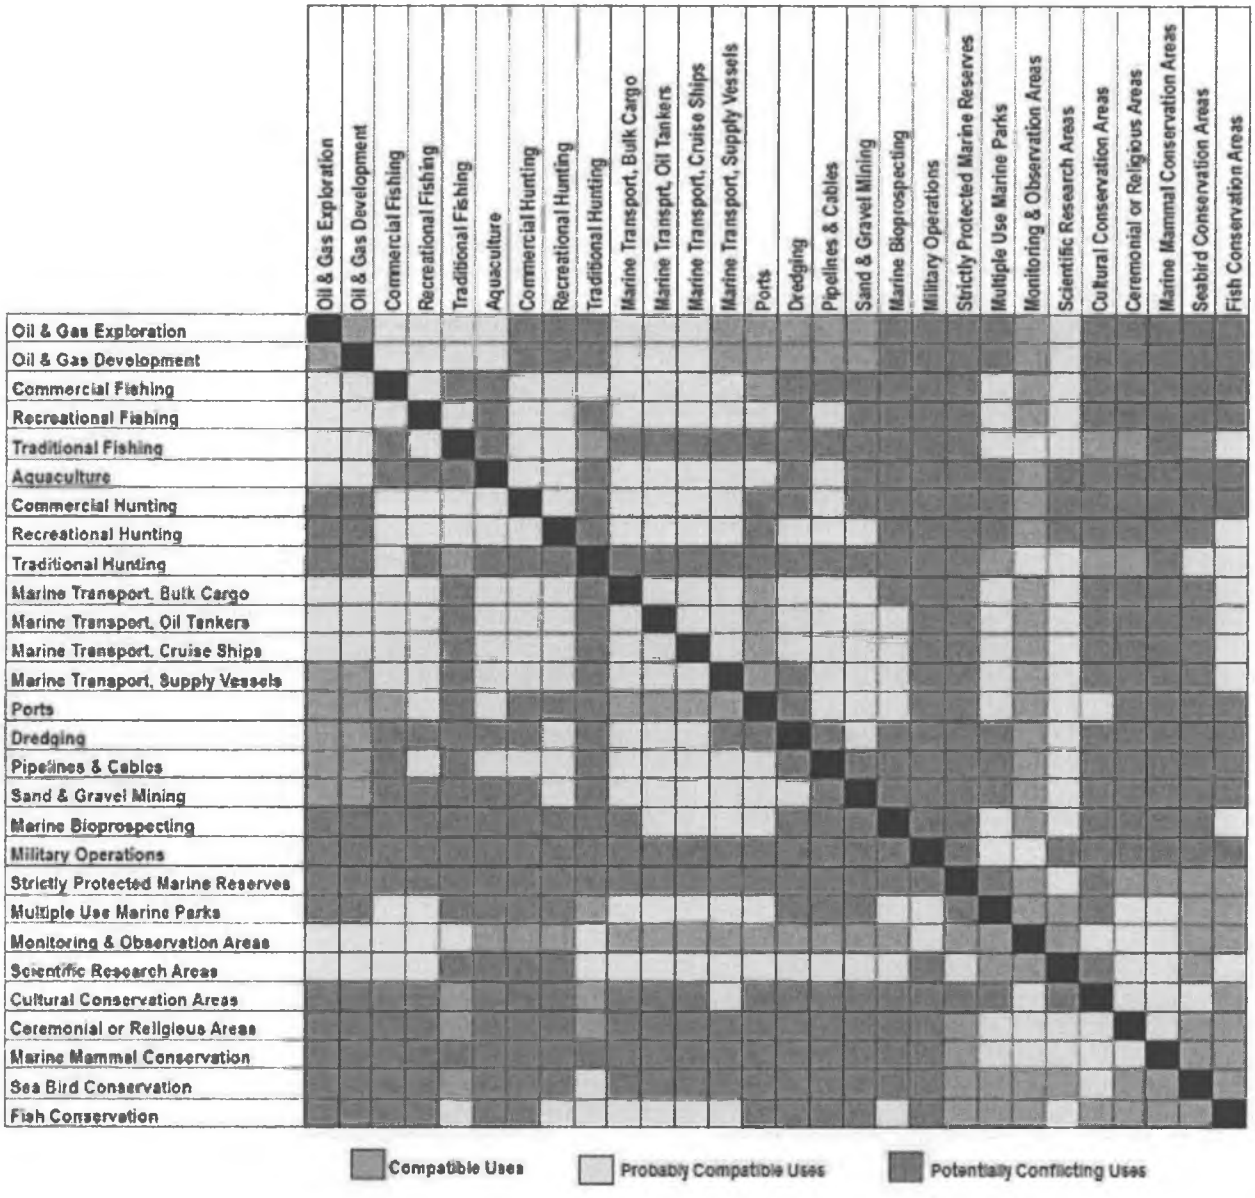
Recent research has estimated the cumulative impacts of human offshore activities on the marine environment at a global scale and concluded that almost half of the world's oceans are strongly affected by multiple stresses. Highly affected regions include the Eastern Caribbean, the North Sea, and Japanese waters. Only a few areas around the North and South poles remain relatively unaffected by human activities. Negative cumulative impacts of human activities on coastal and marine ecosystems would probably be higher if historical effects, unreported extraction, recreational use (including fishing), disease, and point-source pollution were incorporated in future measurements. [18]

Ocean resources are limited both in space and abundance and the pressure on the marine environment, resulting from an expansion of existing uses and the rise of new ones, has been detrimental to many places. Essentially, increased activity in the marine environment has led to two important types of conflict. First, not all uses are compatible with one another and are competing for ocean space or have adverse effects on each other (*user vs. user conflicts*). Numerous examples exist of conflicts between ocean users both globally and locally and include, for example, incompatibilities between the fast-growing, billion-dollar submarine cable industry and fisheries, causing damage to, or loss of, fishing gear or huge repair costs and lost revenues for cable disruptions. [19] Other user conflicts include wind farms located near shipping routes or traffic separation schemes, causing high risks of collisions and loss of cargo. In New Zealand, spatial conflicts have arisen from legislative obligations to uphold the historic and indigenous rights of fishers with more recent obligations toward nature conservation. [20]

Spatial use conflicts also occur within one particular use and refer, for example, to the use of different gear types for fisheries in certain areas, or the competition over use of space between commercial, recreational, and subsistence fisheries. Studies in California have illustrated that new commercial ocean activities will only exacerbate conflicts between users. [21]

Second, not all uses are compatible with the needs of a healthy and sustainable environment and cause conflicts between users and the environment (*user vs. environment conflicts*). Too often, ocean uses are located in sensitive biological and ecological areas with little or no consideration of their impact. Many scientific studies document the degradation of the world's oceans, the decline of marine ecosystems, and the collapse of important fish species, illustrating that this is increasingly impairing the ocean's ability to produce the goods and services essential for life on Earth. [22]

Figure 2. A Preliminary Identification of Potential Use Compatibilities and Conflicts in the Arctic [23]



Many of the conflicts described above can and have been avoided or reduced through marine spatial planning by influencing the location of human activities in space and time. During recent years, marine spatial planning has become increasingly important as a way to make ecosystem-based management[24] a reality in coastal and marine environments.[25] While concepts regarding ecosystem-based management are often considered too broad, too abstract and too complex to enable effective implementation,[26] MSP has proven to be a way to make this process more tangible.[27] Innovative and successful initiatives

Box 2. A Definition of Marine Spatial Planning

Marine spatial planning is a public process of analyzing and allocating the spatial and temporal distribution of human activities in marine areas to achieve ecological, economic, and social goals and objectives that are usually specified through a political process. Its characteristics include:

1. integrated across economic sectors and governmental agencies, and among levels of government;
2. strategic and future-oriented, focused on the long-term;
3. participatory, including stakeholders actively in the process;
4. adaptive, capable of learning by doing;
5. ecosystem-based, balancing ecological, economic, social, and cultural goals and objectives toward sustainable development and the maintenance of ecosystem services;
6. place-based or area-based, i.e., integrated management of all human activities within a spatially demarcated area identified through ecological, socio-economic, and jurisdictional considerations.

Ehler and Douvere, 2007. Visions for a Sea Change [28]

toward the development and implementation of ecosystem-based marine spatial planning have been taken in both highly-used marine areas such as the North Sea, the Baltic Sea, the coastal seas of China, and in large ocean areas such as the exclusive economic zones of Canada, Australia and New Zealand.

It is important to remember that we can only plan and manage human activities in marine areas, not marine ecosystems or components of ecosystems. We can allocate human activities to specific marine areas *by objective*, e.g., development areas or conservation areas, or *by specific uses*, e.g., oil and gas development, offshore aquaculture, or sand and gravel mining.

MSP does not produce a one-time plan. It is a continuing, iterative process that learns and adapts over time. It is comprised of three continuing processes:

1. **Plan-making**, or generating and adopting one or more integrated plans or policy frameworks that have strong spatial dimensions, for the protection, enhancement, and sustainable use of development of a marine area and its resources;
2. **Plan implementation**, including the execution of programmed works or investments, enabling change, encouraging improvement, and through regulation and enforcement of proposed changes and ongoing activities in, on, or over and under the sea, in accordance with the plans; and
3. **Monitoring and evaluation of plan performance**, or assessing the effectiveness of the plans, their time scales and implementation incentives, considering ways in which they need to be improved and establishing review and adaptation procedures.[29]

Box 3. Ten Steps of Marine Spatial Planning

The development and implementation of MSP involves a number of steps, including:

1. Identifying need and establishing authority;
2. Obtaining financial support;
3. Organizing the process through pre-planning;
4. Organizing stakeholder participation;
5. Defining and analyzing existing conditions;
6. Defining and analyzing future conditions;
7. Preparing and approving the spatial management plan;
8. Implementing and enforcing the spatial management plan;
9. Monitoring and evaluating performance; and
10. Adapting the marine spatial management process.

Ehler and Douvere, 2009 [30]

These 10 steps are not simply a linear process that moves sequentially from step to step. Many feedback loops should be built into the process. For example, goals and objectives identified early in the planning process are likely to be modified as costs and benefits of different management measures are identified later in the planning process. Analyses of existing and future conditions will change as new information is identified and incorporated in the planning process. Stakeholder participation will change the planning process as it develops over time. Planning is a dynamic process and planners (and stakeholders) have to be open to accommodating changes as the process evolves over time. Comprehensive MSP provides an integrated framework for management that provides a guide for, but does not replace, single-sector management. For example, MSP can provide important contextual information for guiding marine protected area management or for fisheries management, but does not replace it.

MSP answers three simple questions:

- **Where are we today?** What are the baseline conditions?
- **Where do we want to be?** What are the alternative spatial scenarios of the future? What is the desired vision?
- **How do we get there?** What spatial management measures move us toward the desired future?

MSP does not address all of the management measures that would be included in a comprehensive, integrated marine management plan—*only those management measures that specify where in space and when in time human activities should occur.* Other categories of management measures (Table 1) include:

- **Input measures**, or measures that specify the inputs to human activities in marine areas, such as limitation on the number of boats allowed to fish in a particular area;
- **Process measures**, or measures that specify the nature of the production process of human activities in marine areas, such as standards for "best environmental practices", the labeling or certification of the products and services of sustainable human activities, and codes of conduct; and
- **Output measures**, or measures that specify the outputs of human activities in marine areas, such as limitations on the amount to gravel extracted for the construction of artificial islands or causeways.

Table 1. Examples of Marine Management Measures

Input Measures	Output Measures
Management measures that specify the inputs to human activities in marine areas	Management measures that specify the outputs of human activities in marine areas
Limitation on fishing activity or capacity, e.g., number of vessels allowed to fish in the marine area	Limitation of the amount of pollutants discharged to a marine area from industrial sources, both onshore and offshore
Limitation on shipping vessel size or horsepower	Limitation on ballast water discharges, including alien species and pathogens, from marine transportation
Limitation on number of cruise ships operating in the marine area	Limitation on allowable catch within the marine area
Ship construction standards, e.g., special standards for vessels operating in Arctic waters	Limitation on allowable by-catch within a marine area
Other measures	Limitation on sand and gravel extraction within the marine area
	Other measures
Process Measures	**Spatial/Temporal Measures**
Management measures that specify the nature of the production process of human activities in marine areas	Management measures that specify where in space and when in time human activities can occur in marine areas or zones
Specification of fishing gear, mesh size, etc.	Specification of areas or zones for specific activities, e.g., commercial fishing, indigenous fishing and hunting, oil and gas development, sand extraction, marine transportation, cables and pipelines, military operations—all of the time
Specification of "best available technology" or "best environmental practice"	Specification of areas or zones closed to specific activities, e.g., commercial fishing, oil and gas development, sand extraction, cables and pipelines—all of the time
Standards for ice navigators and for safety and survival for seafarers in polar conditions	Specification of areas or zones open for specific activities, e.g., commercial fishing, oil and gas development, sand extraction, cruise ships, military operations—during specific times
Improved marine charts, aids to navigation, and other marine services	Specification of areas or zones closed to specific activities, e.g., commercial fishing, oil and gas development, sand and gravel extraction, cruise ships—during specific times, seasonal limitations on oil development operations
Increased search and rescue services	Specification of areas or zones closed to all development—all of the time, e.g., strictly protected areas, research areas, no-take, no impact areas
Improved spill response services, e.g., pre-positioning of equipment	Specification of areas or zones open to all development—all of the time, e.g., multiple use areas
Industry codes of practice or conduct	Designation of security zones, precautionary areas, safety zones
Other measures	Designation of critical habitat, environmentally or ecologically sensitive areas
	Designation of a Particularly Sensitive Sea Area (PSSA)
	Limiting activities in areas adjacent to cultural, spiritual, and archeological sites
	Special protection measures for areas of the high seas
	Other measures

Table 2. Benefits of Marine Spatial Planning

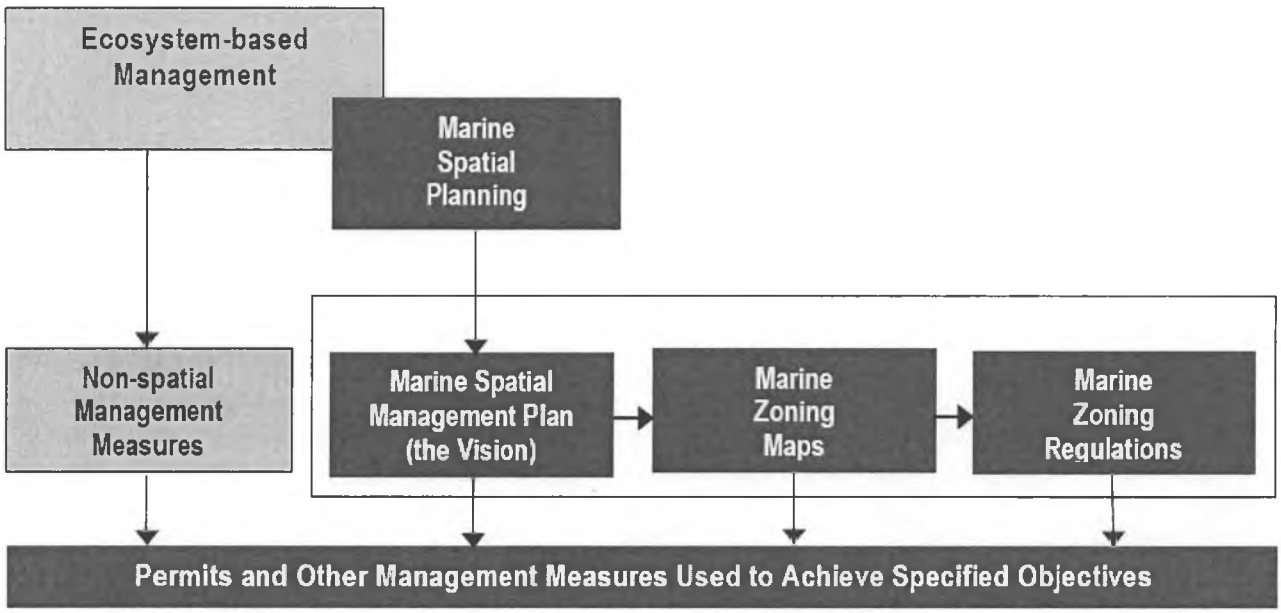
Ecological/environmental benefits	Identification of biological and ecological important areas as a basis for space allocation
	Incorporation of biodiversity objectives into planning and decision-making
	Identification and reduction of conflicts between human use and nature
	Ensures space for biodiversity and nature conservation
	Establish context for planning a network of marine protected areas
	Identification and reduction of the cumulative effects of human activities on marine ecosystems
Economic benefits	Greater certainty of access to desirable areas for new private sector investments, frequently amortized over 20-30 years
	Identification of compatible uses within the same area for development
	Identification and early resolution of conflicts between incompatible uses
	Improved capacity to plan for new and changing human activities, including emerging technologies and their associated effects
	Promotion of the efficient use of resources and space
	Streamlining and transparency in permit and licensing procedures
	Resolution of conflicts at planning level instead of individual project review
	Enables government, industry, and NGOs to work together to identify suitable locations for development and to identify areas where environmental values need to be protected and conservation should take precedence
Social benefits	Improved opportunities for local community and citizen participation
	Identification of effects of decisions on the allocation of ocean space (e.g., closure areas for certain uses, protected areas) on communities
	Identification and improved protection of cultural heritage
	Identification and preservation of social, cultural, and spiritual values related to ocean use
Administrative benefits	Improve consistency and compatibility of regulatory decisions
	Improve information collection, storage and retrieval, access, and sharing
	Improve integration and reduce duplication of effort and its associated waste of resources
	Improve speed, quality, accountability, and transparency of decision making, and reduction of regulatory costs

Modified from Ehler & Douvere (2009) and Tyldesley (2004)

What Are the Outputs of Marine Spatial Planning?

The principal output of MSP is a comprehensive spatial management plan (Figure 2) for a marine area or ecosystem. The plan moves the whole system toward a "vision for the future". It sets out priorities for the area and—more importantly—defines what these priorities mean in time and space. Typically, a comprehensive spatial management plan has a 10- to 20-year horizon and reflects political and social priorities for the area. The comprehensive marine spatial plan is usually implemented through a zoning map(s), zoning regulations, and/or a permit system similarly to a comprehensive regional plan on land. Individual permit decisions made within individual sectors (for example, the fisheries, or oil and gas, or tourism sectors) should be based on the zoning maps and regulations.

Figure 3. *The Outputs of Marine Spatial Planning*



Why Is Stakeholder Participation Critical to Marine Spatial Planning?

Involving key stakeholders in the development of MSP is essential for a number of reasons. Of these, the most important is because MSP aims to achieve multiple objectives (social, economic and ecological) and should therefore reflect as many expectations, opportunities or conflicts that are occurring in the MSP area. The scope and extent of stakeholder involvement differs greatly from country to country and is often culturally influenced. The level of stakeholder involvement will largely depend on the legal or cultural requirements for participation that often exist in each country.

Generally speaking, all individuals, groups or organizations that are in one way or another affected, involved or interested in MSP can be considered stakeholders. However, involving too many stakeholders at the wrong moment or in the wrong form can be very time consuming and can distract resources from the expected or anticipated result. To involve stakeholders effectively (e.g., leading toward expected results) and efficiently (e.g., producing expected results at least-cost), three questions should be asked:

- Who should be involved?
- When should stakeholders be involved?
- How should stakeholders be involved?

Where no legal obligations exist, it is important to define what type of stakeholder participation will be most suitable for a successful result. For instance, involving indigenous people in MSP efforts may not be a legal requirement, but they could however be greatly affected (positively or negatively) by MSP management measures, and should therefore participate.

Wide-ranging and innovative approaches to stakeholder participation and proactive empowerment should be used in the MSP process. Stakeholder participation and involvement in the process should be early, often, and sustained throughout the process. Stakeholder participation and involvement encourages "ownership" of the plan and can engender trust among the various stakeholders. Different types of stakeholder participation, including networked governance (Box 5), should be encouraged at various stages of the MSP process. The key stages at which stakeholders should be involved in the process include:

1. **The planning phase:** Stakeholders need to be involved and contribute to the setting of goals and objectives of MSP. They also need to be involved in the evaluation and choice of specific management measure options and the consequences of these choices on their areas of interest;
2. **The implementation phase:** Stakeholders should be involved in the actual implementation of MSP and its management measures. For example, an approach to enforcement may be identified that would involve local communities in the regulatory and enforcement process. When the local communities understand the problems and benefits of taking action—and agree upon the management measures to be taken—they will be part of the enforcement process, at least to the extent of encouraging compliance; and
3. **The monitoring and evaluation (post-implementation) phase:** Stakeholders should be involved in the evaluation of the overall effectiveness of MSP in achieving goals and objectives. The post-evaluation effort should involve all stakeholders in a discussion to identify plan results, evaluate results against objectives, and plan for the next phase of planning.

Box 5. MSP and Networked Governance

Networked governance is a strategy that recognizes and allows all rights-holders and stakeholders to be part of the decision-making process, in this case, the marine spatial planning process. As opposed to traditional "top-down", command-and-control systems, networked governance involves relevant stakeholders at all levels through less formal channels. The perspectives and positions of all stakeholders are included in defining the management goals and objectives and are used to develop a joint solution, i.e., a marine spatial management plan. The solution then calls for contributions from all stakeholders for its implementation. While ultimate responsibility for political decisions continues to lie with the executive authority (usually the government), it is also possible to construct incentives for ensuring compliance with the plan through heightened standards of accountability. Thorough stakeholder involvement increases each stakeholder's responsibility for their own contributions and makes each one more likely to hold government and other stakeholders accountable for their respective commitments.

Such a regime applied to the Arctic, and highly inclusive of indigenous peoples, would:

- Recognize that Arctic indigenous peoples are not merely stakeholders, but rights-holders to Arctic lands, waters, and resources, and thus have a clear right to participate at any planning or bargaining table;
- Build on the already formal role of Arctic indigenous peoples in regional planning and decision-making, e.g., through the Arctic Council;
- Ensure strong communication between indigenous communities and those making the management decisions affecting their environment;
- Encourage future Arctic developments to provide social equity and sustainable benefits for Arctic peoples;
- Insure that decisions made about the future of the Arctic include protection of the region's unique cultures and environment through recognition of the rights of its peoples;
- Preparing and approving the spatial management plan;
- Implementing and enforcing the spatial management plan;
- Monitoring and evaluating performance; and
- Adapting the marine spatial management process.

Excerpted and modified from a discussion draft paper prepared for the Aspen Institute's Dialogue and Commission on Arctic Climate Change by

Cochrane, Watt-Cloutier, et al.,

February 2010

The critical nature of stakeholder participation and involvement in MSP is discussed at length in Ehler and Douvere and Pomeroy and Douvere. [31,32]

Box 6. An Early Example of MSP and Networked Governance

In 2002 Coastal First Nations, an alliance of First Nation peoples on British Columbia's North and Central Coasts and Haida Gwali, signed an agreement with the Government of Canada to develop a marine use planning process under Canada's Ocean Strategy. Coastal First Nations began marine planning in 2005 along the British Columbia coast, an area now referred to as the Pacific North Coast Integrated Management Area (PNCIMA). Fisheries and Oceans Canada, the Coastal First Nations, and the North Coast-Skeena First Nations Stewardship Society officially agreed on the planning process in 2008. The agreement created a collaborative model for ocean governance that ensures the meaningful participation of First Nations in the development of management plans for marine use in the PNCIMA.

Ethics and values are the roots of traditional land and sea management systems. Although expressed in their own ways, First Nations ethics and values correspond to the scientific principles of ecosystem-based management and provide linkages between the two perspectives.

First Nations Ethics & Values	Scientific Principles
Balance & Interconnectedness	• Integrated Management • Long-term Sustainable Use
Respect & Responsibility	• Inclusive & Participatory • Precautionary Approach
Intergenerational Knowledge	• Adaptive Management • Best Information
Giving and Receiving	• Equitable Sharing

In 2004-05 the Coastal First Nations entered into an Aboriginal Aquatic Resource and Oceans Management agreement with DFO that supported Coastal First Nation consultations with other First Nations within PNCIMA on the collaboratively developed integrated management framework. The Coastal First Nations have built strong alliances with the North Coast - Skeena First Nation Stewardship Society and the Nuxalk First Nation, and all three organizations have agreed to work under the same operational framework. This alliance between all of the Central and North Coast and Haida First Nations on an initiative of this magnitude is unprecedented.

Community involvement and participation in the marine planning process is essential to its success. The primary role of First Nations in this process is to protect and conserve the marine environment on behalf of its community members. However, marine spatial planning is a process that brings together everyone that has an interest in the marine environment and integrates the wide variety of knowledge and interests into a common management plan that meets the needs of all participants. These interests could include not only First Nations peoples, but also federal and provincial governments, coastal communities, non-governmental groups including environmental groups and community groups, and other interests such as fishermen, shipping companies, forestry and fishing companies, recreational groups, mining and energy groups.

First Nations communities are developing MSP processes and products for their communities that are involved at all levels of the MSP process. Communities are the primary drivers in the development of local MSP plans. Marine planning committees/ work groups have been established in each community or area and work on behalf of the community to develop marine plans that reflect the values and interests of the community as a whole. Communication strategies have been developed to ensure transparency in the process and to ensure community members play an active role.

The DFO Aboriginal Aquatic Resources and Ocean Management Program, DFO Oceans, and the Gordon and Betty Moore Foundation provide funding for the MSP work of Coastal First Nations.

For more information go to: coastalfirstnations.ca/activities/marineuse.aspx

Important stakeholders in any Arctic MSP process would include representatives of Indigenous Peoples such as the Aleut International Association, the Arctic Athabaskan Council, the Gwich'in Council International, the Inuit Circumpolar Council, the Russian Association of Indigenous Peoples of the North (RAIPON), and the Saami Council. Representatives of non-governmental organizations such as the Natural Resources Defense Council (NRDC) and the World Wildlife Fund (WWF), representatives of Arctic industries including oil and gas (Royal Dutch Shell, ConocoPhillips, Statoil, GazProm, ExxonMobil), fishing, mining, marine transportation (Murmansk Shipping, Far Eastern Shipping) and tourism, and representatives of Arctic research institutions, such as the University of the Arctic, the University of Tromso, the University of Calgary, the University of Greenland, and the University of Alaska, would all have a stake in the outcomes of MSP. These specific stakeholder examples are illustrative, not exhaustive.

What Are Some Key Principles of Marine Spatial Planning?

MSP should be guided by a set of principles that: (a) determine the nature and characteristics of the MSP process; and (b) reflect the results desired through MSP. The Aspen Institute has identified some examples of specific principles for Arctic governance (p. 50 of this report). Many of these principles can be put into practice through MSP. For example,

- **Ecosystem resilience, integrity and productivity** can be optimized by maintaining food-web (trophic) structure and protecting and restoring biodiversity and available habitat—MSP can be used to identify biologically and ecologically important areas, including fish spawning areas, polar bear denning areas, and migration corridors;
- **A full suite of Arctic ecosystem services**, including the regulation of climate, the provision of food, habitat, and genetic resources, and spiritual and cultural development, to support human well-being on a continuing basis can be maintained through MSP by allocating human activities in time and space with the goal of sustaining those services;
- **Investment in Arctic scientific research and related infrastructure** to ensure sustainable development and environmental protection can be promoted through MSP by the identification of gaps in natural and social science information that is required to implement MSP in the Arctic;
- **Assessing, monitoring and managing multiple human activities using an integrated, adaptive, ecosystem-based management system** that takes into account risks and cumulative and interacting effects can be implemented through MSP, which carries out these activities to deliver an ecosystem-based approach to the management of human activities in marine areas of the Arctic;
- **Ecosystem management processes, based on science and traditional knowledge, can be applied through MSP**, which assesses new and expanded human activities routinely as part of the planning process. MSP identifies spatial and temporal management measures (Table 1) to reduce or eliminate impacts that would be hazards to human health, harm living resources and ecosystems, damage amenities, or interfere with other legitimate uses;
- **The rights, including human rights, of Arctic residents and Arctic indigenous peoples can be respected through a highly participatory and transparent MSP process** that includes all interested stakeholders;
- **Cooperation among Arctic states** to arrive at appropriate standards for managing human activities to meet the special conditions of the Arctic region, while promoting sustainable development, can be promoted through an Arctic-wide MSP process that would identify spatial and temporal management measure that would require international cooperation; and

Box 8. Ten Principles for Marine Spatial Planning

1. **Regulatory authority.** Whether it is an existing agency, an interagency coordinating committee or some newly created body, the department charged with implementing MSP must have clear legal authority to engage in integrated ecosystem management, including the authority to evaluate the efficacy of its decisions and adjust them over time.
2. **Dependable funding.** If MSP is to succeed, government needs to guarantee sufficient and dependable funding to the effort. This funding must be sufficient to cover necessary agency staff, as well as the cost of obtaining the requisite data, ensuring public participation obligations and needs, monitoring, enforcement, and evaluation.
3. **Public and stakeholder participation.** Early and regular consultation with the public and advisors (such as traditional leaders) is the norm, as is rapid dissemination of information, materials, public comments, etc.
4. **Transparency.** The MSP management system should provide for maximum transparency so that the basis for analysis and decision-making is unambiguous and the process by which decisions are made is obvious as the decisions are under consideration.
5. **Real accountability.** Entities charged with implementing MSP must be accountable to the country/state/community for effective implementation and achievement of the goals and objectives outlined in policy and legislation. Accountability can be achieved through several different tools, including setting clear milestone deadlines, linking funding with achievement or performance, issuing performance reports (score cards) for public consumption, or allowing citizen suits to compel agency compliance with substantive and procedural requirements.
6. **Clear objectives and directives.** Critically, any MSP management system should set forth overarching principles, clear tasks, deadlines for completing tasks, directives explaining the standards by which decisions will be measured and made, and the processes for making those decisions, as well as periodic review for determining progress.

7. **Evidence/Science-based decision making.** MSP decision-making should be based on the best readily available science and/or evidence. This standard combines a requirement for using the best science/evidence with the practicality of knowing that decision makers cope with uncertainty and less than perfect information every day. Because it is not always possible to wait for high levels of scientific certainty when resource and economic health are hanging in the balance, the use of best available science is the linchpin to effective policy. Where significant scientific uncertainty exists, the precautionary principle should guide decision-making.
8. **Independent decision-making.** To the greatest extent possible, an MSP management system should attempt to foster independent decision making and reduce the potential for agency capture (by the regulated industry or individuals), political gridlock, or legislative interference (avoid interference induced by favoritism, corruption, or undue influence).
9. **Clear decision-making rules.** Decision making rules should be established up front, leaving no ambiguity regarding how decision outcomes will be achieved.
10. **Adaptive to change.** The systems we develop and use to "manage" linked human-natural ecosystems must include effective feedback and be flexible enough to adjust management practices over time, if necessary. Therefore, an MSP management system should include a robust monitoring program that will allow managers to determine whether both management (e.g., compliance, efficiency, conflict reduction) and ecosystem goals and objectives are being met. In addition, the management system should facilitate the incorporation of new science and information as it becomes available. Similarly, the system should account for the variability of natural systems and the possibility of regime shifts, such as those we are likely to face in the wake of climate change.

Modified from Sivas and Caldwell, 2008 [33]

Why Are General Goals and Measurable Objectives for MSP Important?

Specifying MSP goals and objectives is essential to help focus and tailor MSP efforts toward achieving results in any marine area, including the Arctic. Typically, goals and objectives should be derived from the problems and conflicts identified in the early stages of the MSP process. Despite what is often assumed, goals and objectives are different from one another.

Goals provide the umbrella for development of all other objectives and reflect the principles upon which subsequent objectives are based. For example, the goals of the Arctic Council's Arctic Marine Strategic Plan included:

- Conserve Arctic marine biodiversity and ecosystem function;
- Promote the health and prosperity of all Arctic inhabitants;
- Reduce and prevent pollution in the Arctic marine environment; and
- Advance sustainable Arctic marine resource use. [34]

Examples of MSP-specific goals in the Arctic could include:

- Protect environmentally and ecologically valuable areas;
- Encourage the co-location of compatible human activities;
- Reduce and resolve conflicts among current and future human activities; and
- Reduce and resolve spatial conflicts between current and future human activities and nature.

Characteristics of good objectives are that they are specific, measurable, achievable, relevant, and time-bound, i.e., SMART. Monitoring and evaluating progress toward the achievement of desired outcomes can only be measured when objectives are well specified. Often objectives will be preliminary and indicative when you specify them for the first time, and firmer and better-specified when re-examined later in the MSP process. Examples of well-specified objectives would include:

- Protect 90% of essential habitat for diving birds by 2012;
- Ensure that adequate marine space is available to produce 25% of energy needs from offshore sources by the year 2020;
- Implement a representative network of marine protected areas by 2012; and
- Reduce the time required to make decisions on marine construction permits by 50% by 2015.

Why Are Performance Indicators Important?

The main purpose to establish indicators is to measure, monitor and report on progress toward meeting the goals and objectives of MSP. Indicators have numerous uses and the potential for improving management. They include the ability to monitor and assess conditions and trends, forecast changes and trends (such as providing early warning information), as well as help evaluate the effectiveness of spatial and temporal management measures.

The selection of relevant and practical (i.e., measurable) indicators is one of the most important components of a "results-based" approach to MSP. Table 3 below identifies some characteristics of good indicators. Indicators are needed to monitor progress with respect to inputs, activities, outputs, and outcomes. Progress needs to be monitored at all levels of the system to provide feedback on areas of success, as well as areas where improvements may be needed. Caution should be exercised in defining too many indicators. Choosing the correct indicators is often a trial-and-error process—and may take several iterations. Indicators can be changed—but not too often.

Extensive reviews and examples of ecological, socio-economic, and governance indicators for the performance evaluation of integrated marine management and its measures can be found in Ehler, Pomeroy *et al.*, and Belfiore *et al.*[35,36,37]

Table 3. Characteristics of Good Indicators for MSP

Readily measurable	On the time-scales needed to support spatial management of human activities, using existing instruments, monitoring programs, and available analytical tools
Cost-effective	Monitoring resources are usually limited
Concrete	Indicators that are directly observable and measurable in time and space (rather than those reflecting abstract properties) are desirable because they are more readily interpretable and accepted by diverse stakeholder groups
Interpretable	Indicators should reflect properties of concern to stakeholders; their meaning should be understood by as wide a range of stakeholders as possible
Grounded in theory	Indicators should be based on well-accepted scientific theory, rather than on inadequately defined or poorly validated theoretical links
Sensitive	Indicators should be sensitive to changes in the properties monitored (e.g., able to detect trends in time and space in the properties or effects)
Responsive	Indicators should be able to measure the effects of spatial management measures to provide rapid and reliable feedback on their performance and effects
Specific	Indicators should respond to the properties they are intended to measure rather than to other factors, i.e., it should be possible to distinguish the effects of other factors from the observed responses to spatial management measures

Why Are Monitoring and Evaluation Critical?

Monitoring is a critical and integral element of MSP in the Arctic. In a broader sense, a "monitoring system" includes a range of activities needed to provide information to MSP. These activities include modeling, laboratory and field research, time-series measurements in the field, quality assurance, data analysis, synthesis, and interpretation. What distinguishes a monitoring system from any of these activities taken alone is that a *monitoring system* is integrated and coordinated with the specific goal of producing pre-specified spatial planning information; it is the sensory component of management.

At least two types of monitoring are relevant to marine spatial planning: (1) *assessing* the *state of the system*, e.g., "What is the status of biodiversity in the marine area?"; and (2) measuring the *performance of management measures*, i.e., "Are the spatial and temporal management measures we have implemented producing the outcomes we desire?" These two types of monitoring are closely related.

Sound monitoring program design depends on the following factors:

- The objectives of the monitoring program need to be clearly articulated in terms that pose questions that are meaningful to the public and that provide the basis for the measurement of management performance;
- Not only must data be gathered, but attention must be paid to their management, analysis, synthesis, and interpretation;
- Adequate resources are needed not only for data collection, but for detailed analysis and evaluation over the long term;
- Monitoring programs should be sufficiently flexible to allow for their modification where changes in conditions or new information suggests the need; and
- Provision should be made to ensure that monitoring information should be reported to all stakeholders and rights-holders in a form that is useful to them.

Evaluation is the element of MSP in which the greatest learning occurs. Ideally, it should be a continuous process in which measures or indicators of management performance are defined and systematically compared with program goals and objectives. Evaluation should be undertaken periodically during the lifetime of a MSP program—at least every five years.

MSP initiatives often have goals and objectives that are very vague or general, and therefore are not easily measured. In these cases it is difficult, if not impossible, to determine the extent to which goals and objectives are being achieved. Evaluations, if undertaken at all, tend to fall back on indicators that measure effort (input) rather than results (outputs or outcomes). For example, the number of permits granted or denied might be used as an indicator of the performance of a MSP program rather than the number of use conflicts avoided or area of biologically important marine areas protected.

Meaningful evaluations can be conducted only if the objectives of the MSP program are stated in unambiguous (measurable) terms and if indicators for assessing progress are identified in the planning phase, and monitored afterward. Baseline data are essential. Many evaluations yield ambiguous results because these preconditions for assessing management performance do not exist.

Evaluation should be seen as a critical element of the process of MSP. Integrated and adaptive MSP is based on a circular or iterative—rather than a linear—management process that allows information concerning the past to feed back into and improve the way management is conducted in the future. Evaluation helps management to adapt and improve through a "learning process."

Where Is Marine Spatial Planning Currently Underway?

In many marine places, MSP has already proven to be an operational approach to implementing integrated, ecosystem-based management.[38] Twenty-four MSP programs in nine countries are identified in Table 4. Descriptions of these programs can be found on the UNESCO website on marine spatial planning: www.ioc3.unesco.org/marinesp. A key characteristic of these marine spatial management initiatives is their ability to provide integration across multiple uses and sectors, to minimize conflicts, to maximize sustainable economic development, and to protect important habitat and biodiversity areas.[39]

Table 4. International Examples of Marine Spatial Planning

Country	Plan	Area (km^2)	Time Period
Australia	Great Barrier Reef Marine Park Original Zone Plan	344,400	1983-1988

Current Marine Spatial Planning Activities in the Arctic

Marine spatial planning is already underway in several areas of the Arctic, including Norway, Canada, and to a limited extent, the United States.

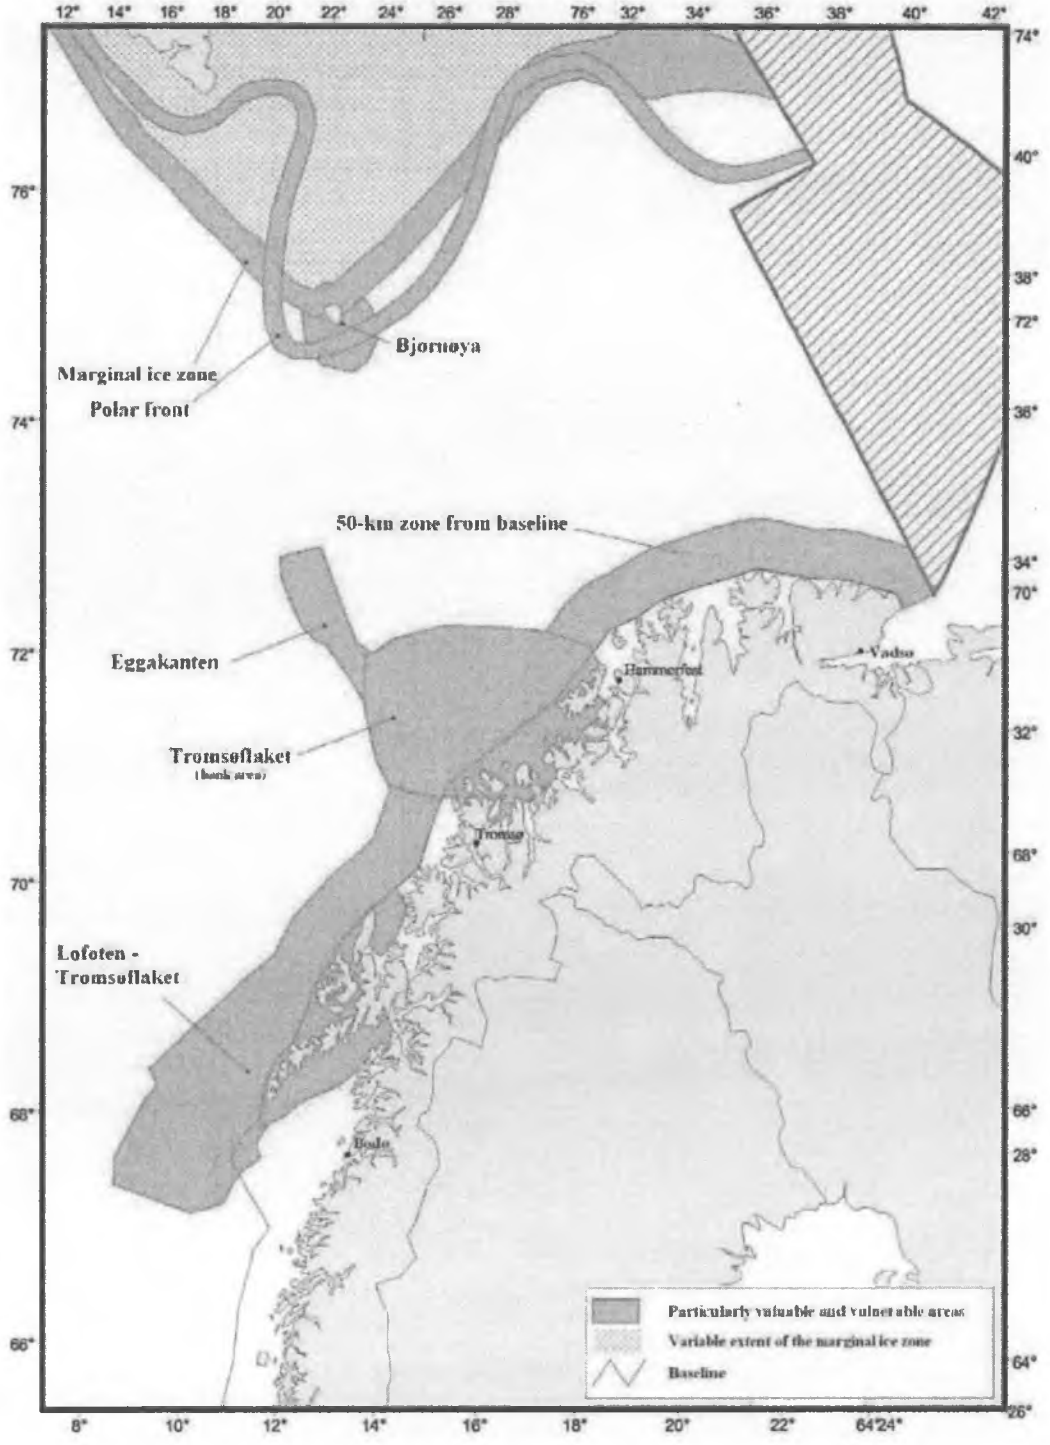
Norway: Marine spatial planning would be a new approach in most areas of the Arctic. However, in Norway, an ecosystem-based, integrated marine management plan, including a marine spatial plan, has been developed for the Barents Sea and the Sea Areas off the Lofoten Islands. It covers all areas offshore of one nautical mile of the coast within the Norwegian EEZ, as well as the fishery protection zone around the Svalbard archipelago—a marine area covering 1.4 million km2. Norway is one of the few countries that have successfully integrated all major economic activities—oil and gas development, fisheries, and marine transport—together with nature conservation in its marine spatial planning activities. The plan for the Barents Sea was initiated in 2002 and completed in 2006; the initial plan is now being revised. An integrated management plan for the Norwegian Sea (1.17 million km2) has also been developed recently. [40]

One of the major issues in the Barents Sea was the potential expansion of oil and gas activities into areas of the Barents Sea used by fisheries and living marine resources. MSP is at the core of the plan, identifying particularly valuable and vulnerable areas, either from ecological and/or human perspectives. Within the plan access to specific areas for human activities is carefully managed, for example, by moving shipping lanes outside Norwegian territorial waters (12 nautical miles), limiting trawling in sensitive areas, not opening most particularly valuable and vulnerable areas to petroleum activities, including the ice edge, and extending marine protected areas and fishery closure areas to protect spawning aggregations, fish eggs and larvae, and juvenile fish and shellfish. [41]

A government-appointed inter-ministry steering group chaired by the Ministry of the Environment and with representatives of relevant ministries led the work on the plan that included evaluation of the cumulative effects of development up to 2020. Development of the plan (2003-2006) followed a three-phase process. First, status reports were prepared by governmental management and research institutions or by consultants, covering the state of the marine environment, the coastal zone, fisheries, aquaculture, especially valuable areas, and shipping. The initial reports uncovered major gaps in current knowledge. Therefore, a key principle of the planning process was to use caution in the face of uncertainty. The plan also had to be adaptive to allow the evaluation of new knowledge as it became available. Determining the boundaries for the plan was another important issue, which included considerations of the ecosystem, economics, and politics, and discussions with the International Council for the Exploration of the Sea (ICES) and other organizations.

The second phase was an analytical one based on the first one. Four extensive government-funded environmental impact assessments (EIAs) were carried out, covering the impact of fisheries, shipping, hydrocarbon extraction, and external pressures (e.g. pollution) on the environment, resources, and local communities. To ensure compatibility among the EIAs, a set of common variables was used to compare impacts among sectors. Impacts were assessed relative to a base year (2003) and relative to expected future impacts up to 2020, with uncertainty obviously increasing over time.

Figure 4. Particularly Valuable and Vulnerable in the Barents Sea
(Royal Norwegian Ministry of the Environment)



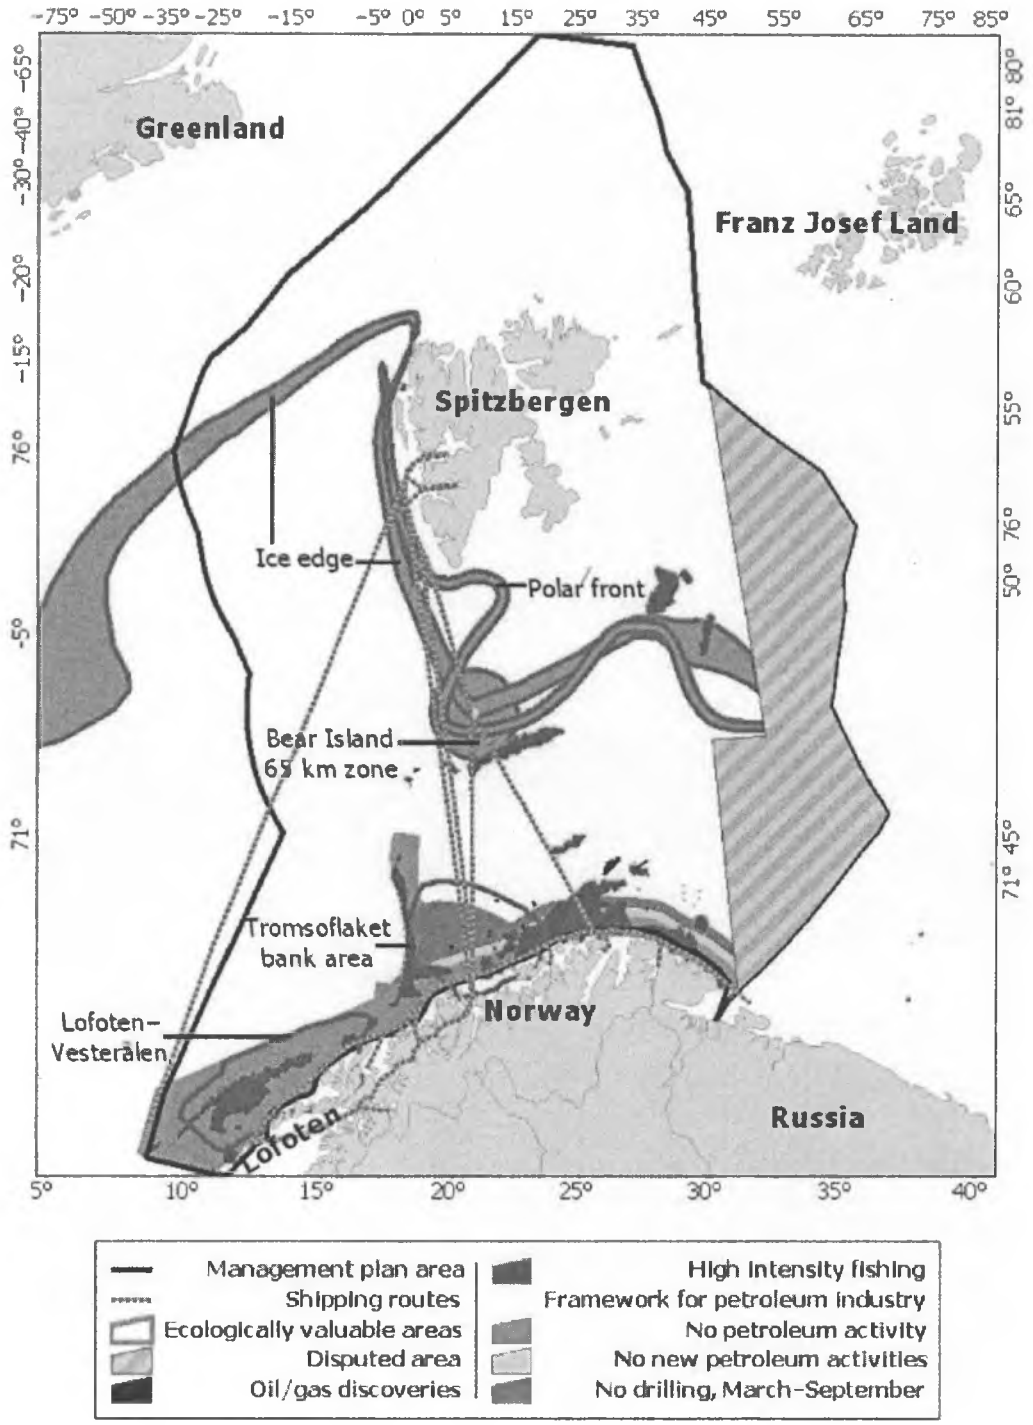
In the third phase, the EIA results were brought together and analyzed in more detail, focusing on: (1) the total impact of all human activities combined, both for the current situation and up to 2020; **(2)** area conflicts among human activities, and between human use and ecologically valuable areas; **(3)** the definition of management goals required for implementation; and **(4)** identification of gaps in current knowledge.

The analysis of total impact was difficult, because knowledge of the cumulative ecological impact of several interacting human effects was limited. Parallel to the second and third phases, a set of operational environmental quality objectives (EcoQOs) was developed, based on the management goals. These covered climate, ice edge, phytoplankton, zooplankton, commercial fish species, non-commercial fish species, benthic organisms, marine mammals, seabirds, alien species, threatened and vulnerable species, and pollutants. Progress toward the EcoQOs is monitored annually.

A central concept of the plan is that it is based on the best available scientific information and takes a precautionary approach, implying a need for revision as new knowledge becomes available. The plan represents a synergy of previously separate management regimes: management of fisheries, shipping, and the hydrocarbon industry are brought together under one umbrella to coordinate efforts and to achieve a healthy ecosystem (Figure 5). **In practice, achieving measurable improvements in all these sectors is the main challenge, and these are envisaged by implementing: (1)** marine spatial planning to resolve conflicts between activities and protecting the environment; **(2)** continuation of established management measures regulating the various activities; **(3)** implementation of EcoQOs; and **(4)** increased focus on international cooperation, especially with Russia, regionally and globally.

The plan identifies ecologically valuable areas and requires strict regulation of activities in these areas. To reduce conflict between fisheries and shipping, Norway has applied (through the International Maritime Organization) to move shipping lanes outside Norwegian territorial waters (its 12-nautical mile limit). To avoid future conflict, some areas will be closed to hydrocarbon exploration and exploitation (Lofoten, Bear Island, the polar front, and the ice edge). The framework for hydrocarbon extraction has been the focus of political debate around the plan, and will probably continue to be so. Several new sector-specific area-based measures are also considered, including plans for extension of marine protected areas and the use of seasonally closed areas to protect spawning aggregations, fish eggs and larvae, and juvenile fish and shellfish.

Figure 5. The Barents Sea Management Area, Showing the Main Fishing Areas, Shipping Lanes, and the Area-based Framework for Hydrocarbon Extraction, and Valuable and Vulnerable Areas

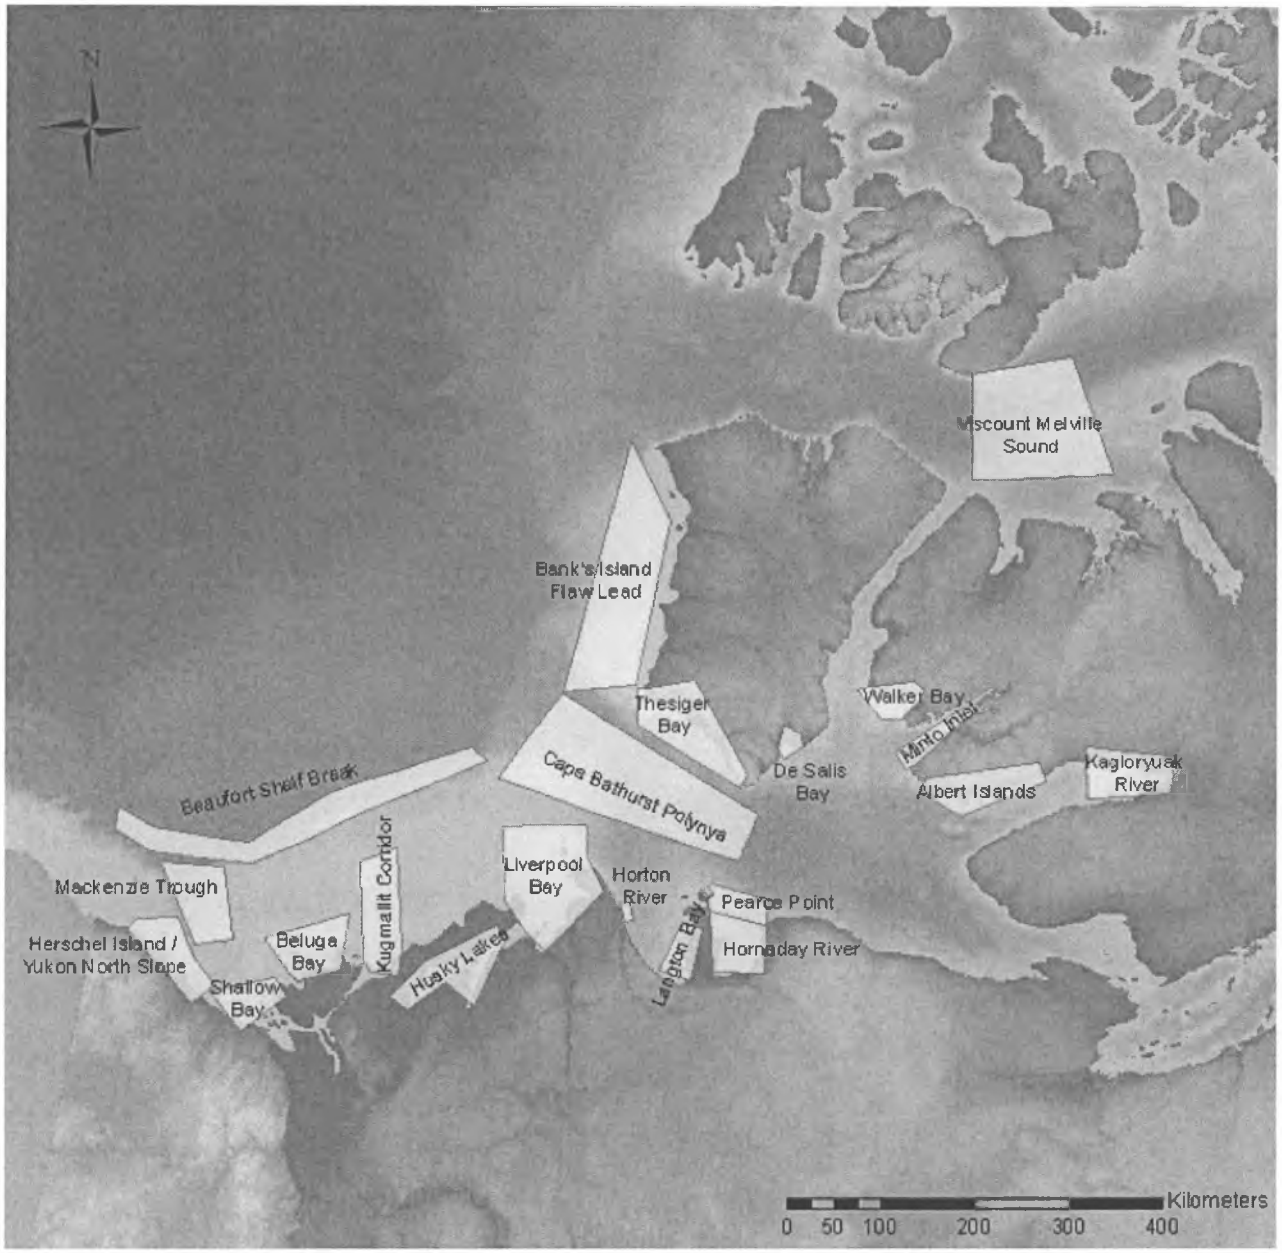


Cooperation among government institutions has been ensured by creating three new advisory groups, all reporting to the governmental steering group: a "monitoring group" responsible for coordinating monitoring activities and reporting annually on the state of the ecosystem, based on the EcoQOs; an operational "risk group" responsible for monitoring potential risks to the ecosystem and ensuring dissemination of information; and an "expert forum" responsible for advice on revisions to the plan. One of the shortcomings of the first Barents Sea planning process was its lack of consultation with the Saami Parliament. [42]

Canada: Canada's Department of Fisheries and Oceans has just completed an integrated management plan for the Canadian portion of the Beaufort Sea (1.75 million km2) as part of a large ecosystem-based management program for five large ocean management areas (LOMAs) in Canada.[43,44] The integrated management plan does not address marine spatial planning, but recommends marine spatial planning be conducted for the Beaufort Sea LOMA. Canada also completed in 2005 an overview of the Beaufort Sea marine ecosystem and more recently in 2009 an atlas of the Beaufort Sea.[45,46] The atlas contains a map of "ecologically and biologically significant areas", based on their biophysical structure and ecological function, created by the Department of Fisheries and Oceans Canada (Fig. 6). A "Beaufort Sea Partnership" is the primary forum for stakeholder engagement in integrated management of the Beaufort Sea LOMA. It is comprised of regional-level representatives and has an open membership, i.e., any organization with an interest in the management of the Beaufort Sea can become a member. The Partnership has about 40 member organizations, including Indigenous Peoples.

The Government of Canada brought its Oceans Act into force on January 31, 1997 making it the first country in the world to have comprehensive oceans management legislation. Canada's Oceans Strategy was finalized in 2002. This policy document defined the vision, principles, and objectives for the management of Canada's estuarine, coastal and marine ecosystems. Funding needed to apply Canada's oceans management legislation and policy became available in 2006 under a Federal initiative known as the Oceans Action Plan. The Beaufort Sea was subsequently named as one of five areas to receive funding. The area contains an estimated one-third of Canada's undeveloped conventional oil and gas potential.

Figure 6. *Ecologically and Biologically Significant Areas of the Beaufort Sea (Department of Fisheries and Oceans Canada, 2009)*



Aboriginal, federal and territorial governments and co-management interests, as well as industry, coastal communities and other interested parties agreed to work together on the implementation of a process that would lead to a plan for managing activities occurring in the Beaufort Sea. Development of the integrated management plan took three years to complete.

The plan is organized around six goals:

- **Governance:** To achieve effective governance for the sustainable use of the Beaufort Sea;
- **Economic:** To foster sustainable economic opportunities and options for Canadians, northerners and coastal communities;
- **Cultural:** To maintain and increase peoples' sense of place and preserve cultural identity and spiritual connections as they relate to oceans and coastal areas;
- **Social:** To improve human capacity, health, quality of life and opportunities as they connect to oceans and coastal areas;
- **Traditional and Local Knowledge:** To promote the value, credibility and use of traditional knowledge (TK) and local knowledge (LK) to current and future generations; and
- **Ecosystem:** To understand the Beaufort Sea ecosystem, to identify important areas and priority species and to maintain or enhance ecosystem integrity.

After securing general agreement on the need for a plan, stakeholders needed to know the current status and trends of the Beaufort Sea's ecosystem to determine what impacts human activities might have on that ecosystem. An ecological assessment was conducted to compile available science and traditional knowledge of the area. The Ecosystem Overview and Assessment Report (EOAR) describes areas and activities that need priority actions. A key part of the EOAR was the identification of Ecologically and Biologically Significant Areas (EBSAs) in the Beaufort Sea (Figure 6). Work leading to the EBSAs was a centerpiece of the planning process. It calls attention to areas that have particularly high ecological or biological significance and require specific management measures and standards to manage them responsibly.

A Social, Cultural and Economic Overview and Assessment Report similar to the EOAR was also completed for the Beaufort Sea LOMA. It is a valuable source of information on key social, cultural, and economic conditions, issues and objectives for the integrated management process. The report is an excellent reference for decision makers requiring information about current and historic ocean-based activities and stakeholder perspectives. Community profiles that outline the social, cultural and economic status of the communities are part of the report.

The Beaufort Sea Planning Office identified some of the benefits of working together on the implementation of the Beaufort Sea integrated management plan as:

- Increased cooperation across departments, governments and other organizations;
- Better integrated responses to cross-cutting issues;
- Better and more timely collection of information on key risks and their relationship to programs and values;

- Ongoing measurement of the actual effects of policies, programs and operations;
- Identification of areas of shared responsibility; and
- Greater accountability for management of shared responsibilities. [47]

USA: In 1988 the U.S. National Oceanic and Atmospheric Administration (NOAA) published the first comprehensive data atlas of the Bering, Chukchi, and Beaufort seas.[48] The NOAA atlas contained 112 maps of the Arctic region, including the Canadian Beaufort Sea and the Soviet Bering and Chukchi seas. Special maps developed for the Arctic atlas included sea-ice dynamics and sea-ice type, marine sediments, chlorophyll-a, and subsistence activities of Alaskan Natives, a particularly important human activity in the Arctic, developed from detailed anthropological field surveys conducted by the Alaska Department of Fish and Game. Unfortunately the NOAA atlas has not been updated, but other mapping activities are now underway in Alaska.[49] In August 2009 Audubon Alaska completed a draft Atlas of the Chukchi and Beaufort Seas. The project area includes the southern Beaufort, southern Chukchi, and northern Bering seas and includes 44 maps covering Alaska's Arctic marine environment. Thematic maps are presented in six categories: physical oceanography, water column and benthic life, fish, mammals, birds, and people. The Coastal Management Program of the North Slope Borough has also developed 31 detailed maps covering its jurisdiction, including subsistence use areas.[50]

Figure 7. *Polar Bear Map from the Audubon Arctic Atlas, 2009*

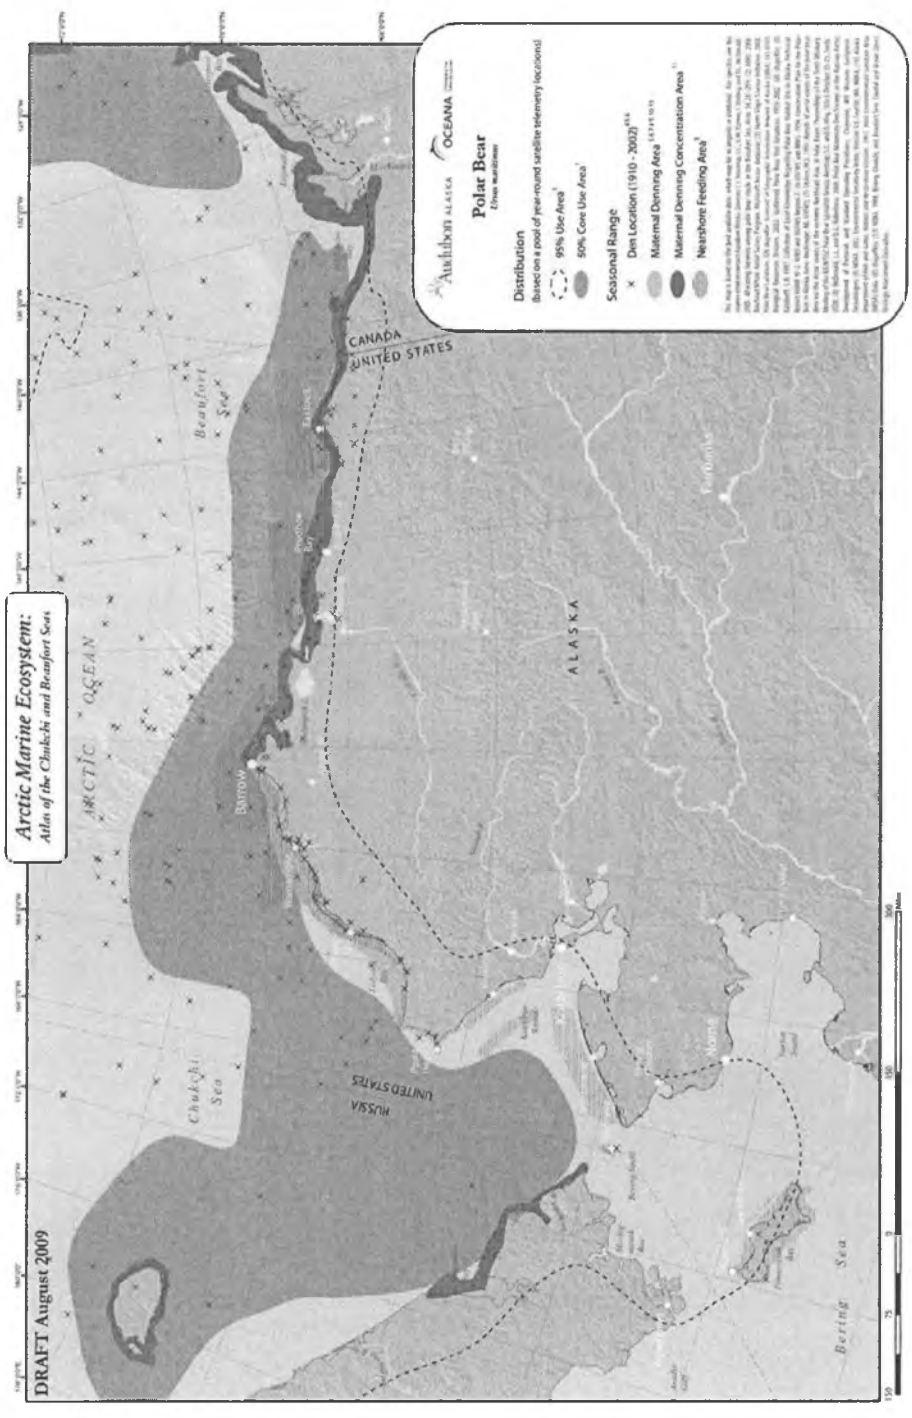


Figure 8. Kaktovik Subsistence Use Area, Resource Atlas, North Slope Borough Coastal Management Program, 2009

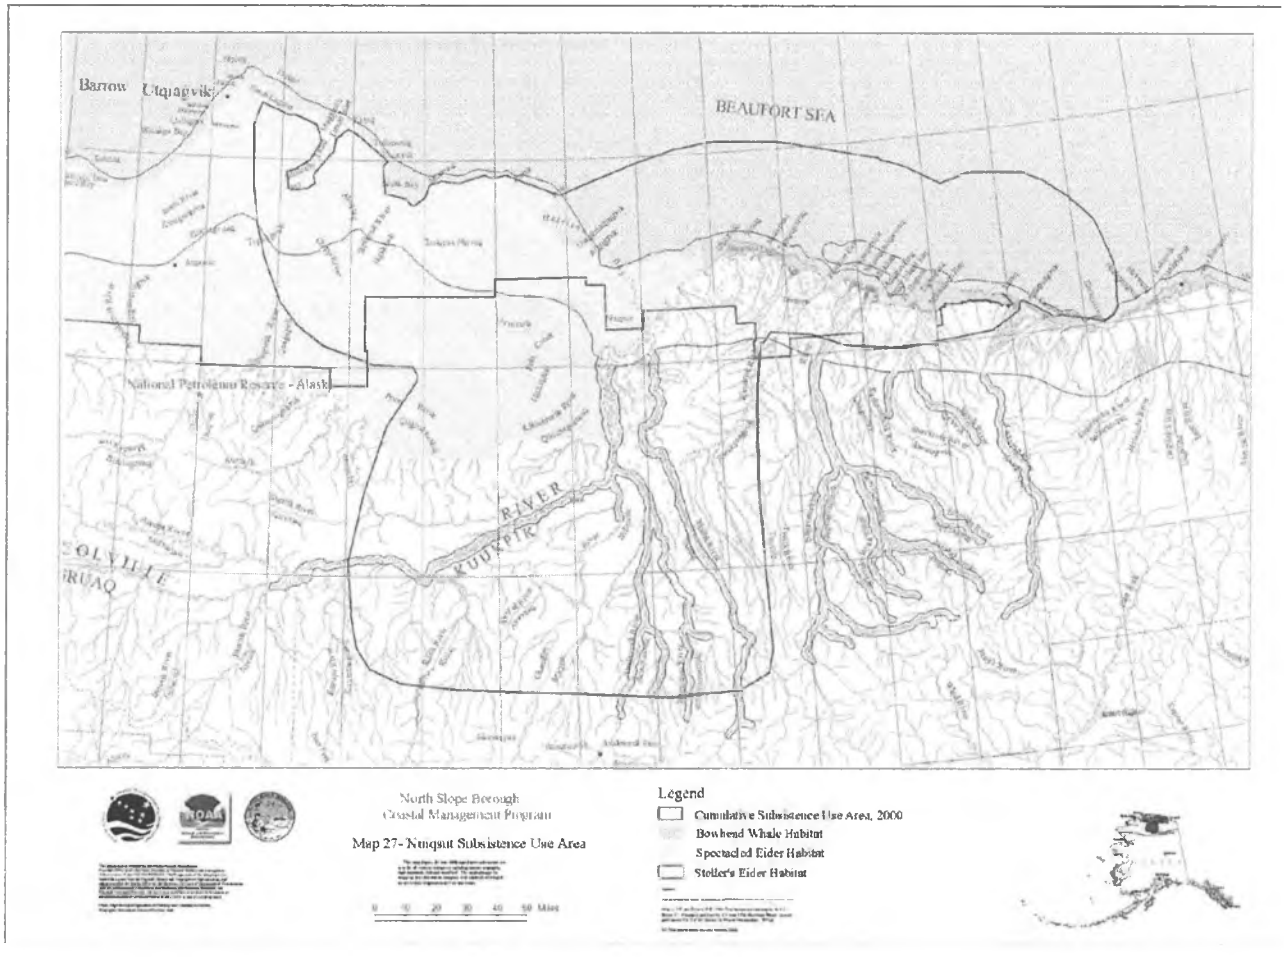
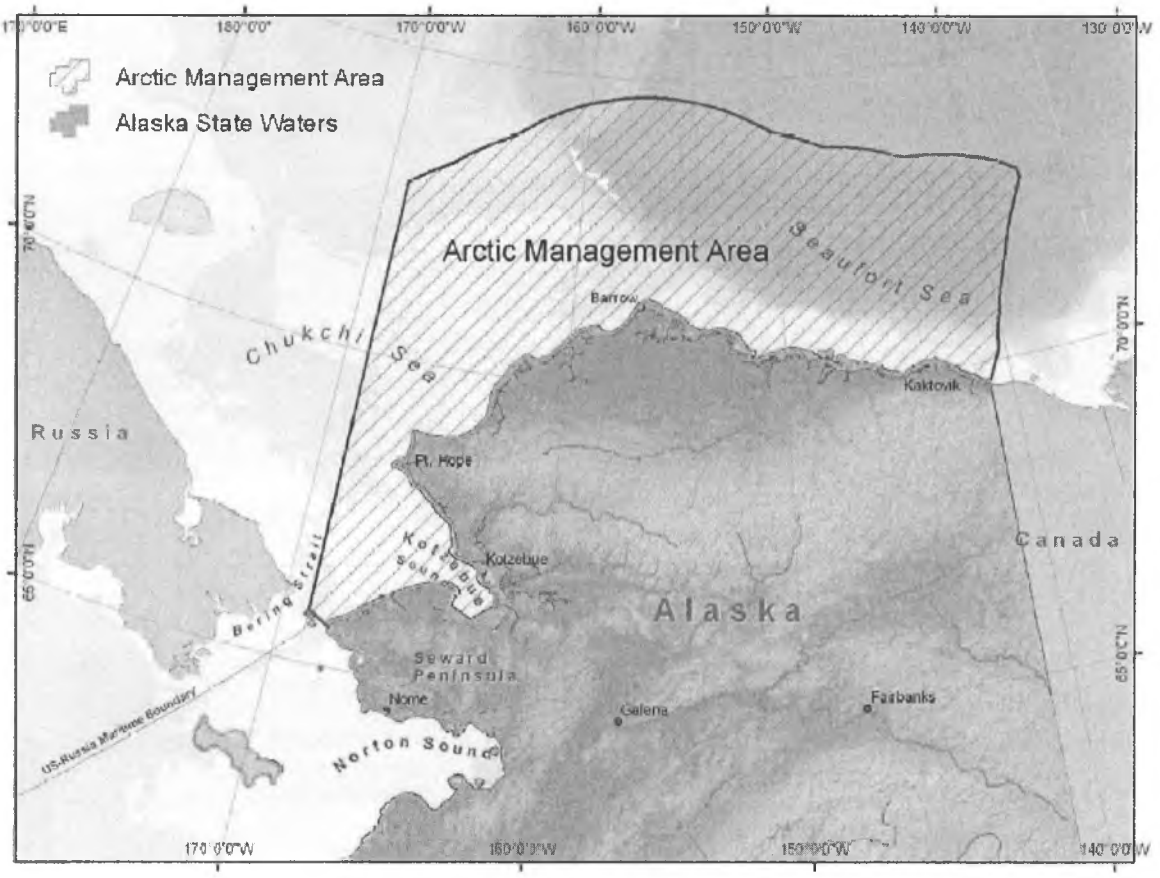


On June 12, 2009, President Obama sent a memorandum to the heads of executive departments and federal agencies establishing an Interagency Ocean Policy Task Force, led by the White House Council on Environmental Quality. The Task Force is charged with developing a recommendation for a national policy that ensures protection, maintenance, and restoration of oceans, coasts and the Great Lakes. It will also recommend a framework for improved stewardship, and effective marine spatial planning. On December 14, 2009, President Obama's Ocean Policy Task Force released its Interim Framework for Effective Coastal and Marine Spatial Planning for a 60-day public review and comment period. The Interim Framework suggests a comprehensive, integrated approach to planning and managing uses and activities. Under the framework, marine spatial planning would be regional in scope, developed cooperatively among Federal, state, tribal, local authorities, and regional governance structures, with substantial stakeholder and public comments. The framework proposes the establishment of nine regional planning bodies, including one for Alaskan waters. A final U.S. Framework for Marine Spatial Planning was issued in July 2010 and on 19 July President Obama signed an executive order that, among other instructions to federal agencies, provides for the development of coastal and marine spatial plans that build upon and improve existing Federal, State,

tribal, local, and regional decision-making and planning processes. The Obama Administration has proposed $20 million in the 2011 NOAA budget to support regional ocean partnerships and MSP.

In August 2009, the U.S. Secretary of Commerce approved a management plan for the fishery resources of the Arctic Management Area. The plan covers the Arctic waters of the United States in the Chukchi and Beaufort seas (Fig. 8). Warming ocean temperatures, migrating fish stocks and shifting sea ice conditions from a changing climate may potentially favor the future development of commercial fisheries. The plan establishes a framework for sustainably managing Arctic fish resources. Using a spatial management measure, the plan initially prohibits commercial fishing in the Arctic waters of the region until more information is available to support sustainable fisheries management.[51] The North Pacific Fishery Management Council approved the plan in February 2009. Final regulations protecting over 500,000 km2 of U.S. Arctic waters from industrial fishing went into effect December 3, 2009. The new regulations close all U.S. waters north of Alaska's Bering Strait to commercial fishing to allow time for more science to assess the health of Arctic Ocean ecosystems.

Figure 9. *Area of the US Arctic Fishery Management Area Closure*



Russia: No references to integrated management or marine spatial planning exist in Russian legislation or regulations. Governmental organizations of the Russian Federation that have responsibilities for marine management operate on a sector-by-sector basis. However, existing legislation does contain areas in which marine spatial planning could be an important instrument for solving the tasks and problems of marine management.

Marine planning is under discussion now only in the Russian academic community. The role of the academic community in this process is to formulate the basic principles of MSP, identify actions toward its implementation, and explain the need to incorporate this system into both national and international law.

Russia has identified biologically important areas. However, no marine areas have been designated as protected areas. Only coastal terrestrial have been designated; a few areas extend one kilometer into the territorial sea.

Pan-Arctic: While most MSP efforts have been focused at the national level, several initiatives have a Pan-Arctic perspective. For example, the Arctic Council has several different spatial data initiatives that are developing regional or circumpolar datasets or to provide a framework that would allow integration, access, and coordination of spatial data on the Arctic. It has discussed the possibility of developing a common interface for access to spatial data.[52] However, existing efforts of the Arctic Council to address cartography, geographic information systems, and spatial analysis have been conducted in isolation with no attempt at harmonization or integration. The Working Group on Emergency Prevention, Preparedness and Response, the Working Group on the Conservation of Arctic Flora and Fauna, and the Arctic Monitoring and Assessment Program have discussed the possibility of developing a common interface for access to spatial data, the first tentative steps toward providing a framework to allow for data standardization and integration within the Arctic Council.

The International Union for the Conservation of Nature (IUCN) and the Natural Resources Defense Council (NRDC) are about to undertake a cooperative Arctic Marine Ecosystem-Based Management Project to explore ways of advancing implementation of ecosystem-based management, and to begin the process of identifying specific ecologically significant and vulnerable marine areas that should be considered for enhanced protection in any new management arrangements. Partners in the project include the Ecologic Institute and the Center for Marine Biodiversity and Conservation (CMBC) at the Scripps Institution of Oceanography, University of California, San Diego. The main outcomes of the IUCN/NRDC Arctic Marine Ecosystem-Based Management Project will include: (1) policy recommendations on management arrangements needed to advance ecosystem-based marine management in the Arctic region; and (2) scientific findings (including maps and reports) on areas of ecological and biological significance or vulnerability that should be considered for enhanced protection in the Arctic. Shell International Exploration and Development and the Prince Albert of Monaco Foundation are co-funding the project.[53]

Another planned IUCN project, the first phase of which will be funded by Shell, will address the assessment of cross-sectoral, cumulative impacts in the Arctic. The project will assess the cumulative impacts of current and future developments on the Arctic environment, and will include a strategy to potentially develop an Arctic management plan or management plan(s) for Arctic regions. The project is divided into four phases and is expected to take at least four years to complete.

The first phase will build the required information network and organize a workshop to develop alternative scenarios for the Arctic. The second phase will identify regional developments and impacts, based on a limited and agreed set of scenarios. A larger group of stakeholders will then work in a third phase to make a strategic and integrated assessment of the potential impacts of the various sectors on the Arctic, their consequences, and advice regarding future choices. The final phase would involve additional stakeholders in assessing the political issues associated with such a forward-looking process.

How Can Marine Spatial Planning in the Arctic be Advanced?

Marine spatial planning is already occurring in the Arctic—at least in Norway (Barents Sea) and to a promising extent in the Canadian Beaufort Sea, and the USA. Only Russia and Greenland lag behind. Several options exist for moving forward:

1. A "Business as Usual", Incremental Approach

Under this option, the national government of Norway will continue to lead the way in the implementation of MSP. It is currently in the process of revising its integrated management plan for the Barents Sea and has just approved an integrated management plan for the Norwegian Sea. It is at least several years ahead of other Arctic countries in focusing on spatial and temporal management measures in its integrated approach to marine management. Canada will probably develop over the next several years a marine spatial management plan for its sector of the Beaufort Sea. However, no current plans exist for marine spatial planning in the remaining part of Canadian Arctic waters. The United States, depending on the outcome of nascent efforts of the Obama Administration to stimulate MSP in American marine areas through its executive order of July 19, 2010 and competitive grants to regional marine management organizations in 2011, could begin MSP in the Arctic seas of Alaska over the next several years. Progress on MSP in Greenland and Russia will continue to lag behind these other national efforts.

2. A Bilateral Approach between National Governments

Several areas have already been identified as potential bilateral projects for integrated marine planning: (1) the area of the USA-Canadian Beaufort Sea, known as the "Beaufort Sea Triangle",[54] and (2) the Norwegian-Russian Barents Sea. In 2005, a Norwegian-Russian working group on the marine environment was established as part of the bilateral marine protection cooperation between Norway and Russia. The working group was established to contribute to closer cooperation on ecosystem-based management of the Barents Sea.[55] In fact, Russian experts were involved in the preparation of parts of Norwegian plan for the Barents Sea, and Norway has discussed the possibility of producing a similar plan for the Russian side of the Barents Sea. Norway and Russia agreed in April 2010 to settle their dispute over the Barents Sea border that had dragged on for decades. However, immediate interests of the two countries appear to be focused on oil and gas development rather than any effort to develop an integrated management plan for the formerly disputed area.[56]

Preliminary work on MSP has begun through the Arctic Council's PAME (Protection of the Arctic Marine Environment) Work Plan for 2009-2011.[57] It is developing pilot projects to make the large marine ecosystem (LME) assessment approach operational (in the Canadian/US Beaufort Sea and the US/Russian Federation West Bering Sea).[58] These initiatives would move MSP in the Arctic forward, but without substantial new infusion of resources, progress is likely to be slow.

3. A "Hot Spot" Approach

Another way to develop a MSP initiative that could produce short-term results would be to identify a "hot spot" area in an Arctic nation that currently has no marine planning activities underway, but one that has the potential for new development. Hot spots of biodiversity and productivity in the Arctic would include flaw lead systems (waterways opening between pack ice and fast ice), polnyas (areas of open water surrounded by sea ice), areas of oceanographic fronts where mixing between cold polar and temperate waters occur, and marginal ice zones. A MSP initiative would be the appropriate approach through which to plan the future of multiple uses, identify areas for conservation, and help identify and rank baseline data gathering and applied research. It would demonstrate a commitment to an ecosystem-based management approach in the Arctic in a practical sense and could test new concepts of networked governance. This alternative could only be undertaken with the approval and cooperation of the host Arctic country.

4. An Arctic-wide, Systems Approach among National Governments

Planning for integrated, ecosystem-based management should be encouraged across Arctic countries—and a focus on MSP could be a first step in that direction. This approach would tackle the entire Arctic region, probably under the aegis of the intergovernmental Arctic Council. While the Arctic Council is not an operational body that can impose obligations on its participants, it could undertake marine spatial *planning* for the entire Arctic region with the understanding that *implementation* of any plan would be the responsibility of individual Arctic coastal nations.

Preliminary work on MSP has begun through the Arctic Council's PAME (Protection of the Arctic Marine Environment) Work Plan for 2009-2011.[59] The PAME continues to review the Arctic Marine Shipping Assessment and the Arctic Offshore Oil and Gas Guidelines. It is developing pilot projects to make the large marine ecosystem (LME) assessment approach operational (in the Canadian/US Beaufort Sea and the US/Russian Federation West Bering Sea).[60] However, *no current plan exists to develop a marine spatial plan for the entire Arctic region.* Given the working arrangement for PAME (two meetings a year) and the level of investment in its work plan (>$140,000 per year), little progress on an Arctic-wide approach to MSP can be expected over the next few years without a substantial infusion of new resources.

5. An Arctic-wide, Systems Approach beyond National Governments

Most current applications of MSP are carried out by national governments and can be characterized as "top down". For example, MSP initiatives in Western Europe, including Norway, have all been led by federal ministries, with varying levels of participation by non-governmental actors and stakeholders.

Another alternative to advancing MSP in the Arctic would explicitly recognize the importance of moving beyond sole reliance on the initiatives of national governments and toward a "networked governance" approach to guide the future of the Arctic development. Networks and partnerships of non-governmental actors including indigenous peoples, environmental non-governmental organizations, academia, and private industry, all of whom have substantial influence over governmental policies and actions, could be used to initiate MSP. Precedents exist. In Belgium, the University of Ghent laid the groundwork for MSP that was later implemented by the national government. In the United States, NGOs and the private sector,

particularly new private users of ocean space, e.g., wind farms and offshore aquaculture, have been particularly influential in the development of a national MSP framework. Local indigenous peoples (Coastal First Nations) have led by example the MSP process in British Columbia from the "bottom up" (See Box 6).

Similarly, Indigenous Peoples from the Arctic could take the initiative to develop an Arctic-wide approach to MSP through a network of their organizations including the Aleut International Association, the Arctic Athabaskan Council, the Gwich'in Council International, the Inuit Circumpolar Council, the Russian Association of Indigenous Peoples of the North (RAIPON), and the Saami Council. While capacity building to begin MSP might be needed, technical advice could be sought from the Coastal First Nations Planning Office in Vancouver, British Columbia, and the Beaufort Sea Planning Office in Inuvik, Northwest Territories, Canada. Initially the Arctic Council Indigenous Peoples Secretariat in Copenhagen, Denmark could provide coordination of this initiative. Alternatively, the initiative could be self-organizing, relying on the interests and initiative of a few indigenous organizations and their leadership. The important role of MSP "champions" within these organizations cannot be over-stated. Getting started and maintaining momentum of a MSP initiative requires early buy-in by leaders and their organizations. Listening to successful stories from the MSP initiative of the Coastal First Nations could build support for an Arctic-wide MSP initiative. New Internet-based, low-cost (or free) communications technology, e.g., face-to-face video calls, video conferencing, and webinars, could be used to supplement or substitute for long-distance Arctic travel.

An initial task would be to find adequate financial support for the initiative that could take 3-4 years to complete a first integrated, ecosystem-based marine spatial plan for the Arctic at the cost of about US$1.5-2 million per year.[61] Total funding required would be about US$ 6-8 million dollars. Funding should be sought from several foundations and the private sector, especially Arctic users.

If funding can be found, then a number of pre-planning tasks should be undertaken including the creation of a MSP team, the development of a work plan, and a definition of boundaries and a time frame for planning, e.g., 10 years, 20 years. Other early tasks would include defining MSP principles and goals (see pp. 25-29 of this report and the UNESCO Guide to MSP for additional details). These tasks should be completed during the first year of planning, if not earlier.

A key task of moving toward an ecosystem-based management approach is the identification of "ecologically or biologically important areas" based on the best available scientific information and local knowledge. Some places in the sea have much greater importance than others for particular species, ecosystems, or processes, as well as for humans, too. "Real estate values" in the sea vary enormously, just as they do on land. Knowing which places are most important to conserve and which places are compatible with development is central to the art of MSP. The output of this task, an Arctic-wide map of these areas, is a requisite for ecosystem-based MSP (additional information on identifying ecologically and biologically important areas can be found on pp. 50-55 of the UNESCO MSP guide. The Pan-Arctic initiatives of IUCN, NRDC, and Shell (an international organization, a NGO, and a business) described in the previous section could substantially contribute to the development of an Arctic-wide marine spatial plan.

Leadership through a MSP initiative by Indigenous Peoples could provide the basis for other stakeholders, e.g., the business and NGO communities, to collaborate in the planning process. Eventually the Arctic Council and national governments would participate, particularly in the implementation of many spatial and temporal management measures.

An Evaluation of the Science Needs to Inform Decisions… USGS Circular 1370 (Ch. 5-8 & Appendices)

Chapter 5

Oil-Spill Risk, Response, and Impact

By Leslie Holland-Bartels and Jonathan J. Kolak

Introduction / Rationale

Parties with interest in oil and gas development decisions in the Arctic Offshore Continental Shelf (OCS) have varying views and concerns over the probability that such activities will result in an oil spill in the Arctic. They also differ in their views of how prepared government and industry are to respond to and understand the consequences of any such spills. The Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) expresses the challenge the Nation faces in understanding and balancing the risks to its environmental assets as it explores and utilizes energy endowments.

> *"Estimating large oil-spill occurrence or large oil-spill contact is an exercise in probability. Uncertainty exists regarding whether exploration or development will occur at all and, if it does, the location, number, and size of large oil spill(s) and the wind, ice, and current conditions at the time of a spill(s). Although some of the uncertainty reflects incomplete or imperfect data, a considerable amount of uncertainty exists simply because it is difficult to predict events 15–40 years into the future" (Minerals Management Service, 2008a).*

The tiered decision process used to inform OCS actions regarding whether and how to proceed with oil and gas development involves making decisions that in the early planning phases have high unknowns but progress to actions whose potential effects and footprint can often be more easily judged. For example, the Federal planning process for oil and gas development steps from general, national OCS-wide 5-year plans, which have the highest unknowns, to lease sale plans, to individual exploration activities, with significantly more project detail. After the U.S. Geological Survey (USGS) OCS Team completed its preliminary examination of documents, it was evident that scientific and technical information related to our Issue Topic of Oil-Spill Response (research needs to allow for an effective and reliable oil-spill response in ice-covered regions) occurs throughout the tiered planning and decision process. Similarly, science needs exist for other agencies that are "downstream" of these planning and decision processes. Within the leasing decision process, for example, there are biological opinions (such as those from the National Marine Fisheries Service, 2008; U.S. Fish and Wildlife Service, 2009) or water and air permit actions (from the U.S. Environmental Protection Agency). There are other processes outside the leasing process that also have a critical nexus to decision making about energy development, and these also require information. For example, while not specific to any leasing process, the Alaska Regional Response Team (ARRT; 2010) provides Federal, State, and local governmental agencies with the means to participate in response to pollution incidents. The ARRT also provides these governments' overall joint spill preparedness and response plans, and its policies on spill countermeasure use are important to spill response in the Arctic and elsewhere. Industry may have the capability to use dispersants; however, they cannot do so without following ARRT guidelines. Similarly, the Natural Resource Damage Assessment (NRDA; National Oceanic and Atmospheric Administration, 2011), which takes place after a spill event and is outside of the BOEMRE program, is an important consideration within the decision framework of many of those that participated in our expert consultations. The main questions are, can the environmental consequences of any potential oil spill in the Arctic be understood and quantified sufficiently to judge the risks and benefits of energy development, and can restoration be accomplished should a spill occur? Uncertainty in the answer to those questions influences public perception, which in turn feeds

into the various permitting processes, or into legislative or litigation action. Planning and (or) regulatory actions are taken by a wide range of entities that require scientific and technological information. Based on these considerations we reframed our assignment to consider science needs within the full array of issues that influence the public's perception on the ability to develop effective and reliable responses to oil spills in the Arctic.

First, we provide a brief description of major on-going efforts that identify necessary science and related technologies to help minimize the probabilities of an oil spill and to improve spill preparedness activities. We then focus our examination on how scientific information informs and what gaps might exist for these subjects: (1) estimating the potential effects of oil spills in pre-decisional planning, (2) informing spill contingency planning and spill response, and (3) informing post-spill damage assessment and restoration considerations. At the conclusion of this chapter, we bring in materials first presented in Chapter 4, Climate Change Considerations related to potential future climate conditions in the Arctic and how any changes in environmental conditions might influence our present understanding of oil-spill risk, response, and impact.

Overarching Efforts and Real-Time Communications

The engagement and investment to develop data, approaches, and technologies that inform effective spill response comprise an ongoing and rapidly evolving effort that the USGS OCS Team wanted to ensure was not lost as we delve into specific details later in this chapter. It is best reflected in the numerous on-going study programs and recent documents, forums, and bibliographies that examine research and other preparedness issues. The BOEMRE environmental (Bureau of Ocean Energy Management, Regulation and Enforcement, 2010b) and technology (Bureau of Ocean Energy Management, Regulation and Enforcement, 2010c) programs and ongoing Joint Industry Program (JIP) activities, such as SINTEF (2010), provide up-to-date links to proposed, ongoing, and completed projects. The Prince William Sound Oil Spill Recovery Institute, established by Congress under the Oil Pollution Action of 1990 to support research, education, and demonstration projects designed to address oil spills in Arctic and sub-Arctic marine environments, maintains an active program to examine science associated with issues like the fate and effects of spilled oil in the Arctic and the ability of spill responders to mitigate impacts of spilled oil as reflected in their 2011–2015 Research Plan (Prince William Sound Oil Spill Recovery Institute, 2010).

Scientists, managers, and regulators meet often in a variety of venues to present the most recent progress and challenges. For example, the 2011 Alaska Marine Science Symposium sponsored a workshop "Lessons Learned from the Gulf of Mexico" (http://vislab-ccom.unh.edu/~schwehr/2011AkMarSciSym/, accessed March 30, 2011). Speakers discussed aspects of the *Deepwater Horizon* oil-spill response approaches and challenges as they might inform Alaska spill preparedness. The 2007 International Oil and Ice Workshop (http://www.boemre.gov/tarprojects/587/webpages/home.html, accessed May 5, 2011), the second such workshop, brought together an international audience to advance knowledge of spill response in cold water and ice, including remote sensing, enhancements to mechanical recovery systems, chemical herders in ice, cold-water dispersants, experimental spills, case studies, and ongoing and future research programs. The bi-national U.S. and Canada Northern Oil and Gas Research Forum and the BOEMRE Information Technology Meetings offer opportunities to share new information in many topical areas. Discussions cover, for example, environmental conditions in exploration areas, interaction of oil and gas activities with sensitive coastal habitats, ice engineering for offshore operations, oil-spill prevention and management in the Arctic, and monitoring for cumulative effects. Presentations are publicly available (for example, North Slope Science Initiative, 2010; Bureau of Ocean Energy Management, Regulation and Enforcement, 2011a). Focused workshops, such as the U.S. Coast Guard (2010) on operating in the Arctic or Coastal Response Research Center (2009, 2010), examine factors to improve preparation and response to marine incidents and document practitioner perspectives on operational and science gaps. A wide variety of near real-time information related to oil and gas development considerations is generated and shared in a variety of these forums. The question is not if such information is being produced, but rather what that information is and how it moves into the appropriate planning and decision processes of regulators and other vested parties.

5.01. Finding: The level of information and the number of entities generating scientific and technical information on spill preparedness topics are increasing exponentially as enhanced attention is turned towards the Arctic in general, and resource development more specifically. Individually, sources are well structured, but they roll up to a complex information challenge. It is difficult to know which identified needs are being addressed fully or partially, what new issues or insights have emerged, or how one should weigh the importance of identified gaps.

5.01. Recommendation: The coordinated organization of data for access and distribution by all parties of particular workshop findings and recommendations would improve the value of such forums to help guide science planning and funding decisions. A holistic and up-to-date analysis of recommendations and insights presented in these "real-time" symposia also would help clarify and bring more transparency to what new or continued science investments are needed. Potential approaches to consider are systems similar to the National Biological Information Infrastructure portal (http://www.nbii.gov/) or enhancements of existing systems, such as Alaska Ocean Observing System (AOOS) (http://www.aoos.org/) or the North Slope Science Initiative (http://www.northslope.org/).

Minimize Spill Probabilities Through Infrastructure Decisions

The USGS OCS Team is not well positioned to rigorously consider the state of knowledge or key information and technology gaps related to infrastructure engineering. However, it generally is accepted that effective Arctic technologies are the first step in overall oil-spill risk minimization. In addition to technologies, a sound understanding of bathymetry, ice scour, and shoreline erosion data and processes can improve infrastructure siting decisions. The BOEMRE has an active program to develop safety-related information in advance of future operations in the Arctic. As part of their Technology Assessment and Research Program, engineering properties and forces of moving ice on structures and pipelines are being studied (http://www.boemre.gov/tarprojectcategories/ice.htm, accessed March 30, 2011). The IMV Projects Atlantic (2008) assessed the current state of offshore technology in Arctic and sub-Arctic regions that might be applied in the Beaufort, Chukchi, and Bering Seas. They suggested the following to be valuable:

- development of a regional ice gouge database for the U.S. Beaufort and Chukchi Seas;
- identification of ice gouge recurrence rates;
- collection of multi-year ice thickness distribution, ridge dimensions and frequency within a floe, floe-size distribution, floe-speed distribution;
- definition of first-year ice thickness distribution, ridge dimensions;
- development of a regional geotechnical database;
- advancements in allowable/acceptable pipeline strain limits, repair techniques, leak detection systems;
- advancements in subsea protection systems, and trenching technologies;
- increased clarity on emergency well-control requirements; and
- advancements in determining maximum gouge depth based on ice strength and driving forces.

The IMV Projects Atlantic authors also examined open-water conditions with large fetches and waves because of the potential and now realized higher waves resulting from greater ice-free periods. The authors felt limited in their ability to consider this topic and supported the need for the compilation and collection of ice, meteorological, and oceanographic information to be used by all parties involved in infrastructure decisions. The generation of such data is an ongoing process within the BOEMRE annual studies process.

As noted above, information exchanges, such as the bi-national U.S. and Canada Northern Oil and Gas Forums, offer the best insight into topics that need to be addressed in the near term. Practitioners are investigating approaches to address ice forces on offshore platforms; offshore structure design challenges from ice load, scour, and thaw strain; predictive advances for critical sea-ice characteristics; extreme ice events; and impacts of increased open-water summer storms. These and other international forums support rapid and efficient transfer of state-of-the-art information on advancing technological challenges and successes.

5.02. Finding: Significant coordinated international effort by industry and governments is taking place to develop safe and effective infrastructure and technologies to access energy resources in ice-covered Arctic waters. It appears that potential individual stress points are being well analyzed. Practitioners are investigating approaches to address offshore structure design challenges from forces, such as: ice load, scour, and thaw strain; and predictive advances for critical sea-ice characteristics, extreme ice events, and impacts of increased open-water summer storms. It was not evident to us how these efforts come together in a holistic analysis of full system risks to identify sensitive infrastructure components and the priority science and technology needed to enhance performance and safety. The types of physical threats to infrastructure related to ice (described above) generally are known but their distribution and the degree of the threat across the geography of potential leasing areas were not fully evident in our limited examination.

5.02. Recommendation: Efforts by the BOEMRE and industry to facilitate discussions of infrastructure needs and advances should receive continued support. For example, the recommendations of the BOEMRE-commissioned study by IMV Projects Atlantic (2008) to compile and collect ice, meteorological, and oceanographic information to be used by all parties involved in infrastructure decisions should continue to be considered and incorporated into the annual Federal and industry work planning process. However, many-faceted and different entities examine infrastructure needs and potential solutions and this is a highly technical discipline. Thus, communication of advances and discussion of remaining critical needs could be enhanced through a coordinated, transparent full-cycle risk model. While this would be valuable within the engineering and technical community, such an approach also could provide a more effective means for the non-engineering community to see, understand, and engage in discussions about development benefits and risks.

Assessing Risks and Potential Effects of Oil Spills

Background

Oil-spill risk analyses and their models and input data requirements used in Beaufort Sea and Chukchi Sea Planning Area decisions follow national protocols outlined in numerous documents (for example, Minerals Management Service, 2006 [appendix C], 2008a; Bureau of Ocean Energy Management, Regulation and Enforcement, 2010a). The major modeled components in these analyses include estimates of spill occurrence, spill trajectories, oil weathering patterns, and intersection probabilities with specific landscape units that are used to estimate fate and effect.

Two key probability analyses are considered—the hazard-based Conditional Probability and the risk-based Combined Probability. The former assumes a spill has occurred and then estimates the percent chance that a large spill would reach coastal habitats or other critical assets (for example, archeological sites, harbors). The latter expresses the percent chance of one or more oil spills ≥1,000 barrels (bbl) occurring and that such oil contacts a certain environmental resource area or land segment. The chance of one or more large spills occurring is derived from the spill rate (obtained from a fault-tree analysis discussed below) and the assumed resource volume. These analytically derived risk probabilities are subsequently combined with best available ecological information to qualitatively express potential impacts as illustrated in this excerpt from the Minerals Management Service (2007):

> " The Oil-Spill-Risk Analysis (OSRA) model estimates a 40% chance of one or more large spills ≥1,000 bbl occurring over the production life of Alternative I, but only 1% chance of one or more large spills occurring and contacting the U.S. Chukchi coastline within 3 days over the production life of Alternative I. If a large oil spill did contact this coastline, the oil probably would persist in a few of the tidal and subtidal sediments for a couple of decades, leading to a local but moderate effect on the few intertidal lower trophic-level organisms. The chance of one or more large spills contacting the U.S. Chukchi coastline increases to 6% within 30 days over the production life of Alternative I, demonstrating the advantages of requirements for rapid response capability."

Estimation of Spill Occurrence

Because there is limited Arctic OCS development, sufficient historical data on offshore Arctic oil spills do not exist to calculate spill probabilities directly. The BOEMRE has used Gulf of Mexico (GOM) and Pacific OCS data as analogs. However, since 2002, the BOEMRE has modified and supplemented these data to represent expected Arctic performance for large spills through a statistical fault-tree approach (for example, Bercha Group, Inc., 2006a, 2006b, 2008a, 2008b). Figure 5–1 shows a typical fault tree for both large pipeline and platform spills. Input rational is developed for Arctic modified effects, such as for process plant and storage tank release, structural failure, storms, and collision events (table 5–1). Arctic-unique effects are additive components whose quantifications are done in a "relatively cursory" way based on judgment (Minerals Management Service, 2006, appendix C). Updating the methodology and input data are a regular part of the BOEMRE Alaska OCS annual study planning process. For example, the 2011 proposed plan includes the updating of the fault-tree analyses with any new oil-spill occurrence reports, geohazard data, or GOM OCS historical data inputs; generation of fault-tree analyses for Arctic oil and gas lease sales based on the BOEMRE exploration and development scenarios; and generating life-of-field oil-spill occurrence rates and indicators (Prentki, 2010).

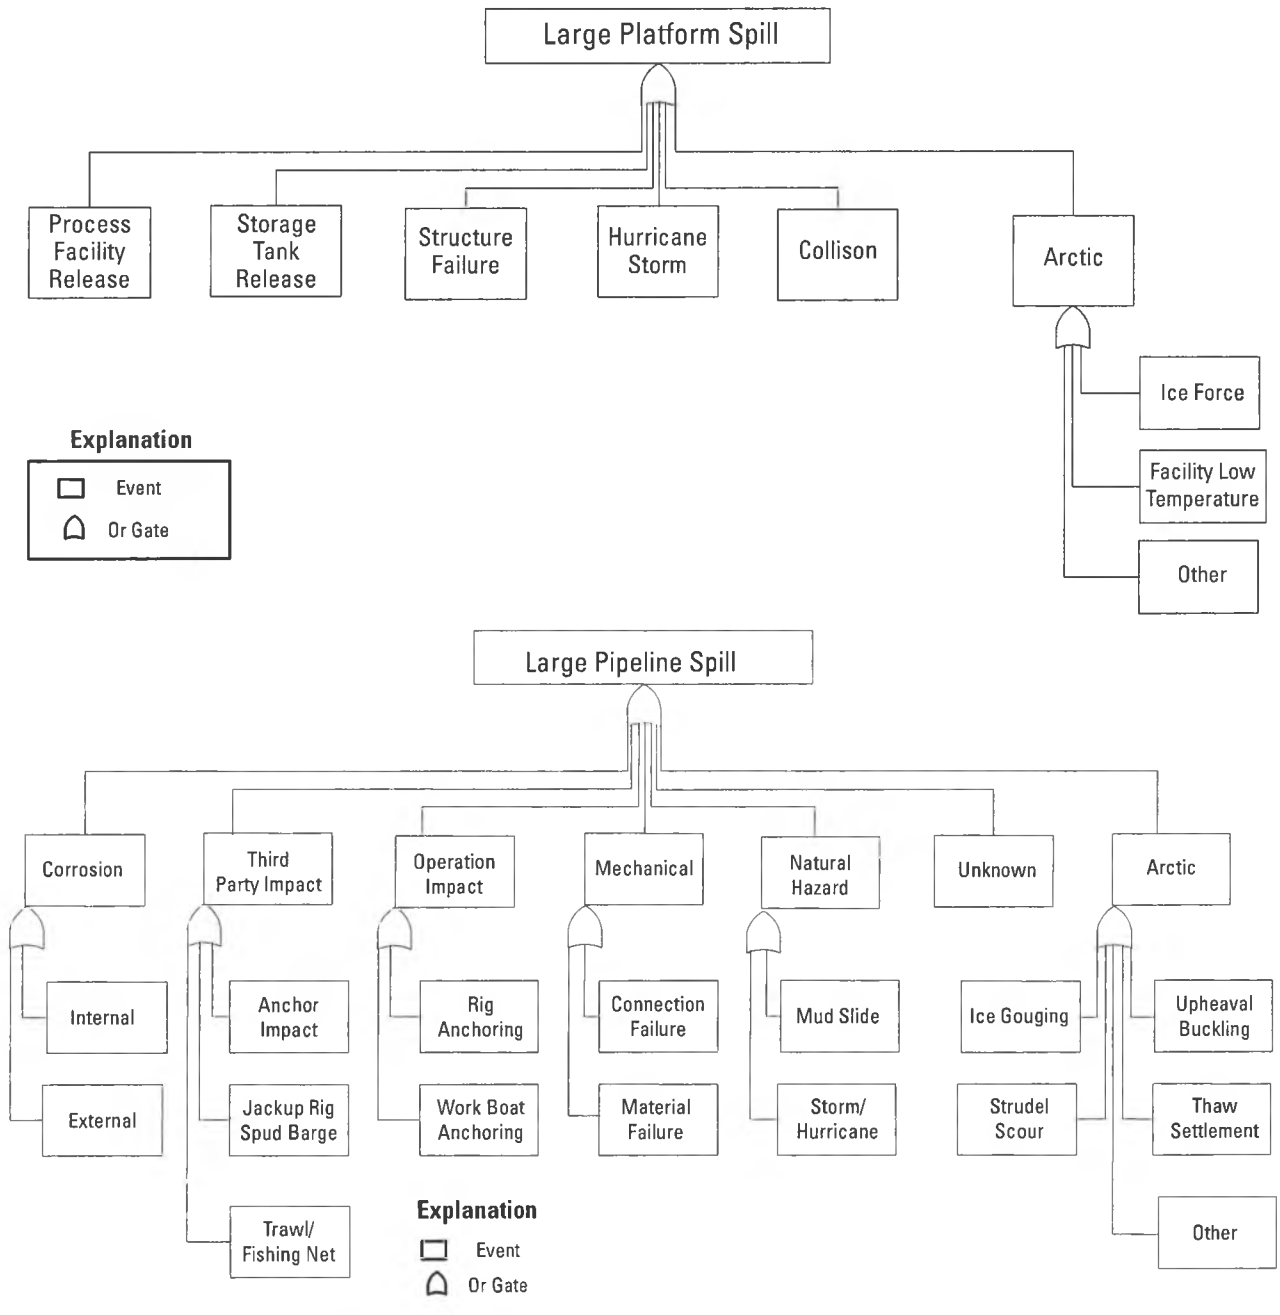

Figure 5–1. Typical fault tree for pipeline or large platform spill outlining key inputs including Arctic-specific factors, such as upheaval bucking, ice gouging, thaw settlement, scour and ice force, and facility temperature (Minerals Management Service, 2006, appendix C, figs. C–2 and C–3).

Table 5–1. Example of platform fault-tree input rational for Arctic modifications and unique considerations from Gulf of Mexico base data.

[Minerals Management Service, 2006, appendix C, table C–2. **Spill size:** All, all spill sizes combined; SM, small (≥50 and <100 bbl) and medium (≥100 and <1,000 bbl); HL, large (≥1,000 and <10,000 bbl) and huge (≥10,000 bbl)]

Event classification	Spill size	Percentage of frequency change			Reason
		Shallow	Medium	Deep	
Arctic modified

5.03. Finding: The spill probability—fault-tree process—is a well documented, transparent, and best available approach to deal with estimations of spill likelihood in the Arctic OCS given that regional historical data on spills are not available. However, the approach depends on accurate adjustments of non-Arctic data to likely Arctic outcomes, which are admittedly done in a somewhat cursory manner. Climate change considerations also may alter the validity of spill frequency adjustments. For example, adjustment of GOM spill frequency probabilities downward because of an assumption that storms are less severe in the Arctic and that a reduced collision rate exists because of less traffic (table 5–1) as compared to GOM values may need to be reconsidered. For example, increases in storm severity and traffic patterns have already been observed and may increase in response to changing climate and ice conditions in the Arctic (see Chapter 4, Climate Change Considerations).

5.03. Recommendation: Continued updating of spill data, re-examination of statistical approaches used in the application of non-Arctic analogs (see Eschenbach and others, 2010), and rigorous development and incorporation of climate-influenced forecasts on factors such as storms, vessel traffic, or other fault-tree model adjustments would provide improved understanding of and confidence in spill risk estimates over the proposed project life.

Spilled-Oil Weathering and Persistence

The weathering characteristics of spilled oil influence the range of drift and spreading considered within spill trajectory assessments and dictate the effectiveness of chemical dispersants, *in-situ* burning, or mechanical responses (Daling and others, 1997; Prenki and others, 2004; fig. 5–2). The BOEMRE employs the Norwegian-developed and field tested (Daling and others, 1997; Daling and Strøm, 1999) SINTEF Oil Weathering Model (OWM) that incorporates oil density, viscosity, pour point, flash point, and water content and physical processes, such as spreading, evaporation, oil-in-water dispersion, and water uptake, as factors within its model-weathering calculations. The OWM is run over a 30-day time horizon, but has not been verified against field data for more than 4–5 days, nor does the SINTEF OWM incorporate the effects of currents, beaching, photo-oxidation, microbiological degradation, adsorption to particles, or encapsulation by ice that might affect degradation rates and toxicological characteristics. A summary of the model and uses within OCS analyses are presented by Prentki and others (2004).

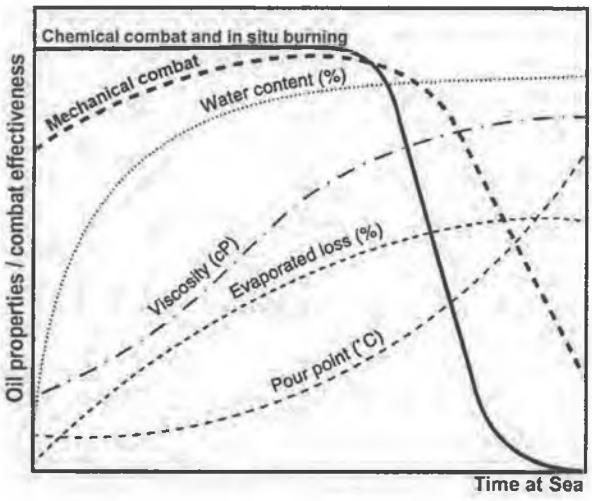

Figure 5–2. Schematic from Daling and others (1997, fig. 2) showing how oil properties change over time and influence spill response tool effectiveness.

Weathering is the combination of numerous physical, chemical, and biogeochemical processes acting to alter the phase and (or) composition of the oil. The processes affecting the weathering of oil spilled in open water, even in cold-water environments, generally are well understood (Fingas, 2008b). Many of the fundamental processes—such as evaporation, dissolution, spreading, and photodegradation—affecting oil weathering in the Arctic also occur elsewhere, but may occur at different rates given the specific meteorological conditions present in the Arctic. Yet, when compared with the current body of knowledge regarding oil weathering processes in open-water and temperate conditions, the body of knowledge regarding these processes in the context of Arctic oil spills is "very limited" (Brandvik and Faksness, 2009).

Laboratory testing provides a view into the nominal response of various oil types to weathering under different environmental conditions. Simulations of spills in various ice conditions have been done (for example, Prentki and others, 2004), but with limited field testing. The JIP on oil spill contingency for Arctic and ice-covered waters addresses some of these shortfalls by conducting a suite of studies from laboratory testing to full-scale field tests. Efforts, such as those by Brandvik and others (2010a) to conduct mesoscale weathering experiments in both the laboratory and at small-scale field scales, provide data to improve the capacity of oil weathering models to better predict oil weathering in cold and ice scenarios. Oil properties (for example, evaporation, emulsification, natural dispersion, flash point) have been experimentally assessed in the laboratory through time in different ice coverages (for example, 0, 30, 50, 70, 90 percent) and for different oils; these assessments directly inform spill response planning. Mesoscale field experiments conducted under the JIP, such as those conducted in Svalbard, Norway (Brandvik and others, 2010a) reduce the uncertainties of oil behavior characteristics that are critical to spill trajectory models and spill contingency plan strategies. For example, Brandvik and others (2010a) found that ice presence can slow weathering processes such as evaporation and emulsification, and can extend the operational window for the use of tools such as dispersants and *in-situ* burning.

Oil emulsification is an important weathering process to understand because emulsification can inhibit the effectiveness of oil-spill countermeasures, and preserve some of the constituents in oil that would otherwise tend to degrade—such as n-alkanes and some classes of polycyclic aromatic hydrocarbons (PAHs). This preservation also can prolong the potential for spilled oil to serve as a source of toxic contaminants, such as PAHs, to the environment. For example, Short and others (2007) noted that residual emulsified oil ("oil mousse") contained abundant levels of these compounds in subsurface sediments of Prince William Sound shorelines some 16 years after the *Exxon Valdez* oil spill, indicating that the "…remaining subsurface oil may persist for decades with little change."

There has been extensive study of water-in-oil emulsions (Fingas, 2008b) under different conditions ranging in scale from laboratory bench top to field tests. Three categories of emulsions—stable, unstable, and meso-stable—with distinct

physical properties generally are recognized. For example, viscosity can vary by several orders of magnitude across these categories, and thus have ramifications for the fate and transport of emulsified oil in the marine environment. The composition of the source oil is a key factor affecting the potential of forming and the resulting stability of emulsions. The addition of energy, such as through wave action, is needed to initiate emulsification, but the threshold energy level needed to initiate this process is not well understood. Recent attempts to derive empirical models describing the formation of oil-in-water emulsions have been hindered by our limited understanding of the chemical behavior of oil constituents in the environment (Fingas, 2008b).

Sea ice also can affect the formation of water-in-oil emulsions. Studies conducted on the fate of oil released in multi-year ice documented that ice morphology is a key parameter affecting oil weathering in the presence of ice (Payne and others, 1991). These researchers have observed that

> "[m]elting first-year ice produced substantial amounts of slush ice, and a stable water-in-oil emulsion of Prudhoe Bay crude oil containing up to 60 percent water was formed within 4 hours of the onset of wave agitation in this slush ice field. In contrast, rotting multi-year ice appeared to have a much lower tendency to produce a slush ice matrix during melting, and the formation of stable water-in-oil emulsions occurred over a relatively longer period of time."

A better understanding of these processes could help delineate the timeframe over which emulsions can form and the "time window" for effective operational response. Knowledge of the stability of emulsions over time underpins monitoring the fate and transport of spilled oil through trajectory modeling and the compilation of oil weathering budgets.

Full-scale field experiments provide invaluable ground-truthing and adaptive learning opportunities. Few such experiments have been conducted in the Arctic and none in U.S. waters. Sørstrøm (2009) and Brandvik and others (2010b) document the most recent large-scale effort conducted in the Barents Sea in spring 2009. Oil weathering experiments, oil distribution and bioavailability, and actual systems of spill contingency were assessed. Field data support findings from mesoscale laboratory efforts on the nature of physical and chemical change as oil weathers under ice conditions.

Persistence of oil was significantly underestimated after the *Exxon Valdez* oil spill. Short and others (2007) found that during early stages of the spill, less viscous oil readily percolated into finer grained beaches and, as the spill progressed along the Gulf of Alaska, more exposed and bouldered beaches allowed the increasingly viscous oil to percolate into "protected" interstitial areas. It remains unclear what "refugia" sea ice and eroding shoreline characteristics in the Arctic may offer oil and what might be the influences on the spatial or temporal degradation of oil. Oil spilled under the ice may be incorporated into the ice sheet where comparatively little weathering/degradation may occur; however, during the spring melt, the encapsulated oil may be released and undergo evaporation and other processes. For this reason, the effect of sea ice on oil weathering is a critical consideration to oil spill contingency planning and response in the Arctic. A substantial body of work was conducted during the 1970s and 1980s to characterize the fundamental processes affecting how oil may become incorporated within ice, and subsequently affect oil weathering (Payne and others, 1991). This incorporation may occur fairly rapidly, in as little as 18 to 72 hours, depending on the time of year (Dickins and Buist, 1981). Recent studies of oil-in-ice interactions addressed a knowledge gap pertaining to how these interactions may affect the efficacy and (or) timing of the potential deployment of spill countermeasures. Brandvik and Faksness (2009) reported that:

> "[o]perationally important weathering processes for oil spill operations like water uptake, emulsion stability and viscosity vary with oil type. Normally they increase relatively fast with increased weathering time in open water. In ice-infested water, several studies have indicated that this increase with time (for example, water content) can be drastically changed depending on ice type, ice coverage and energy conditions in the ice. Little knowledge concerning this is available today, and only for a limited number of oil types and ice regimes… ."

One example of the need to understand these processes in the context of oil-spill response operations is as follows:

> "after only a few hours of weathering on open waters, an oil spill may become too viscous for application of dispersants; yet that same spilled oil, if associated with dense ice, may be amenable to treatment with dispersants even after several days of weathering" (Brandvik and Faksness, 2009).

As a result, the presence of sea ice may serve to inhibit natural weathering processes, and could thus serve to expand the operational "time window" for deployment of spill countermeasures.

Seasonal variations in sea ice also merit consideration for oil-spill response. For example, if oil was spilled under ice in the spring (after May), the oil might not become encapsulated in the ice due to insufficient new ice growth before seasonal melting commenced (Buist and others, 2008a). Conversely, a spill occurring just prior to or during freeze-up (Lewis and others, 2008) may become rapidly incorporated in ice, such that response efforts could include a combination of oil recovery and ice tracking and monitoring operations. State-of-the-art models, such as the SINTEF model, require detailed

physical and chemical information to characterize the oil-ice interaction; such level of detail typically is not available (Brandvik and others, 2006). Further, Brandvik and others (2006) reported that the state of modeling of oil weathering in the presence of sea ice remained constrained by the ability to model sea-ice physics at the appropriate scale. The need to further refine and verify these models of physical processes on oil fate and transport is identified as an information need for oil-spill response in the Arctic (U.S. Arctic Research Commission, 2010).

One of the key processes of oil weathering is the extent and nature of interaction of oil with brine channels in ice. For example, in earlier studies, Payne and others (1991) noted that

> "[i]f oil is released into water under freezing conditions of active ice growth, lower molecular weight aromatic components can be advected with the sinking brine generated during frazil ice formation to the stable bottom boundary layer where, as conservative dissolved compounds, they can persist without evaporation for periods of up to several months."

To further investigate the fate of hydrocarbons from spilled oil in ice, Faksness and Brandvik (2008) conducted field experiments to evaluate the potential for dissolution of water-soluble components (WSCs) into and through first-year (annual) ice. The transport of WSCs from the oil through the ice was documented, and low but detectable concentrations of these components at the bottom of the ice core were measured. This transport mechanism may serve as a vector by which biota at the bottom of the ice sheet are exposed to these WSCs, with the potential for entrainment into the Arctic marine food web. The authors compared the field studies with laboratory experiments—using the Chemical Response to Oil Spills: Ecological Effect Research Forum procedure—and the similar distribution of WSCs in both sets of samples was interpreted to reflect that the brine channels in the ice sheet serve as a transport mechanism of WSCs from oil, through ice via the channels, and into the underlying water.

Natural biodegradation of oil in the marine environment is part of the process of oil weathering, and biostimulation and bioaugmentation have been considered as oil-spill countermeasures (Swannell and others, 1996). In general, however, oil biodegradation rates are difficult to predict, given the influence of oil type, variability of substrates, and other variable factors, such as temperature and nutrients (Zahed and others, 2010). In 1981, an experimental spill, known as the Baffin Island Oil Spill (BIOS) Project, was conducted on the northern tip of Baffin Island in Nunavut, Canada, as a means of studying natural biodegradation from an Arctic marine oil spill (Sergy and Blackall, 1987). Although much of the original oil has naturally degraded over time, follow-up studies have shown that some patches of the spilled oil remain essentially unaltered after decades of exposure (Prince and others, 2002). The interactions with sea ice may affect oil biodegradation processes, and can provide routes for components from spilled oil to enter the Arctic marine food web (Faksness and Brandvik, 2008).

A good understanding of ambient microbial communities and processes is needed for the water column, sediments, and ice to understand the potential for microbial degradation of oil in the Arctic, and the potential impact of this on oil fate and ecosystem uptake. There have been recent activities to increase our knowledge in these areas (Interagency Coordinating Committee on Oil Pollution Research, 2009). Braddock and others (2004) noted that despite large-scale development on the Alaska North Slope, there was limited understanding of microbial communities in this setting, and much of this derived from studies that were decades old. Garneau and others (2009) reiterated this point, noting that the microbial characteristics of the coastal Arctic Ocean have been little explored, but that studies conducted to date on the Mackenzie Shelf in the Beaufort Sea provide information on the existence of diverse and active microbial communities, with variation among communities across salinity gradients. A survey of microbial populations from offshore of Barrow and

5.04. Finding: The interaction of ice and oil has long been recognized as an important factor affecting oil fate and toxicity in the Arctic environment. Recent studies have focused on oil-water partitioning (water-soluble compounds, WSCs) associated with ice melt and brine channel flux in the ice column.

5.04. Recommendation: There is a need to better understand oil-in-ice weathering, particularly as it relates to the effectiveness of spill response countermeasures and the potential for ecosystem exposure. Oil-water partitioning is recognized as needing further study, especially the potential toxicity of the partitioned phases, as oil trapped in ice may remain relatively fresh (that is, toxic). This process also points to the potential for a longer term spill response that follows the initial event for potentially several months given seasonal changes to the ice column (melting).

Prudhoe Bay, Alaska, provides a more recent characterization of endemic populations and metabolic capability to degrade petroleum hydrocarbons (Braddock and others, 2004). Braddock and others (2004) reported that the total microscopic counts of bacteria and culturable heterotrophs in the sediment samples were comparable with estimates from studies conducted in the 1970s and 1980s in the same areas. Kirchman and others (2010) investigated potential seasonal and spatial variations of bacterial community structures in the Arctic Ocean to help improve the fundamental understanding of relationships between bacteria and phytoplankton in the Arctic Ocean, which appear to differ from those found in lower latitude oceans. This information helps inform our understanding of primary production during the rapid transition from spring to summer when ice coverage decreases in the Arctic Ocean. In water column samples collected from various locations in the Chukchi and Beaufort Seas, there generally was no significant seasonal variation in communities despite strong seasonal gradients in biogeochemical properties (Kirchman and others, 2010). These findings may have ramifications regarding the ecophysiological flexibility of bacterial communities in the areas sampled (Kirchman and others, 2010). This is an area for further research as it could have implications for the adaptability of indigenous microbial communities to changes in carbon source, such as in the event of an oil spill.

Recent studies following the *Deepwater Horizon* oil spill have shown the importance of characterizing not only the indigenous microbial communities in benthic sediments, but also those in the water column. In particular, Hazen and others (2010) reported natural biodegradation of the dispersed oil plume in deep water. Because the microbial communities appeared to rapidly adapt—as reflected in hydrocarbon-degrading genes—in response to the oil plume, the researchers concluded that there was potential for intrinsic bioremediation of oil contaminants in the deep sea. As such, these communities may have an important role in the fate of hydrocarbons in the GOM (Hazen and others, 2010). Analogous studies of indigenous microbial populations in the Arctic are warranted to gain a better understanding of the potential for these processes to naturally attenuate an Arctic oil spill.

Oil-Spill-Trajectory Models

The OSRA Model (Smith and others, 1982) as refined by Labelle and Anderson (1985), Ji and others (2004), and others simulates oil-spill transport and is dependent on realistic wind velocity and ocean surface current data, as well as accurate information of the ecological, economic, and (or) social resources located along coastlines that might be transected by oil. State-of-the-art trajectory models and quality input data for spill trajectory likelihoods are represented by analyses for the GOM. Johnson and others (2007) reaffirm the conclusions of Ji and others (2004) that oil-spill risk analyses are dependent on detailed information of ocean currents and wind fields. The ocean current inputs are computed from an ocean circulation model driven by analyzed meteorological forces through models such as the Princeton-Dynalysis Ocean Model, which have been extensively assessed with field observations in the GOM (Herring and others, 1999) including data from some 340 drifting buoys (Ji and others, 2004). Similar rigorous data are not presently available for the Arctic OCS, but a strong scientific framework is emerging for 3-D coupled ice-ocean models and 2-D ice-associated oil spill models (for example, Wang and others 2003, 2010) that will improve as knowledge about oceanographic characteristics of the Beaufort and Chukchi Seas increases. Efforts to understand and address data insufficiencies are the focus of numerous ongoing studies by BOEMRE, the Alaska Ocean Observing System, and others.

5.05. Finding: Natural biodegradation of oil in the marine environment is part of the process of oil weathering. The presence of microbial communities gives rise to the potential for intrinsic bioremediation of oil spills. Indigenous microbial populations in the Arctic may play an important role in the fate of hydrocarbons following an oil spill. However, the effect of these populations on such oil weathering in the Arctic is not well understood.

5.05. Recommendation: Recent studies underscore the need to better characterize Arctic-based indigenous microbial populations in the water column and benthic sediment, and define rates of microbial processes. This will ultimately allow for the full characterization of the role such communities have in the oil weathering process.

Well documented analyses of data and technology needs for meteorological and physical oceanography can be found in Beaufort Sea assessments by Hoefler Consulting (2006, 2007) and Weingartner and others (2010a). Present Arctic assets are listed within the interactive Alaska Ocean Observing System's Arctic Assets Application (fig. 5–3). Hoefler Consulting (2006) recommends the establishment of a redundant sensor system. The current lack of redundancy may result in a critical link remaining down for some time should it fail, due to weather and logistical limitations to access the site and the cost of site visits. Such a system also would serve as an enhanced Arctic coast-wide network to serve spill response goals and inform broader questions such as how climate change may affect system dynamics (fig. 5–4). Weingartner and others (2010a) outline a series of large-scale studies that would help define the critical oceanographic characteristics of the Beaufort Sea OCS to better inform pre- and post-spill modeling/response. These also would define environmentally sensitive marine areas by examining oceanographic exchanges, understanding shelf-basin exchange via wind and eddies, better defining characteristics of the coastal boundary and under-ice river plumes, and defining the sea-ice boundary through examination of thickness and under-ice topography. New analyses of mooring data by Weingartner and others (2009) provide a scientific foundation to understand likely movement of a spill in near-shore waters, such as oil spilled beneath landfast ice. Such work appears to be more mature for the Beaufort Sea dating back to efforts under the 1970s Outer Continental Shelf Environmental Assessment Program (OCSEAP, for example, Aagaard, 1981), but attention to Chukchi Sea conditions has increased (for example, Weingartner and others, 2005). Newly installed high-frequency land-based radar (fig. 5–5) holds promise to provide near-shore real-time current data of value for spill modeling, as well as for spill response (Potter and Weingartner, 2009; Weingartner and others, 2010b). The International Ocean Observing System (2009) presents partner perspectives on the present needs for this technology for all their regional networks. Should development in the Arctic OCS continue, it is likely that an increased number of such sites should be considered. Regardless of the development future, while the number of Arctic sites presently is not dramatically different from those in the GOM, the Arctic has fewer oceanographic assets (for example, buoys) in general and would benefit from increased access to this new technology. Analyses critical to such large-scale integrated efforts to better understand oceanographic circulation factors in Arctic oil-spill risk analyses are ongoing through BOEMRE (fig. 5–6).

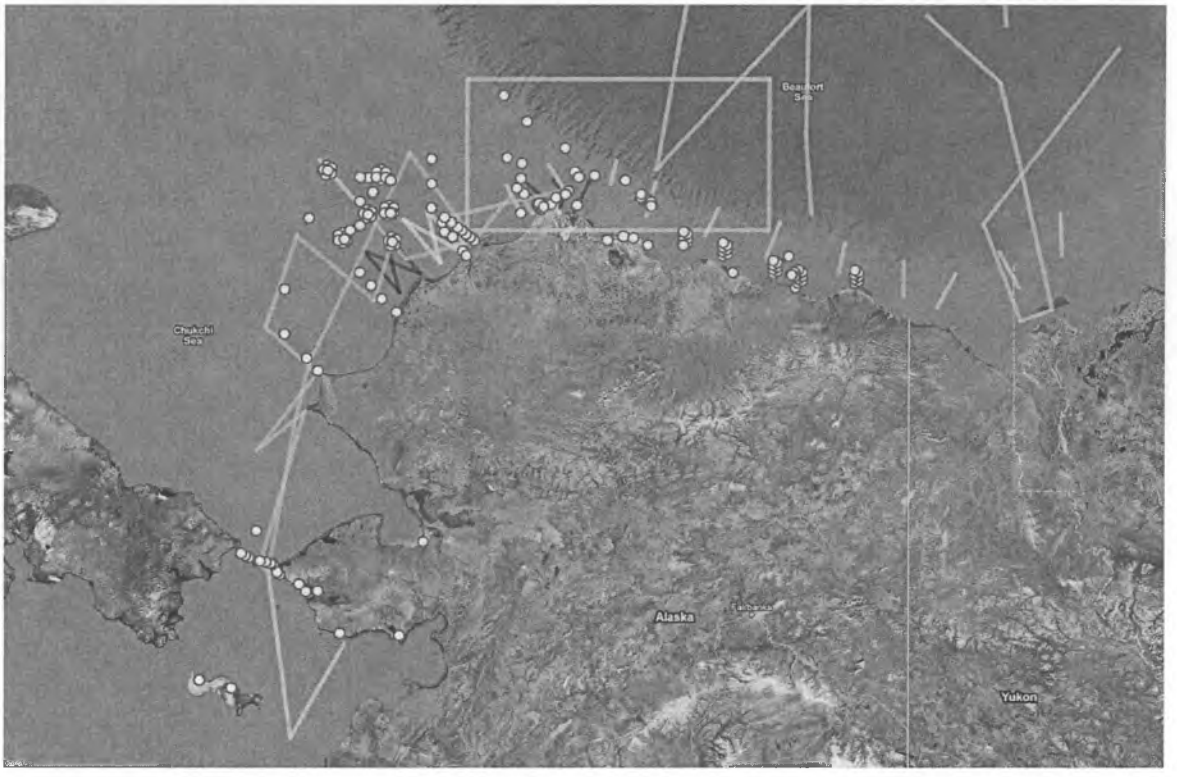

Figure 5–3. Examples of recent oceanographic cruises and sensor assets in the Beaufort and Chukchi Seas taken from the interactive Alaska Ocean Observing System's Arctic Assets Application. (Screen grab: http://data.aoos.org/maps/arctic_assets.php, last accessed February 1, 2011.)

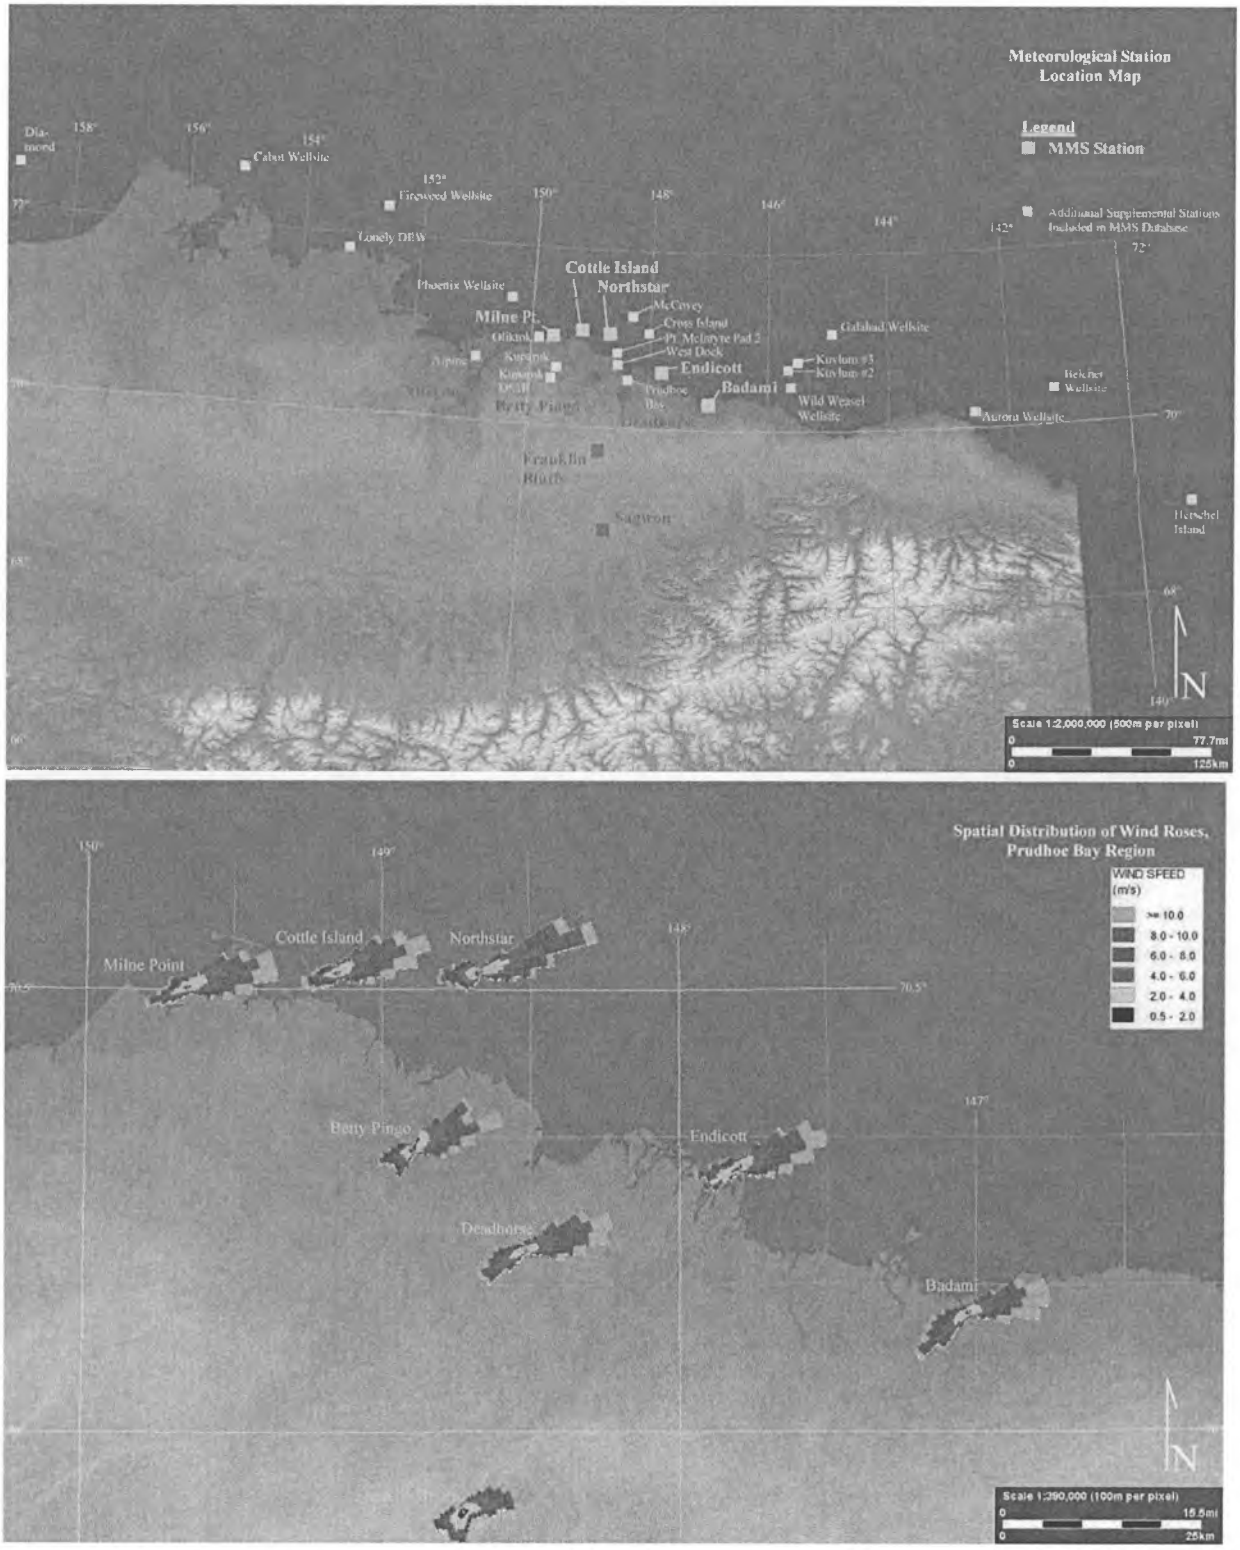

Figure 5–4. Examples of meteorological sites for the Beaufort Sea and spatial distribution wind roses generated by such stations, and other meteorological data useful for spill planning and response (from Hoefler Consulting, 2007, figs. 3–2, 4–21). (MMS, Minerals Management Service.)

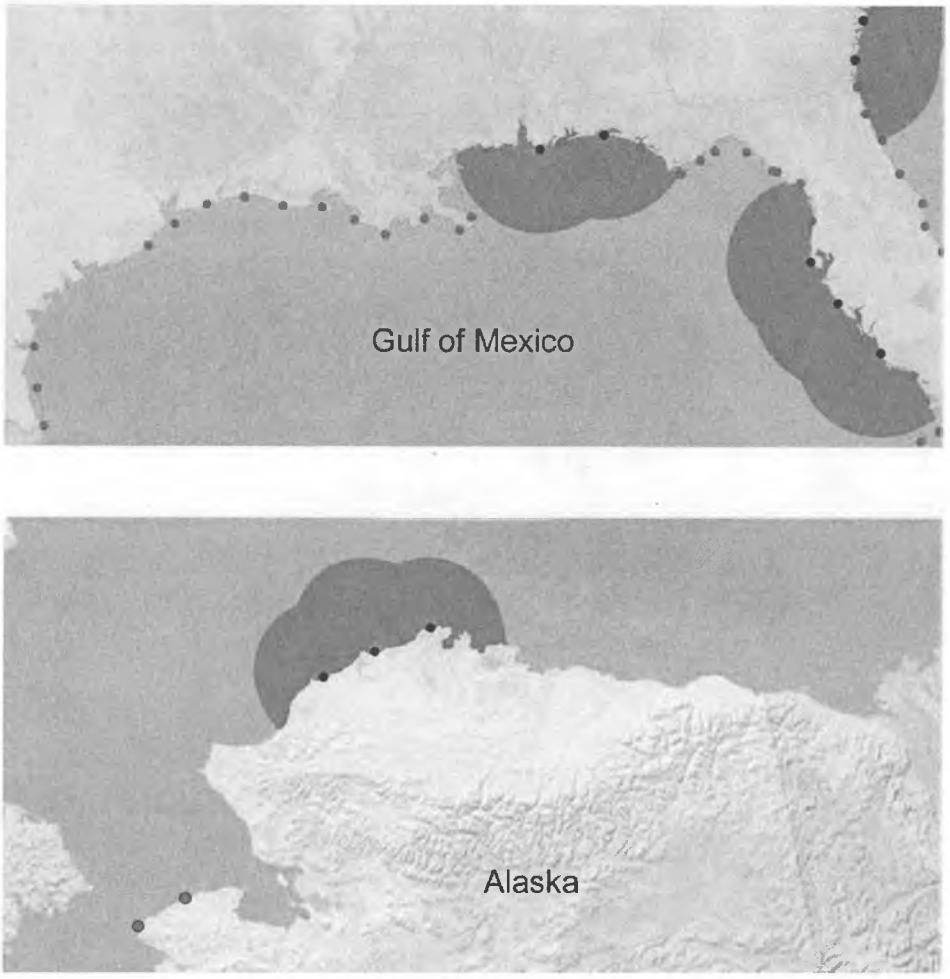

Figure 5–5. Existing High Frequency Radar (HFR) sites (black dots) and proposed sites (blue dots) modified from International Ocean Observing System (2009). The map of Alaska's North Slope and the Gulf of Mexico are to scale to demonstrate existing and proposed coverages (indicated by green areas) for these two major OCS regions.

5.06. Finding: The modeling framework used by the BOEMRE throughout its OCS program is well developed and has undergone rigorous analysis. However, physical oceanography and meteorology of the Arctic OCS are highly dynamic and not well understood because of the challenge of instrumenting a remote ice-influenced system such as the Arctic OCS. This is particularly true for the Chukchi Sea. Thus, the physical understanding of the Arctic OCS needed to inform models is not comparable with that of the GOM. This also is true for circulation or weather modeling that informs oil-spill-trajectory models. Outputs from such trajectory models influence ecological affect analyses, which are limited by the accuracy and precision of the physical data that inform them.

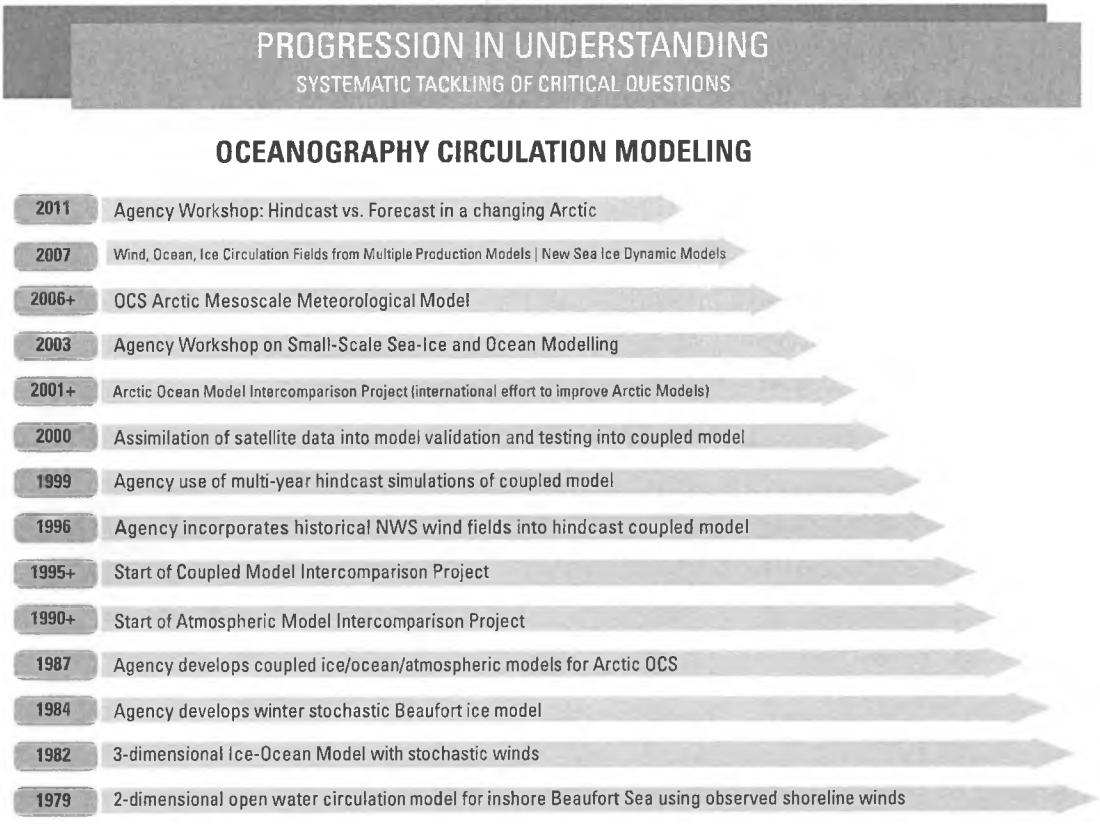

Figure 5–6. Schematic illustrating the progression of science developed under the BOEMRE OCS Environmental Studies Program to better inform an understanding of ocean circulation critical to topics such as oil-spill-trajectory models [Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE), written commun., 2011].

5.06. Recommendation: Existing recommendations for the Beaufort Sea from Weingartner and others (2010a) and Hoefler Consulting (2006, 2007), if implemented, could significantly improve the weather and oceanographic data required by trajectory models. These recommendations include establishment of a redundant meteorological sensor system to enhance Arctic coast-wide spill response goals and a series of large-scale studies of oceanographic exchanges, shelf-basin exchanges via wind and eddies, coastal boundary, under-ice river plumes, and sea-ice boundary to better inform pre- and post-spill modeling and response. We did not find similar synthesized recommendations for the Chukchi Sea. If they do not exist, then producing such analyses would be quite valuable to improve model confidence. Physical oceanographic and meteorological data help inform a wide variety of issues in the Arctic. The international Arctic resource community might benefit from a broader discussion on core data needs and the efficient development of multi-purpose, multi-agency monitoring networks to inform energy development needs as well as climate forecasting, aviation, and shipping safety. The visualization and serving of data through a fully operational Arctic node similar to that of the Alaska Ocean Observing System would help ensure efficient access to information and improved asset planning that is critical in the Arctic where scientific instrumentation costs are high.

Ecological and Social Resource Intersection Analyses

Ultimately, oil-spill-trajectory models and their supporting oceanographic inputs are used to inform analyses of potential effects of spills on areas of environmental, social, and (or) economic interest. The processes described in the section "Oil-Spill-Trajectory Models" define where oil might transect an area (for example, shoreline, reef, migration route) in a very quantitative analytical approach that can be tested for sensitivity and become a foundation for documented improvement when new data or insights are developed (for example, Wang and others, 2010). The value of the area (for example, for subsistence, cultural needs, community infrastructure, or wildlife habitat) is based on best available information. Analysts designate segments important to various resources, and the time periods that those resources occupy that spatial location. This process is often done collaboratively through "expert" discussions and reviews of available literature and is well presented, for example, in the Draft Environmental Impact Statement for the Beaufort and Chukchi Seas multiple lease sales 209, 212, 217, 221 (Minerals Management Service, 2008a). An example of an Environmental Resource Area (ERA) designation and supporting scientific literature (fig. 5–7, table 5–2) helps illustrate the scientific foundation behind the resource designations. There is a significant range in the data that support ERAs from quite limited or dated [for example the Outer Kotzebue Sound (ERA 57)] to those with some 10 supporting sources covering some 40 years (for example the Chukchi Spring Lead System, ERA 19, table 5–2). The USGS OCS Team believes that the literature presented represents a current picture of available scientific information. However, unlike the earlier components of the Risk Assessment Process, the ecological considerations in the assessment are qualitative in nature with no measures of data quality or data uncertainty. It is difficult to judge the value of existing information in the decision-making process, or where and what new ecological data would result in substantially improved decision making. In other words, one cannot run a sensitivity analysis under the present process to examine how important the limitations of the literature or variation in expert opinion might be to the decision-making process.

The challenge to quantitatively include ecological resources is not unique to the Arctic OCS process, but exists throughout the discipline of environmental assessment. Emerging information products and tools, such as those developed by the Alaska Ocean Observing System and Smith's (2010) Arctic Marine Synthesis: Atlas of the Chukchi and Beaufort Seas, represent emergent approaches about data quality and sufficiency that can be built upon. These products and tools represent great advances for the Arctic, where much remains unknown; many different entities conduct work; the landscapes are remote and enormous; and each piece of information is expensive to collect. Even with such tools, insights into what ecological resources might be at risk and the data gaps that are most critical to fill will rely on a mix of expert knowledge and existing data for some time. Structured Decision Making and its supporting tools, from the simplest influence diagrams to the more complex mixed analytical and expert Bayesian Network models, provide discipline to technical or value-based deliberations (for example, Varis 1997; Faber and others, 2002) and can provide inputs to and complement existing regulatory processes. These tools are particularly helpful when there is disagreement about whether a decision needs more information and what information might improve that decision.

5.07. Finding: Oil-spill risk assessment processes have a strong, transparent, and quantitative model framework through the spill-trajectory model phase. The social and (or) ecological value of an area and the potential impact should oil transect it is based on "expert" discussions and review of available literature. They are more qualitative in nature, with limited measures of data quality or data uncertainty expressed.

5.07. Recommendation: The application of the maturing science of Structured Decision Making and supporting tools (from the simplest influence diagrams to the more complex mixed analytical and expert Bayesian Network models) could provide a transparent and quantitative discipline to technical or value-based deliberations. Such collaborative processes could help better define what uncertainty is unacceptable to vested parties and what new information could address that uncertainty in a structured and testable manner.

Science and Oil-Spill Contingency Planning

Contingency plans, as defined under the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (http://www.epa.gov/oem/content/lawsregs/ncpover.htm), require information, much of which is not within the purview of science (for example, response resources, command and control structures, communications, and relationship to other plans). Here, we discuss points where scientific insights and data help inform the planning process. For example, the 2008 International Oil Spill Conference (2008) outlined factors that may be desired in plans (table 5–3). The areas of potential spill coverage must be defined based on scenarios identified in a risk analysis. Presently, for the Arctic such scenarios are limited (Alaska Regional Response Team, 2010). Whether part of the formal NCP process or not, assessment of risk and development of plans include spill scenarios, surface trajectories, subsurface trajectories, stochastic modeling, real-time forecasting, oil characterization, oil fate and effects modeling, and oil weathering. Much of the foundational science for these elements is similar to that required in oil-spill risk assessments detailed previously and will not be described again.

During our expert consultations, participants raised a number of issues relevant to this topic. Potential spill volume is an early input to and an overriding influence on the spill scenario and requires an understanding of the source reservoir volume and pressure. Several entities we met with felt there was insufficient information to reasonably constrain estimates of likely spill volume. In particular, Coast Guard leaders responsible for spill response in the Arctic felt this was an essential input to the series of downstream decisions that they must make within spill contingency plans.

Table 5–3. Spill Response Planning and Assessment Categories as suggested in the 2008 International Oil Spill Conference proposed guide on response planning and readiness assessments.

[Modified from International Oil Spill Conference, 2008, table 1]

Setting the Stage	**Operational Response**
1. Legislation and regulation	16. Source control, salvage, and firefighting
2. Multi-national agreements	17. Response technologies
Developing a Plan	18. Waste management
3. Resources at risk	19. Wildlife recovery
4. Spill risk analysis	**Response Support**
5. Risk minimization	20. Spill monitoring, tracking, and sampling
6. Evaluation of response technologies	21. Cleanup assessment
7. Net environmental benefit analysis	22. Data management and success
8. Expert information sources	23. Logistics
9. Contingency planning	24. Finance, administration, and procurement
Organization and Communications	25. Demobilization
10. Response management systems	**Developing and Sustaining Response Capability and Readiness**
11. Notification systems	26. Exercises
12. Communications	27. Training
13. Safety for responders and public	28. Sustainability and improvement
14. Security	
15. Public information development and distribution	

5.08. Finding: Because of the frontier nature of oil and gas exploration in the U.S. Arctic, few empirical data are available to constrain the estimates of oil reservoir volume and pressure patterns throughout the Arctic OCS, which results in uncertainty within spill risk assessments and oil-spill contingency planning.

5.08. Recommendation: A national investment in foundational geologic and geophysical data can provide an improved understanding of how oil and gas resources are formed and emplaced in reservoirs in the Arctic. However, substantial improvements in estimates will require data from exploration wells that are made publicly available.

In our consultations, various parties expressed the need to develop and test approaches to address "Organization and Communication" capacities for spill response. For example, the National Oceanic and Atmospheric Administration (NOAA) and key partners are actively expanding the successful Emergency Response Management Application (ERMA®) system, most recently used during the *Deepwater Horizon* oil spill in the GOM, to Arctic planning and response. This geospatial decision-support tool combines product output from NOAA sources as well as datasets agreed upon by stakeholders (Coastal Response Research Center, 2011) to provide onsite coordinators critical background and real-time data.

We are not aware of any large-scale field testing of the types of assets and communications that must come together rapidly and successfully for a spill event in the Beaufort or Chukchi Seas. However, the 2009 "Sound Predictions" effort by the Alaska Ocean Observing System (AOOS; 2009) and others in Prince William Sound (Gulf of Alaska) is an example of operational testing that can better improve the science/data component of oil-spill response. Through such field experimentation, the accuracy of ocean current and weather model forecasts, data access, and the utility of an ocean observing system for oil-spill response can be assessed and improved. Underpinning any of these efforts is the need to have data easily accessible and current. The Alaska Data Integration Working Group (2011) is a broad effort to facilitate improved data transparency and access across organizations that will feed well into the needs of Arctic ERMA® and AOOS.

5.09. Finding: Management, spill response, and science communities are actively engaged in developing essential decision support and ocean observing systems. However, these systems are not yet fully funded, operational, or fully tested for Arctic waters.

5.09. Recommendation: Significant improvements in spill preparedness could be accomplished through the completion of decision support and data systems, such as the Arctic Emergency Response Management Application, the Alaska Ocean Observing System, and the State-Federal Alaska Data Integration Working Group. Field testing of assets and data systems as was done in the 2009 "Sound Predictions" experiment in Prince William Sound, Alaska, could significantly improve preparedness by highlighting significant data and operational needs.

Oil-Spill Response

All spill response requires effective planning, tracking, surveillance, and understanding of environmental considerations. For the Arctic, the unique challenge is to understand how oil will move if spilled; how it will respond to environmental conditions; what natural and cultural resources and historical properties are at risk; and how effective response tools will be in cold and ice-covered conditions. Many of the topics we have discussed in our oil-spill risk assessment sections inform actions during oil-spill response. The need for a multi-faceted science and technology effort as the foundation to an efficient and effective oil-spill response capacity is widely understood particularly because of unique Arctic challenges and is evident in the focus on this topic applied under the BOEMRE OCS research program (fig. 5–8).

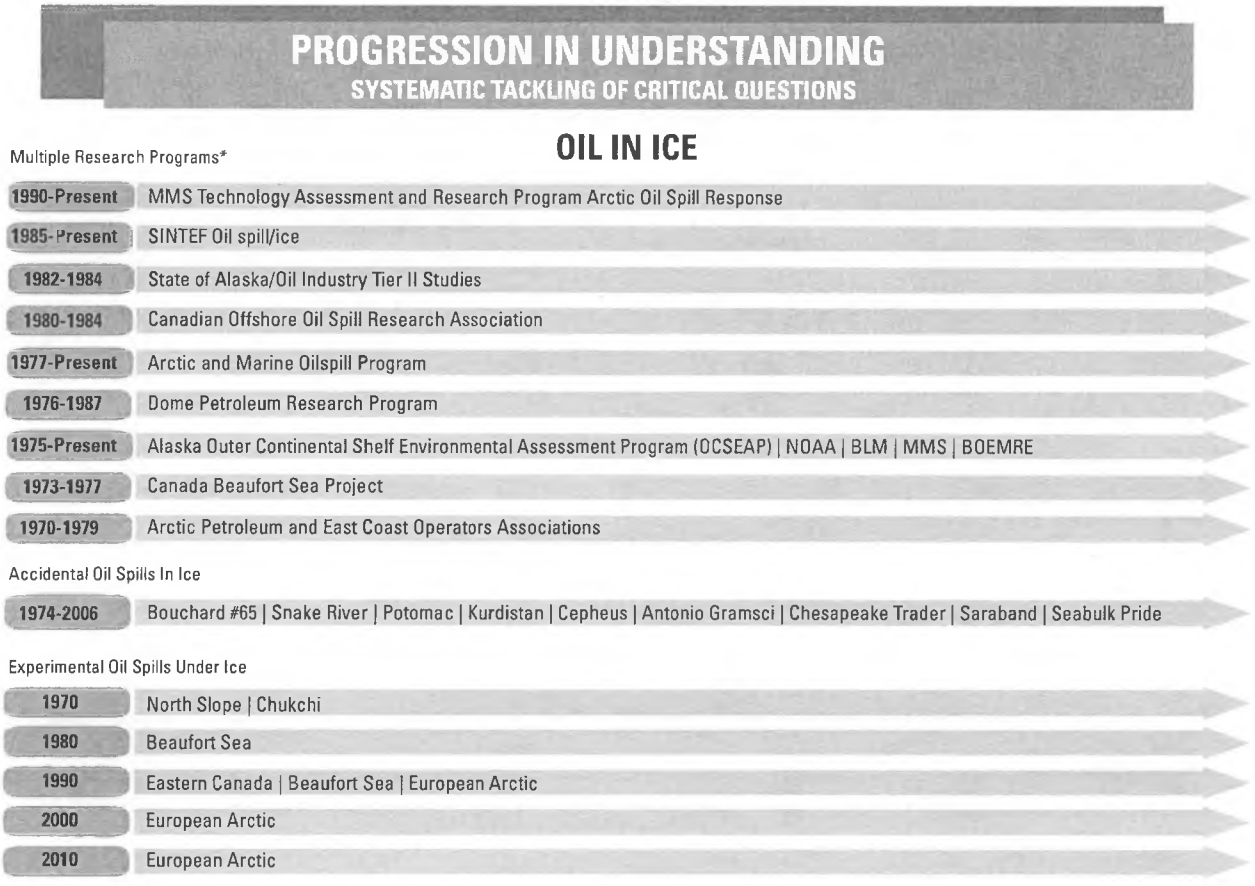

Figure 5–8. Schematic illustrating progression of science developed under the BOEMRE OCS Environmental Studies Program to better understand the behavior of oil in ice [Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE), written commun., 2011]. BLM, Bureau of Land Management; MMS, Minerals Management Service (now BOEMRE); NOAA, National Oceanic and Atmospheric Administration; OCSEAP, Outer Continental Shelf Environmental Assessment Program.

Response Gap

In later sections, we focus on the various spill response methods and technologies as they relate to Arctic and ice-covered waters. Those included are containment and mechanical recovery, burning, bioremediation, and enhanced dispersion. The materials we discuss in those sections highlight the scientific issues, progress, and information gaps that have been expressed for each of the various tools. However, here we discuss the broader issue of oil-spill countermeasures and the topic of "response gap." Lessons learned from the 1989 *Exxon Valdez* oil spill in the sub-Arctic waters of Prince William Sound Alaska (see appendix D) and the most recent 2010 *Deepwater Horizon* oil spill in the GOM (National Commission on the BP Deepwater Horizon Oil Spill and Offshore Drilling, 2011) reiterate that there is no single response technique suitable for all circumstances. The National Research Council (NRC; 2003) stated that reliance on only one recovery system is "unlikely to be successful" to respond to an oil spill offshore of the Alaska North Slope. Most recently, Lee (2010) emphasized the need for the availability of multiple tools, and the challenges in the Arctic of ice dynamics, cold temperatures, and limited light in the winter. Many individual tools will not be available to responders at specific times because of wind, sea, ice, or light conditions (table 5–4; also see Nuka Research and Planning Group, LCC, 2007b; Nuka Research and Planning Group, LCC and Pearson Consulting, LCC, 2010). Understanding what combination of countermeasures will likely be available under the temporal and spatial variability of the Arctic is essential to assess environmental risks from any potential spilled oil. Beyond that, as discussed previously in Chapter 4. Climate Change Considerations, environmental conditions in the Arctic that affect countermeasure effectiveness are changing. And they are changing in complex ways not yet understood.

5.10. Finding: While efforts are ongoing to develop countermeasures to address the potential of an oil spill in Arctic and ice-covered waters, it remains unclear when and where any one of these countermeasures, or countermeasures in combination, will be available under current and future weather, sea state, ice, and light conditions of the Arctic—or whether they will work even if available.

5.10. Recommendation: Spill planning and response would benefit from a collaboratively derived Response Gap analysis of countermeasures, a rigorous analysis of the likelihood of the availability of a multi-countermeasure suite in different Arctic locations and seasons, and the forecasting of climate change influences on the Response Gap. While industry is responsible for stockpiling response equipment, continuation of the Federal and Joint Industry Program approach could inform efforts to develop suites of new technologies and approaches to improve effective response in the Arctic. An independent analysis of the Response Gap could help better articulate what overall risks exist from potential failures in spill response.

Mechanical Containment and Recovery

A number of recent advances have been made in mechanical containment and recovery devices as oil-spill mitigation countermeasures (Brandvik and others, 2006; Minerals Management Service, 2008b). However, the effectiveness of mechanical countermeasures, particularly in ice-infested waters, poses an ongoing challenge (World Wildlife Fund, 2009). In a recent review of technologies to improve oil-spill response effectiveness in the Arctic, Nuka Research and Planning Group, LCC (2007a) documented a number of promising mechanical recovery technologies that could be utilized in open water, but some of these lacked sufficient field testing in ice conditions to evaluate their effectiveness. Mechanical containment and recovery countermeasures, such as booming, sorbents, and skimmers, are affected by the presence of sea ice. Their recovery rate of spilled oil diminishes rapidly with increasing amounts of sea ice. For example, ice can induce tears in booming, or can clog skimmer systems and prevent them from encountering spilled oil. One additional challenge with mechanical recovery systems is the need for a platform from which to operate or deploy, requiring the availability of ice-class vessels, tugs, or barges to support response activities (World Wildlife Fund, 2009). With sea ice coverage greater than about 60 percent, the ice itself can potentially serve as a natural containment barrier (Dickins and Buist, 1999). There also is a need for mechanical recovery systems capable of removing oil that is under the ice (Brandvik and others, 2006).

There are a number of types of booms available depending on whether the purpose of the booming is to contain the spill for recovery purposes (containment or diversion booming) or to protect sensitive areas from the spilled oil (exclusion or deflection booming) (DeCola and others, 2006). Recent advances in technology have been made to extend the capability of ice booms, adapting technology that had been in use for several decades to protect water intakes upstream of hydroelectric power plants into a countermeasure for oil-spill response. Ice booms also have the capability to assist other mechanical recovery systems by providing an ice-free environment, and in separating oil from ice

Table 5–4. One example of physical and timing limitations on oil-spill response tools for the U.S. Arctic.

[From Nuka Research and Planning Group, LCC and Pearson Consulting, LCC (2010, tables 6–1, 6–2). Color code: Green, conditions generally considered to be favorable; yellow, conditions may impede response operations; red, response would not be possible. **Visibility:** Moderate, light fog or less than 1 mile visibility; Low, heavy fog, less than one-quarter mile visibility, or darkness. n/a, not applicable; mph, miles per hour; ft, feet]

(Abdelnour and Comfort, 2001; Abdelnour and others, 2001). Fire-resistant booms also have been developed for *in-situ* burning, as a means of containing and concentrating the oil into a layer atop the water surface that is sufficiently thick to sustain ignition and burning (Tebeau, 2003; Potter and Buist, 2008). There are a couple notable partnerships that culminated in the development of mechanical oil recovery systems for deployment in ice-infested waters—the Mechanical Oil Recovery in Ice-Infested Waters (MORICE) project (Jensen and Mullin, 2003) and the Lamor Oil Ice Separator (LOIS) (Minerals Management Service, 2008b). The concept for MORICE emerged from a review of the status of mechanical recovery devices and culminated in the development of a full-scale system that was tested at the National Oil Spill Response Research and Renewable Energy Test Facility in 2002, under a variety of ice conditions and under relatively mild weather conditions (Jensen and Mullin, 2003). The LOIS is a commercially available mechanical recovery system consisting of an oscillating ice grid that washes oil from ice chunks as they move along a grid; the oil is subsequently concentrated for recovery by a skimmer (Minerals Management Service, 2008b).

Skimming systems are designed to recover oil from the water surface. Recent overviews of the state-of-the-art of these technologies are given in Brandvik and others (2006), Nuka Research and Planning Group, LLC (2007a), Hänninen and Sassi (2010), S.L. Ross Environmental Research, Ltd., and others (2010), and Fingas (2011a). There have been recent efforts to develop standardized testing protocols for determining the recovery capacity of skimmer systems (Schmidt and others, 2009). Oleophilic skimmers are the most common type of mechanical oil-spill response equipment (Broje and Keller, 2006). Efforts to develop better skimmer systems for cold and ice conditions (Broje and Keller, 2006; Keller and Clark, 2008) have found they still have limited oil encounter and recovery rates. Thus, S.L. Ross Environmental Research, Ltd., and others (2010) recommended that deployment of skimmers in the Beaufort Sea may be best suited for responding to oil spills covering a small area and with relatively small ice pieces, given the current limitations of the oil encounter and recovery rates.

The National Research Council review (2003) cited results from a Robertson and DeCola (2001) study involving a field trial using a barge-based recovery system in a simulated spill response on the North Slope under varying seasonal ice conditions. The authors found that realistic maximum operation limits for mechanical recovery of a simulated spill ranged from about 0 to 1 percent in fall ice conditions; about 10 percent in spring ice conditions without ice management; and about 30 percent in spring ice conditions with extensive ice management. The National Research Council (2003) noted that given these estimates, reliance only on mechanical recovery systems to respond to an oil spill offshore of the Alaska North Slope is "unlikely to be successful." They called into question the viability of mechanical recovery technologies to clean up spills, particularly large oil spills, in broken ice, citing statements by the Alaska Department of Environmental Conservation that the mechanical recovery technologies available then were not likely to be successful in the Beaufort and Chukchi Seas. The NRC also noted that the results of research on the effectiveness and environmental liabilities and advantages of alternative countermeasures, such as dispersants and *in-situ* burning, especially in broken-ice conditions, would be useful in facilitating needed contingency planning. The potential scale of the response needed to an offshore oil spill in ice-infested waters is a major challenge to the mechanical recovery systems, as many of these technologies appear best suited for batch recovery of spilled oil in pits or ice leads (Nuka Research and Planning Group, LLC, 2007a). In a recent review commissioned by the Canadian Environmental Studies Research Funds, S.L. Ross Environmental Research, Ltd., and others (2010) noted that

> "[t]here has been little research done with regard to the problem of removing oil from larger ice floes with diameters ranging from 10s to 1,000s of meters that typify breakup and pack ice conditions during winter in the Beaufort Sea."

5.11. Finding: There are a number of recent technological advances in mechanical containment and recovery devices as oil-spill mitigation countermeasures. The effectiveness of mechanical countermeasures, particularly in ice-infested waters, poses an ongoing challenge. Scaling up test results from laboratory- and mesoscale testing into practical field recovery rates is a recognized information need. Further, an understanding of the types and (or) amounts of platforms needed to deploy these devices is needed. This lack of information currently is a limiting factor in translating the technological advances from these devices into an operational context, particularly at the scale at which these devices might be deployed in response to a large spill event in the presence of sea ice.

5.11. Recommendation: An evaluation of the presence or lack of standardized testing approaches (especially wave tanks), the cross-comparability of results, and collaborative development of protocols would be beneficial. This information would inform the practical recovery limits that can be achieved during response operations, and refine our understanding of the appropriate setting and scale at which these devices could be effectively deployed. Finally, there remains a need to further develop mechanical recovery systems to recover oil accumulated under ice.

In a recent review of countermeasure technologies for spill response in Beaufort Sea spring breakup or fall-freeze-up seasons, Solsberg (2008) reported that there have been advances made in mechanical recovery systems. However, many of these may face severe limitations during deployment due to ice-processing challenges, extreme weather (freezing) conditions, and changing conditions in the ice itself. Nuka Research and Planning Group, LLC (2007b) points out that the range of ice conditions that may be encountered in the Beaufort Sea is an important factor when determining what types of technologies are "appropriate and reliable" for oil-spill response and recovery. For example,

> "[a]vailable estimates from mechanical response in broken ice vary from 1 to 20 percent depending on the degree of ice coverage and if responding during freeze-up or spring break-up. This compares with estimates of 5 to 30 percent for open ocean response without broken ice. Recent barge trials on the Beaufort Sea demonstrated that even trace amounts of ice (less than 1/10 ice coverage) can cause significantly reduced efficiencies in mechanical recovery" (Minerals Management Service, 2008b).

One of the challenges to oil recovery in ice-infested waters is the availability of ice coverage information on the time scales (shorter) and conditions (dynamic) of a spill response operation. Solsberg (2008) noted that

> "[a] common way of presenting the potential use of countermeasures in Arctic conditions is a chart or table that assigns the standard approaches of mechanical operations, *in-situ* burning and dispersant application to a specific range of ice cover. The problem with this approach, however, is that conditions in Beaufort Sea ice are so dynamic during the transition seasons that any response would likely prove to be limited to a small (time) window of opportunity—leave alone the obvious safety concerns."

For any countermeasure, and mechanical recovery systems in particular, it is important to have a better understanding of ice drift and oil movement so as to inform response operations and deployment of appropriate countermeasures (Solsberg, 2008). The ability to predict ice movements to inform the use of mechanical recovery systems dovetails with other information needs for an improved understanding of the Arctic Ocean and sea ice. Uniting monitoring and process studies and facilitating modeling at different scales will lead to better understanding of sea ice response to various forcing factors (U.S. Arctic Research Commission, 2010).

5.12. Finding: One of the challenges to mechanical oil recovery in ice-infested waters is the availability of ice coverage information, on the short time scales and in the dynamic conditions of a spill response operation.

5.12. Recommendation: There is a need to develop a system with the ability to make short-term ice dynamics forecasts to inform windows for mechanical recovery operations and to improve recovery technologies in the "ice gap" (about 30 to 70 percent ice coverage). From an operational perspective, there also is a need for information to inform response planning in the event of shifting ice coverage.

In-Situ Burning

In-situ burning (ISB) has been studied for several decades as a response tool for oil spills in ice. Some of the earliest activities were laboratory, tank, and field studies conducted in the 1970s associated with drilling in the Canadian Beaufort Sea (Potter and Buist, 2008). Later oil exploration efforts in Svalbard (1980–94) also considered ISB as a primary countermeasure for use in Arctic oil spills (Brandvik and others, 2006).

One of the key challenges to the effectiveness of ISB is maintaining sufficient thickness of oil to sustain a burn. The minimum ignitable thickness of a fresh crude oil slick on water is about 1 mm, whereas for aged, unemulsified crude oil the minimum thickness is on the order of 2–5 mm (Potter and Buist, 2008). Emulsification is an important process affecting the effectiveness or the response window of opportunity for use of ISB, because the oil in the emulsion is not able to reach a temperature to burn until the water is first boiled off (Potter and Buist, 2008). Emissions from ISB include the release to the atmosphere as well as burn residue. The residue from an ISB may float on water or sink, depending on the oil type and the extent of the burn.

There is a large body of scientific work based on laboratory, mesoscale, and to some extent field trials that demonstrate ISB to be effective in removing oil from the water surface under Arctic conditions, but it remains to be determined whether these results translate into real-world conditions. The effectiveness of ISB can be affected by weather and sea-state conditions, but ice is a particular challenge. At ice coverage exceeding 70 percent, ISB can be conducted without any mechanical containment systems, as the ice provides a natural barrier to restrict the movement of oil across the water surface. At ice concentrations less than

30 percent, open-water ISB may be feasible (Brandvik and others, 2006; Potter and Buist, 2008), including the use of oil containment with a fire-resistant boom. Ice concentrations of 30–70 percent are considered to be the "most difficult from an *in-situ* burning perspective" (Juurmaa, 2006). The particular challenge for ISB in ice concentrations in this range is that these ice concentrations are high enough to impede the effectiveness of mechanical containment systems, yet too low to serve as a natural containment barrier for the oil (Brandvik and others, 2006; Potter and Buist, 2008).

In addition to the abundance of sea ice, the type of sea ice present can impact the effectiveness of ISB. S.L. Ross Environmental Research, Ltd., and others (1998) reported that for freeze-up scenarios at low and medium ice concentration, ISB offered little advantage over containment and recovery techniques. However, there was potential to contain and burn oil in their 70-percent ice scenario as suggested above. For break-up scenarios, burning on water provided effectiveness similar to containment and recovery. And, burning oil on floes or concentrated in melt pools was as effective as on-water burning or containment and recovery approaches. Conducting ISB in pack ice during break-up may be more effective at removing spilled oil than when there is a similar amount of ice coverage during the fall freeze-up, because the fall freeze-up generates significant amounts of slush ice that can impede containment of slicks (Potter and Buist, 2008). In a recent review of countermeasures in the Beaufort Sea, Solsberg (2008) noted that

> "...the relative behaviour of spilled oil and ice require further investigation to determine how feasible it is, in fact, to burn oil during the transition seasons .... While small and meso-scale testing is needed, field work is the ultimate means of measuring the feasibility of burning."

Brandvik and others (2010a) report ISB efficiencies ranging from 50 to 90 percent from a field test (during about 70–90 percent ice coverage) and mesoscale laboratory experiments in a wave tank under varying ice coverage conditions (at 0, 50, and 90 percent). In field and the mesoscale trials at 90-percent ice coverage, ISB had a longer window of opportunity (about 120 and about 140 hours, respectively). Mesoscale experiments at 0-percent ice coverage had less than a 5-hour window of opportunity and slightly better at 50-percent ice coverage (about 10 hours). The authors concluded that the favorable comparisons among results from the field test and mesoscale basin experiments at high percentage ice coverage were an indication that the mesoscale trials could be considered to reflect realistic conditions (Brandvik and others, 2010a). In the course of the field experiment, the authors noted that strong winds caused the dense ice field being tested to move at a rate of approximately 40 km/d (Brandvik and others, 2010b), underscoring the need for information on weather and coupled ice-transport conditions to inform potential oil-spill responses operations.

As we discussed in section, "Spilled-Oil Weathering and Persistence," in the event spilled oil becomes entrained in ice, the rate of oil weathering may be slowed to the extent that the response window for using ISB is expanded. For example, oil in brine channels could potentially be released during spring ice melt in melt pools. Oil that is released from ice during the melting and collects in pools atop the pack ice may be treatable by ISB (Brandvik and others, 2010a). However, this approach could provide an additional exposure route to wildlife given that melt pools can form thaw holes, which in turn may serve as breathing holes for wildlife and provide an important ecosystem for other marine life (World Wildlife Fund, 2009). Features such as leads, polynyas, and ice edges tend to be focal points of biological activity, as well as targets for pooled spilled oil (World Wildlife Fund, 2009).

5.13. Finding: There is a large body of scientific work demonstrating that *in-situ* burning (ISB) of oil is effective in removing spilled oil from the water surface under certain experimentally controlled Arctic conditions. However, there are insufficient data to assess the effectiveness of ISB under the full suite of real-world conditions that might be experienced during a response to an oil spill.

5.13. Recommendation: Many of the mesoscale and field tests show a considerable range in the *in-situ* burning (ISB) effectiveness. However, because ISB is one of the few response options that exist for the Arctic, it is important to conduct additional research to improve its effectiveness. Thus, further focused study is essential to better define the applicability of ISB under various conditions.

There are a number of studies on the emissions from ISB, including air emissions (soot and gases) and ISB residues, which could float to the water surface or sink to the ocean floor. Recent syntheses of the state-of-knowledge on atmospheric emissions from ISB are given in Potter and Buist (2008), S.L. Ross Environmental Research, Ltd., and others (2010), and Fingas (2011b). Recent studies of atmospheric emissions from ISB point to the need for an expanded characterization of the composition of air emissions. For example, Aurell and Gullett (2010) studied atmospheric ISB emissions in the GOM during the *Deepwater Horizon* oil-spill response and found examples of halogenated organic compounds (toxic environmental pollutants) above background levels. These results contrast with previous conclusions drawn from limited mesoscale laboratory studies of ISB. These compounds have potential health effects, such as immunotoxicity, carcinogenicity, and teratogenicity. S.L. Ross Environmental Research, Ltd., and others (2010) provide an overview of the environmental issues with ISB and the evolution of ISB procedures confirming that most research has focused on characterizing the atmospheric emissions from ISB with fewer studies characterizing and testing for potential toxicity arising from ISB residues. Nuka Research and Planning Group, LCC and Pearson Consulting, LCC (2010) point out that earlier studies have shown that there is greater potential for ISB to form residues in the presence of sea ice than when ISB is conducted in open water—citing Fingas (2004) and Buist and others (2003). Previous studies have acknowledged that ISB residues may contain toxic materials, and should be removed from the marine environment where possible (Nuka Research and Planning Group, LCC and Pearson Consulting, LCC, 2010). Nuka Research and Planning Group, LCC, and Pearson Consulting, LCC (2010) cite previous studies, such as the American Petroleum Institute (2004) that investigated the proclivity for ISB residues to sink and identified the need for technologies to recover sunken ISB residues. Potter and Buist (2008) stated that residues from efficient burns of crude oil generally are environmentally inert, but that potential environmental effects are derived from physical properties, including whether residues float or sink, and what chemical constituents are retained. In that regard, the potential for residues that will sink can be predicted based on the properties of the initial oil to some extent.

Several field and mesoscale efforts are informative on the topic of concentrations of toxics (for example, polycyclic aromatic hydrocarbons or PAHs) resulting from ISB. One foundational study is the Newfoundland Offshore Burn Experiment (NOBE; Fingas and others, 1995). In addition to extensive characterization of the atmospheric emissions, including soot and gases, from the NOBE, Fingas and others (1995) also analyzed the residue from the experiment. They reported that the residues resembled highly weathered oil with lower amounts of PAHs than the starting oil. However, Brenner and others (1990) found that PAH concentrations in ISB residues and Alberta sweet crude oil samples were comparable and that there was a lower total amount of PAHs emitted via smoke at thinner slick layers (2-mm versus 10-mm layer). In a synthesis of data from 45 mesoscale burns, Fingas and others (2001) found that PAHs in the soot and residue were about 2–8 percent of that in the starting oil. Wang and others (1999) conducted detailed chemical analyses on ISB residues from several mesoscale burns in Mobile Bay, AL. They concluded that high-molecular weight PAHs were derived largely from the combustion process itself. Garrett and others (2000) also support this finding. Therefore, there is a need for thorough chemical analysis in conjunction with measurement of ISB effectiveness under mesoscale and larger test conditions. The potential for less effective burns resulting from ice and weather conditions may yield higher amounts of high-molecular weight PAHs. This is consistent with Buist and others (1999) who found that the chemical composition of residue depends on the parent oil, the degree of weathering, and the efficiency of the burn. Levels of PAHs in residue could be as much as 40 percent more than in the parent, but considering the volume reduction accomplished by burning, the total amount of PAHs could be a fraction of what was in the slick before ignition.

There has been limited research on the toxicological effects of burnt oil relative to other oil-spill remediation techniques and some results appear contradictory (Cohen and Nugegoda, 2000). DeCola and others (2006) echoed this idea and stated that few published data exist on sublethal effects of burn residues, and no information on impacts of burn residues to benthic-feeding whales. Some insights on the comparative toxicity of ISB residues can be gleaned from Cohen and Nugegoda (2000). They tested the water accommodated fraction (WAF) from crude oil, chemically dispersed crude, and burnt crude oil. They found that of the three elements, dispersed crude oil WAF was the most toxic and burnt crude oil WAF was the least toxic to their marine fish test species. But, they also noted that sublethal toxicities of crude oil WAF and burnt crude oil WAF were observed at dilutions seven to eight times less than in the dispersed crude oil WAF. These results leave the relative toxicity ISB residue on marine organisms unclear.

Despite the relatively few studies characterizing ISB residues and potential toxicological or other effects, there appears to be a general operational consensus that

ISB residues should be collected and removed from the environment (for example, Buist and others 1999). This concept is included in the ARRT's *In-Situ* Burning Guidelines for Alaska, Revision 1 (Alaska Department of Environmental Conservation and others, 2008), which states that

> "[t]he toxicological properties and effects of the residue demonstrate the need and importance of a residue recovery plan which is an operational requirement."

They further note that the longer term effects of ISB residues on marine organisms have not been investigated.

Recently, in the *Deepwater Horizon* oil-spill response, the National Marine Fisheries Service and others (2010) issued a temporary emergency rule closing a specific portion of the GOM to red shrimp fishing due to the presence of ISB residues. Such actions underscore the continuing need for additional information on the composition, characteristics, bioavailability/bioaccessibility of ISB residues, as well as emissions from ISB, to inform response decisions and natural resource damage assessments and restoration activities.

5.14. Finding: There are relatively few studies characterizing emissions and residues from *in-situ* burning (ISB), including their potential toxicology. However, the studies that do exist suggest there is a potential for health effects from compounds released from ISB. Robust characterization of likely ISB air plumes and toxicological testing, especially on potential effects to benthic organisms, of ISB residue are lacking.

5.14. Recommendation: Our review underscores the importance of three points:

1. There is a need for thorough chemical analysis and measurement of *in-situ* burning (ISB) effectiveness under mesoscale and larger test conditions.
2. Better characterization of ISB residues is needed, especially toxicity, physical properties, and bioavailability of contaminants contained within the residue matrix; this is especially true in relation to potential effects to benthic communities.
3. Improving pre- and post-spill plume modeling would help inform whether or not an ISB should be conducted and would facilitate On-Scene Coordinator decisions on measures to protect local populations. The potential effect of "fall out" from a smoke plume that goes over land-based (plant) subsistence resources is of particular concern.

Dispersants

Dispersants are chemical mixtures consisting of three main items: surfactants, solvents, and additives. The surfactant molecules contain components that tend to bond with water (hydrophilic) and others that tend to bond with oil (oleophilic). Thus, the aim of dispersants as a spill mitigation countermeasure is not to reduce the volume of spilled oil in the environment—in contrast with other countermeasures such as mechanical recovery and ISB—but rather to facilitate the mixing and dispersion of spilled oil within the water column by promoting the formation of tiny oil droplets and preventing the recoalescence of those droplets into larger accumulations, such as slicks. The National Research Council recently (2005) conducted an extensive review of the effectiveness and impacts from the application of dispersants to oil spills, which we will summarize briefly here. Based on our expert consultations, the findings in the NRC report remain valid and applicable to the issue of data gaps for the Arctic. They noted that the

> "...objective of dispersant use is to enhance the amount of oil that physically mixes into the water column, reducing the potential that a surface slick will contaminate shoreline habitats... [but] increase[s] the potential exposure of water-column and benthic biota to spilled oil. Dispersant application thus represents a conscious decision to increase the hydrocarbon load... on one component of the ecosystem...reducing the load on another... This trade-off reflects the complex interplay of many variables, including the type of oil spilled, the volume of the spill, sea state and weather, water depth, degree of turbulence (thus mixing and dilution of the oil), and relative abundance and life stages of resident organisms" (National Research Council, 2005).

Some of the key questions regarding dispersant applications, and recommendations for research priorities most applicable to our assignment from National Research Council (2005) are:

- Is the spilled oil or refined product known to be dispersible?

  Example: The need for research into the mechanisms and rates of weathering processes—including parameters such as the rheology of chemistry of both oil and dispersants and energy dissipation—affecting the chemical effectiveness of dispersants, including both bench-scale and well-coordinated wave-tank studies.

- Are the environmental conditions conducive to the successful application of dispersants and their effectiveness?

  Example: The need for research in support of modeling and forecasting of the effectiveness of a dispersant application, including the need for data from wave-tank studies and the updating of protocols for Specialized Monitoring of Advanced Response Technologies.

- Will the effective use of dispersants reduce the impacts of the spill to shoreline and water surface resources without significantly increasing impacts to water-column and benthic resources?

  Example: The need for research into improving oil trajectory and fate models for both planning and real-time decision-making needs, with appropriately designed experiments to verify and validate these models. Such experiments could include research into quantifying weathering rates and fate of chemically dispersed oil droplets relative to undispersed oil.

Subsequent research activities have targeted these knowledge gaps, some of which are highlighted in the Biennial Report of the Interagency Coordinating Committee on Oil Pollution Research (2009) and the synthesis of the Arctic Oil Spill Response Research and Development Program (Minerals Management Service, 2008b). Fingas (2008a) also conducted a review of scientific literature related to oil-spill dispersants, spanning the years 1997–2008 and noted that a Canadian Research Council workshop on dispersant research priorities established priorities similar to those of the NRC.

5.15. Finding: Although significant research and technological studies have examined chemical dispersants over the past decade, including focus on cold-water and Arctic applications, the scientific understanding is yet incomplete.

5.15. Recommendation: Our examination suggests that substantial scientific and technical work as outlined by various expert groups still must be done before dispersants can be considered a practical response tool for the Arctic.

There has been recent work to develop new formulations of dispersants (Nedwed and others, 2008) that can be applied to an oil slick as a gel, and thus potentially be more effective on oils with higher viscosities. Such advances may hold promise for extending the response window for dispersant application by facilitating use on higher viscosity oil slicks stemming from either weathering oil or due to the cold temperatures.

Li and others (2008) note that two of the most important factors in the effectiveness of a chemical dispersant are the energy dissipation rate which affects the penetration of oil into the bulk aqueous phase and the particle size distribution of the dispersed oil. Waves can provide a significant source of mixing energy to the dispersion process. Thus the effectiveness of dispersants is derived from a physical-chemical process that includes the chemical properties of the oil and dispersant, and the physical action of the waves (National Research Council, 2005; Li and others, 2008). Vörösmarty and others (2010) note that sea-ice cover is especially important to address in studies of Arctic Ocean circulation given the unique momentum and buoyancy forcing that arise from overlying sea-ice cover. Furthermore, dispersants can be effective in broken ice provided there is some mixing energy available, and wave reflection among broken and brash ice may serve as highly localized sources of mixing energy (Minerals Management Service, 2008b). Given this potential source of mixing energy, there also is a need to characterize specific energy distributions on a more localized scale, that is, at the point of dispersant application, such as energy added from the ship's propellers or via high-pressure water systems to enhance mixing (Sørstrøm and others, 2010). A recent study by Nedwed and others (2007) tested the potential for an azimuthal stern drive (ASD) from an icebreaker as a means to provide the mixing energy necessary to disperse chemically treated oil slicks in broken ice. The authors found that this approach holds promise for mixing and dispersion of oil spilled on top of and under continuous ice and within leads, and could significantly supplement the dispersion that would take place with wave energy alone.

The issue of energy dissipation may help to describe some of the disparity observed across studies. For example, Belore and others (2009) in a study of dispersant application at the National Oil Spill Response Research and Renewable Energy Test Facility achieved dispersant effectiveness results that generally were higher than results from similar testing at a different facility, and the authors postulate this difference could have been due to higher wave energies achieved during their tank studies. Likewise, Venosa and others (2008) in a series of wave tank experiments found that the energy of the system had a strong influence on the ability to transfer oil from the surface into the water column even with the aid of dispersants. Further, Venosa and others (2008) noted a difference in the effectiveness of the two dispersants they tested and postulated that some dispersants may be more suitable for low- to moderate-energy settings, whereas others may be better suited for application in moderate to higher energy conditions.

As discussed previously, the weathering of oil entrained in sea ice may be inhibited. When it is subsequently released as the ice melts, the timeframe may be significantly extended for dispersant use as a countermeasure (Dickins and others, 2008; Brandvik and others, 2010a). This process would significantly alter the paradigm under which the "response window" for application of dispersants to spilled oil is viewed (Lewis and Daling, 2007). Further characterization of the effectiveness of dispersants under these conditions is needed to inform the "response window." This underscores the recommendation raised in National Research Council (2005) that

> "[r]elevant state and federal agencies and industry should develop and implement a focused series of studies that will enable the technical support staff advising decisionmakers to better predict the effectiveness of dispersant application for different oil types and environmental conditions over time."

Brandvik and others (2006) report that dispersants can be a suitable mitigation countermeasure in Arctic waters, both open water and up to 50-percent ice covered. In a recent review of dispersant effectiveness under Arctic conditions, Lewis and Daling (2007) identify that factors such as salinity of sea ice and colder temperatures affect the viscosity of spilled oil and may reduce the effectiveness of dispersant applications. These conditions also inhibit oil weathering factors, such as the formation of emulsions (Fingas, 2008b). Thus, the window of opportunity during which dispersants may be effective may be extended. Laboratory studies by Moles and others (2002) found that at the conditions typical of Alaskan estuaries and marine waters, dispersant effectiveness was at study detection limits (less than 10 percent). Some dispersants are more sensitive to salinity and temperature, and measured effectiveness can vary by roughly a factor of 10 or more (Lewis and Daling, 2007). However, recent results from tests conducted at the National Oil Spill Response Research and Renewable Energy Test Facility using four Alaskan North Slope crude oils and two dispersants found that the dispersants were more than 90 percent effective at dispersing fresh and weathered forms of the oils under cold weather conditions (Mullin and others, 2008; Belore and others, 2009).

5.16. Finding: How environmental conditions might actually affect dispersant effectiveness during oil-spill response is not yet well understood. As noted in our review, it has not yet been established whether wave-tank experimental conditions are typical or representative of wave conditions that could be encountered at sea with ice present. Factors, such as salinity and temperature, also can vary dispersant effectiveness by a factor of 10 or more.

5.16. Recommendation: We concur with the National Research Council (2005) recommendation that a focused series of studies should be developed and implemented that will enable practitioners to better predict the effectiveness of dispersant use for different oil and environmental conditions. For example, further study of oceanographic characteristics such as salinity, temperature, and circulation and wave patterns, and the influence of sea ice cover on these, in the Arctic Ocean would facilitate our understanding of the magnitude of the effectiveness of dispersants as a countermeasure against an oil spill in the Beaufort and Chukchi Seas. This information, aided by increased monitoring and prediction of winds, currents, temperature, and salinity, would be particularly useful in understanding the regional aspects of dispersant applications.

In addition to understanding the window of opportunity during which dispersants can be successfully used, there is a need to improve our understanding of the long-term viability of the dispersed oil. Fingas (2008a) reported that many researchers recognize that oil-spill dispersants are not stable and will destabilize and rise to the surface: half-lives of dispersions may be between 4 and 24 hours. However, in a recent study (Nedwed and others, 2007) using an ASD icebreaker to enhance mixing energy in a Canadian basin test, the researchers postulated that the dispersed oil would be "... unlikely to resurface even in very low energy conditions" based on their study results.

There is uncertainty regarding the effects of dispersants on marine organisms in the Arctic (World Wildlife Fund, 2009). One of the uncertainties is the potential effect of dispersants on the natural processes of microbial degradation of oil and how this may affect the toxicity of the residual oil. One of the key compound classes within crude oil, in terms of toxicity and other long-term deleterious effects on ecosystems, are PAHs, yet there are few studies to date that quantify the fate and potential for biodegradation of these compounds (National Research Council, 2005). Recent reviews (National Research Council, 2005; Fingas, 2008a) indicate that a scientific consensus regarding the effect of dispersants on toxicity of dispersed oil and effects on biodegradation of oil is lacking. The National Research Council (2005) concluded that there was no compelling evidence that the toxicity of chemically dispersed oil is enhanced relative to that of physically dispersed oil or that there were any reproducible effects of chemical dispersion on the rate of biodegradation of crude oil. However, Fingas (2008a) reported that

> "[i]t is clear, on the basis of current literature that the surfactants in some of the current dispersant formulations can inhibit biodegradation."

Lindstrom and Braddock (2002) reported that "the effect of dispersant on biodegradation of a specific hydrocarbon was not predictable by class [of hydrocarbon]" and either an increase or a decrease in the toxicity of the residual oil could result. Adding to this discussion, Zahed and others, 2010) found that the dispersant Corexit 9500 appeared to enhance biodegradation of crude oil, including at higher initial concentrations of crude oil, based on laboratory-scale bioremediation trials.

In contrast, there are a number of earlier studies indicating that chemically dispersed oil is more toxic to marine organisms than untreated oil (Pew Environment Group, 2010). The National Research Council (2005) found that

> "[i]n order to better understand the fate and effects of dispersed oil, studies should be conducted to estimate the relative contribution to toxicity of dissolved-, colloidal-, and particulate phase oil in representative species."

Fingas (2008a) states that

> "[l]ong-term effects of chemically-dispersed oil are poorly-studied and relatively unknown at this point in time. Again little has changed from the first review in 2002, but it is very clear now that the toxicity of dispersed oil is greater than that of physically dispersed oil, primarily because of the large increase (5 to 50 times) in the amount of aromatics and PAHs in the water column."

Subsea dispersants were used for the first time during the *Deepwater Horizon* oil spill and in larger quantities, both surface and subsurface, than during any previous spill (Pew Environment Group, 2010). Given this large-scale application of dispersants, there is a critical need to understand the potential toxicity of dispersants and other effects on marine organisms (Judson and others, 2010). Samples collected following the application of dispersants to the *Deepwater Horizon* oil spill have documented the presence of one of the dispersant surfactants in deepwater hydrocarbon plumes at 1,000–1,200 m water depth (Kujawinski and others, 2011). The researchers concluded that the surfactant itself underwent no biodegradation. Researchers also noted that they could not yet determine if the dispersant application successfully reduced the size of the oil droplets or facilitated the entrainment of these droplets within the deepwater plume (Kujawinski and others, 2011). Finally, because of the emphasis now placed on subsea dispersant use by the National Response Team, it will be important to address research needs regarding such use. However, the USGS OCS Team had insufficient time to consider this new emerging issue. We note here that further consideration of the potential applicability of the technique to Arctic scenarios and any unique Arctic consequences of such use should be assessed.

5.17. Finding: The interplay of factors such as weather and sea ice on the "window of opportunity" for use of dispersants and how sea-ice conditions may affect the stability of dispersed oil is yet not well understood. The understanding of the potential toxicological effects of dispersants on Arctic ecosystems is lacking.

5.17. Recommendation: Surface dispersants are used in response to oil spills internationally, but improving the understanding of the "window of opportunity" for potential deployment of all dispersants in the Arctic is needed. A more extensive understanding of the toxic and sublethal effects and ramifications for microbial communities (and the natural biodegradation of oil) also is needed.

Chemical Herders

Chemical herders—also referred to as oil collecting agents—are chemicals applied to the water surrounding an oil spill in order to thicken the spill, without the need for mechanical containment, to a point that it can sustain a burn (Buist and others, 2008a; Minerals Management Service, 2008b). Chemical herders constitute an oil-spill countermeasure that can be used in conjunction with ISB (Sørstrøm and others, 2010). This is because one of the critically limiting factors with ISB is the need to have a slick that is sufficiently thick to sustain a burn. Recent studies are also investigating the potential for application of chemical herders to enhance mechanical recovery of oil when used in conjunction with deployment of skimmers, and the potential for herding agents to contract the slick area, and thus improve the efficacy of dispersant applications (S.L. Ross Environmental Research, Ltd., 2010).

Chemical herders have been available for several decades (Buist and others, 2008b), but not used extensively offshore to date because they are effective under largely calm conditions (S.L. Ross Environmental Research, Ltd., 2010). There are currently no commercially available chemical herders approved for use in Arctic waters (World Wildlife Fund, 2009).

Reviews on the state-of-the-art of oil-spill countermeasures, as by D.F. Dickins Associates, Ltd. (2004), have identified chemical herder behavior in ice environments as a knowledge gap. Subsequent research activities (Interagency Coordinating Committee on Oil Pollution Research, 2009; Minerals Management Service, 2008b; and Buist and others, 2008a) have sought to address this gap. Recent studies have focused on the potential utility of herders in responding to oil spills in cold waters, and particularly in ice-covered waters. For example, Minerals Management Service (2008b) suggested that

> "[i]n loose broken ice.... conditions, even with no possibility of booming, if these slicks could be thickened to the 2- to 5-mm range, effective burns could be conducted."

In this context, herding agents may be helpful in the "ice response gap" window of 30- to 70-percent coverage (World Wildlife Fund, 2009).

These recent studies (as with ISB and dispersants) involved public-private sector collaborations, such as BOEMRE and ExxonMobil (Minerals Management Service, 2008b), and the JIP on oil-spill contingency for Arctic and ice-covered waters. International cooperation, at a variety of scales, also has facilitated research from laboratory testing to mid-scale testing at the U.S. Army Cold Regions Research and Engineering Laboratory, the National Oil Spill Response Research and Renewable Energy Test Facility, and the Fire Training Grounds in Prudhoe Bay, Alaska. Recently, two full-scale burn experiments involving the use of chemical herders were conducted in the offshore of Svalbard, Norway (Minerals Management Service, 2008b; Pew Environment Group, 2010). One large-scale experiment with chemical herders was carried out on a free-floating crude oil slick in low (10 percent) ice coverage as part of the JIP Oil-in-Ice effort in 2008 (Sørstrøm and others, 2010). One of the formulations used in recent studies of chemical herders in cold-water conditions is the U.S. Navy cold-water herder formulation (Buist and others, 2008b; Buist, 2010). This herding agent was successful in producing slicks in excess of 3 mm and in significantly contracting oil slicks in the presence of ice (Buist, 2010). One of the recommendations from this work is to conduct a large-scale field trial to test the effectiveness of chemical herding (as a precursor to ISB) in pack ice, and to investigate the influence of wind and sea conditions on this potential spill mitigation countermeasure. One of the key objectives would be to determine how long a herded slick can maintain its thickness with regular re-application of the surfactant under a realistic scale (Buist, 2010). New formulations of chemical herders are under development and testing (Buist and others, 2010).

While an important measure in support of ISB, the application of chemical herders may affect other recovery and mitigation countermeasures. S.L. Ross Environmental Research, Ltd. (2010) notes that

> "...the active ingredient in herding agents (the surfactant) renders sorbent pads less hydrophobic and their water retention increases considerably. This could be a significant detriment to oleophilic skimmers such as drums, discs and rope mops whose recovery surfaces contact herding agent (SIC). This should not be an issue with other skimmers types such as weirs and vacuums."

The question of potential toxicity of chemical herding agents to marine species is noted in the literature (Buist and others, 2008a; World Wildlife Fund, 2009). Although direct toxicity data appear to be lacking, it has been postulated that the risk posed to the marine environment may be modest (Buist and others, 2008b). Buist and others (2008a) note that toxicity data on the U.S. National Contingency Plan (NCP) website indicate that one herder, for example, is only about one-half as toxic as approved chemical dispersants. Toxicity information, from Material Safety Data Sheets, for the components of the U.S. Navy chemical herder is given in Buist (2010). However, information on toxicity that is currently required in Subpart J of the NCP does not necessarily relate to species of concern to Alaska. Research on the potential toxicity of chemical herders to Arctic and subsistence marine organisms would help determine if short- and (or) long-term effects might occur.

5.18. Finding: Although chemical herders are important to improved effectiveness of *in-situ* burn countermeasures, they affect oil recovery efficiencies from various mechanical recovery systems. The resulting trade-offs in countermeasure efficiencies are not fully understood under Arctic field conditions. The toxicity of chemical herders to organisms may not be significant, but this belief has not been validated for Arctic species of concern.

5.18. Recommendation: A better understanding of the comparative value and impact of chemical herders may be warranted to inform oil-spill response scenarios and the timing for deployment of various countermeasures, particularly given the potential for a second-stage recovery effort during ice melt to target oil that had previously been entrained in sea ice. Developing toxicological data for Arctic species of interest would better define the relative value and impact of chemical herders within the countermeasure suite of available tools.

Oil-Mineral Aggregates

The association of oil and fine mineral particulates, typically referred to as oil-mineral aggregates (OMAs) or oil-suspended particulate matter aggregates and oil and fine particle interaction, has long been recognized as a process by which hydrocarbons are transported in marine systems (Owens, 1999). Several case studies, spills of opportunity, and field studies—such as the Baffin Island Oil Spill (BIOS) project—have demonstrated that this oil-clay flocculation process merits consideration in conjunction with other oil-degradation processes (physical weathering, photodegradation, and biodegradation) in understanding the natural attenuation and removal of oil from shorelines (Owens and others, 1994). This process garnered considerable attention in studies of coastal processes following the *Exxon Valdez* oil spill, as researchers noted the association between oil and mineral fines as a mechanism for the natural removal and attenuation of hydrocarbons on the shoreline (Bragg and Yang, 1995). Once formed, OMAs are relatively stable structures, the particle-size distribution and density (or buoyancy) of which are dependent on the mineral-to-oil ratio (MOR) in the structure. Both the composition of the oil and the type of mineral fines can affect this ratio (Zhang and others, 2010). Some basic OMA properties are in need of further study, such as the size distribution of the OMAs, particularly in the presence of dispersants, and how this may affect the settling velocity of OMAs in the water column. There is relatively little known about the specific effect of salinity and clay mineral type on OMA formation (Li and others, 2007). The Arctic Ocean in general is fresher than other marine environments studied. Thus, understanding how regional salinity may affect OMA formation is important. Further, the potential timing of a spill event could influence these processes. For example, should a spill coincide with the spring melt (Yunker and others, 2002), associated discharge pulse from the Mackenzie River system salinity levels would be greatly reduced at some regional scale. The discharge from this fluvial system could significantly affect the salinity and (or) suspended particulate matter (SPM) concentrations, particularly in the nearshore environment. The fate and transport of OMAs are important considerations for oil-spill-trajectory modeling in nearshore waters (Sterling and others, 2004).

Given the natural propensity for oil and SPM to form OMAs, there exists the potential that OMAs also could be used as an oil-spill countermeasure. The Canadian Coast Guard has recently conducted studies looking into the potential utility of this process as a countermeasure to combat oil spills in ice-covered waters (Cloutier and Doyon, 2008). The Centre for Offshore Oil, Gas and Energy Research also is conducting research into this potential use of OMAs, such as the application of mineral fines as a powder or an aerosol mixture to oil slicks at the surface (Lee and others, 2009). In the event additional mixing energy is needed, one potential mechanism under consideration is adding mixing energy to accelerate the OMA formation process (Lee and others, 2009). Utilization of the OMA formation process may be a helpful tool to address the 'ice response gap' in which conventional mechanical technologies may not be effective (Lee and others, 2009).

If OMAs are considered for use in the Arctic, a thorough understanding of how OMAs are incorporated into the sea ice, such as slush, is needed. This understanding is important to oil fate and transport analyses, as OMAs could be transported with the slush ice away from the site of the spill. Payne and others (1991) studied the process by which oil-contaminated sediments could be incorporated into sea ice and thus it is likely that sea ice also could have scavenging potential for OMAs and facilitate greater dispersal of oil (as OMA) over a much larger area.

There is a need to understand how the potential process of OMA formation may be affected by other countermeasures used in response to an oil spill. For example,

> "[t]he synergistic effect of dispersants and mineral fines enhances the transfer of oil from the surface downward into the water column; and a large number of small particles is produced as a result of interaction of dispersants and mineral fines with crude oil" (Li and others, 2008).

Li and others (2007) utilized wave-tank studies to examine these processes, and found that OMA formation can occur with both physically- and chemically-dispersed oil. These studies were conducted under breaking waves. Absent this energy, it is unclear of the effect. Li and others (2007) note that additional factors, such as oil type and weathering state, the type of mineral fines, and the MOR are areas for future study as well as testing under a variety of sea-energy conditions.

Detection, Monitoring, and Tracking

There are numerous technologies available for use in detecting and tracking oil spills on open water, and on top of, within, or under sea ice. These can include: GPS tracking buoys (Dickins and Buist, 1999); tethered balloons (Dome Petroleum Limited and others, 1982); satellite imagery; airborne reconnaissance; trained visual observers; ground, airborne, and space remote sensing technologies; vessel surveillance; optical methods (still and video cameras); unmanned aerial systems (Lehr, 2008); and on-ice surveys. Recent technological advances in the development of lightweight sensors with improved sensitivity (Brown and Fingas, 2009) can augment the utility of these platforms through deployment of multi-sensor systems. For example, there are now efforts investigating the use of a tethered balloon to carry a visible and infrared surveillance system as a means of augmenting real-time spill monitoring capabilities (Prince William Sound Oil Spill Recovery Institute, 2009). In oil-spill response, a suite of these techniques is needed to accommodate the spatial and temporal (especially real-time) needs, as many factors, such as percent ice coverage and thickness, oil slick thickness, oil type and state of weathering, and weather conditions, affect the utility of these technologies. Several recent syntheses, including Dickins (2010), S.L. Ross Environmental Research, Ltd., and others (2010), Interagency Coordinating Committee on Oil Polution Research (2009), Brown and Fingas (2009), Jha and others (2008), Minerals Management Service (2008b), and Tebeau (2003), have documented advances in these technologies over the past decade.

In a review of these technologies and their general effectiveness in response, DeCola and others (2006) noted that

> "estimates vary regarding the impacts of sea ice on spill surveillance and tracking. Response experts often use 50 percent ice coverage as a rule-of-thumb for defining the extent to which open water detection and mapping may be applied. When ice coverage exceeds 50 percent, methods such as visual observation become much less reliable because of problems in detecting the presence of oil in ice leads; however, remote sensing technologies may still apply."

Some technologies require further testing under Arctic conditions. For example, a critical gap identified in spill response is the lack of capability to accurately measure and map the thickness of oil on water and to rapidly send this information to response personnel in the command post (Mineral Management Service, 2008b). World Wildlife Fund (2009) noted that the combination of multi-spectral aerial imagery and infrared detection shows promise for mapping oil slick thickness, but that these tools need further refinement under Arctic conditions and with specific Arctic oil types in order to better demonstrate their feasibility as an operational tool in Arctic oil-spill response. Similarly, DeCola and others (2006) stated that the

> "latest generation of high resolution radar satellites could be used to map large spills in an open pack condition, but radar signatures of new ice, oil, and calm water can be very confusing."

Several recent BOEMRE efforts focus on mapping the thickness of oil, including Bureau of Ocean Energy Management, Regulation and Enforcement (2011b).

In a study of ground penetrating radar (GPR), D.F. Dickins Associates (2005) found that, at frequencies above 800 MHz, GPR yielded clear, well defined frequency, phase, and amplitude anomalies where oil was known to be present at the ice/water interface and trapped within ice tested under lab conditions. The agreement of experimental results with initial modeling indicates the potential to accurately predict GPR response to a variety of Arctic spill scenarios and radar parameters.

Overall, the results clearly demonstrate the potential for detecting oil under sea ice with GPR. Measurements with GPR and airborne radar were conducted over an intentional oil spill in Svea, Svalbard, Norway, in April 2006 and in April 2008 (Dickins and others, 2008). The overall results from two field tests are very promising in that they indicate that GPR using currently available systems is capable of detecting and mapping oil in ice over a broad operational time window from early to late winter, typically November to April in the Beaufort Sea area. This timeframe covers approximately 70 percent of the nearshore fast ice season in most years. The current generation GPR is capable of mapping oil under or trapped within growing winter ice from 30 to 210 cm. Minimum oil thickness detection limit appears to be roughly 2 cm.

Airborne radar also was tested and found to detect oil on frozen ground under snow and oil encapsulated in or under fresh ice. The test also showed that radar can detect oil in and under first year ice with relatively even top and bottom surfaces. Detecting oil through multi-year ice or rafter/ridged first year ice is expected to be difficult because of the voids and jumbled blocks of rough ice which may scatter the radar signal in many different directions.

The time of year also may be important to the detection of oil on or under ice. The overall results from a Dickins and Bradford (2008) study of airborne radar system capabilities in selected Arctic spill scenarios indicate that currently available systems are capable of detecting and mapping oil in ice over a broad operational time window in the Beaufort Sea area. The most reliable months for detection are January and February with results in November, December, and March depending on the internal brine volume of the ice (combination of salinity and temperature). There are still challenges in detecting oil early in the winter with thin, high salinity ice sheets (October) and in the spring (May/June) with warm thick ice having a high volume of liquid brine. During these periods, higher powered radar systems and (or) a corresponding improvement in signal to noise ratios would need to be developed to cover the beginning and end phases of the ice cycle. Detection of trapped oil is not as critical during May and June, however, as the oil will naturally surface through the porous ice and provide a clear visual indication of the presence of residual trapped oil.

Based on previous work, there are limited prospects for developing operational radar based systems to detect oil in sea ice that is floating, but not bottom fast ice. The optimum direction for future radar research and development needs to focus on systems that can evolve into practical operational devices, readily deployed and maintained in Arctic conditions. Future tests need to combine both laboratory and field trials with oil spilled under ice. A sole reliance on laboratory or tank tests will not provide an adequate basis for developing operational systems for future use.

Satellite imagery also is an important component and can inform oil-spill response and other operations in the Arctic, although radar systems are the most practical because of their ability to be used during both the day and the night, and during most cloud cover conditions. For example, as part of the JIP Oil-in-Ice project to assess the overall capabilities of Synthetic Aperture Radar satellites to detect oil spills in ice and monitor ice conditions, Babiker and others (2010) commented that high quality ice information and all-weather satellite coverage is viewed as essential by most companies with operators in the Arctic. Regular satellite surveillance minimizes the need for floating rigs to disconnect riser and drill string in response to advancing ice features and reduces spill risk. In addition, seismic surveys may be completed more efficiently by taking into account ice conditions.

The most effective solution may not be a single sensor, but rather could require the integration of several different technologies (Brown and Fingas, 2009). In a recent review of the state-of-knowledge regarding airborne remote sensing, Dickins and Andersen (2010) noted that multi-spectral remote sensing, when supplemented by visual observation from trained observers, is presently the most effective method for detecting and mapping the presence and spatial distribution of oil on water. There have been many recent studies to test a variety of sensors under different conditions. In their review, Jha and others (2008) stated that laser fluorosensors were the best available sensor for oil-spill surveillance, given the ability to detect oil against many backgrounds, including ice and the shoreline. However, the authors cautioned that no single sensor is capable of providing all requisite information needed to support an effective oil-spill surveillance operation. Advances in technology also may be needed to produce smaller, less energy-intensive systems that could be installed on smaller airframes that are more widely available and (or) affordable to oil-spill responders and government regulators (Brown and Fingas, 2009).

5.19. Finding: There are numerous technologies available for use in detecting and tracking oil spills on open water and in or under sea ice, with varying levels of detection and spatial resolution. Improvements have been made to individual sensors over the past decade; these improvements are documented in a number of available syntheses. Of these, the laser fluorosensor is among the most highly regarded in terms of ability to detect oil in certain snow and ice conditions (Brown and Fingas, 2009). However, there is consensus in the scientific and response communities that no single sensor or approach is sufficient to address all the needs for effective Arctic oil-spill response, particularly given other challenges, such as long hours of darkness and the presence of sea ice. In this regard, high quality ice information and all-weather satellite coverage are viewed as essential by most Arctic operators (Arctic Council, 2009). Given the limitations for each individual type of sensor, packages of multi-sensor systems appear to hold the most promise for versatile and comprehensive remote sensing. Hence, there is growing emphasis on the development of multi-sensor systems that can be deployed from a variety of platforms.

5.19. Recommendation:

1. For spilled oil detection in and (or) under ice, two avenues stand out as the likely focus of future development: acoustics (including the potential use of ultrasound), and electromagnetic (primarily the wave domain systems commonly referred to as impulse radars or ground-penetrating radars). Further testing could be pursued in both these areas. Continued development of practical operational systems for detecting oil in or under ice will be extremely challenging. It is recommended that the latest evolution of the acoustic system first tried in the 1980s be tested over a realistic mix of first year sea ice under field conditions. At the same time, it would be valuable to test the capabilities of the latest generation of ground-penetrating radars in areas of bottom-fast ice where the interface is ice to frozen sediment rather than ice to water.
2. Of the sensors currently available, the laser fluorosensor appears to hold the most promise, given its potential to detect oil in the presence of ice and snow. However, to facilitate broader use of this sensor and its incorporation into multi-sensory packages that can be deployed from a variety of platforms, a reduction in the size and energy consumption—requiring advances in solid-state laser technology—of these systems is critical (Brown and Fingas, 2009).
3. More work is needed on testing of multi-sensor systems to inform remote-sensing operations for spill response. In particular, expanded testing of unmanned aircraft systems is needed to augment observations from trained observers.
4. Research is needed to enhance satellite remote sensing and surface validation capabilities, including development and (or) refinement of satellite-based oil detection algorithms for ice-covered areas.
5. Assessing system performance under real-world conditions during a future offshore controlled spill exercise is seen as a critical need. Such an exercise would provide information essential to refining these capabilities from an operational standpoint.

Field Trials and International Coordination

The National Research Council (1994) recommended

> "the design and completion of one or more experimental oil spills in the general area of the Chukchi and Beaufort Seas. We believe that experimental spills are essential because they can contribute to the scientific understanding of processes, and fill data gaps, about the interaction of ice and oil. These tests also can contribute to accurate assessments of the abilities and limits of countermeasures, and remediation and restoration procedures. The data from recent tests should be evaluated. Carefully controlled field tests would be an invaluable extension of such work into a realistic environmental setting."

This finding appears to remain valid today. The lack of any consistent regulatory framework to facilitate field trials with oil represents a critical science and technology obstacle to achieving real progress in the field of at-sea spill response. Most significant technical advances in Arctic spill response can be attributed to a series of highly successful field trials with oil carried out in U.S., Canadian, and Norwegian waters. Many of these trials have involved moderate-size releases at an affordable cost and have been carried out safely and in an environmentally responsible manner with a high degree of confidence, through a rigorous process of program design and execution. A major point regarding the near-term possibilities for new field trials with oil revolves around the likelihood of obtaining appropriate permits for such experimentation (D.F. Dickins and Associates, 2004). Permits, obtainable in Canada and Norway, are considered unlikely in the United States given that all permit applications have been declined during the last 10 years and no spills in U.S. waters for experimental purposes have been allowed for nearly two decades.

Certainly the previously discussed JIP efforts represent a strong international science and technical collaboration. In addition, at a government level, the Emergency Prevention Preparedness and Response (EPPR) Working Group establishes a framework for future cooperation in responding to the threat of environmental emergencies in the Arctic. The EPPR works within the Arctic Environmental Protection Strategy (AEPS), which was adopted by Canada, Denmark/Greenland, Finland, Iceland, Norway, the Russian Federation, Sweden and the United States through the Ministerial Declaration at Rovaniemi, Finland in 1991. The other working groups within AEPS are the Arctic Monitoring and Assessment Program, Protection of the Arctic Marine Environment, Conservation of Arctic Flora and Fauna, and Sustainable Development and Utilization. The EPPR Working Group provides a forum in which member governments and indigenous peoples work to better prevent, prepare for, and respond to environmental threats from discharges of pollution from activities which take place in the Arctic. The EPPR operates through a system of National Contacts and meets at least annually to assess progress and to develop EPPR Work Plans. EPPR efforts include risk analyses; response exercises for emergencies such as radiological accidents and major oil spills; assessing environmental agreements; evaluating warning systems and communication networks; and sharing experience and technical information, including research and development data.

While not in Arctic waters, CANUSDIX, an effort between Canada and the United States, is a unique annual exercise held near Dixon Entrance, at the southern tip of the Alaskan panhandle and is an example of an innovative combination of spill scenarios, training workshops, equipment deployment, and coordinated multi-year planning (for example, see Canadian Coast Guard, 2010). Like the Arctic, coordinated planning and exercising by partner agencies are a necessity for Dixon Entrance, an environment that also is remote, environmentally sensitive, and characterized by severe weather and limited infrastructure (Gardner and others, 2008).

5.20. Finding: Exercises such as CANUSDIX, an annual emergency response exercise between Canada and the United States near Dixon Entrance at the southern tip of the Alaskan panhandle, and the previously discussed Alaska Ocean Observing System's and others "Sound Predictions" effort in Prince William Sound, Gulf of Alaska, provide practical means to not only identify operational weaknesses but are the only existing practical tools to routinely determine if and what model, real-time data, and data management uncertainties and weaknesses significantly affect desired operational outcomes.

5.20. Recommendation: Efforts to conduct exercises such as CANUSDIX and "Sound Predictions" in the Arctic could significantly advance understanding of the tactical science and information issues that must be addressed. Even if there is not a broader acceptance of conducting actual oil-spill field trials, having scientific protocols in place to take advantage of "spills of opportunities" are essential.

Natural Damage Assessment, Recovery, and Restoration Phase

Background

Discussed in this section are those research needs required to defensibly assess resource injuries, recovery progress, and restoration approaches should oil be released. Our intent is not to suggest that a spill is likely, but to think through such a scenario in a very broad sense and identify approaches and types of scientific information that might reduce societal uncertainties about government capacity to deal with the consequences of oil spills in the Beaufort Sea or Chukchi Sea Planning Areas.

The primary legal framework to determine resource damage is vested within the Natural Resource Damage Assessment (NRDA) process. The NRDA generally is implemented in three phases, which require the natural resource trustees, which in the case of a spill in the Beaufort or Chukchi Seas include the State of Alaska, NOAA, and the Department of the Interior (DOI), to:

1. Determine whether injury to public trust resources has occurred (Preliminary Assessment);
2. Quantify injuries and identify possible restoration projects (Injury Assessment/Restoration Planning); and
3. Implement restoration strategies and monitor effectiveness of such actions.

These are straightforward in language but as stated by the National Oceanic and Atmospheric Administration (2011):

> "Although the concept of assessing injuries may sound simple, understanding complex ecosystems, the services these ecosystems provide, and the injuries caused by oil and hazardous substances takes time—often years. The season the resource was injured, the type of oil or hazardous substance, and the amount and duration of the release are among the factors that affect how quickly resources are assessed and restoration and recovery occurs. The rigorous scientific studies that are necessary to prove injury to resources and services—and withstand scrutiny in a court of law—also may take years to implement and complete."

It is unlikely that even with foreknowledge of where and when an oil spill might occur the suite of baseline information useful to NRDA would be fully available (for example, population, physiological, or toxicological). This is particularly true for the Arctic OCS because of the suite of physical and ecological uncertainties discussed throughout this report, as well as the practical challenges inherent in Arctic research in general. Here, because of the nature of our assignment, we have not attempted to review the scientific literature that would inform the likely exponential suite of possible scenarios and associated potential injured resources that would inform the NRDA-related activities. Instead, we examine strategic science and approach capacities in the Arctic and potential gaps in those capacities that might be informative. We also take advantage of insights gained from the 1989 *Exxon Valdez* oil spill (appendix D) in Prince William Sound, Alaska (http://www.evostc.state.ak.us/ website, accessed May 11, 2011), and the more recent *Deepwater Horizon* oil spill in the GOM to inform our assignment.

Scenarios and Science Planning

Both the *Exxon Valdez* oil spill and the 2010 *Deepwater Horizon* oil spill demonstrate the logistical, technical, and scientific challenges of responding to rare, but significant events. The success of the NRDA process, particularly in the "Preliminary Assessment" stage is dependent on the rigorous collection of time critical and (or) ephemeral information. Previous large oil spills have demonstrated that access to immediate post-spill survival, physiological, behavioral, toxicological, and habitat information could have improved the ultimate level of confidence in NRDA findings. Despite previous lessons learned from the *Exxon Valdez* oil spill, coordinated science plans for the integrated collection of critical data needed for NRDA-related activities have not been prepared in the areas of proposed development. A coordinated joint State–Federal Gulf Coast Ecosystem Restoration Council to inform strategic and efficient restoration efforts into the future has been proposed (Recommendation E6: National Commission on the BP Deepwater Horizon Oil Spill and Offshore Drilling, 2011) as was the case after the *Exxon Valdez* oil spill; however, the opportunity to collect much of the time critical data will be past before such establishment. In the case of the *Deepwater Horizon* oil spill, the region had fairly easy and robust access to scientific capacities (multiple Federal and State laboratories, academic specialists), extensive citizen volunteers to help capture early resource mortality data, and community infrastructure (for example, boats), all of which improved the likelihood that critical early post-spill data were captured. The Arctic OCS and coastal environment is not similarly positioned.

Although the *Exxon Valdez* oil spill is scientifically informative for many aspects of our later discussions, it was a spill that occurred from tanker grounding rather than from drilling activities. Thus, contemporary environmental studies of the nature produced through the BOEMRE Environmental Studies Program for the Arctic OCS described previously were not available. The spill also occurred after a period of ocean climate regime shift (for example, Anderson and Piatt, 1999), whose consequence to effective injury and recovery assessment was not well understood for some time into restoration efforts. In that regard, our existing scientific foundation and progress towards expanded understanding of the distribution of species, potential fate and effect of oil, and the nature of environmental change (including changing climate scenarios) could be argued to be more robust than was available for Prince William Sound in 1989. There is the current effort invested in environmental studies under the BOEMRE, project efforts by industry (for example, Funk and others, 2010), the agency mission-specific monitoring ongoing at both Federal and State levels, and the broad collation and synthesis efforts by many parties (for example, Smith, 2010).

The existing Oil Spill Risk Assessment (OSRA) framework described earlier, while at some level limited because of the qualitative manner in which ecological information is presently incorporated, does provide information on likely landscapes and resources affected under simulated spills. This foundation is valuable and provides information useful to better understand and narrow the range *a priori* of likely NRDA injured resources under the various oil-spill scenarios.

In the report prepared by Integral Consulting Inc. (2006) for the *Exxon Valdez* Oil Spill Trustees Council, scientists who gained experience from the *Exxon Valdez* oil spill provided a strong foundation for understanding the types of scientific information needed to assess recovery status, lingering oil impacts, and restoration progress to inform what types of "pre-spill" data should be readily available (fig. 5–9). Information on population characteristics (for example, abundance and productivity, physiological metrics, and habitat) and exposure metrics (for example, bioaccessibility, exposure pathways, and biomarkers) all must come together in a weight-of-evidence to inform NRDA activities (Integral Consulting Inc., 2006, fig. B–4).

5.21. Finding: The remoteness of the Arctic OCS, the small resident population, and limited community infrastructure likely would limit the probability of early science responses that were seen during the *Deepwater Horizon* or *Exxon Valdez* oil spills, resulting in the loss of time-critical data informative to Natural Resource Damage Assessment.

5.21. Recommendation: The development and pre-positioning of a multi-agency coordinated Oil Spill Science Contingency Plan could potentially mitigate some of the challenges inherent in spill response in the Arctic. The planning process itself would be valuable by identifying what skills and protocols exist or need to be developed. The *Deepwater Horizon* oil-spill response demonstrated the need for local citizen engagement in sample collections. This is likely more true in the Arctic, due to access limitations. Local community members could be the first available on scene. Consideration of a "Citizen Scientist" program as a component of Science Contingency Plans might be fruitful.

5.22. Finding: The Oil Spill Risk Assessment (OSRA) process employed by the BOEMRE provides information to help define where natural resources might be exposed to oil under various spill scenarios.

5.22. Recommendation: A strategic follow-on analysis to the present Environment Resource Area OSRA that would examine the state of knowledge of specific NRDA metrics (for example, see fig. 5–9) could help identify specific population, physiological, habitat, and exposure data for future NRDA activities. This would help establish priorities for needed science under BOEMRE-focused planning as well as ongoing efforts by science and resource agencies.

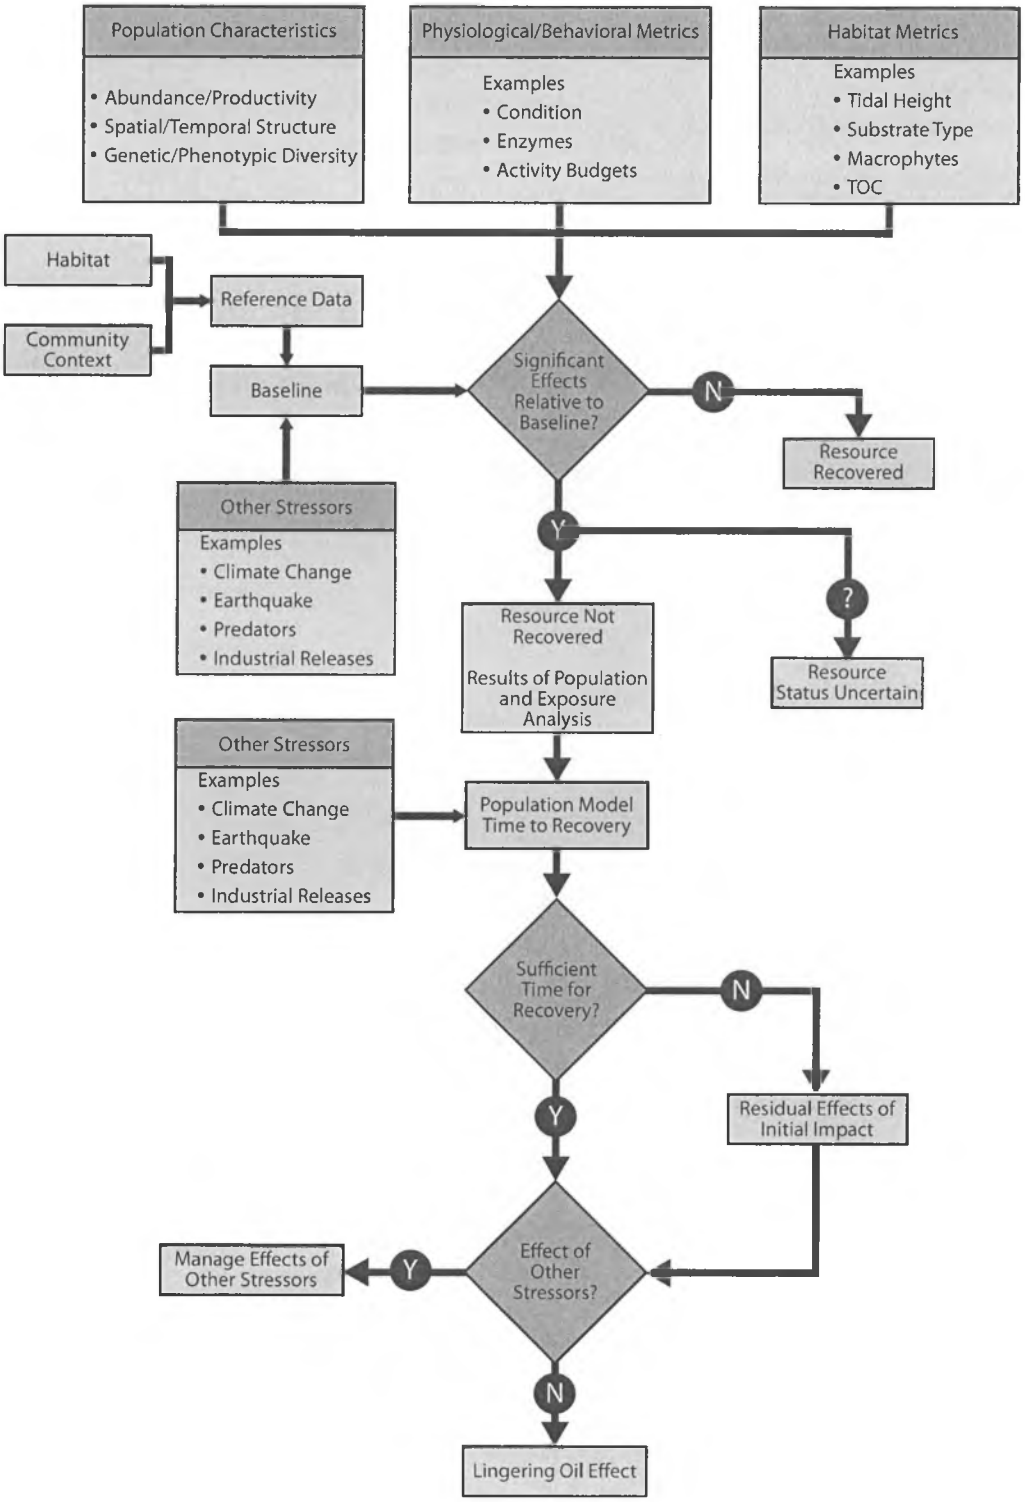

Figure 5–9. Factors incorporated into population level evaluations of recovery status (modified from Integral Consulting Inc., 2006, figs. B3 and B5). TOC, total organic carbon; N, No; Y, Yes.

Integrated Monitoring and Process Understanding

As discussed elsewhere in our report, there are high accumulated uncertainties associated with any development activity in the Arctic and what science is "essential" to informing decisions. In addition to project uncertainty, climate changes may affect the relevancy of historical data to future decisions, and there is a huge spatial extent under consideration. Thus, having the "right" science, at the "right" time, and at the "right" scale is problematic. In such an environment, there may be great value to a more aggressive science strategy to integrate sampling approaches to ultimately improve inferences from sampling available at one scale to another, or one time or location to another. As discussed above, the same could be said for the ability to develop a full pre-understanding of all the essential NRDA metrics for each potential injured resource (or resource being examined in pre-decisional leasing documents). Here, we discuss several elements of this challenge and potential approaches to provide some level of mitigation.

Several existing study programs for the Beaufort and (or) Chukchi Seas serve as examples of approaches that may provide the framework for improving our ability to scale understanding from one level to another. The BOEMRE has undertaken a wide variety of integrated monitoring efforts over the last decade. These include:

1. ANIMIDA, the "Arctic Nearshore Impact Monitoring in the Development Area" study designed to assess potential environmental contaminant inputs from Beaufort Sea oil and gas development and its continuation cANIMIDA (for example, Boehm, 2001; Neff and Associates, LLC, 2010), and
2. COMIDA, the "Chukchi Sea Offshore Monitoring in Drilling Area" effort which conducts an extensive multi-study examination of the environment.

Both these efforts provide a mid-scale view of environmental background conditions associated with prospects. When coupled with the more detailed prospect-specific industry efforts such as those in the Chukchi Sea Lease Area, significant process and scaleable information could be generated informative to both permitting and future NRDA needs (fig. 5–10).

Another approach that is likely valuable in the effort to better generate and understand factors critical to NRDA, particularly in a changing climate, is formal integrated multidisciplinary monitoring and process studies. The *Exxon Valdez* oil spill can be used as an example to gain perspective—more than 30 biological resource types were considered to be injured by the *Exxon Valdez* Oil Spill Trustee Council during the *Exxon Valdez* Oil Spill NRDA process (*Exxon Valdez* Oil Spill Trustee Council, 2001) with the majority recovered or recovering and four viewed as not recovered or recovery unknown by 2010 (*Exxon Valdez* Oil Spill Trustee Council, 2010). The challenge faced by the Trustee Council to judge recovery was largely due to:

1. Variability in population estimates as a result of highly mobile fish, birds, and marine mammals causing wide confidence limits for population size estimation;
2. Lack of pre-spill data;
3. Interaction of the spill and other natural factors (for example, climate) that constrained the ability to judge the role of oil in population status; and
4. Geographic scale of studies conducted both before and after the spill which ranged from scales to assess populations to others keyed to localized effects and oil exposure.

To compensate for incomplete information, injury often was inferred from comparisons of oiled and unoiled areas, with recovery defined as a return to conditions comparable to those of unoiled areas. Confidence in such designs is limited because of natural variability among sites oiled and unoiled prior to a spill. Ultimately, efforts turned towards the development of ecosystem-based integrated studies to attempt to better establish population status relative to recovery and factors still constraining recovery through a weight-of-evidence approach across suites of species whose status remained uncertain (*Exxon Valdez* Oil Spill Trustee Council, 1994). Efforts like those described in Peterson and Holland-Bartels (2002) for a suite of species whose recovery status was still uncertain or deemed non-recovered after extensive study and some 5 years after the oil spill highlight that coordinated multi-species sampling and coupled hypothesis-driven studies can mitigate many weaknesses in incomplete pre-spill data. Efforts such as those proposed by Grebmeier and others (2010) for a Distributed Biological Observatory (DBO) or underway in the Bering Sea and Aleutian Island Integrated Ecosystem Research Program (BSIERP, http://bsierp.nprb.org/) of the North Pacific Research Board and National Science Foundation offer examples of approaches that could well serve the full suite of interested parties and their decision-making requirements that cascade out of DOI OCS decisions.

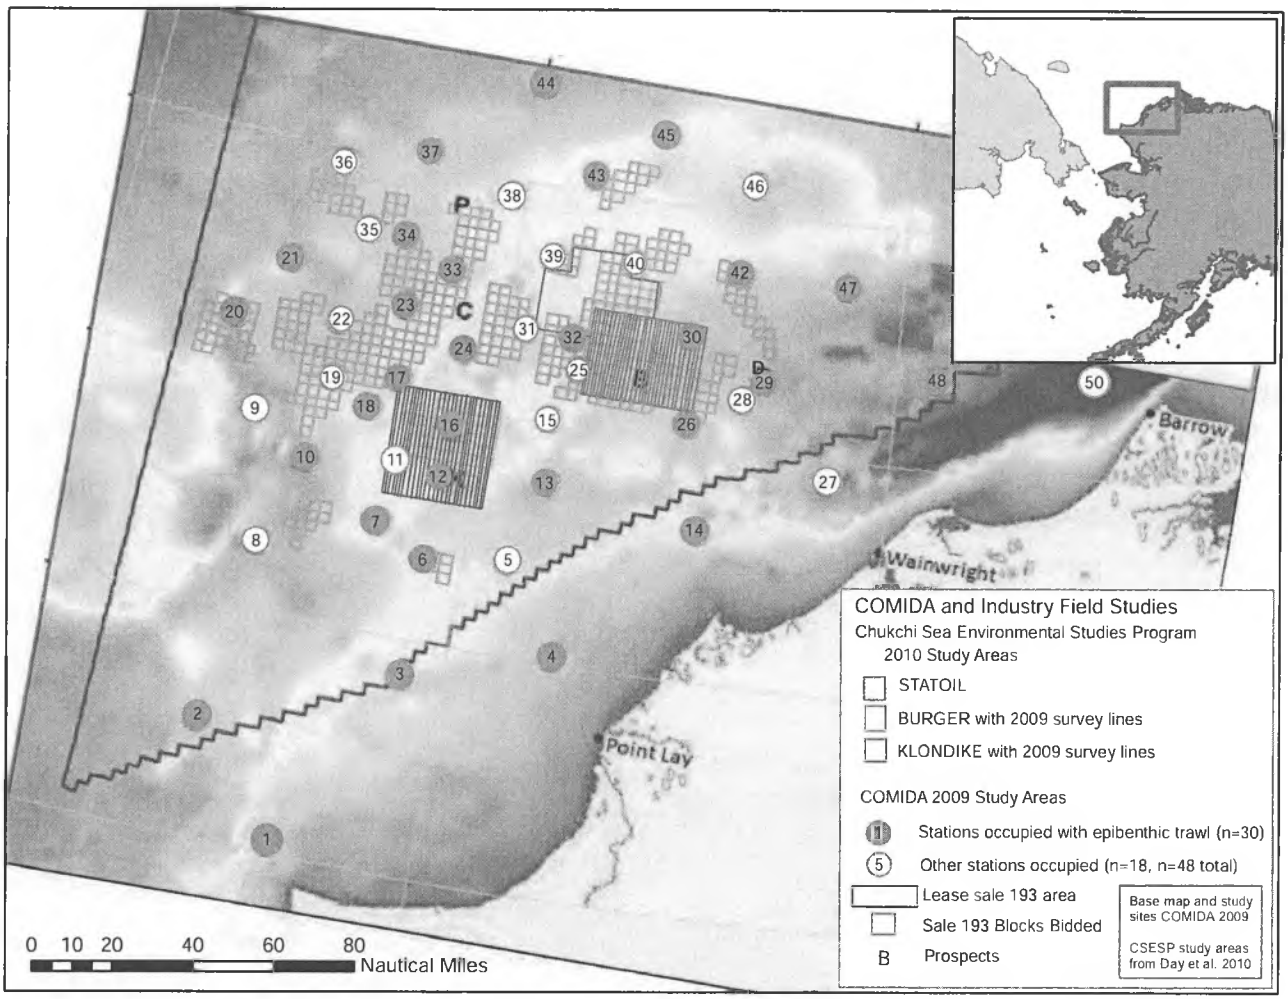

Figure 5–10. Example of the BOEMRE-sponsored COMIDA sampling and the more spatially detailed industry-sponsored sampling (modified from Dunton, 2010; Day, 2010).

5.23. Finding: Significant advances have taken place with the COMIDA ("Chukchi Sea Offshore Monitoring in Drilling Area") and cANIMIDA ("continuation of the Arctic Nearshore Impact Monitoring in the Development Area")-like efforts funded by the BOEMRE and the more spatially detailed efforts by industry. Such efforts individually provide critical information on ecosystems, potential anthropogenic effects from development, and climate factors.

5.23. Recommendation: The benefits from these individual efforts to improve scientifically defensible inference of findings to different geographic and temporal scales could be significantly enhanced through additional focused coordination and joint study planning. Discussions in a workshop format to outline specific experimental designs presently employed and to discuss fruitful efforts to link study efforts might be beneficial as one approach.

The DBO (fig. 5–11), as envisioned by Grebmeier and others (2010), would provide a monitoring and experimental framework:

> "...to detect, measure, and track the combined effects of changing oceanographic conditions on the ecosystem....[with] holistic, integrating measurements of basic oceanographic variables [and] with data on species- and trophic level interactions, from primary producers to marine mammals... The DBO is envisioned as an array to identify and consistently monitor biophysical responses in four pivotal geographic areas that exhibit high productivity, biodiversity, and rates of change. ...The DBO would support a suite of *in-situ* time-series measurements to evaluate ecosystem status, supplemented by satellite observations. Sea ice observations include ice and snow thickness and biological sampling to evaluate changes to productivity in sea ice systems and habitat sustainability for predators."

A DBO approach, which would bring value to resource missions beyond that required by the BOEMRE, would require a concerted multi-agency and international planning effort. However, once established, a DBO might provide a critical and essential complement to mission-specific sampling by the BOEMRE and species studies by NOAA, U.S. Fish and Wildlife Service, and (or) the State of Alaska. This is particularly true as climate is hypothesized to force significant ecosystem-level changes that will require rigorous understanding if they are to be defensibly incorporated into OCS-specific or the broad array of other agencies mission considerations.

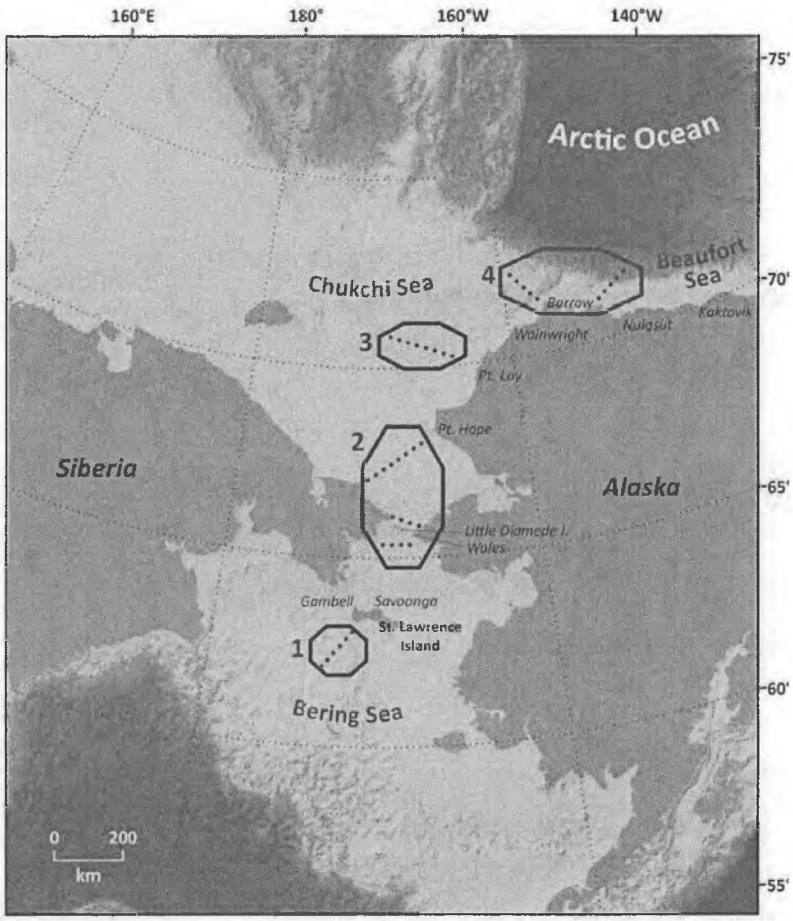

Figure 5–11. Schematic of the location of the proposed Distributed Biological Observatory for standard hydrological and biological measurements in the Bering, Chukchi, and Beaufort Seas (Grebmeier and others, 2010).

5.24. Finding: The Arctic environment is highly variable both physically and biologically. Here, it is difficult to conduct and maintain the suite of individual surveys and sampling efforts of ecosystem components at sufficient levels to understand potential future impacts from development. As was demonstrated in the *Exxon Valdez* Trustee Council recovery science efforts, this is particularly true for information needed to establish population status.

5.24. Recommendation: The Distributed Biological Observatory concept is one that holds significant scientific promise to mitigate some of the major constraints to a defensible science framework for critical Arctic decision making.

5.25. Finding: Similar to findings 5.23 and 5.24, the nature of resource variability and uncertainty in the Arctic challenges the development of the full suite of scientific information needed by decision makers and vested parties relative to resource management in the Arctic.

5.25. Recommendation: The BSIERP (North Pacific Research Board-National Science Foundation Bering Sea and Aleutian Island Integrated Ecosystem Research Project) and the DBO (Distributed Biological Observatory) concepts and enhanced industry-COMIDA ("Chukchi Sea Offshore Monitoring in Drilling Area")-like efforts offer the potential to create a transparent and scientifically rigorous study framework to support and enhance existing BOEMRE and other organizational interests in the Arctic.

Finally, the conceptual approach used by the North Pacific Research Board in its BSIERP, which considers commercial fishery research within the context of an ecosystem framework, offers another successful approach to understanding anthropogenic factors in the context of complex ecosystems and changing environments (North Pacific Research Board, 2006). The BSIERP was envisioned to address scientific challenges to effective fishery management associated with expected changes in the ecosystem such as:

- "Physical phenomena (for example, weather patterns, sea ice characteristics, transport, mixed layer dynamics, temperature, nutrient fluxes);
- Composition, abundance, distribution, and demographic parameters of biological components from plankton to seabirds and marine mammals;
- Strength of existing predator-prey linkages and development of new linkages;
- Human strategies for resource extraction, transportation, and community adaptation."

This effort considered hypotheses that included how the distributions and abundances of species might be changing; characteristics of physical and chemical attribute change; changes in lower trophic level production; processes controlling energy pathways; the role of climate change in these processes; and the economic and sociological impacts of a changing ecosystem on the coastal communities and resource users of the Bering Sea. The concepts and the efficient approaches forwarded under the BSIERP (fig. 5–12) are appealing when considering the functionally similar challenges of resource decision making for the Arctic.

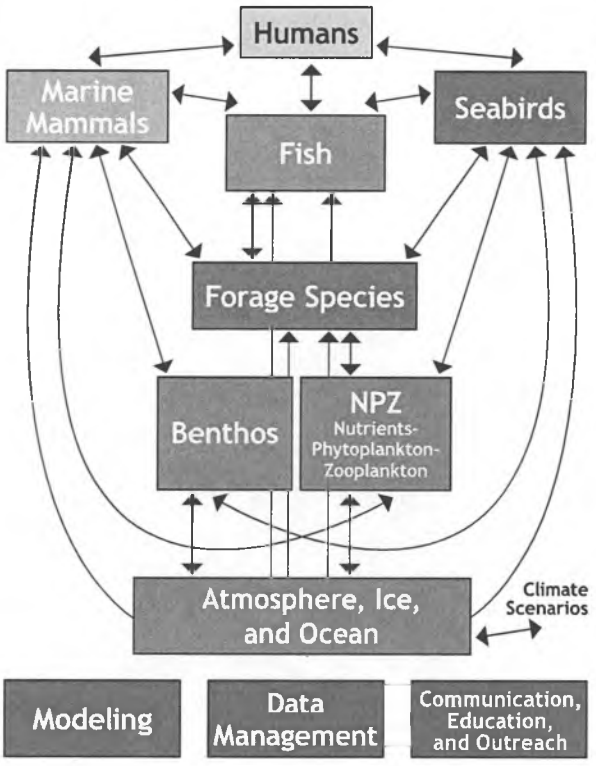

Figure 5–12. Conceptual design of the North Pacific Research Board Bering Sea and Aleutian Island Integrated Ecosystem Program. Graphic available at: http://doc.nprb.org/web/BSIERP/zzWebsite/proj_mgmt/01.10_bsag_web.pdf, accessed March 8, 2011.

As a final consideration, any of these larger integrated approaches, as well as the existing BOEMRE program, requires input from many other resource programs. Should these efforts be lost or reduced, the science-based decision making about oil and gas development in the Arctic may be compromised. For example, Grabmeier and others (2010) discuss that the DBO would require collaboration and joint data collection with vessel cruises through the Pacific Arctic Group network of governments and scientists working in the Pacific Arctic, inclusion within international Sustaining Arctic Observing Networks, and (or) Arctic Council (website: http://www.arctic-council.org/, accessed May 10, 2011) efforts. The BSIERP, as mentioned previously, is a close partnership with the National Science Foundation with strong in-kind funding leverage from mission work from many State and Federal agencies. Thus, not only is the support for new collaborations key to developing enhanced insights for oil and gas development in the Arctic, but also the maintenance of core agency mission work. One only has to turn to the

environmental documents of the BOEMRE (for example, Minerals Management Service, 2006) or to the data sources that were the basis of "The Arctic Marine Synthesis: Atlas of the Chukchi and Beaufort Seas" document (Smith, 2010) to capture the critical nature of core mission work of other Federal and State agencies. The amount of such existing work is encouraging, but the general quality as defined by spatial and temporal coverage should be increased (appendix E, table E–1).

5.26. Finding: The information that presently supports science-based decision making on oil and gas development in the Arctic comes from both the topic-focused work of agencies such as BOEMRE, and the efforts of broader agency-specific mission work of many Federal, State, community, and nongovernmental entities.

5.26. Recommendation: The ability to develop oil and gas resources in as safe and environmentally sound a way as feasible relies on many data sources outside the formal annual planning process of the BOEMRE. Understanding the potential jeopardy these data collections might be in across organizations because of different planning processes and national and regional priorities, and development of a strategic collaboration to maintain and enhance such scientific efforts could prove valuable. Such information could be identified as part of an overall science plan.

Oil-Spill Risk, Response, and Impact Under Future Climate Considerations

In Chapter 4, Climate Change Considerations, the authors discuss how physical characteristics important to oil-spill risk, response, and impact may change under climate forecasts in the next 50 years. A number of significant changes are expected to occur in the physical environment of the Beaufort and Chukchi Seas. Some of these changes will stress the biological systems that are so highly adapted to the extreme conditions of this region. These changes are also expected to affect the environment in which Arctic OCS exploration and development activities occur. Some climate changes will mitigate the environmental risks of energy development in the region, while others will compound them. The interactions between future climate change over the next 50 years and potential energy development within the Arctic OCS are described briefly in the following paragraphs.

- *Temperature:* Extremely cold temperatures are cited as a factor contributing to the risk of accidents and spills. The large warming projected to occur within the Arctic OCS during autumn and winter is expected to reduce the risk of accidents and spills during those seasons, as is the more modest warming during spring.
- *Sea Ice:* The Chukchi and Beaufort shelves are expected to be ice-free for a greater period of time each year. This will reduce the portion of the year when the presence of sea ice may contribute to the risk of accidents resulting in spills, and will increase the time when spill sites will be accessible to vessels without icebreaking capabilities. Mechanical devices for recovering oil (booms, skimmers, pumps) may function more effectively for a greater part of the year. However, sea ice will still be present throughout winter and spring. With its projected reduced thickness, the ice pack will be more dynamic, increasing the risk of spill-producing accidents during these seasons. Oil-spill response may be more difficult in the more dynamic sea-ice environment.
- *Clouds:* The increasing prevalence of low-level clouds and fog during the open-water season will increase the occurrence of poor-visibility conditions during summer and autumn. In addition, these poor-visibility conditions are expected to occur over a greater fraction of the year, extending into late autumn. Poor visibility is a factor that increases the risk of accidents resulting in oil spills, makes vessel and aircraft operations extremely dangerous, increases the response time of vessels and aircraft trying to respond to an accident or spill, hampers onsite spill response operations once the needed equipment and personnel arrive, and makes it difficult to monitor the location and condition of a spill by using aircraft. The projected increase in high-level clouds (all seasons) compounds the problem by limiting satellite-based surveillance. In contrast to summer and autumn, the occurrence of low-level clouds and fog is not projected to change substantially during winter or spring.
- *Icing Conditions:* Icing conditions present a significant hazard in the Arctic, both to personnel and equipment. These conditions are expected to occur more frequently during autumn. Icing conditions increase the risk of accidents resulting in oil spills, make aircraft operations extremely dangerous, increase the response time of aircraft trying to respond to an accident or spill, and hamper onsite spill response operations once the needed equipment and personnel arrive. This is primarily an autumn phenomena, and is not expected to increase risks during winter, spring, or summer.

- *Precipitation:* The increasing frequency and intensity of precipitation (all seasons), as well as the number of wet days, may elevate the risk of accidents resulting in oil spills. Such conditions also may make it more difficult to respond to spills when they occur. Increased precipitation during winter and spring may contribute to the severity of 'white-out' conditions which greatly reduce visibility. The projected increase in precipitation is expected to reduce the salinity of the surface waters in the Beaufort and Chukchi Seas, potentially reducing the effectiveness of chemical dispersants applied to oil spills.

- *Storms:* A number of physical arguments suggest Arctic cyclones, including Polar Lows, will become more frequent and (or) more intense during autumn and winter. Although this projected change has not yet been rigorously tested (and so is uncertain), we note that there are no physical arguments to suggest storms will become less frequent and (or) less intense during these seasons. An increase in storminess during autumn and winter, if it occurs, will increase the risk of accidents resulting in oil spills if oil and gas operations are conducted during those seasons. Such storms would increase the frequency of strong winds (autumn, winter) and rough seas (autumn). High winds can prevent or hamper aircraft and vessel access to spill sites, adversely affecting spill response times. Mechanical recovery systems and ISB are hampered by high winds. Accurate application of chemical dispersants is more difficult during high winds. However, rough seas may enhance the effectiveness of chemical dispersants once applied to a spill. Rough seas, drifting pack ice, and storm surges may cause significant damage to offshore equipment, artificial islands, and onshore coastal infrastructure. At this time, there are no convincing arguments that storms will become either more or less frequent during spring or summer.

- *Sea-Level Rise:* Artificial islands and causeways built for offshore energy development will be increasingly vulnerable to inundation from sea-level rise and damage from storm surges. This risk can be substantially reduced through proper engineering that takes sea-level rise into account.

- *Coastal Zone:* Land-based infrastructure (for example, pipelines, storage tanks) designed to support offshore energy development will be much more vulnerable to damage due to sea-level rise, storm surges, permafrost degradation, and accelerated coastal erosion. Proper engineering and site selection may mitigate this risk to a large extent.

Chapter 6

Marine Mammals and Anthropogenic Noise

By Deborah R. Hutchinson and Richard C. Ferrero

Introduction

In the ocean realm, where vision often is limited by turbidity and darkness, marine mammals rely upon hearing as their primary sense. The scientific consensus is that audition is used in a wide range of activities, for example, to communicate, to forage, to hunt, to sense the environment, to navigate, to socialize, to seek mates, to find open water amidst ice, and to flee predators. Cetacean and pinniped auditory systems are adapted to exploit the ease with which sound travels in water—roughly five times faster than in air, and for far greater distances. For marine mammals, the oceans are relatively opaque to light, but transparent to sound.

The oceans also are noisy places. Among the natural contributors to ocean ambient noise are wind, rain, waves, ice cracking, surf, earthquakes, volcanoes, lightning strikes, and biological sources including the wide array of sounds made by marine mammals. Superimposed on these sounds are manmade ("anthropogenic") sounds from shipping, industrial activities, naval operations, marine research, aquaculture, and aircraft, among others. For the same reasons that marine mammals use sound for survival and reproduction, humans use sound as the most cost-effective and efficient tool for remote sensing and mapping of the seafloor and sub-seafloor to understand, among other issues, habitats and mineral and energy resources. The characteristics of all these sources of sound can be intermittent or sustained, loud or barely audible, and cover a wide range of frequencies (for example, Wenz, 1962). The Arctic Outer Continental Shelf (OCS) is one of the few relatively pristine regions on Earth where shipping and coastal community development is minimal. With the possible exception of the Prudhoe Bay region, the introduction of anthropogenic sound also has been minimal, because of the harsh ice-covered, cold, and remote location. Hence the Arctic offers the potential opportunity to understand the impacts of anthropogenic sound before animals have become widely sensitized, habituated, or disturbed by chronic manmade sounds.

It has been recognized for some time that human-generated noise has the potential to have deleterious effects on marine mammals (for example, Payne and Webb, 1971; Greene and Richardson, 1988; Richardson and others, 1995; Gordon and others, 2004; Southall and others, 2007; Tyack, 2008, 2009). Elevated background noise from manmade sources may prevent animals from hearing sounds they use for their survival or reproduction (masking). Manmade sound may trigger behavior changes, such as avoidance or displacement, which interrupts normal activities. Loud sounds may cause temporary or permanent changes in hearing. Some sounds also may initiate physiological stress responses or even physical injury that could affect survival or reproduction. The great challenge in understanding these impacts is that studying wild populations of Arctic marine mammals is expensive, difficult, and sometimes dangerous. Furthermore, extrapolating limited observations from individual animals to understand longer term characteristics of a population is often more speculative than substantive.

The past two decades have witnessed a growth in concern about and research into human-generated sound in the oceans and its potential impacts on the health and sustainability of marine mammals. A synthesis book was published in 1995 (Richardson and others, 1995). Four National Research Council (NRC) reports have directly explored the association between anthropogenic noise and marine mammals (National Research Council, 1994, 2000, 2003a, 2005). The Marine Mammal Commission also has published synthesis documents (Vos and Reeves, 2005; Marine Mammal Commission, 2007; Simpkins and others, 2007; Bradley and Stern, 2008). Additional syntheses have explored the effects of anthropogenic sound on marine mammals, including seismic studies (for example, Ketten, 1997; Popper and others, 1997; National Resources Defense Council, 1999; Au and others, 2000; Wartzok and others, 2004; Southall and others, 2007; Tyack, 2008; Marine Ecology Progress Series, 2009). Special studies have investigated the effects of oil and gas activities, particularly seismic experiments, on marine mammals (for example, National Research Council, 2003b; Tolstoy and others, 2009); and a Joint Industry Project (JIP) on sound produced from exploration and production (E&P) developed a report identifying knowledge gaps and recommended research for anthropogenic sound and marine life (Thorson and others, 2005). Phase 2 of this JIP lasted from 2006 to 2009 with additional publications (International Association of Oil & Gas Producers, 2011) and a third phase began in January 2010. The U.S. interagency task force on Anthropogenic Sound and the Marine Environment issued an integrated research plan in 2009 (Southall and others, 2009). Since 2006, the Acoustic Ecology Institute has released annual summaries of science, policy, and legal developments related to ocean noise (Acoustic Ecology Institute, 2007).

Marine mammals known to occur in the U.S. Arctic OCS include both year-round or seasonal inhabitants as well as a broader collection of occasional visitors. Cetaceans most notably associated with the Beaufort and Chukchi Seas include bowhead, beluga, and gray whales with less frequent sightings of harbor porpoise, and fin, humpback, and killer whales. Five pinniped species are found in these waters, including ringed, bearded, ribbon, and spotted seals, as well as Pacific walrus. Likewise, polar bears are found throughout this area.

In this chapter, which focuses on the impacts of sound in the Arctic, we emphasize species that could potentially be affected at the population level (owing to more frequent occurrence than the occasional visit)—bowhead, beluga, and gray whales; ringed, ribbon, bearded, and spotted seals; Pacific walrus; and polar bears (table 6–1). In addition, several of these species warrant close attention given their legal status. Bowhead and fin whales have long been listed as endangered under the Endangered Species Act (ESA). The polar bear was listed as threatened in 2008 (U.S. Fish and Wildlife Service, 2008) and in November 2010, the U.S. Fish and Wildlife Service (USFWS) further designated critical habitat for the polar bear (U.S. Fish and Wildlife Service, 2010). The gray whale was considered endangered until 1994, when it was delisted (National Marine Fisheries Service, 1994). Among the pinnipeds, National Marine Fisheries Service (NMFS) initiated an ESA consultation for the four Arctic seal species—the ribbon seal (National Marine Fisheries Service, 2008a) and the spotted seal (National Marine Fisheries Service, 2009a) did not warrant listing action for U.S. waters; however, in December 2010, NMFS proposed that the U.S. Arctic populations of the bearded (National Marine Fisheries Service, 2010a) and ringed (National Marine Fisheries Service, 2010b) seals warranted threatened listings. USFWS recently published a finding for Pacific walrus of warranted but precluded under ESA (U.S. Fish and Wildlife Service, 2011).

Aside from these species or population specific considerations, this collection of marine mammals derives unique stewardship consideration through multiple layers of legislative mandate. The Marine Mammal Protection Act (MMPA), the Endangered Species Act (ESA), and the National Environmental Policy Act (NEPA) are important drivers in management decisions and the need for science to support them. Of these and with particular relevance to this report, NEPA particularly affects the Department of the Interior because of the regulatory responsibilities of the Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) for offshore oil and gas development. The National Oceanic and Atmospheric Administration (NOAA)/NMFS and USFWS share responsibility for implementing MMPA and ESA, with a particular concern for authorizing activities that produce anthropogenic sound in the oceans.

Table 6–1. Marine mammals of concern in the Arctic Outer Continental Shelf.

[From Allen and Angliss (2010) unless otherwise noted. **Locale:** B, Beaufort abundance; C, Chukchi abundance; P, Pacific abundance; T, total abundance. **Population status:** +, increasing; ?, unknown. **MMPA** (Marine Mammal Protection Act) **ESA** (Endangered Species Act) **status:** From http://www.nmfs.noaa.gov/pr/species/: Cd, candidate; E, endangered; D, depleted; DL, delisted; Th, threatened]

Common name	Latin name	Locale	Stock abundance	Population status	MMPA ESA status
Bowhead whale	*Balaena mysticetus*	T	9,400	+	E,D
Beluga whale	*Delphinapterus leucas*	B	32,500	?	
		C	3,700	?	
Gray whale	*Eschrichtius robustus*	P	17,500	+	DL
Ringed seal	*Pusa hispida*	T	?	?	Cd
Ribbon seal	*Histriophoca fasciata*	T	?	?	
Bearded seal	*Erignathus barbatus*	T	?	?	Cd
Spotted seal	*Phoca largha*	T	?	?	
Pacific walrus	*Odobenus rosmarus divergens*	T	129,000	?	Cd[1]
Polar bear	*Ursus maritimus*	C	2,000	?	Th
		B	1,800	?	

[1]U.S. Fish and Wildlife Service (2011).

Despite the research and interest in the impacts of noise on marine mammals, considerable controversy surrounds how MMPA, NEPA, and ESA are applied to regulate offshore activities and protect marine mammals. A recent court case in the Arctic OCS is the July 2010 decision halting activities under Lease Sale 193 in the Chukchi Sea citing the need for further environmental review. Tension exists between the advocates for more precautionary approaches to decision making and regulation (National Resources Defense Council, 1999) and the regulatory agencies implementing MMPA and ESA (that is, NMFS and USFWS). Both behavioral and auditory effects associated with anthropogenic sound are considered "takes" under MMPA and ESA, especially if the effects are considered "biologically significant," a finding that also is controversial in how "biologically significant" is determined and applied (National Research Council, 2003a, 2005).

6.01. Finding: For all the many studies conducted on ocean noise and marine mammals, large uncertainty still exists in extrapolating how impacts of noise on individual animals may affect survivorship or reproductive rates of populations. The National Research Council (2005) addressed how to determine "when noise causes biologically significant effects" (subtitle of the report) but the proposed model involves five core components for which transition inputs and outputs are not always specified or quantified (for example, Clark and others, 2009). More work is needed that is designed to determine how to most effectively determine the impacts of noise at both individual and population levels.

6.01. Recommendation: Investment in efforts such as those of BP and the North Slope Borough with the University of California, Santa Barbara—Cumulative Effects of Anthropogenic Underwater Sound on Marine Mammals—which is to summarize and synthesize the literature on effects of anthropogenic sound on marine mammals, develop suggested approaches for routinely assess such effects, and to define fruitful avenues of future research (http://www.eri.ucsb.edu/adminstrative/research_awards_icess, accessed April 1, 2011)—and the conduct of resulting high priority research would improve the science foundation for a myriad of planning and permitting actions related to Arctic OCS.

Finally, marine mammals are integral to the culture and identity of the Iñupiat Native community of the North Slope of Alaska. The bowhead whale is a vital dietary component, source of bone and baleen for traditional crafts, and an essential symbol of the subsistence culture of the Iñupiat community. The MMPA protections for marine mammals include making them available for subsistence hunting. Annual hunting quotas for the bowhead whale are determined by the International Whaling Commission. The U.S. quotas are allotted to the 11 North Slope communities by the Alaska Eskimo Whaling Commission. For 2010, NOAA issued a quota of 75 strikes to the Alaska Eskimo Whaling Commission. Walruses, polar bears, and seals also are hunted and used by the Native community. A significant recurring concern of the Native community is that oil and gas related activities may displace marine mammals from hunting grounds, thereby threatening the livelihood and existence of the Native community. Moreover, they seek to ensure that local traditional knowledge is used to augment understanding of seasonal movements, distributions, and abundance of marine mammals (for example, Noongwook and others, 2007).

In response to concerns about noise associated with oil and gas activities in the Arctic, NOAA/NMFS initiated an Environmental Impact Statement (EIS) on the effects of Arctic OCS oil and gas activities (seismic and exploratory drilling), and held scoping meetings in February and March 2010, in seven North Slope villages and Anchorage (National Marine Fisheries Service, 2010d). The EIS, still in preparation, examines the effects of oil and gas activities, including noise, on marine mammal species and stocks, as well as their effects on communities and subsistence.

Characterization of Sound in the Oceans

Sound is not intuitive to measure or describe. Technically, sound travels in water as a mechanical vibration, or pressure wave (also called a p-wave) comprising mechanical particle motion oscillations associated with alternating compressions and rarefactions. The physics of sound measurement and transmission are covered in many places and are only briefly summarized here, for example, American National Standards Institute (1986, 1994), Richardson and others (1995), National Research Council (2003), and Erbe (2011). Sound is composed of waves of varying frequencies (measured in cycles/second, Hz) that are of sufficient strength to be detected. In basic terms, sound can be loud or soft, high frequency or low frequency, continuous or pulsed, and its measured loudness and pitch will depend on how distant or close one is to the source. The description of sound necessarily involves relative measures of its character (for example, compared to a reference), and will depend on whether the measurement is done at the source or at some distance from the source. Complicating the characterization is that sound in water attenuates and weakens as it travels ("propagates") away from the source, depending on factors such as salinity and temperature of the water, presence or absence of ice, reflection off the sea or ice surface, the depth of the water, and hardness of the seafloor (in coastal waters). Because higher sound frequencies attenuate more rapidly, low-frequency sounds also travel farther than higher frequency sounds. Hence the sound characteristics at the source (where the sound is created) may have very different characteristics by the time they travel to the marine mammal (where the sound is received).

The methods used to measure sound magnitude include pressure, energy, and intensity. For any acoustic wave, the measure of the pressure on the sound wave can be from zero-to-peak (zero to maximum pressure), peak-to-peak (maximum negative to maximum positive pressure), or a root-mean-squared (rms) value (average of the squared pressure over the duration of a pulse) (fig. 6–1). Sound Pressure Level (SPL) gives the sound pressure relative to a reference pressure, which for water is 1 micropascal (μPa). Because of the large dynamic range of sound pressures, the decibel unit (dB) quantifies pressures (relative to the reference pressure) on a logarithmic scale, so that the SPL of a sound in water using the rms value is given as 20log10(P/Pref), where Pref is 1 μPa and the units are dB re 1 μPa (rms). Sounds at the source typically are standardized to 1 m distance from the source and are given in units of dB re 1 μPa (rms) at 1 m. Sound Pressure Level using the rms approach is the current metric used in MMPA for establishing zones of safety for marine mammals.

Sound also can be characterized by energy, which integrates the pressure through a time window and is proportional to the time integral of pressure squared. Typically, 1 second is the standard for the time, and is referred to as a Sound Exposure Level (SEL), in units of dB re 1 μPa2s. Intensity measures the energy that passes through a unit area per unit time and also generally is derived from pressure squared. Sound Exposure Level is sometimes used to understand sound propagation for seismic arrays (Tolstoy and others, 2009).

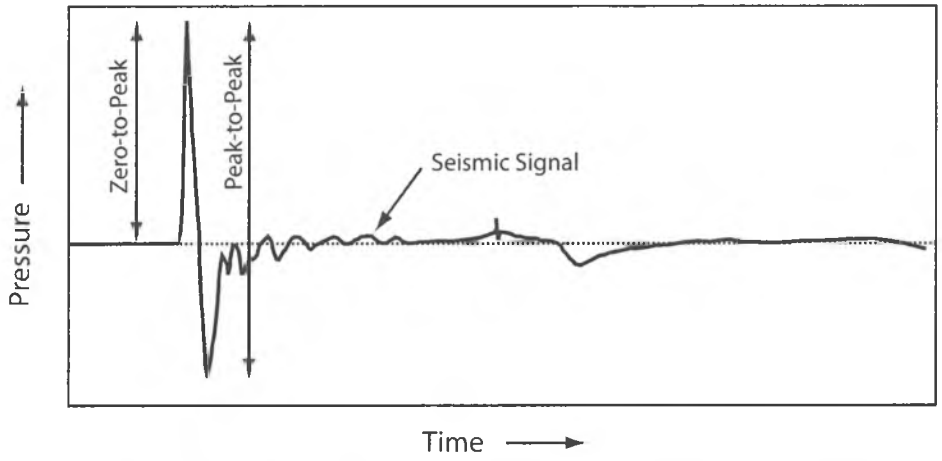

Figure 6–1. Example of a seismic sound signal showing how zero-to-peak and peak-to-peak pressure would be measured.

The use of the logarithmic scale can be confusing. For example, a doubling of pressure will add 6 dB to the SPL, whereas a doubling of intensity adds only 3 dB. For a sound pulse such as an airgun, where the pulse duration is less than 1 second, the SEL value will always be less than the SPL (rms) value. Further, the SPL (rms) will be less than SPL (zero-to-peak) and both will be less than SPL (peak-to-peak). Hence it is important to be rigorous in describing and measuring sound levels to specify SPL versus SEL and to identify whether SPL is for peak-to-peak, zero-to-peak, or rms. The media frequently quote dB estimates for measurements that do not specify the type of SPL or SEL measurement. Further, dB measurements in water use a reference of 1 μPa whereas for air the reference is 20 μPa, rendering comparisons between the two inappropriate. Imprecision in describing sound adds confusion and sometimes alarm to reasoned public discourse. Because sound also contains different frequency contents, the SPL of different sound sources in not necessarily additive (and, if additive, must be added using logarithmic, rather than linear, rules).

Airgun size is classified by its chamber volume. The way this volume is related to level of sound also is not linear. Excellent summaries describe how changes in source strength, operating pressure, and number of airguns in an array affect SPL measurements (Dragoset, 1990, 2000).

Although the current regulatory framework uses the SPL (rms) pressure measurement, some researchers have suggested that the energy metric, SEL, is more useful because total energy enables sounds of differing durations to be more readily compared (for example, Southall and others, 2007; Tolstoy and others, 2009). It perhaps may be most useful to use both. Extremely high but nearly instantaneous sound waves have low energy levels (because the energy is averaged over a much longer time frame than the duration of the pulse), but may still cause damage to auditory or other tissues. Additionally, cumulative energy contained in low-amplitude sounds may interfere with hearing after long exposures. As an example, one can imagine how a gunshot or firecracker going off near one's ear would affect hearing, and also imagine how working with constant background noise for a long period of time also might affect hearing.

Different animal species have different frequency sensitivities. Five functional hearing groups of marine mammals exist based on their presumed hearing frequency range (for example, Southall and others, 2007), which are summarized in table 6–2. Only four of these apply to the Arctic marine mammals of interest (the high-frequency cetaceans, such as harbor porpoise, which are only seasonally present in the Arctic in low abundance, are not among the subjects of this chapter). It is important to note that sound frequencies particularly greater than 1,000 Hz (1 kHz) attenuate rapidly in water.

A useful diagram summarizing the magnitude and frequency of different kinds of sounds found in the oceans is that created by Wenz (1962), which is still widely used (fig. 6–2).

Table 6–2. Arctic Outer Continental Shelf Marine Mammal Hearing Groups.

[Modified from Southall and others (2007) for the marine mammals of interest in this report. Hz, hertz; kHz, kilohertz]

Functional hearing group	Genera	Estimated auditory bandwidth
Low-frequency cetaceans	*Balaena, Eschrichtius*	7 Hz – 22 kHz
Mid-frequency cetaceans	*Delphinus*	150 Hz – 160 kHz
High-frequency cetaceans	(none)	200 Hz – 180 kHz
Pinnipeds in water	*Erignathus, Histriophoca, Pusa*	75 Hz – 75 kHz
Pinnipeds in air	(same as species in water)	75 Hz – 30 kHz

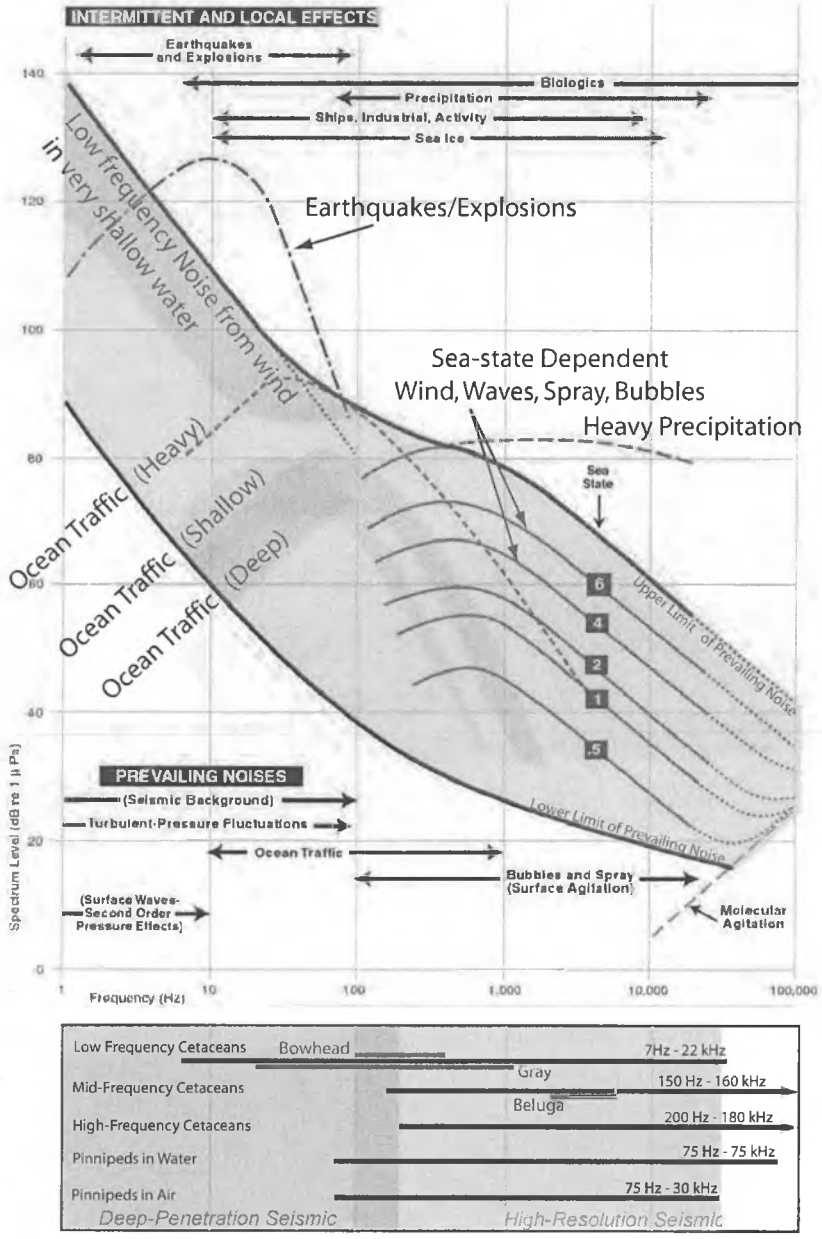

Figure 6–2. Upper: diagram showing pressure spectral density of marine ambient noise modified from Wenz (1962) and National Research Council (2003b). The gray shaded region gives the general band of ambient noise and the contained curves identify specific sources of sound contributing to the ambient noise. Lower: marine mammal hearing groups and their estimated auditory bandwidth (black lines) as defined by Southall and others (2007). Dominant bandwidth for selected whales (red lines) is from National Research Council (2000). Approximate frequency ranges for deep-penetration (blue) and high-resolution (green) seismic surveys are superimposed on the cetacean ranges.

Anthropogenic Sound Categories

For the purposes of understanding anthropogenic sound in the Arctic OCS, we use seven categories of sound. These categories discriminate among the source level, frequency (Hz), and temporal patterns of the sound. The source level is the SPL (rms) measured or estimated/modeled at 1 m from the source. The frequency is captured as a power spectrum that relates sound level and frequency. The temporal pattern of sound refers to its occurrence, as in transient (for example, explosion), continuous (for example, drilling), or pulsed (for example, seismic airguns). The seven categories are:

1. Deep-penetration seismic surveys

Deep-penetration, low-frequency seismic surveys are considered to be high-energy intermittent pulsed sounds, typically two-dimensional (2-D) regional surveys and three-dimensional (3-D) local surveys utilizing airgun arrays consisting of several large to many small airguns. The frequency level generally is from several to 100–250 Hz. The purpose of these surveys is to image geology at moderate to crustal depths for geologic framework and exploration purposes.

Statistics maintained by BOEMRE (See websites accessed April 30, 2011, at http://alaska.boemre.gov/re/permits/xpermits/arctic_charts.pdf, http://alaska.boemre.gov/re/permits/xpermits/arctic_table.pdf, and http://alaska.boemre.gov/fo/Geohazards/chukchi_hazard_surveys.mdb) show that deep-penetration surveys in the Beaufort and Chukchi regions for oil and gas exploration have been historically, and continue to be, the most plentiful types of surveys conducted. Since 1968, there have been 119 open-water exploration surveys in the Beaufort region and 48 in the Chukchi region. An additional 67 on-ice seismic surveys were conducted in the Beaufort region between 1970 and 2000. The peak in seismic permits for both areas occurred in the early to mid-1980s with a maximum of nine permits issued for marine 2-D geophysical surveys in the Beaufort region in 1984 and a maximum of six permits for similar work in the Chukchi region in 1985 (fig. 6–3). Recently (since 1994), there have been no 2-D surveys in the Beaufort region and only one in the Chukchi region (in 2006). This decrease in 2-D surveys contrasts with the growth of 3-D exploration surveys: since 1990, there have been ten 3-D surveys in the Beaufort region, but only three in the Chukchi region. The trends from these permits suggest that future oil and gas seismic exploration activity in the Beaufort and Chukchi regions is likely to be with 3-D surveys. Details about the surveys, such as time of year, lease block locations, and duration of surveys are available from BOEMRE. These BOEMRE statistics do not include seismic programs that might have occurred in Canada or Russia for oil and gas activities (for which the air gun sounds could propagate into U.S. waters). Nor do the BOEMRE statistics cover seismic activities conducted by U.S. or foreign research groups for non-petroleum related purposes (for example, 2005 NSF-funded seismic transect across the pole aboard the U.S. Coast Guard Cutter (USCGC) *Healy*, or the 2007–10 United Nations Convention on Law of the Sea (UNCLOS) work conducted aboard the Canadian icebreaker CGGS *Louis S. St-Laurent*). Hence these statistics are representative of the bulk of the seismic exploration work, but underestimate total seismic activities.

6.02. Finding: Despite the large number of seismic surveys conducted over time in the Beaufort and Chukchi Seas, an inventory/database of seismic sound sources used in the Arctic Ocean does not exist.

6.02. Recommendation: Such an inventory would provide standardized information about source arrays (for example, number of airguns, dimensions of arrays, frequencies, firing pressure), physical oceanographic conditions at the time of measurement, and timing and duration of surveys. Such a database could be used to evaluate multiple sound sources that a marine mammal might hear in space and time, and help validate models that estimate sound propagation. The database may ultimately reduce the need for expensive or redundant acoustic modeling and monitoring, especially in sensitive or biologically significant habitats as well as contribute to developing more effective mitigation strategies.

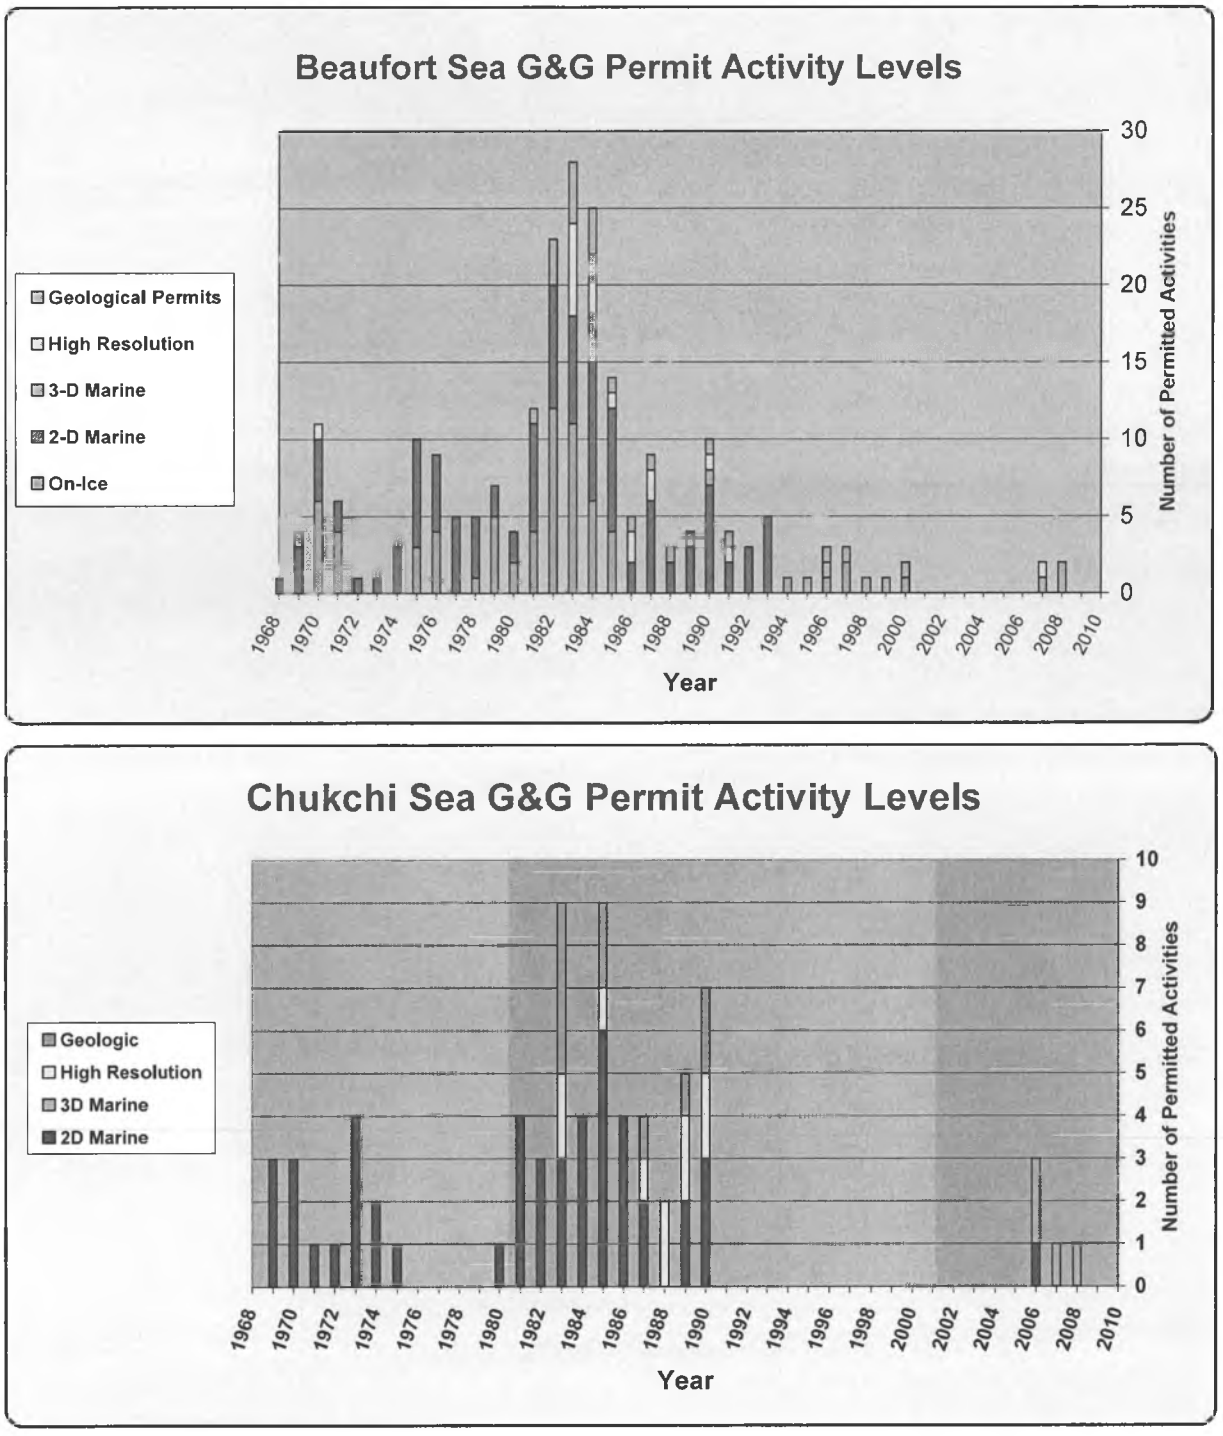

Figure 6–3. BOEMRE permitted exploration seismic activities in the Beaufort (upper) and Chukchi (lower) Seas since 1968. High-resolution seismic surveys done to address site-specific hazards related to drilling are not included in this chart. The peak number of seismic surveys occurred in the 1980s. Source: Bureau of Ocean Energy Management, Regulation and Enforcement, written commun., February 2011. G&G, geological and geophysical.

2. High-resolution seismic surveys

High-resolution seismic surveys are considered to be mid-to high-frequency, low-energy intermittent pulsed sound, typically used in shallow hazards surveys for siting drill holes (including strudel surveys to understand ice scour) or high-resolution surveys for understanding near-seafloor geologic evolution. The sources usually are not airgun arrays but consist of boomer, sparker, chirp, and individual (or arrays of several) small water guns or Generator-Injector airguns (GI-guns). The frequency range generally is from 100 Hz to several kilohertz.

High-resolution surveys related to oil and gas activities have occurred in the Beaufort Sea [see Minerals Management Service (2007) for permitted activities and see Horowitz (2002) for additional high-resolution surveys in the Beaufort Sea] and Chukchi Sea (see Minerals Management Service, 2007). These surveys are required to address safety and risk assessment prior to siting final drill locations. Hence, these kinds of surveys are expected to increase when drilling resumes in order to satisfy permitting requirements. Because of the generally lower energy and higher frequencies associated with these surveys, these surveys are often considered to be lower impact on marine mammals, although some studies are beginning to question this conclusion (for example, Southall and others, 2007).

The distinction between deep-penetration and high-resolution seismic categories separates both the frequency and energy levels of the different survey types. Figure 6–2 shows how the deep-penetration surveys overlap primarily with the low-frequency cetaceans (such as the bowhead and gray whales). The high-resolution surveys overlap primarily with the mid- and high-frequency cetaceans (such as the beluga whale). Figure 6–4 illustrates how the higher energy of the deep-penetration surveys results in significantly larger zones of mitigation under MMPA compared to high-resolution seismic surveys.

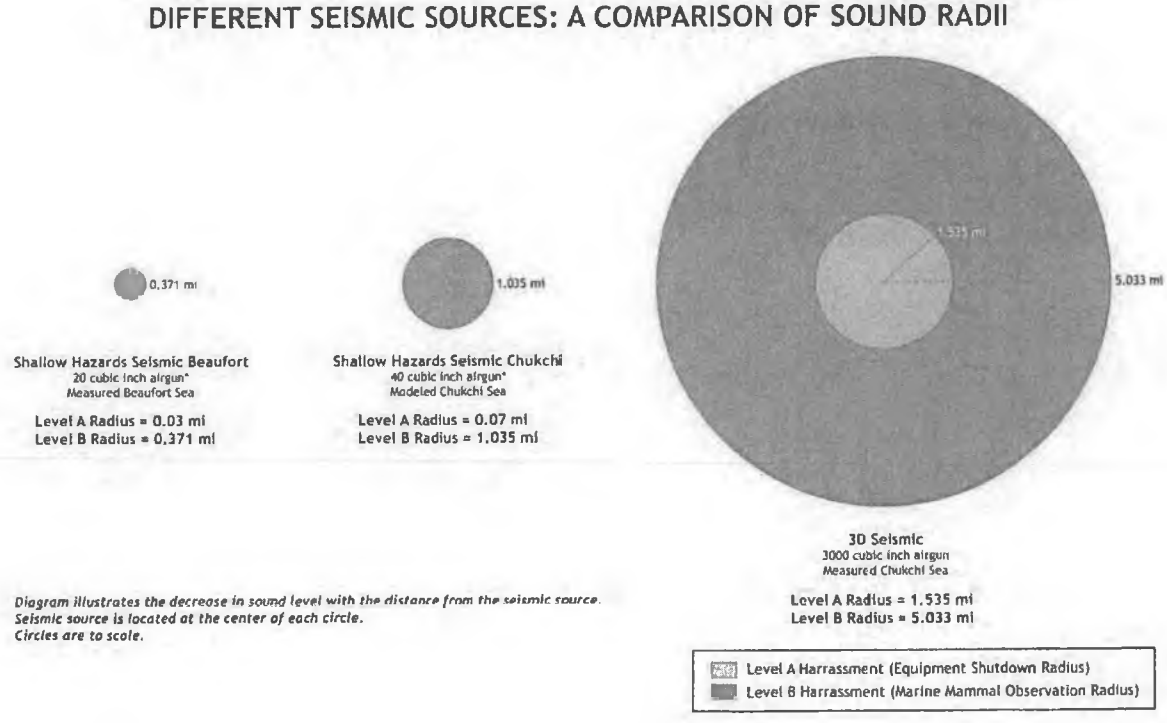

Figure 6–4. Comparison of zones of mitigation under MMPA for deep-penetration (right) and high-resolution seismic surveys (middle, left). Inner and outer circles are for Level A and B harassment, respectively. Source: Jana Lage, Bureau of Ocean Energy Management, Regulation and Enforcement, January 2011.

3. Drilling activities

Drilling activities generate continuous, generally low-energy sound at low frequencies (for example, less than several tens of hertz) that decay to ambient noise levels within 1 to several kilometers (Richardson and others, 1995). There are variations depending on type of drill rig (for example, gravel island versus semi-submersible) and type of drilling (for example, rotary versus hammering).

Drilling in the Arctic OCS has been limited to shelf-depth waters (generally less than 100 m water depth). Winter ice currently precludes the installation of year-round floating or semisubmersible drill rigs used in conventional open-water deep-water drilling operations. Benchmark noise studies of gravel-island and shallow-water caisson and semisubmersible drilling have been done for the Beaufort OCS around Prudhoe Bay (Greene, 1987; Richardson and others, 1995). Additional monitoring of the noise of drilling continues through the present (for example, with the BP Liberty gravel-island drilling reported in the last 3 years of NOAA/BOEMRE Arctic Ocean Open Water meetings). The data collected as part of monitoring are not publicly available, and the reports associated with these monitoring studies show images and analyses that are sometimes in peer-reviewed journals (for example, Blackwell and others, 2004a), but generally only available in gray literature.

4. Ships/Vessels

Ship and vessel noise is continuous and consists of a combination of frequencies that are both broadband (over a range of frequencies) and narrow band (tonal at specific frequencies). Ships are considered a major contributor to ocean noise at frequencies less than 500 Hz (National Research Council, 2005) with significant spatial variability associated with shipping lanes and ports. Levels and frequencies of sounds are dependent on vessel size, design, and mode of propulsion. Smaller vessels with small propellers and high revolutions per minute generate noise at higher frequencies. There is an abundant literature on shipping noise (for example, National Research Council, 2005).

Although there are currently no commercial shipping lanes in the Arctic OCS, the possibility exists for these routes to develop as summer ice retreats or disappears with climate warming, as well as for large cruise vessels to bring tourists to the Beaufort and Chukchi Seas. Currently, the commercial ship traffic occurs with barges in the near shore in open water during the summer, primarily to re-supply the Native community with bulk supplies. Gray literature exists for the sounds made by individual ships participating in oil and gas activities in the Arctic OCS as a result of permits issued under MMPA that generally require measurements of ship noise prior to the start of exploration activities. These data are not readily available digitally, although reports written as a result of the oil and gas activity sometimes include summaries of the noise studies.

6.03. Finding: As in Finding 6.02 for seismic survey-generated noise, there is a similar lack of an organized inventory/database for the noise generated by vessel types that presently frequent the Arctic Ocean, or may do so in the future with changing ice conditions.

6.03. Recommendation: An inventory and synthesis of vessel noise for vessels used in the Arctic Ocean will enable researchers to understand the contributions of potential new ship traffic to ambient background levels of noise in the Arctic. This inventory/database should contain standardized information about vessel noise, duration, time of measurement, and location. Most industry exploration activities measure ship noise prior to commencing surveying as part of the permitting process.

5. Icebreaking

Icebreaking is a special category of ship and vessel noise that is associated with higher levels of sound because of the additional power required for a vessel to break thin ice continuously or thicker ice through backing and ramming.

Icebreaking also is unique to ice-covered regions such as the Arctic. Some of the earliest studies on the sound of icebreaking were done in the Arctic (for example, Richardson and others, 1995, and references therein) and these studies continue to be cited extensively in the absence of more recent publications. Roth and Schmidt (2010) presents interpretations of the noise of icebreaking for USCGC *Healy* during a 2008 cruise and compares SPLs at 5/10 ice coverage and greater. The noise of continuous icebreaking exceeded the noise of backing and ramming by about 5 dB. The inclusion of icebreaking as potential impact for Level B marine mammal harassment under MMPA is new in 2010 (Haley and others, 2010).

6.04. Finding: Icebreakers, an important subset of vessels used in the Arctic from a noise and marine mammal encounter perspective, are highlighted in addition to the more general vessel topic of Finding 6.03. There are essentially no data relating the noise of icebreaking to the type of icebreaker, and the character of the ice (for example, percent coverage, age of ice, thickness of ice). Preliminary data included in Haley and others (2010) suggest that the noise from icebreaking is not of higher amplitude than a modest seismic array. But, the paucity of data on icebreaker-generated noise is particularly critical because of sea ice's importance as habitat for many marine mammals. It is difficult at present, if not impossible, to know how to define "takes" from icebreaking or how to predict its impact on marine mammals.

6.04. Recommendation: As in Recommendations 6.02 and 6.03, the development of a standardized inventory/database would greatly facilitate the accumulation of information required to better understand the characteristics of icebreaker-generated noise under different ice, oceanographic, and operating conditions.

6. Construction

Construction for the purposes of this report is considered to include localized relatively brief duration or one-time noise associated with, for example, siting drill rigs, installing pipelines, developing shore-based infrastructure such as docks and piers, building ice roads on sea ice, and so on. Similar to drilling activities, the noise associated with construction generally is at the lower frequencies (less than several hundred hertz) and attenuates relatively close to the location of construction. Unlike drilling, the noise generally is short-term for the duration of the construction project only.

For the Arctic OCS, shore-fast and winter sea ice preclude year-round floating or surface structures. Hence the noise of construction has been limited to near-shore (Beaufort) and shallow water (Chukchi) seasonal activities. A large literature exists on the sounds of construction related to developing the Liberty and Northstar prospects in the Beaufort Sea (for example, Richardson and others, 1995). Dredging is not yet an activity conducted along the North Slope (Beaufort/Chukchi) shorelines.

7. Aircraft overflight

Aircraft (including helicopters and fixed-wing aircraft) are a special category of noise because of (a) the potential transient nature of the noise, (b) the complications of relating source level and propagation paths through air and water, and (c) the potential impacts to marine mammals (seals, walrus, and polar bear) that spend considerable time out of the water. It is only for a relatively narrow angular cone beneath the aircraft (about 13° for calm water, Richardson and others, 1995) that the noise of the aircraft penetrates into the water. At larger angles, the sound is effectively reflected at the sea surface. Hence, the height and speed of the aircraft, in addition to the noise it generates, affect how much of the ocean surface will be insonified. Moreover, a persistent challenge in interpreting observations of marine mammal behavior associated with the presence of aircraft is to know whether the aircraft sound or the visual presence of the aircraft has triggered the disturbance.

In the Arctic OCS, aircraft are used in offshore oil and gas activities as well as in conducting monitoring and population assessments of marine mammals (for example, Bowhead Whale Aerial Survey Program, BWASP). Shell also has proposed using drones to monitor for marine mammals near seismic operations (A. Macrander, Shell Exploration and Production, oral commun., March 2010) to augment visual monitoring in areas far offshore (such as the Chukchi) where manned fixed-wing aircraft monitoring is impractical or unsafe.

6.05. Finding: Aircraft represent another potential sound source that must be considered along with seismic (Finding 6.02), vessel (Finding 6.03), and icebreaker (Finding 6.04) sources. Very little information exists that quantifies aircraft noise as a function of aircraft type and approach geometry.

6.05. Recommendation: Information that quantifies aircraft noise as a function of aircraft type and approach geometry would help to understand the responses of several species of Arctic OCS marine mammals to overflight.

8. Other Considerations

To completely understand the contribution and impacts of anthropogenic noise to the environment, knowledge of the levels and spatial-temporal variability of background (ambient, non-anthropogenic) noise is essential, as well as which anthropogenic sounds occur simultaneously. The magnitude of ambient sound gives context to understanding increased sound levels from anthropogenic sources. However, it is important to correctly characterize the sound, because not all these sounds are additive when occurring together, owing to the different frequencies, shapes, and amplitudes of the different sources of sound.

6.06. Finding: The overall ambient noise budgets of the Arctic, particularly how they vary temporally (for example, seasonally) and spatially (for example, shallow versus deep water) are not well known. Very little data exist to inventory the seasonal and spatial levels of ambient noise in the Beaufort and Chukchi Seas. Some annual measurements in specific locations are beginning to be done and seasonal measurements are recorded as by-recordings of listening to and locating whale calls before, during, and after seismic surveys in the Beaufort and Chukchi Seas (for example, Blackwell and others, 2007; Kosiara and others, 2008).

6.06. Recommendation: A time-series database of ambient ocean noise for the Arctic will be essential for understanding the changes to ambient noise created through climate warming and seasonal reductions in sea ice so that the distinction of impacts between anthropogenic and natural sources on marine mammals can be made.

A little-studied factor that also will affect sound measurements in the oceans is ocean acidification, the process by which the oceans become more acidic because of the anthropogenic emissions of carbon dioxide (for example, Ilyina and others, 2009). Because propagation of sound in the oceans is affected by the dissolved chemical constituents, an increase in ocean acidity will decrease the absorbtion of sound, that is, increase the propagation of sound. According to models, this affect may be greatest in high latitudes in the frequency ranges of 100 Hz to 10 kHz, or exactly in the range that encompasses both deep-penetration and high-frequency seismic surveys (Ilyina and others, 2009).

Potential Effects of Sound Exposure

A range of effects may result from exposure of marine mammals to anthropogenic sound, ranging from no observable effect to physical injury or, in the extreme, death. As with people, the reactions of marine mammals can depend on factors such as species, individual, age, sex, prior experience with the sound, activity at the time of the sound, and behavioral state. When observing animals in the natural environment, external non-auditory stimuli also may affect reactions. In this section, we describe some of the potential effects of exposure to anthropogenic sound sources, which may or may not result in observable or measurable behavioral changes.

1. No Observable Effect

Marine mammals have been observed in close proximity to loud sound sources associated with oil and gas activities (for example, Richardson and others, 1995). They could be unaffected by the sound, they could be tolerating the sound because critical resources were in the area (food, mates, open water, haulout sites, and so on), or they could be deaf. The individuals could be unaffected because their auditory systems are insensitive to the frequency-intensity combinations of the sound. Alternatively, the individuals may be able to detect the sound, and may have reacted during their first exposures, but over time have learned that the sound is of no consequence and thus have become habituated, evidence of which is reduced or absent response during subsequent exposures.

There are documented cases of apparent tolerance of marine mammals to noise, which also demonstrate much variability. For example, bowhead whales tolerated an increase in 40 dB in seismic survey noise when feeding in summer as opposed to during the fall migration (Richardson and others, 1995, 1999).

2. Sensitization

Sensitization occurs when an individual associates a specific sound with a specific outcome that alters the animal's behavior. Evidence of sensitization is observed in animals that change their behavior when they receive sound levels that are far below levels associated with auditory interference or injury. For example, seals that survive hunting or harassment (for example, by humans, polar bears, or killer whales) likely will take the appropriate actions as soon as they detect sounds made by the hunters in the future.

3. Avoidance/Displacement

Marine mammals may avoid sound sources, or be displaced from areas associated with the sound. This behavior has been observed in bowhead whales from underwater acoustic monitoring, which has shown that the calls of bowhead whales deflect seaward away from the sound of airguns during nearshore seismic surveys (Blackwell and others, 2007). An uncertainty associated with this deflection behavior is whether all whales exhibited the displacement or only those whales making calls. When whales cease calling in the presence of nearby seismic signals, this is a variant on avoidance and displacement (for example, Blackwell and others, 2010).

4. Masking

Masking is the decreased ability to detect one sound due to the presence of another sound. Fletcher (1940) suggested that masking of a signal is especially pronounced if the frequency spectrum of the masking noise overlaps within a critical band around the frequency of the signal. Most anthropogenic underwater activities produce sound at frequencies below 1 kHz, which is within the frequency band used for communication signals of baleen whales, and some toothed whales, such as belugas (for example, Clark and others, 2009). It may not be possible to distinguish hearing loss (that is, an animal that fails to detect a signal because of reduced hearing) from masking (that is, an animal with a normally functioning auditory system that fails to detect a signal because it is masked by a louder sound of similar frequency).

An increase in ambient ocean noise (for example, by increased shipping in a region) can contribute to masking. If marine mammal navigation or communication signals are masked by anthropogenic noise, there will be obvious implications for population cohesion and other social interactions. However, it is important to note that masking has never been conclusively demonstrated in free-ranging marine mammals, only implied by observations of animals changing their calling in the presence of anthropogenic sound.

5. Auditory Threshold Shift

Exposure to loud or repetitive sounds may degrade the individual's ability to hear, with effects ranging from reversible temporary threshold shifts (TTS) to permanent reduction in thresholds (PTS) at narrow or broad frequencies (Kryter, 1994). TTS is recoverable and is considered to result from the temporary, noninjurious distortion of hearing-related tissues. An animal that experiences a TTS suffers no injury to its auditory system but temporarily may not perceive some sounds due to the reduction in sensitivity. In contrast, PTS results from the nonrecoverable destruction of tissues within the auditory system and is considered an injury in the U.S. regulatory environment (see summary in Southall and others, 2007). Recent anatomical and behavioral studies suggest that cetaceans may be more resistant than many land mammals to TTS, having evolved in a relatively high noise environment. Data suggest, however, that, like humans, cetaceans suffer from hearing loss as a result of increasing age (Ketten, 1997).

6. Physiological Stress Responses

Although several reviews have entertained the possibility that noise induces a physiological stress response in marine mammals, there have been few studies. Romano and others (2004) exposed a captive beluga whale to sounds from a seismic water gun and measured various hormones in the blood, including cortisol, before and after exposure. They measured changes that were considered detrimental. These changes increased with increasing sound levels. Thomas and others (1990), however, did not find elevated stress hormone levels in the blood after playbacks of oil drilling platform noise to captive belugas. Because of the inherent difficulty, if not impossibility, of taking frequent tissue or blood samples from live wild animals, conclusions about physiological stress responses will remain the purview of studies of captive animals.

7. Physical Injury

PTS is considered an injury and can occur either after long exposure to a sound (for example, Richardson and others, 1995) or from instantaneous exposure to very high sound levels, such as an explosion. There is some speculation that anthropogenic sound has the ability to induce other injurious effects, such as debilitating bubble formation or tissue damage in deep- or long-diving species (Houser and others, 2001). While evidence of tissue damage (including auditory structures) has been reported, this has been associated with exposure to extremely loud sounds associated with use of explosives or military training and testing (Jepson and others, 2003; National Research Council, 2005). To the best of our knowledge, this has little relevance to the sound sources and levels and environmental acoustics associated with OCS oil and gas exploration and production.

8. Cascading Effects

Vessel noise, in addition to potentially impacting marine mammals, produces sounds in the hearing range of fish (Amoser and others, 2004). If anthropogenic sound affects the distribution of fish, it could therefore impact marine

mammals that rely on those fish. Vessels (that is, trawlers, ferries, small boats) also can alter behavior in fish (for example, induce avoidance, alter swimming speed and direction, and alter schooling behavior), similar to marine mammals (for example, Engås and others, 1995).

Although the above list produces convenient categories for describing the possible effects of sound on marine mammals, in actuality, linking an effect to an observation and an explanation is much more difficult. For example, if a marine mammal tolerates a sound, it may represent acclimation or habituation of some kind, but it also may represent an unrelenting need, for example, for feeding or reproduction, to remain in a particular location despite exposure to a potentially damaging sound. Alternatively, the sound may be harmless. Science, however, is based on observations, and in the absence of observable changes, it is risky to attempt to speculate about contributions of potential invisible factors.

6.07. Finding: Substantial challenges exist to confidently interpret the magnitude and significance of the potential effects of anthropogenic sound on marine mammals. Limitations in our understanding affect the confidence that many entities expressed during the USGS OCS Team expert consultations (see appendix A). The topic of the impact of anthropogenic sound on marine mammals remains a key topic of concern.

6.07. Recommendation: Continued or new attention to the following topics could significantly improve the assessment and potential mitigation of human-generated noise effects on marine mammals of concern. Some of these challenges are:

1. Attempting to distinguish between transient or ephemeral behavioral effects of sound versus those that are more meaningful to survival or reproduction. An example would be walruses waking up and raising their heads when they hear a sound, as compared to injury or mortality caused by the same walruses stampeding into the water when they hear a sound. A second example would be the movement of animals away from a sound source—is displacement fractional relative to the animals' normal movements, or is it substantial, and how long does it persist?
2. Using observations of individual animals to make inferences about possible implications for populations. In general, the body of available scientific information supports the potential for near-term reaction of individuals to various forms of anthropogenic sound sources, but long-term impacts at the population level are not well understood.
3. Using one set of observations for predicting reactions when the interaction parameters are different. The same sounds may elicit different responses at different times of year or in different locations associated with different types of activity (for example, migration, feeding, reproduction, sheltering).
4. The degree to which context of a sound influences a reaction. In some instances, animals of a given species may occupy locations with substantial types of some noise (for example, pipe-driving) but avoid other locations where the anthropogenic sound levels are much lower. For example, ringed seals may forage nearby active seismic surveys, but escape reactions will be elicited when they detect faint sounds of polar bears or subsistence hunting boats.
5. The degree to which we can discriminate between the effects of sound, other aspects of human activity, and environment variation, especially for understanding behavior of animals in the wild. An animal that is observed in close proximity to a loud sound source could be unaffected by the sound, it could be tolerating the sound because critical resources were in the area (for example, food, mates, open water, haulout sites), or it could be deaf. The observed behavior is the sum of the external environmental stimuli detected by the animal, behavior of its peers, behavior of other species, plus the animal's physiological state. Further, if the source of sound has been close enough to the animal that it was visible and perhaps detectable by other sensory cues, such as odor or vibration, the animal could be reacting to these other cues. Unless research demonstrates that individuals are exposed only to sound, the precautionary interpretation is that the sound can be associated with the behavior rather than that the sound explains the behavior.
6. Quantifying secondary or cumulative effects of sound on population persistence. While sound may alter the behavior of individual animals, other factors also may affect outcomes (for example if sound caused prey abundance or availability to change). Cumulative effects also may occur but are difficult to quantify (for example, if physiological stress caused by sound exposure combines with stress induced by environmental contaminants to affect a population). These are difficult, if not impossible, measurements to make on wild animals.

Monitoring and Mitigation

Both the ESA and the MMPA require monitoring and mitigation measures to protect marine mammals from potential harm caused by exposure to anthropogenic sound sources. The MMPA places a moratorium on "takes" of marine mammals, in which "take" means "to hunt, harass, capture or kill" (from National Marine Fisheries Service, 2008b). Exceptions exist, for example, for subsistence hunting, and exceptions also can be granted for example, for incidental takes associated with fishing. For permitting, harassment for MMPA is further defined as level A (in which the harassment has the potential to cause death or injury) or level B (in which the harassment has the potential to disturb the animal by disrupting its behavior) (National Marine Fisheries Services, 2009b).

The USGS OCS Team's expert consultations (appendix A) raised concerns about both monitoring and mitigation strategies, particularly by the Marine Mammal Commission and the Alaskan Native Community. Protected species observers are required participants on many oil and gas exploration and development activities to monitor marine mammals and determine when mitigation strategies must be implemented. Data recorded by these observers are inconsistent. This inconsistency limits how these datasets can be integrated and merged for a more complete picture of marine mammal behavior in the presence of anthropogenic sound. As technology advances, the requirements for monitoring also have evolved, so that deficiencies in visual observations (for example, only possible for daylight hours) can be augmented by acoustic observations (for example, passive acoustic monitoring). Despite the array of tools available for monitoring (ship observations, aerial observations, acoustic monitoring, infrared detection, and so on), no single monitoring strategy gives a complete picture of the marine mammal presence. Hence monitoring contains inherent uncertainty about missing animals, which raises questions about how effective monitoring is for ensuring whether "takes" occur.

Mitigation also is problematic. First, the objectives of mitigation (for example, to avoid hearing impairment or to minimize disturbance) may require multiple criteria. Yet, a single, simple criterion is the easiest to implement. Second, some mitigation measures significantly restrict human activities with little evidence of benefit to marine mammals. Third, a standard mitigation strategy is applied broadly (for example, one for cetaceans, another for pinnipeds). Yet, the hearing ranges and communication frequencies differ for different species, raising questions whether mitigations strategies should be specific to a species (for example, Southall and others, 2007). Fourth, practical decisions about regulatory and mitigation issues are being made based on best available, but incomplete, knowledge which raises questions about how defensible these decisions are. And, finally, many concerns and questions raised by managers require integration across a range of temporal and spatial scales, involve understanding the ecosystem in which the marine mammals live, and now commonly require evaluating species responses to climate change. Regulators and scientists are in agreement that additional data are needed for each marine mammal species, such as baseline data on current abundance, seasonal distribution, movements, population dynamics, and other basic biological information.

Bowhead Whale (*Balaena mysticetus*)

Of the five recognized stocks of bowhead whales, the Bering-Chukchi-Beaufort (BCB) stock frequents the Alaska Arctic coastal area. As part of its annual migration, the bowhead whale passes from the Bering Sea to the Chukchi and Beaufort Seas en route to its summer grounds in the Canadian Arctic and returns to the northern Bering Sea in the autumn (Moore and Reeves, 1993; Moore and others, 2000). Its migration routes along the Alaska coastline and in the Chukchi Sea (fig. 6–5) overlap with the current areas of leasing and oil and gas exploration and production.

Of the baleen whales, the U.S. bowhead is among the most studied. The convergence of three events served to promote research about the bowhead whale. First was the recognized depletion of the bowhead population, initially in the early 1900s when it was given protected status by the International Convention for the Regulation of Whaling and later when the bowhead was listed as endangered under the ESA of 1973 and further protected by MMPA. Second was the controversy accompanying the proposed ban on subsistence whaling by the International Whaling Commission in 1977, which led to negotiation of a reduced subsistence harvest to be accompanied by expanded research about the bowhead. Finally, the mid-1970s initiated the first oil and gas activities in the Arctic OCS for which research into the impacts of oil and gas activities on the bowhead whale was required under ESA and MMPA. Consequently, the late 1970s and early 1980s were a time of many observations and publications about BCB bowhead whales, especially as they reacted to anthropogenic activities (for example, Richardson and others, 1986, 1987). These early studies were followed by seminal syntheses in the 1990s (for example, Richardson and others, 1995) and served to raise awareness more broadly of marine mammal and ocean sound issues (for example, National Research Council, 1994). As mentioned earlier, the bowhead whale is still listed as endangered under ESA. The Native community participates in setting hunting quotas and bowhead management through the Alaska Eskimo Whaling Commission (2007, website accessed April 30, 2011, at http://www.alaska-aewc.com/aboutus.asp).

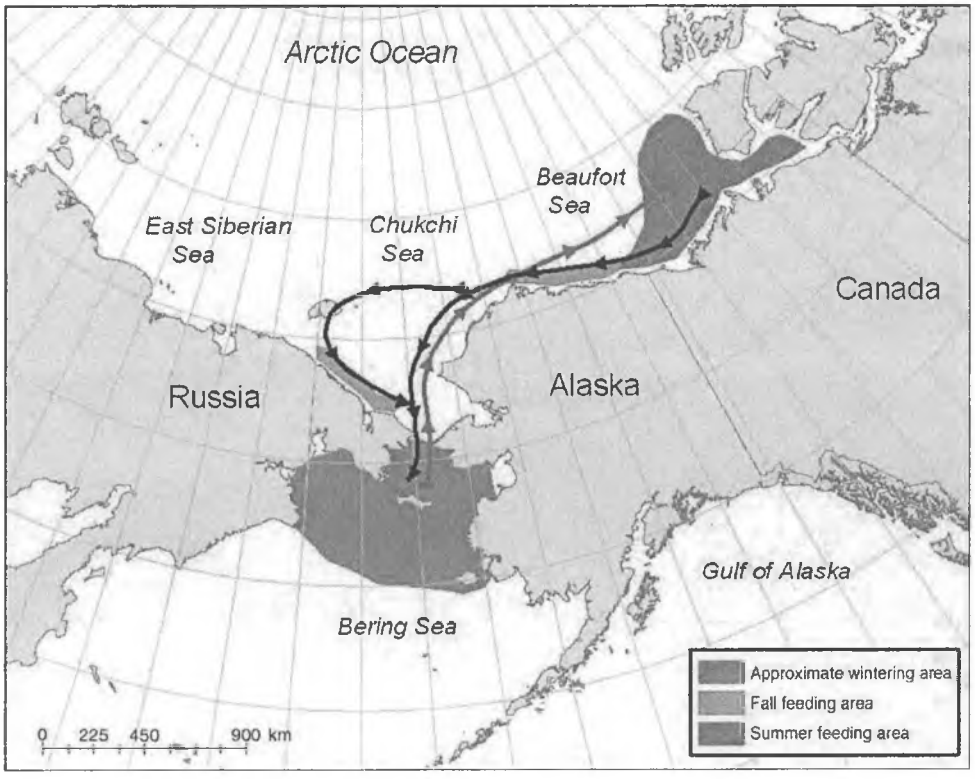

Figure 6–5. Seasonal occurrences of the Bowhead whale in winter (blue), summer (purple), and fall (green) migration feeding areas, together with general migration paths (arrows). From Moore and Laidre (2006).

Many of these early studies combined observations of bowhead behavior with anthropogenic noise, for example seismic surveys (Fraker and others, 1985; Richardson and others, 1986), ship movement (LGL Ecological Research Associates, Inc., 1982), drilling and dredging (Richardson and others, 1987, 1990), icebreaking (Richardson and others, 1995), and aircraft noise (Richardson and others, 1985). Details of these studies identify sound levels, whale distances from the sound sources, context of whale activities where available (for example, feeding, migrating), and behavioral changes. These studies also revealed the general vocalization frequencies of bowhead whales (100–400 Hz dominant, 25–3,500 Hz range), calling patterns, and loudness (for example, Ljungblad and others, 1982; Clark and Johnson, 1984; Würsig and others, 1989; Würsig and Clark, 1993), although the age, sex, and activity associated with the individuals making the sounds were largely unknown. Missing from these early studies is whether the observed behaviors and (or) behavior changes are biologically meaningful and affect the survival of either the individual or the bowhead population. The BCB bowhead population, however, is estimated at about 9,400 and is increasing at about 3 per year (Allen and Angliss, 2010).

Since the mid-1990s, both observational data and new kinds of studies have focused on understanding the habitat, behavior, and distribution of BCB bowhead whales, both in relation to anthropogenic noise and as baseline data to help understand the life histories of the species. One of the longest term monitoring programs is the Bowhead Whale Aerial Survey Project (BWASP; Bureau of Ocean Energy Management, Regulation and Enforcement, 2011) begun in 1979 and now a multi-agency effort to understand the distribution of whales during the summer, open-water months. A parallel effort, the Chukchi Offshore Monitoring in Drilling Area (COMIDA), began in 2008. One objective of this effort was to study the distribution of whales during the summer, open-water months in the Chukchi Sea Planning Area, a resumption of similar surveys that were conducted for many years between 1979 and 1991. The Bowhead Whale Feeding Ecology Study (BOWFEST) is a multiyear and multi-organization collaborative study integrating aerial surveys, physical oceanography, acoustic monitoring, local traditional knowledge, and ecosystem analysis to understand the late summer distribution of bowhead whales and sources of food in the vicinity of Barrow, Alaska (for example, Ashjian and others, 2010; Moore and others, 2010). The aerial surveys also can be used to study other topics, such as the relationship

between the ice edge and location of migration (Treacy, 2002; Treacy and others, 2006). Researchers are conducting long-term (multi-year) deployments of acoustic buoys to record ambient ocean noise and build baseline time series datasets of ambient ocean noise, at least for the few locations where the buoys are located (Scripps Whale Acoustic Lab, 2007). Most of these long-term and new-generation studies are funded to collect data for better understanding the impact of petroleum-related activities on the bowhead whale.

A significant database of bowhead whale vocalizations exists as a result of BOEMRE research (for example, Heimlich and others, 2010) and both BP and Shell drilling and seismic activities in the Beaufort Sea (for example, Blackwell and others, 2007). The BOEMRE research has utilized long-term buoy deployments as part of BOWFEST. BP has utilized Directional Autonomous Seafloor Acoustic Recorders (DASARs) to localize and record bowhead whale calls around the Northstar production facility on a gravel island offshore Prudhoe Bay. This monitoring has occurred since the facility began production in 2000. Shell also has funded acquisition of acoustic data from multiple arrays of DASARs on the Beaufort Shelf as part of its monitoring and mitigation strategy for its seismic exploration program (for example, Thode and others, 2008). DASARs have been deployed in multiple years for more than 50 days in open-water conditions with the intention of being able to conduct statistical analyses of whale vocalizations before, during, and after seismic surveys (for example, Mathias and others, 2008). Despite shorter peer-reviewed publications interpreting the results of these studies, these databases of vocalizations generally are proprietary and the substantive reports associated with full analysis reside in industry archives that are not routinely accessible by the public. These DASAR records also have been used to investigate long-range sound propagation under the ice and in open water north of Alaska (Thode and others, 2010).

Perhaps the greatest challenge in observations of any marine mammal, including the bowhead, is that of visual observations (such as with BWASP) can miss animals that are submerged or hidden, and acoustic monitoring (such as with DASARs) misses animals that are not vocalizing. Adding a new dimension to understanding the behavior and distribution of bowhead whales is a tagging program that began in 2006, utilizing Native community whaling captains and scientists working together to tag bowheads in the Barrow (AK) and Tuktoyaktuk (Canada) areas. Satellite tracking of individual whales has provided information on dive behavior, movement and use of habitat (Alaska Department of Fish and Game, 2011). Integrating these observations with the details of seismic (or other anthropogenic) noise is not always rigorous because the details of the seismic (or other anthropogenic) signals are not always publicized or known other than in a general sense.

For the seven noise categories, we discuss observations of bowhead behavior for all but the seismic low-energy category. In the summers of 1980–84, general activities of bowheads exposed to underwater pulses from seismic vessels 6–99 km away were observed (Richardson and others, 1986). Activities were indistinguishable from those without seismic noise; there was no detectable avoidance. In a test involving a seismic vessel (30 airguns, source level 248 dB re: 1 μPa, closest point of approach = 1.5 km), bowheads began to orient away when the airgun array began to fire 7.5 km away. However, some whales continued apparent near-bottom feeding until the vessel was 3 km away. In general, bowheads exhibit avoidance reactions when they receive seismic pulses stronger than about 160 dB re: 1 μPa. Evidence of reactions to lower received levels remains inconclusive.

Playback studies have found that most bowhead whales avoided drillship or dredging noise with broad-band frequency range (20–1,000 Hz) when received levels were around 115 dB re 1μPa, levels that could occur 3–11 km from typical drilling and dredging vessels (Richardson and others, 1990). This equates to a response threshold of about 110 dB re 1μPa in the 1/3-octave band where industrial noise is most prominent. Whales may be observed in locations with higher noise levels, possibly because alternative habitat is not available (Richardson and Greene, 1993).

Bowheads reacted to boats or small ships in two main ways. When boats were nearby, whales altered their surfacing and diving patterns by decreasing the mean time at the surface and mean dive duration. When boats closed to within 3 km, the whales, in addition to the above responses, swam rapidly away from the boat and scattered (LGL Ecological Research Associates, Inc., 1982). In contrast, bowheads were sighted as close as 6 km from a seismic ship firing 12 large sleeve exploders. Surfacing and respiration behavior was similar to that without seismic noise.

Bowhead whales were less responsive to passing aircraft when actively engaged in feeding, social activities, or mating, than when resting (Richardson and others, 1995). Opportunistic observations of behavioral responses of bowhead whales to a helicopter and fixed-wing aircraft suggested that the helicopter elicited only few responses, and most of those occurred when the helicopter was at altitudes equal to or less than 150 m and lateral distances equal to or less than 250 m. For the fixed-wing aircraft, very few bowheads were observed to react, and of those, most reactions occurred when the fixed-wing aircraft was at altitudes equal to or less than 182 m and lateral distances equal to or less than 250 m. Most observations of aircraft disturbance have been made from aircraft creating the disturbance, greatly limiting what can be observed, and precluding comparison of behavior before, during, and after disturbance.

In many of these studies, conclusions often have qualifications, for example, of bowhead deflection in one observation but not in another. These studies have raised the importance of understanding context of the whale activity at the time of the observation. Limited visual or acoustic observations of wild animals or of small sample sizes emphasize the difficulty of generalizing from specific animals in specific conditions to conclusions about the potential effects on the population. As a whole, there are essentially no observations about physical injury or quantitative indicators of stress responses, because of the difficulty of making these measurements on wild animals. Moreover, although there are exceptions, physiological measures of stress rarely point to a single causal factor and thus typically are better indices of overall health of the habitat in which the population lives.

6.08. Finding: There are many observations and databases related to bowhead whales, but no major integration or synthesis, especially for linkages to anthropogenic noise.

6.08. Recommendation: A synthesis of existing databases on bowhead population abundance and structure with databases giving sources and levels of anthropogenic noise would provide a comprehensive framework for analyzing how sounds impact the whales. This would presumably require public access to the many databases that are within government and industry purview for rigorous integration. Particularly illustrative will be integrating observations from tagged animals to overall activities.

For the first time in 2010, NOAA, together with BOEMRE conducted a peer-review analysis of applications for oil-and-gas-related activities in the Beaufort and Chukchi OCS areas, and has publicly released the summary of their findings (National Marine Fisheries Service, 2010e). One of the recommendations is to consider sound from an ecosystem perspective. They recommend transitioning away from using a single metric of acoustic exposure (that is, sound pressure level) to measure the potential effects of anthropogenic sound on marine mammals; and to integrate single-criteria mitigation strategies (the practical approach) with comprehensive assessment. Additional recommendations for improving aerial surveys, near-field and far-field visual monitoring, and collecting routine baseline biological information were included. This peer-review panel integrated scientists, regulators, and members of the Native community.

For all that is known about the BCB bowhead whale and behavior in the presence of anthropogenic sounds, relatively little is known about long-term trends or the biological significance of these observations. During the Incidental Harassment Authorization permitting process for seismic surveys, NOAA receives comments from the Native community, non-governmental organizations, and the Marine Mammal Commission (among others) that tend to consistently cluster into categories:

6.09. Finding: Although research is ongoing, the understanding of essential spatial and temporal habitat needs of the bowhead whale, particularly the oceanographic parameters that most influence foraging, breeding, raising young, and migrating is not yet sufficient to confidently determine the times and places where whales might be most impacted by anthropogenic sounds.

6.09. Recommendation: Understanding the essential spatial and temporal habitat needs for the bowhead whale (for example, Ashjian and others, 2010) needs to include those areas where the introduction of anthropogenic sounds might significantly disrupt the whale at key parts of its life cycle. This knowledge base should incorporate local traditional knowledge of bowhead whales (and other marine mammals) and their habitat contributed by the Native community.

(a) More baseline data are needed to understand behavior when there are no seismic surveys;

(b) More verification of sound source levels is required;

(c) More holistic monitoring strategies that integrate visual, acoustic, and other observations are needed; and

(d) More precautionary approaches to mitigation and defining the radii of safety zones are warranted.

6.10. Finding: Much scientific attention focuses on understanding the cumulative impacts of anthropogenic sounds at the population demographic level for marine mammals, in large part because of regulatory requirements. However, the USGS OCS Team heard often in our expert consultations that how noise affects individual behaviors, short of any health effect, is of great importance to Native communities because of concerns of impacts on potential hunting success of the subsistence community (see appendix A). For example, if the impact means a whale deflects offshore it then is unavailable for subsistence use.

6.10. Recommendation: Behavioral alterations are important factors that need to be understood and monitored to ensure effective mitigation during the hunting seasons to minimize impacts to subsistence hunting. This issue would benefit from enhanced integration of industry and agency acoustical monitoring network data (whale vocalizations), satellite telemetry data of whale movements, local traditional knowledge observations, and application of new statistical approaches to assess behavioral responses (for example, Blackwell and others, 2010) as a framework to better judge under what conditions whales may behaviorally respond to (for example, avoid) noise sources.

Beluga Whale (*Delphinapterus leucas*)

The Beluga, or white, whale has long been known to be a highly vocal species (for example, Schevill and Lawrence, 1949) and carries the nickname of canary of the sea. Using sound, particularly for echolocation, is a trademark of this species (Au and others, 1985, 1987).

Beluga whales are managed as two distinct populations in the Arctic OCS: the Eastern Chukchi stock and the Beaufort stock. This distinction is based on distribution patterns (Lowry and others, 1989) and is supported by molecular genetic studies (O'Corry-Crowe and others, 1997). The Beaufort stock is estimated to be ten times larger than the Eastern Chukchi stock (32,500 versus 3,700; Allen and Angliss, 2010). Neither of the Eastern Chukchi or Beaufort stocks is considered threatened or endangered (National Marine Fisheries Service, 2010f). Analysis of biological samples of beluga whales harvested for subsistence use has revealed much about stock structure, contaminant levels, age, growth, and reproductive status, though these statistics may be biased by hunting method (for example, Suydam, 2009). Belugas are harvested primarily by villages along the Chukchi Sea: a recent analysis of historical data showed that only 1 percent of the subsistence take of whales in Barrow between 1962 and 1982 was beluga whales, and none were harvested between 1987 and 1989 (Braund and Kruse, 2009). The Native community participates in managing the Eastern Chukchi and Beaufort stocks through the Alaska Beluga Whale Committee.

Beluga whales also were among the first whales tagged and tracked in the Arctic (National Marine Fisheries Service, 2010g). These early tagging studies revealed that some beluga whales ventured deep within ice of greater than 90 percent coverage in the summer (for example, Suydam and others, 2005). These tagging studies have been used to understand beluga movement and distribution (for example, Richard and others, 2001; Suydam and others, 2001) as well as diving behavior (Heide-Jørgensen and others, 1998; Kingsley and others, 2001). Arctic OCS belugas migrate annually from their wintering grounds presumably in the Bering Sea to their summer grounds in the Chukchi and Beaufort Seas (Allen and Angliss, 2010). Thus it is important to include seasonal information for understanding potential effects of anthropogenic sound on these stocks.

Beluga whales survive in captivity and are therefore accessible for research on life habit and functions that could not be conducted easily on whales in the wild. For example, they can directionally echolocate targets in a narrow and slightly upward tilted forward direction (Penner and others, 1986; Au and others, 1987). Although the underwater hearing sensitivity of belugas is quite large (Awbrey and others, 1988; Johnson and others, 1989b), they are most sensitive to about 20–80 kHz, which is mostly above the frequencies produced in large energy low-frequency seismic surveys used in oil exploration (fig. 6–2). In-air hearing has not been measured in belugas, but cetacean ears are adapted for underwater function and thus in-air hearing likely is very insensitive. Belugas also have been extensively studied for temporary threshold shifts in hearing, documented through disruption of trained behaviors (Finneran and others, 2000, 2002; Schlundt and others, 2000). Full recovery of baseline hearing and responses occurred within hours. These studies suggest that there is potential for acoustic disturbance, possibly from low-frequency surveys but more likely from higher frequency sound than is used in deep-penetration surveys.

There are many published studies about hearing, behavior, and responses of beluga whales to the kinds of sounds associated with Arctic oil and gas activities. When exposed to vessel noise, beluga whales can exhibit a variety of behaviors ranging from no response to fleeing (see Wartzok and others, 2004). Behavioral responses associated with this type of noise exposure often are considered transient. An unknown is whether repeated short-term behavioral responses translate to cumulative or population-level impacts (Bejder and others, 2006). At this time, there is limited information on whether and to what extent beluga whale migration will be affected by changes in shipping.

Beluga reactions to icebreaking are among the most cited and dramatic in the literature. Observations of changes in pod cohesion, surfacing behavior, and call types indicate that belugas detected the presence of icebreaker vessels at distances greater than 80 km. They exhibited strong avoidance responses at distances 35–50 km away and travelled up to 80 km from the ship track and typically remained away for 1–2 days (Finley and others, 1990). Bioacoustic models suggest that bubbler systems and cavitation associated with icebreaker movement have the ability to potentially mask hearing and vocalization of Arctic inhabitants (Erbe and Farmer, 1998, 2000). For beluga whales, it was hypothesized that the zone of masking could extend from 14 to 71 km from the source (Erbe and Farmer, 2000). There is an increased possibility of temporary threshold shift if animals are exposed

6.11. Finding: Beluga whales appear to be unusually sensitive to the sounds of icebreaking.

6.11. Recommendation: Understanding the sensitivity of beluga whales to icebreaking might require knowledge of the history of exposure to icebreaking or other anthropogenic factors to account for the possibility that some belugas may be either habituated or sensitized to this type of human activity. Application of telemetry to capture information on individual movement histories and access to noise histories (for example, from inventories suggested in Findings 6.02, 6.03, and 6.04) may be required.

to these types of sounds for an extended duration (that is, for animals that do not or cannot alter behavior to avoid this type of exposure if, for example, they are confined to a lead within heavy ice).

The reaction of beluga whales to drilling activities has been mixed and may be related to context. Observations have been made around "operational" artificial islands (Fraker, 1977a, 1977b; Fraker and Fraker, 1979), around a stationary drillship (Norton Fraker and Fraker, 1982), and in playback experiments with drilling noise (Richardson and others, 1990, 1991a). The variety of responses (or lack of responses) from these observations "may be another example of the degree to which belugas can adapt to repeated or ongoing manmade noise when it is not associated with negative consequences" (Richardson and others, 1995, p. 283).

Short-term behavioral responses of beluga whales to helicopters and fixed-wing aircraft have been noted since the late 1970s. Behaviors classified as reactions consisted of short surfacings, immediate dives or turns, changes in behavior state, vigorous swimming, and breaching (Caron and Smith, 1990; Richardson and others, 1991b, 1995). For both helicopters and fixed-wing aircrafts, the observed avoidance reactions by belugas generally occurred when the aircraft was at altitudes equal to or less than 150 m and lateral distances equal to or less than 250 m. The dominant low-frequency components of aircraft sound may be inaudible, or at most only weakly audible, to belugas. Mid-frequency sound components, visual cues, or both, probably are important in eliciting beluga reactions to aircraft.

6.12. Finding: The present understanding of the essential spatial and temporal habitat needs of the beluga whale in the Arctic is limited and constrains the ability to confidently understand and efficiently mitigate potential anthropogenic noise impacts. Similar data limitations exist for many other marine mammal species that will be noted in subsequent Findings and Recommendations.

6.12. Recommendation: Better understanding and inventory of essential spatial and temporal habitat needs of the beluga whale, particularly the oceanographic parameters that determine foraging, breeding, raising young, and migrating, will help managers determine how best to protect belugas from the impacts of anthropogenic sounds. Knowledge of these critical habitats for the beluga whale will enable managers to better identify and protect those places and times where the introduction of anthropogenic noise might significantly disrupt the whale at key parts of its life cycle.

Gray Whale (*Eschrichtius robustus*)

The gray whales that frequent the Chukchi and Beaufort Seas are managed as part of the eastern North Pacific gray whale population. Gray whales were first listed as endangered in 1970 in the Endangered Species Conservation Act, the precursor of the Endangered Species Act. After status reviews in 1984 and 1991, the eastern North Pacific gray whale was delisted from ESA in 1994 (see historical summary in National Marine Fisheries Service, 1994). The NMFS conducted a 5-year status review of the stock in 1999 (Rugh and others, 1999). In October 2010, the NMFS received a petition to again list the gray whale under ESA (California Gray Whale Coalition, 2010), but declined to do so in the 60-day review (National Marine Fisheries Service, 2010c). The eastern Pacific stock has an estimated minimum population size of about 17,500 with a population increasing at 1.9–2.6 percent per year (Allen and Angliss, 2010). Gray whales typically are not harvested as a subsistence resource.

Gray whales engage in one of the longest annual migrations of any marine mammal, travelling thousands of kilometers from as far south as Baja California in the winter to the Chukchi Sea in the summer. Although gray whales sometimes are seen around Barrow, they are a rare occurrence when seen east of Barrow in the Beaufort Sea (Nelson and others, 1993). The long coastal migration may expose this whale to more anthropogenic threats than the other Arctic whales because of its migration past major urban centers and sources of pollution (Rugh and others, 1999). There are some indications that, in the last decade, gray whales have moved farther into the Beaufort Sea and delayed their southbound migration in the fall (for example, Moore and others, 2003, 2007; Moore and Overland, 2008). Gray whales have been sighted more frequently near Barrow and their calls have been recorded in instruments deployed on the Beaufort Shelf during the winter (Stafford and others, 2007). Some of these changes may be related to changes in the physical environment of the north Bering Sea (Grebmeier and others, 2006).

Studies show gray whales, similar to other baleen whales, produce sounds generally below 1 kHz (Crane and Lashkari, 1996). Whereas gray whale response to anthropogenic sound has been studied in lower latitudes, the degree to which those results are predictive of whale responses in the Arctic OCS areas is speculative in part because the whales have highly structured annual cycles of feeding (summer in high latitudes) and breeding (winter in low latitudes). In one experiment with a long-range sonar, migrating whales avoided exposure to the signals when the source was placed within their migration corridor (Clark and others, 1999). However, in all cases, whales resumed their normal activities within tens of

minutes after the initial exposure to the signal, making minor course changes to go around the source. When the source was relocated outside of the migration corridor, but with the signal level increased so as to reproduce the same sound field inside the corridor, the whales continued their migration unabated. This result stresses the importance of context in interpreting animals' responses to underwater sounds (Clark and others, 1999).

Gray whale responses to airgun shots included changes in swimming speed and direction away from the sound sources (Malme and others, 1984), changes from feeding with a resumption of feeding after exposure (Malme and others, 1988), changes in call rates and structure (Dahlheim, 1987), and changes in surface behavior (Moore and Clarke, 2002). Some behavioral responses were dramatic—whales were seen to move into the shallow surf zone and into sound shadows of rocks (Malme and others, 1983, 1984). Approximately one-half of the gray whales exposed to a single airgun in the Bering Sea showed avoidance and noticeable changes in respiration behavior (Malme and others, 1986, 1988). There is essentially no information describing gray whale behavior in the presence of mid- and high-frequency pulsed sources.

Drilling and other continuous sounds have triggered avoidance responses in playback experiments with migrating gray whales (Malme and others, 1983, 1984). There are some data suggesting that gray whales respond to variations in underwater noise by changing the structure and timing of their calls (Dahlheim and others, 1984; Dahlheim, 1987), but it is unknown whether these changes in calling affected survival or reproduction. Gray whales were virtually absent from a wintering lagoon in Baja California, for several years during which shipping increased, possibly caused by the near-constant dredging needed to keep the channel open. Whales returned to the lagoon after shipping decreased (Jones and Swartz, 1984). Much of the nearshore range of the gray whale is heavily used by vessels and other human activity, which suggests habituation to or coexistence with noisy human activities (Richardson and others, 1995).

Gray whale responses to aircraft are variable and may be context dependent. Some observations suggest that mother-calf pairs off Alaska may be particularly sensitive to small (for example, turboprop) survey aircraft (Ljungblad and others, 1983). Mating gray whales did not react immediately to the arrival of a survey aircraft but dispersed after it had circled for a few minutes (Clarke and others, 1989). Migrating gray whales rarely showed detectable reactions to a straight-line overflight by a fixed-wing aircraft at 60 m altitude (Green and others, 1992). Playbacks of helicopter noise caused minor avoidance reactions in gray whales, suggesting that helicopter sound (rather than visual cues) could affect gray whales (Malme and others, 1983).

6.13. Finding: The present understanding of the essential spatial and temporal habitat needs of the gray whale in the Arctic is limited and constrains the ability to presently confidently understand and efficiently mitigate potential anthropogenic noise impacts.

6.13. Recommendation: Better understanding and inventory are needed of essential spatial and temporal habitat needs of the gray whale during its summering in the Chukchi and Beaufort Seas, particularly the oceanographic parameters that determine foraging, breeding, raising young, and migrating. Knowledge of these essential habitats for the gray whale will enable managers to better identify and protect those places and times where the introduction of anthropogenic noise might significantly disrupt the whale at key parts of its life cycle. The Chukchi Sea is of primary interest because it is a major foraging ground for the gray whale (Rice and Wolman, 1971; Fay, 1982). Because the development of petroleum resources (or mining for sand) in the Chukchi Sea could occur in regions of high concentration of prey species, the gray whale may be particularly vulnerable to petroleum-related development in the Arctic OCS (Nelson and others, 1994).

Polar Bear (*Ursus maritimus*)

Polar bears, the top predators in the Arctic marine ecosystem, are managed as two distinct populations, the southern Beaufort stock (primarily in the southern Beaufort Sea) and the Chukchi-Bering stock, which occurs farther south and west in both the U.S. and Russian Chukchi Sea (Amstrup and others, 2004). Based on satellite radio-telemetry data, a large overlap occurs between these two populations (Amstrup and others, 2004, 2005). In 2008, the U.S. Fish and Wildlife Service (2008) published a final determination to list polar bears as threatened under ESA. In 2010, the USFWS further published a final determination of critical habitat associated with the listing (U.S. Fish and Wildlife Service, 2010).

Polar bears are a well-studied Arctic marine mammal. Research on polar bears in Alaska has occurred since the late 1960s and numerous estimates of population stock exist (for example, Amstrup, 1986, 1995; McDonald and Amstrup, 2001; Allen and Angliss, 2010). Radiotelemetry was initiated in 1981, followed soon after with satellite telemetry, for understanding survival and recruitment. Genetic studies have helped identify discrete populations (for example, Paetkau and others, 1999; Amstrup, 2003). Sufficient data exist to model their distribution and denning patterns and examine population status and trends (for example, Aars and others, 2006).

Studies also have associated polar bears with "ecoregions" (for example, Amstrup and others, 2007). Polar bears tend to be more abundant over shallow water of the polar continental shelves, suggesting that these areas of higher productivity and therefore higher concentrations of potential prey are preferred habitat (Amstrup and others, 2000, 2004; Durner and others, 2007). Polar bears move in response to changing ice conditions and prey availability (Stirling and others, 1993; Arthur and others, 1996; Ferguson and others, 2000a, 2000b; Mauritzen and others, 2001; Durner and others, 2004, 2006, 2009). There are some data indicating that polar bear distribution may reflect factors such as prey availability, energetic costs, and safer ice conditions (for example, Mauritzen and others, 2003).

Despite the abundant research on the baseline biological information of the polar bear, relatively little information exists regarding its hearing, use of its auditory functions in survival or reproduction, and impacts from anthropogenic sounds. Importantly, in contrast to other marine mammals, the polar bear spends most of its life out of the water. When swimming, it carries its head above the water surface. Thus, while extremely intense underwater sound may impact a polar bear while in the water, the impacts of anthropogenic sound are considered primarily to be from sounds in air.

There are no measurements of the underwater hearing of polar bears. In-air hearing was measured using evoked auditory potentials on three anesthetized polar bears for frequencies of 1.4–22.5 kHz (Nachtigall and others, 2007). Results can not be taken as measures of absolute sensitivity, but sensitivity was relatively flat across the range of frequencies tested with a slight peak from about 11.2–22.5 kHz.

Ecological observations support these measured hearing ranges. Ringed seals (*Phoca hispida*) and bearded seals (*Erignathus barbatus*) are prominent in the diet of polar bears. Ringed seals produce underwater sounds in these frequency ranges (2–8 kHz; Stirling, 1973) suggesting that polar bear hearing can optimally detect and locate this preferred prey. Playback of ringed seal calls in the air has triggered changes in behavior in captive polar bears (for example, Cushing and others, 1988). Polar bears also may be able to detect and locate bearded seals by their distinctive underwater trills (Stirling and Thomas, 2003).

Many observations document polar bear responses to anthropogenic sound. On-ice seismic techniques (Vibroseis) have caused polar bears to locally (and temporarily) leave the area (Richardson and others, 1995). Moore and Quimby (1975) reported that females with cubs abandoned their dens during nearby seismic exploration activity, and this effect was more pronounced early in the denning season (Linnell and others, 2000). Polar bears appear to tolerate sounds and vibrations associated with stationary drill rigs on caissons and artificial islands (Stirling, 1988; Amstrup, 1993). Polar bear reactions to vessels and icebreakers are unremarkable (Fay and others, 1984). Reactions may include walking, running, or swimming away, and generally are of short duration; some bears show no reactions (for example, Richardson and others, 1995, and references therein). Helicopters are sometimes used to frighten polar bears away from human activities or facilities, and low-flying aircraft are known to cause polar bears to run away (Shideler, 1993). In general, these studies support the notion that polar bears may be sensitive to some kinds of in-air sounds.

6.14. Finding: Joint industry-agency programs have successfully mitigated, to date, the disturbance effects of oil and gas activities, including noise, on polar bears in the U.S. Arctic. An example of this has been the development of polar bear denning models to help define potential denning sites for avoidance during winter on-land seismic surveys and the application of Forward-Looking Infrared (FLIR) imagery for real-time monitoring and den avoidance. But declines in sea ice are resulting in changes in polar bear distribution and in denning habitat, as well as body condition and survival patterns, and portend declines in overall population size.

6.14. Recommendation: Broadly, and with respect to noise, to successfully mitigate the effects of existing and new development in the Arctic under changing climate conditions will require continual reassessment of what is understood about polar bear distribution and habitats to ensure mitigation measures are accomplishing intended outcomes.

Ice Seals

Of the Arctic marine mammals, ice seals remain the least known and studied. For each of the ice seal species, the 2009 stock assessment begins "A reliable minimum population estimate for this stock cannot presently be determined because current reliable estimates of abundance are not available" (Allen and Angliss, 2010). Subsistence harvests are incompletely known (for example, Allen and Angliss, 2010). Some progress is being made to identify habitat requirements (for example, Cameron and others, 2010). The large range over which these animals are found, their generally low densities, cryptic or incompletely understood behaviors, their habitat across multiple political boundaries, lack of information about how ice seals use habitat, the inability to correct inventories for seals in the water, and the high costs associated with surveying large areas remain the greatest impediments to improving the knowledge base (Boveng and others, 2008, 2009).

6.15. Finding: There is a basic lack of information about ice seals. Key information about the abundance, distribution, and vital aspects of ice seals is incomplete. (Information on ice seal auditory characteristics and response to sound also is lacking and will be discussed in Findings and Recommendations 6.16 and 6.17).

6.15. Recommendation: Habitat requirements of ice seals need to be better identified and quantified, particularly the importance of habitat in the context of seasonal activities. Annual harvest rates for subsistence needs should be estimated more consistently. Knowledge of such basic biological information should be integrated across political boundaries of the Nations in which the species occur (for example, Canada and Russia). For example, ringed seals from the Beaufort and Chukchi Seas were radio- and satellite-tracked showing that in the summer, they ranged up to 1,800 km from their winter/spring home, but returned to the same small (1–2 km^2) winter sites (Kelly and others, 2010). During the ice-bound winter and spring (including breeding season), ringed seals are therefore spatially limited in their foraging ability for significant parts of the year. If ringed seals cannot habituate to oil and gas activities or utilize human-free habitat, they may be limited in their ability to adapt.

Four species of ice seals are found in the Chukchi and Beaufort Seas: bearded (*Erignathus barbatus*), ribbon (*Histriophoca fasciata*), ringed (*Pusa hispida*), and spotted (*Phoca largha*). In contrast to the three species that are year-round Beaufort and Chukchi inhabitants, the spotted seal is only a seasonal summer visitor to the Beaufort and Chukchi Seas. Neither spotted nor ribbon seals are listed as threatened or endangered according to ESA (table 6–3).

The distribution and life history of these seals are intimately linked to the presence of ice and snow: mating occurs near the ice edge; subnivean lairs (for the ringed seals) are utilized as dens for whelping and nurturing pups; whelping coincides with near-maximum ice extent; and adult seals undergo annual molting after which seals spend prolonged periods out of water on the ice warming the skin in the sun during late spring and summer (Hopcroft and others, 2008). The timing of snow and ice melt may be critical to the survival or reproduction of ringed seals (for example, Kelly, 2001; Smith and Harwood, 2001; Stirling and Smith, 2004). When they are not breeding, ice seals may move hundreds or thousands of miles through the Arctic and surrounding waters (Kapel and others, 1998; Lowry and others, 1998; Harwood and others, 2000).

During the late 1970s and 1980s, the OCS Environmental Assessment Program (OCSEAP) funded and supported numerous studies of ice seals in conjunction with the increased OCS exploration activities in the Arctic, identifying some of the diet and trophic relations for these animals. After a hiatus in the 1990s, renewed research began with the formation of the Ice Seals Committee in 2005 consisting of members of the Native community for the purpose of developing a coordinated plan for management of ice seals in Alaska (for example, Ice Seal Committee, 2006). Tagging of bearded seals (starting in 2004) and ringed seals (starting in 2007) initiated with the Native village of Kotzebue (http://kotzebueira.org, accessed April 14, 2011) and biologists significantly added to the knowledge base about specific individuals for the duration

Table 6–3. Ice Seals—Endangered Species Act (ESA) Information.

Seal	Status review	Federal Register Notice	ESA listed for the Arctic
Bearded	Cameron and others, 2010	December 10, 2010	Candidate
Ribbon	Boveng and others, 2008	December 30, 2008	No
Ringed	Kelly and others, 2010	December 10, 2010	Candidate
Spotted	Boveng and others, 2009	October 20, 2009 October 22, 2010	No

of the tagging (generally less than 1 year). Each of the ice seal species has undergone extensive reviews in the past 4 years as part of the process by which the NOAA determines whether the species should be listed under the ESA. The major reviews summarizing biological knowledge of the species and associated Federal Register notices for ice seals are given in table 6–3.

Bearded and ringed seals are primary prey of polar bears as well as food for the Native community. The bearded seal is the largest of the seals and preys on benthic organisms. Hence they are more frequently found in shallow water areas where light can sustain a benthic ecosystem (for example, less than 200 m water depth). The ringed seal, also an important food source for the Native community, is the smallest of the ice seals and feeds on fish, so it can travel long distances over deep water along and within the ice (Kelly and others, 2010).

As with other marine mammals, ice seals are thought to use sound to aid in navigation, to socialize, and to avoid predators. Typically, pinnipeds are thought to spend as much as 80 percent of their time in the water (Gordon and others, 2004); thus anthropogenic sound associated with seismic surveys, vessel noise, icebreaking, and drilling may potentially disturb their habitat, distribution, and behavior. Ice seals make variable vocalizations in the water, generally associated with mating (for example, Watkins and Ray, 1977; Boveng and others, 2009; Cameron and others, 2010). The underwater hearing sensitivity for ringed seals showed peak sensitivities between about 4–16 kHz, although sensitivity to frequencies below 1 kHz was not measured (Terhune and Ronald, 1975). Based on the similarity of these hearing ranges to the hearing of many other pinnipeds, one might expect that the other ice seals also have hearing at similar ranges (Moore and Schusterman, 1987). A recent review suggests that the auditory bandwidth generalized for all pinnipeds in water should be about 75 Hz – 75 kHz (Southall and others, 2007). Most seismic surveys have peak energy below 200 Hz, hence the level of disturbance expected from large seismic surveys is at the low end of pinniped hearing.

6.16. Finding: Basic auditory information about ice seals is lacking.

6.16. Recommendation: Key information about the amplitude, character, seasonal variation, and function of vocalizations of ice seals as well as studies of pinniped diving profiles, auditory structures, and physiological effects of sound are needed. This information is essential for determining whether and how anthropogenic sounds could mask, impact, or injure these animals.

The effects of seismic surveys on ice seals have been summarized in the 2010 status review of the bearded seal:

> "Reported seal responses to seismic surveys have been variable and often contradictory, although they do suggest that pinnipeds frequently do not avoid the area within a few hundred meters of operating airgun arrays (Brueggeman and others, 1991; Harris and others, 2001; Miller and Davis, 2002). Telemetry work by Thompson and others (1998) indicated that harbor seals and grey seals (*Halichoerus grypus*) exhibit strong avoidance behavior of small seismic airgun arrays, including swimming rapidly away from seismic sources, ceasing feeding activities, and hauling out, possibly to avoid underwater noise. The behavior of most of the seals reportedly returned to normal within 2 hours of the seismic array falling silent. The authors suggested that responses to more powerful commercial arrays might be more dramatic and occur at greater ranges."
>
> (Cameron and others, 2010, p. 162)

Tagging studies conducted on ringed seals in 2001, when Canadian marine seismic surveys were occurring, did not appear to affect the timing or route of the western fall migration of ringed seals in the Beaufort Sea (Cott and others, 2003). Ringed seals in the Prudhoe Bay region often tolerated exposure to high received levels (180–190 dB re: 1 µPa rms) of low-frequency sound pulses from airgun arrays, with little evidence of changes in behavior and no more than localized avoidance (Harris and others, 2001; Moulton and Lawson, 2002). Many seals remained within 100–200 m of the operating airguns, which is often within the radius where received sound levels are greater than 190 dB re 1 µPa (rms). There are seemingly inconsistent results concerning reactions of seals to small airgun sources (Blackwell and others, 2004b). The seals may initially show an avoidance response to these sounds, but rapidly habituate, demonstrated by their adjustment to Acoustic Harassment Devices that are similar to sounds used in sub-bottom surveys (Richardson, 2002).

There are few data on auditory threshold shifts, either temporary or permanent, for ice seals. In experiments done primarily on sea lions, the results from pulsed sounds (Finneran and others, 2003) and continuous, but lower energy, octave band noise (Kastak and others, 1999, 2005) demonstrated the importance of considering both amplitude and duration when estimating the impacts of sounds on marine mammals and these results are reiterated by Southall and others (2007). Each of the ice seal reviews conducted by the NOAA (table 6–3) suggested that "Although it is unlikely that airgun operations during most seismic surveys would cause PTS in (bearded, ribbon, ringed, or ice) seals, caution is warranted given the limited knowledge about noise induced hearing damage in this species."

Reactions of most pinnipeds to drilling and related activities have not been extensively studied. Ringed seals are often seen near drillships drilling in the Arctic during summer and autumn. As part of construction efforts for the Northstar oil production island 5 km offshore of Long Island, northwest of Prudhoe Bay, Alaska, in the western Beaufort Sea, ringed seals showed little or no reaction to any industrial noise except approaching helicopters (Blackwell and others, 2004b). There is no evidence of reduced seal densities near the Northstar gravel island drilling platform (Moulton and others, 2003). Very few data exist for the effects of vessels and icebreaking on ice seals, but observations suggest sensitivity occurs only when icebreaking occurred within several hundred meters of the seals (for example, Kanik and others, 1980; Brueggeman and others, 1992). It was not clear whether vessel noise or visual cues triggered the escape responses.

Noise disturbance to ice seals also must account for in-air sound, although few data exist for this. When on the ice, ringed seals and bearded seals often dive when approached by low-flying aircraft or helicopters, but do not always do so (Burns and others, 1982). Spotted seals may be particularly sensitive to low-flying aircraft leading to concerns about potential separation of mothers and pups during nursing (Frost and others, 1993; Richardson and others, 1995). The levels of received sound are unknown in these observations.

6.17. Finding: There is a lack of information on the response of ice seals to aircraft or differential response to fixed-wing aircraft versus helicopter.

6.17. Recommendation: Controlled exposure (sound playback) experiments with ice seals might aid in understanding their hearing sensitivities and reactions. At any given moment, behavior in free-ranging animals is controlled by a multitude of factors including the individual's internal physiological state, physical environmental conditions, time of day and time of year, the behavior and distribution of peers, behavior and distribution of other species (including predators and prey), and human activity. When making passive observations, any observed behavior in an individual may be caused by the anthropogenic factor under study, other natural factors, or some combination of both. Controlled exposure is a quasi-experimental method used to evaluate response to sound by observing the behavior of free-ranging animals before, during, and after exposure to specific sound (for example, Tyack, 2009), either by playback of recorded sounds using an underwater sound system or by controlling the sound of a vessel, sensor (for example, sonar), or tool (for example, airgun, bubbler, pipe driver).

These experiments might determine whether observed responses could have been caused by the sight, sound, or vibration associated with the noise.

Pacific Walrus (*Odobenus rosmarus divergens*)

The Pacific walrus ranges across the continental shelf of the Bering and Chukchi Seas but is only infrequently observed in the Beaufort Sea (for example, Allen and Angliss, 2010). Walruses winter in the Bering Sea in large communities and move north with the ice edge as the pack ice recedes each summer (Fay, 1982). Ice is essential for their existence, providing a location to rest, molt, give birth, and escape predators (Richard, 1990). Land aggregations are becoming more common as the ice recedes north of the Chukchi and Beaufort Shelf edges (Jay and Fischbach, 2008). Although walruses can dive deeper than 200 m (Born and others, 2005), they typically live where water depths are less than 80 m so that the benthic communities they prefer for prey are more easily reached (Fay and Burns, 1988; Jay and others, 2001). Radio tags and more recently satellite tags are beginning to yield more continuous measurements of walrus activities (Jay and Fischbach, 2008). Walruses can significantly disturb seafloor sediment during feeding on benthic organisms, and are thought to be a major influence the structure of benthic ecosystems of the Chukchi and Bering Seas (for example, Oliver and others, 1983).

The current estimate of minimum population size for the Pacific walrus is approximately 129,000 individuals, with insufficient data to determine annual trends in abundance (Allen and Angliss, 2010). As a result of a petition filed by the Center for Biological Diversity in 2008, the USFWS issued a 90-day finding on September 10, 2009, that the petitioners had submitted enough scientific information to indicate that listing of the Pacific walrus under ESA may be warranted (U.S. Fish and Wildlife Service, 2009). On February 10, 2011, the USFWS issued their 12-month finding that listing the Pacific walrus as endangered or threatened is "warranted but precluded" (U.S. Fish and Wildlife Service, 2011).

Walruses can be extremely vocal when out of the water and produce a variety of sounds in the water (Ray and Watkins, 1975). Only the male walrus makes the unusual "bell" sound comprising two frequencies produced in succession (Schevill and others, 1966). Tests of hearing on captive walruses indicate that underwater hearing sensitivity covers a broad range of frequencies, with the best hearing generally above 1 kHz, although sensitivity was good down to 125 Hz (Kastelein and others, 2002). In-air hearing sensitivity was measured from 125 Hz to 8 kHz, with best sensitivity between 1 and 8 kHz and rapid decline below 1 kHz (Kastelein and others, 1993, 1996). Similar to ice seals, low-frequency seismic surveys are likely to impact the low-end of the walrus hearing spectrum whereas medium- to high-frequency hazards surveys are more likely to coincide with the range of walrus hearing.

Walrus appear to be sensitive to some noises and can stampede from haulouts in response to sight, sound, and odors of humans (for example, Fischbach and others, 2009). It is not currently understood whether these reactions are uniformly caused by visual, olfactory, or vibrational cues rather than noise. A similar uncertainty exists about the cause of some walrus reactions to vessels either in open water or during icebreaking, particularly whether avoidance responses are triggered by ship noise versus sight and smell of the vessel (for example, Fay and Kelly, 1982; Fay and others, 1984). When near icebreakers, most walruses on ice were more cautious of vessels compared to walruses in the water (Fay and others, 1984). The observed reactions were commonly waking up, raising their heads, or entering the water. Some walruses in the water reacted by hauling themselves out of the water.

Walrus responses to drilling operations are closely linked to icebreaking because of ice management during drilling. During the 1989–91 drilling of the Popcorn, Burger, Crackerjack, and Diamond wells in the Chukchi Sea (Minerals Management Service, 2005), escape responses were more frequent the closer the icebreaker operated to the walrus (Brueggeman and others, 1990, 1991, 1992). Evidence from aerial surveys in one study suggested that walruses may have avoided the area of icebreaking by as much as 10–15 km (Brueggeman and others, 1990), which contrasts with reports of avoidance only at much shorter distances (Fay and others, 1984). Icebreaking may have the potential to cause behavioral avoidance or injury, and for these communal large animals, may degrade habitat by reducing floe size and availability for haul out. Animals that show no avoidance may be undisturbed, but alternatively may be disturbed but have no avenue of escape.

Responses of walrus to aircraft (both helicopters and fixed-wing aircraft) were similar, in that the level of response was usually related to distance and altitude of the approaching aircraft (Johnson and others, 1989a). Aircraft overflight of walrus haulout locations have triggered stampedes from flight elevations of 150–800 m (Fay, 1981; Ovsyanikov and others, 1994). Stampedes may lead to trauma, injury, and death of walruses, particularly calves. One study identified different reaction distances depending on whether a helicopter approached the walrus group from an upwind or downwind direction (Fay and others, 1984), raising the possibility that smell could have been a factor in the response.

6.18. Finding: Considerable uncertainty exists about whether walrus reactions to anthropogenic activities are caused by sight, sound, or smell. Quantitative data are lacking about the character of deep-penetration, high-resolution seismic and other acoustic sounds (such as sonar or chirp) and the responses of walruses to these sounds.

6.18. Recommendation: Basic information about walrus reactions to anthropogenic sound, particularly seismic and acoustic sounds, needs to be better documented and studied. Detailed studies that examine responses in controlled environments could help efficiently elucidate key areas of walrus response. This information coupled with quantitative characterizations of anthropogenic noise sources could better define whether and how these kinds of anthropogenic sounds could mask, impact, or injure walrus.

6.19. Finding: There is a newly emerging, yet still incomplete understanding of the manner in which walruses select their benthic foraging habitats (Jay and others, 2011) and limited information on the role of walruses in ecosystem structure. Such information is needed (in concert with information in Recommendation 6.18) to assess if seasonal, annual, or persistent sources of anthropogenic sound may cause walruses to avoid certain places or times. And, if so, what the effect might be to both population and ecosystem.

6.19. Recommendation: Better understanding and inventory of essential spatial and temporal habitat needs of Pacific walrus during its summering in the Chukchi Sea, particularly the oceanographic parameters that determine foraging, are needed. Should evidence develop that walrus are displaced due to human-generated sound, future studies will be needed to assess if cascading ecological consequences result. Walrus modify the seafloor during their foraging by resuspending sediments, which in turn may enhance primary productivity by releasing nutrients into the water and maintaining sand substrates on the seafloor as fine-grained muds and silts are suspended, for example, and carried by the Alaska Coastal Current (Nelson and others, 1994).

Conclusions: While scientific uncertainty exists regarding the scope and nature of environmental disturbances arising from anthropogenic sound sources in the oceans, and particularly in the Beaufort and Chukchi Seas, some simple conclusions may still be drawn.

- Sound is of vital biological importance to the marine mammals of interest in the Arctic, and anthropogenic noise can have various adverse effects. The wide-scale introduction of commercial, military, and research activities into Arctic areas that will accompany oil and gas activities, with concomitant associated increases in anthropogenic sound, are very likely to impact both the acoustic environment and the sound-centric marine mammals living there.
- Vessel activities and other industrial sound sources increase sound in the oceans; the Beaufort and Chukchi Seas offer the unique opportunity to measure and understand both the increase in anthropogenic sound and its potential impacts on marine mammals because these areas are essentially pristine with limited anthropogenic sound sources compared to the rest of the oceans around the United States.
- Different species hear and use sound differently. Therefore, impacts from anthropogenic sound will vary by sound source (for example, vessel operation, seismic, and hydroacoustic devices, icebreaker operations), as well as by marine mammal species.
- Very few of the impacts from anthropogenic sound are expected to include direct physical injuries to hearing (or other systems) of the marine mammals.
- Concern regarding behavioral disturbance and avoidance of key areas is a major concern for the Native community. Any change in individual marine mammal behavior that causes the animal to move away from coastal waters, particularly the bowhead whale, has the potential to make the animals unavailable for subsistence hunting.
- Cumulative-, population-, and ecosystem-level impacts of exposure to chronic sources of anthropogenic sound from oil and gas activities remain poorly understood but are important considerations, particularly for the survival, sustainability, and reproductive health of marine mammals.
- Key knowledge gaps include baseline data from which to measure the changes that might be caused by the introduction of anthropogenic sound, inventories of anthropogenic sound (especially vessels and seismic sources), and the spatial and temporal habitat needs of the marine mammals of concern.
- The Native community has much at stake in the regulatory process and has much knowledge, both traditional and local, to offer in augmenting scientific studies about marine mammals and anthropogenic sound.

Chapter 7

Cumulative Impacts

By Brenda Pierce

Introduction

The final topic the USGS OCS Team was asked to consider was that of cumulative effects. Here we examine the state of cumulative impact or effect assessment approaches and the present challenges of conducting science-based cumulative effect analyses in the Arctic. Cumulative impacts are the combined, incremental effects of human activity.

Cumulative impacts can result from factors that may be insignificant by themselves but significant when interacting and (or) accumulating over time and space, through repetition, or in combination with other effects. When actions are considered individually or independently, their combined consequences—or cumulative impact—may not be fully considered or evaluated. This results in not understanding, and not considering, the long range impact of multiple decisions over a large area.

The impetus to study and evaluate cumulative impacts lies with the passage of the National Environmental Policy Act (NEPA) of 1969. The NEPA requires Federal agencies to develop Environmental Impact Statements and Environmental Assessments for major projects. However, if these studies are done independently of one another and considered separately, the studies may not take into account cumulative effects from each activity on the whole and the projects' effects may not be fully accounted for nor be taken into account in the final decision.

The Council on Environmental Quality (CEQ) was established under NEPA. The CEQ's regulations (40 CFR Part 1500–1508) implementing the procedural provisions of the NEPA (Council on Environmental Quality, 1997) define cumulative effects as:

> "The impact of the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions."

The words "effects" and "impacts" are used synonymously in CEQ's NEPA regulations, which govern NEPA implementation (Council on Environmental Quality, 1984). Effects and (or) impacts are meant to be inclusive and include ecological, aesthetic, historical, economic, social, and health, and are both beneficial and detrimental.

Cumulative effects result from spatial (geographic) and temporal (time) environmental disturbances and both must be given consideration in analyzing cumulative impacts.

The National Research Council (NRC) conducted a study on the cumulative effects of oil and gas activities on Alaska's North Slope (National Research Council, 2003). That study, which focused on the onshore portion of oil and gas development, is the most comprehensive look at the considerations that should go into cumulative impact analyses. The National Research Council (2003) emphasized the fact that significant research has been carried out in Arctic Alaska over the last several decades, but that an integrated, comprehensive assessment of those effects has not been attempted. That is still true today—there are a significant number of important and landmark environmental studies, and there are some studies of cumulative effects, but no integrated, comprehensive assessment of those effects has been conducted or even attempted.

Policy decisions are usually made at the regional or national level, but environmental effects are usually analyzed and assessed at the project level. Decisions and permitting of industrial activities are often done on a case by case basis by many different entities and therefore without the benefit of a comprehensive plan or understanding of the scope, intensity, and consequences of the industrial activities. Long-term decision making and land and resource management must take into account the cumulative impact of the nature and extent of the benefits and challenges and the costs of both.

Considerations in Conducting Cumulative Impact Studies

The Council on Environmental Quality's (1997) guidance emphasizes the need to incorporate a cumulative impact evaluation in the development of alternatives for an Environmental Analysis or Environmental Impact Statement. It stresses that only by considering cumulative effects can appropriate mitigation and monitoring measures be effectively developed.

The CEQ suggests that in conducting cumulative impact analysis, the life cycle of effects and impact zones, rather than individual projects, should be evaluated. It emphasizes that looking at the affected environment in a cumulative impact analysis is basically the same as it is in a project-specific analysis, with the important addition that the analysis should be extended in terms of geography, time, and the potential for resource or system interactions. In project-specific NEPA analysis, description of the affected environment is based on a list of resources that may be directly or indirectly affected by the proposed project. In cumulative effects analysis, there is an attempt to identify and characterize effects of other actions, including those of other geographic areas or other time frames, on these same resources.

To conduct a cumulative effects analysis, one should understand what would occur in the absence of a given activity. This is best done when there are reliable baseline data available for the analysis and by using tools that indicate ecological integrity and landscape conditions. This is important because when an analysis is performed, the baseline or thresholds of environmental change are set, thus influencing the cumulative impact assessment. Effects typically accumulate as the result of repeated activities, but also may be affected by a single action or event if significant. Therefore, a full cumulative impact analysis requires multiple assessments.

It is very important to be transparent regarding the uncertainties associated with any of these studies, especially in cumulative impact. There will always be uncertainty, as there will never be enough data and information on every facet of the impact of development to know the impact in its full extent. Therefore, it is important to be transparent about what data do or do not exist and what is modeled and what is empirical, so the users of the information understand the extent of the uncertainty surrounding the assessment or impact.

Conducting cumulative impact analysis needs to be an iterative process. Results from cumulative impact assessments should contribute to refining alternatives and designing mitigation techniques and approaches. Thus, monitoring change and the accuracy of the predictions made is an important part of cumulative impact analysis and contributes directly to the success of the mitigation measures.

The U.S. Environmental Protection Agency (USEPA) has review guidance regarding the NEPA and cumulative effects and suggests that its reviewers determine whether resources are cumulatively impacted by considering the following (U.S. Environmental Protection Agency, 1999):

1. Whether the resource is vulnerable to incremental effects;
2. Whether the proposed action is one of several similar actions in the same geographic area;
3. Whether other activities in the area have similar effects on resources;
4. Whether these effects have been historically significant for this resource; and
5. Whether other analyses in the area have identified a cumulative effects concern.

Some project analyses consider only certain resources and only direct impacts or limited impacts among those particular resources. To conduct a cumulative impact analysis, consideration must be given to a broader array of effects, such as ecosystems functions (for example, ability to minimize downstream flooding or improve water quality) instead of simply the acreage of wetland potentially lost by a project. Other potential effects to consider, as suggested by the U.S. Environmental Protection Agency (1999), include changes in hydrologic patterns, alteration of discharge and water retention rates, changes in water velocity, secondary or tertiary effects of chemicals in the wetland and how plants may take up those chemicals, to name just a few.

Additionally, some analyses limit the area considered to those areas over which an agency might have direct purview or management authority (U.S. Environmental Protection Agency, 1999). This limits the full evaluation of cumulative impacts, because impacts may be caused by factors outside the specific project's spatial or temporal scope, including the life of the project. For example, the effects sometimes last longer than the project's useful life, and (or) future related or unrelated projects will be additive to the effects of the one considered project, and so should not be evaluated independently.

The USEPA guidance document (U.S. Environmental Protection Agency, 1999) points out that past environmental conditions are not adequately addressed in most cumulative impact analyses—not fully analyzing how the system has changed from previous conditions and thus not fully accounting for the cumulative impact. Because the Arctic has had very little development thus far, we are in a somewhat unique situation in which there have been few previous impacts so today's conditions form our baseline.

It is true that there have been activities in the Arctic, including seismic surveys in State and Federal waters, some drilling, acoustic surveys, vessel traffic, aircraft surveys, and hunting activities, but the amount is less than in many other areas under consideration for oil and gas development. Human industrial activities in the Alaskan Arctic have been limited primarily to petroleum-related activities in the southeastern Beaufort Sea. The Arctic environment is experiencing large-scale transformation associated with climate change that eventually may result in an opening of frontier areas to increased human developments and commerce associated with fisheries, shipping, and tourism. The relative absence of human activity presents a unique regional opportunity to develop and analyze the cumulative impacts in a relatively pristine environment and show how cumulative effects can be studied and properly evaluated.

To evaluate or analyze cumulative impacts, one needs to determine whether the effects interact or accumulate over time and space. Effects most often accumulate as a result of repeated or compounded activities. However, individual or single actions also can contribute to cumulative impacts, especially if the effects persist for a long time and (or) are augmented by the effects of other activities. As early as 1986, a National Research Council (1986) study identified the most important factors in regards to cumulative effects (and were reiterated in the 2003 NRC study). These factors generally agree with the Council on Environmental Quality's (1997) identified examples of cumulative effects:

- Time crowding—frequent and repeated effects on a single environmental medium.
- Space crowding—high density of effects on a single environmental medium.
- Compounding effects—synergistic effects attributable to multiple sources on a single environmental medium.
- Thresholds—effects that become qualitatively different once some threshold of disturbance is reached.
- Nibbling—progressive loss of habitat resulting from a sequence of activities, each of which is fairly innocuous, but the consequences for the environment accumulate.

Because cumulative impact assessments are difficult undertakings, the National Research Council (2003) described several essential components:

- Specify the class of actions whose effects are to be analyzed.
- Designate the appropriate time and space domain in which the relevant actions occur.
- Identify and characterize the set of receptors to be assessed.
- Determine the magnitude of effects on receptors and whether those effects are accumulating.

Thus, for example, specific *activities* might include seismic exploration and whether these activities had significant effects on specific *receptors*, such as specific species or subsistence hunting. One of the most challenging aspects of conducting a cumulative impact analysis is determining the area and vulnerable resources over which the effects have occurred or will occur.

In addition to identifying and evaluating the accumulation of effects, factors such as magnitude, biotic impact, recovery times, and socioeconomic importance must be evaluated.

Arctic Alaska

Energy and mineral resources are significant in Arctic Alaska (Chapter 2, Geological Context), and the large potential of oil and natural gas resources is of near term interest. Production of some of these resources is already underway, especially onshore, yet many of the areas of Arctic Alaska have not yet been influenced by such industrial activity. As sea ice continues to retreat and allows for more navigation, use of Arctic waters for activities, such as tourism and shipping, is expected to add to the effects of industrial development. Further complicating the issues are those of transboundary impacts—including the United States and Canada for the Beaufort Sea and the United States and Russia for the Chukchi Sea. These factors complicate the delineation and understanding of cumulative impacts, as well as the ability to develop effective monitoring.

There are benefits to energy and mineral production, but there also are social and environmental costs and impacts. Each individual development activity affects the ecosystem, including marine life, habitat, air quality, water quality, and local communities. These effects, combined with those of other projects or activities, will have unanticipated additional, or cumulative, impacts. Climate change adds significant complexity to cumulative impacts, perhaps more so in the Arctic where its effects may be more pronounced. The climate of the Arctic (Chapter 4, Climate Change Considerations) is a complicating factor in evaluating cumulative impacts in that recovery from disturbance in the Arctic may take much longer than in warmer climates.

Cumulative effects analyses have been done by various groups since the passage of the NEPA, but conducting such analyses remains extremely challenging because of the complexity and variety of factors that might impact cumulative disturbances. Although studies and research have been done by many organizations on many factors in the Arctic, there has been relatively little specific focus on a holistic, integrated, comprehensive assessment of cumulative effects of industrial activities in the Arctic.

An additional complicating factor is that Arctic research is conducted by a myriad of entities, and the management of Arctic resources is overseen by many different groups with different mandates, interests, and budgets, and thus research needs. Different agencies have different responsibilities—for air, water, endangered and (or) migratory species, and so on. No single organization has the responsibility for comprehensive planning for oil and gas development in Arctic Alaska. This is, in part, why much of the information is not synthesized or integrated. There is value to having different groups conduct research and analysis, and to some degree management, but there needs to be more coordination and an integrated decision-making process for these large areas that are potentially going to be developed. If an integrated decision-making process is not implemented, then the project-based approach to environmental impact analysis will preclude true cumulative impact analysis or evaluation.

7.01. Finding: Cumulative effects analysis can benefit from applications of sophisticated geospatial technologies, regular synthesis of environmental data and information, ecological forecasting, and multidimensional evaluations of planned human developments. These elements exist for the Arctic OCS at some level, but are insufficient or not well integrated to support comprehensive cumulative impact analyses.

7.01. Recommendation: More coordination and comprehensive planning are needed among the various stakeholders in the Arctic, including those with responsibility for resources, those that conduct research, and those that use resources. These groups should all have input into coordinated, comprehensive cumulative impact analyses. Shared stakeholder visions regarding purpose and data sharing may reduce redundancies and help streamline regulatory processes. These actions must be informed by improved access to information through geospatial technologies, regular synthesis of research, forecasting, and multidimensional evaluations of human developments.

Further complicating the analysis of cumulative impact, especially in the Arctic, the National Research Council study (2003) pointed out that technological advances have significantly changed many factors related to petroleum development, including the type of resource obtained, as well as how and where it can be produced (for example, directional drilling, ice roads, and so on). Technology develops very rapidly when the stakes are large, and it adds a complicating factor to predicting cumulative impact. Climate change, also, significantly impacts the ability to predict or even determine cumulative impact. As climate change is expected to accelerate in the future, its effect on cumulative impact is difficult to predict. It will, however, likely influence petroleum and other development and in turn, those activities on the environment.

The National Research Council (2003) study outlined specific issues (only some of which follow) that must be addressed when considering cumulative effects on Arctic Alaska. Many of these issues are related to onshore development, as the study was focused on the Alaska's North Slope. However, this list, which is not comprehensive, gives a sense of the many issues that must be considered when addressing comprehensive cumulative impact assessments:

- Industrial activity has grown on the North Slope with oil field development, pad development, interconnecting roads, pipelines, power lines, and other infrastructure. Environmental effects of these structures occur both at the site as well as up to a few miles/several kilometers away, but visual impact can be farther. There also is an issue of legacy sites, including abandoned infrastructure and unrestored landscapes. However, there has been significant improvement in reducing the drilling footprint with technological advances, such as directional drilling, replacing gravel pads with ice pads, and other developments.
- Off-road damage to tundra originates primarily from seismic operations. Most of the damage is legacy damage, caused by earlier surveys, but is long term and persistent. Technology, as well as seasonal limitations to off-road travel, has substantially improved and has significantly reduced, but not totally eliminated, damage to the tundra. It is difficult to predict what will be the impact as drilling expands into new areas and as climate continues to warm.
- Roads affect areas of development like they do in many areas by increasing dust, habitat fragmentation, and permafrost effects. Roads also can allow access by hunters, tourists, and others to an area previously difficult to access. Yet, roads can enhance communications among isolated communities and increase contacts between the North Slope and those communities outside the area.

- Animal and plant impacts (terrestrial and marine) include those to bowhead whales and denning polar bears. These may affect predator densities (related to new food sources people bring to the oil fields) and may impact the reproductive capabilities of some species, but that is not yet known. Some species on the North Slope are in decline here and elsewhere, and industrial activities may affect those trends. The Arctic Coastal Plain contains some of the richest areas of Arctic fens, thaw lakes, and tussock tundra in the World. Despite its low biological productivity, the Arctic Ocean supports a specialized biotic community, especially near the coast. Many species of plants and animals are found onshore and offshore.

- Oil spills to date have been from pipelines but there have been no major oil spills from oil field operations. Small spills in the oil fields are not large enough nor frequent enough to be considered in a cumulative impact evaluation, but a future large oil spill, especially offshore in sea ice, would likely accumulate, especially as there is no comprehensive method for clean-up of spilled oil in sea ice.

- Air quality and the effects of air pollution on the North Slope are areas in which relatively little research is conducted. As a result, there is no quantitative baseline and it is very difficult to determine local effects from long-range transport of air contaminants.

- Human factors—

  Socioeconomic changes.—Oil development, and attendant modern Western culture, has resulted in major and most likely irreversible changes to North Slope communities. Changes include funds for schools, housing, health care, and other community services, as well as changes in culture, diet, disease, and economic systems. These changes, which are viewed by some as both positive and negative, are complex and cumulative, because they are multifactoral and interactive. Just as oil revenues have changed the North Slope community, both positively and negatively, declining revenues also will affect life there and additional cumulative impacts will occur should financial resources decline.

  Impact on subsistence activities.—The Iñupiat of the North Slope have a nutritional and cultural relationship with the bowhead whale and offshore industrial activity is largely viewed as a major threat. Bowhead whales are affected by noise (as discussed in Chapter 6, Marine Mammals and Anthropogenic Noise), which alters their migratory pathways, which in turn puts hunters at risk by having to travel farther, by increasing exposure to adverse weather, and by increasing the possibility that the whale meat will not last on the return journey home. Increasing awareness of these risks has led to agreements on limiting or moving activities, but the Iñupiat still view the possibility of an offshore oil spill as a potential catastrophe. These threats are cumulative because they interact and because they are repeated with each new lease sale or activity.

  Aesthetic, cultural, spiritual impacts.—Oil development activities have changed the Alaskan landscape so that there is an accumulation of aesthetic, cultural, and spiritual consequences, including lessening scenic values and diminishment of the solitude of the area, the wilderness, and the "spirit of the land."

  Human health effects.—The direct health effects of petroleum activities have not been well documented in Arctic villages. Within Native communities, there are increased alcohol and drug use, increasing obesity, and other issues, but it is not possible to determine which are specifically tied to petroleum activities. Effects on traditional foods and their consumption are of great concern. It also is not possible to determine the degree to which increased financial resources have contributed to improving the quality of health care and accessibility and have offset the adverse effects of oil and the oil industry.

7.02. Finding: There are no known studies that attempt to separate the effects of oil and gas activities from other causes of socioeconomic change in communities of the North Slope of Alaska.

7.02. Recommendation: Develop a cost/benefit analysis of petroleum activities on residents of the North Slope of Alaska, to understand what effect onshore development has had and to provide a baseline for the effects of potential offshore development.

The National Research Council (2003) cumulative effects report makes the point that some information on the effects of development should be gathered concurrent with information on oil and gas activities, so as to maximize learning opportunities and promote better and (or) adaptive management. The study recommended filling the knowledge gaps by undertaking numerous studies. We have only included those that have specific impact on offshore development potential:

1. Comprehensive planning—decisions generally are made on a case-by-case basis, without a comprehensive plan or regulatory strategy;
2. Ecosystem research—ecosystem-level research is largely lacking at the regional scale in Arctic Alaska; most studies have been local in nature;
3. Offshore oil spills—this was of such concern to the NRC committee that it recommended research into mitigating their effects, as well as research in how to deflect marine mammals from spill areas, and clean-up technologies should a spill occur;
4. Zones of influence—impacts from industrial development are not limited to the specific area of development, but extend some ways beyond and there is a need for quantification of those effects;
5. Human communities—there is important missing information on the effects (beneficial and harmful) to the North Slope communities; a better mechanism is needed to increase Alaska Native input into the research process and a way to translate their observations into hypotheses that can be addressed by research;
6. Human health effects—health effects of oil and gas activities are not well documented;
7. Air contamination and its effects;
8. Bowhead whales—better information is needed on the migratory and acoustic behavior of bowhead whales, including from multiple sources and their feeding patterns;
9. How to deal with uncertainty—because there will never be sufficient data to meet all needs for information, transparency is needed when a model or statistical evaluation is performed to assess an environmental effect, which gives voice to the uncertainty surrounding the use of models;
10. Trade-offs—effects of industrial development may accumulate despite efforts to minimize impacts; it is open to discussion whether the benefits derived from oil and gas activities are worth the trade-offs of their impacts; the nature and extent of these impacts must be fully acknowledged and incorporated into regulatory strategies and decision making.

There is a significant body of work on the actual and potential effect of oil and gas activity in Arctic Alaska, as well as on the physical, biotic, and human environment that could be used for cumulative impact analysis. For example, the Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) provided figure 7–1 showing the progression in understanding through time of the social systems in Arctic Alaska. This is but one organization that funds research in the Arctic.

The BOEMRE formally consults with other organizations regarding environmental impacts on potential petroleum development in the Beaufort and Chukchi Seas, including the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). These organizations have published biological opinions and environmental impact statements regarding development (National Marine Fisheries Service, 2008, 2009; National Oceanic and Atmospheric Administration, 2009; U.S. Fish and Wildlife Service, 2009).

There is a growing recognition of the interaction of factors and issues. Shell Gulf of Mexico Inc. submitted an Exploration Plan to the BOEMRE for several exploration blocks from OCS Lease Sale 193 (February 2008) in the Chukchi Sea, Alaska, in July 2009 to conduct exploration drilling and evaluate petroleum potential in three prospects (Minerals Management Service, 2009). Shell proposed to drill several exploration wells within its lease blocks. Its Exploration Plan (EP) includes an environmental impact analysis, a Chukchi Sea Regional oil discharge prevention and contingency plan, environmental monitoring information, site-specific geohazards survey data and assessment, and mitigation measures. With the EP, Shell submitted a Plan of Cooperation to reduce potential conflicts with subsistence activities, and a description of their Cultural Awareness and Health, Safety, Security, and Environmental Awareness Programs. In addition to these documents, Shell submitted reports relating to distribution and abundance of seabirds, acoustic modeling of underwater noise, bird strike avoidance, marine mammal surveys, and drill mud impacts from exploratory drilling.

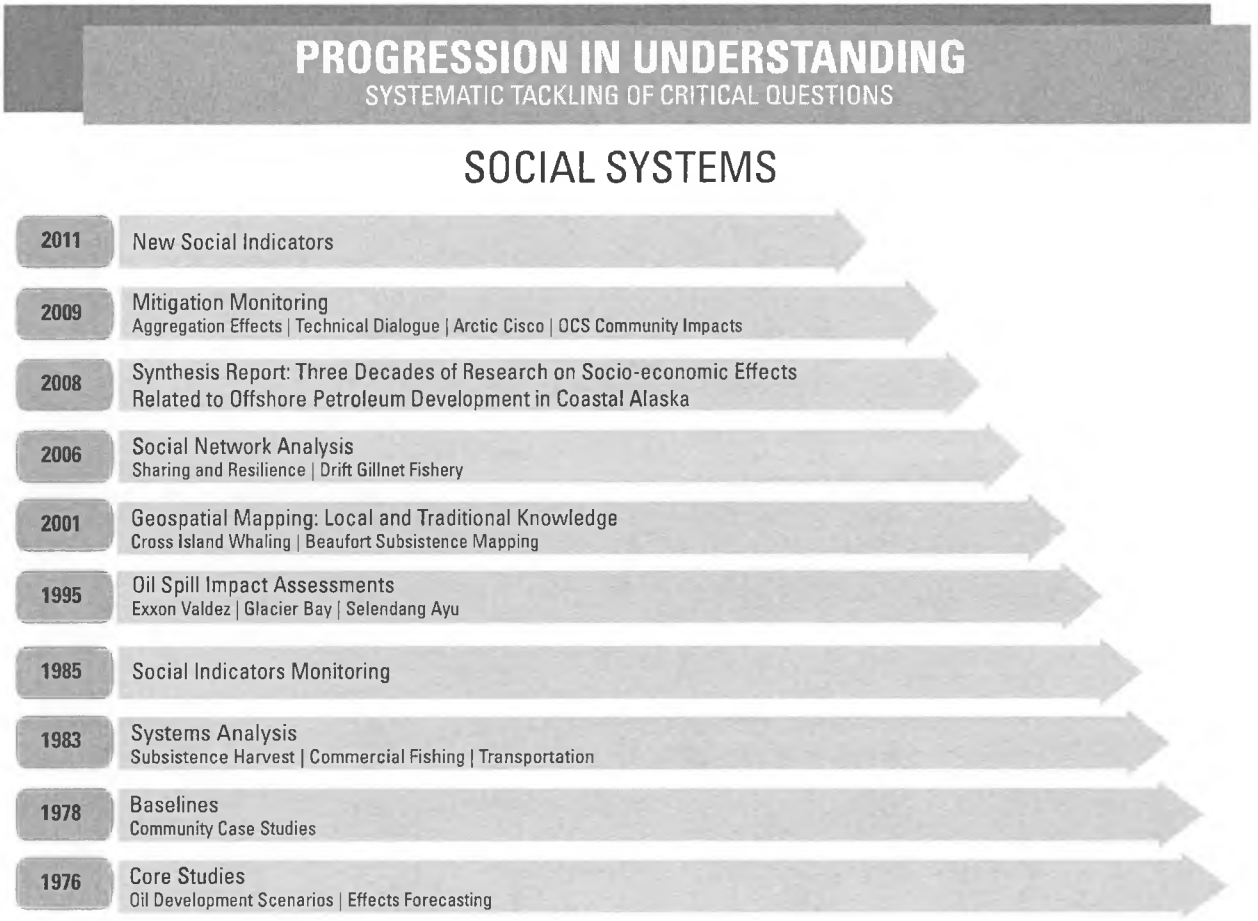

Figure 7–1. Example of studies funded by the Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE, written commun., 2011).

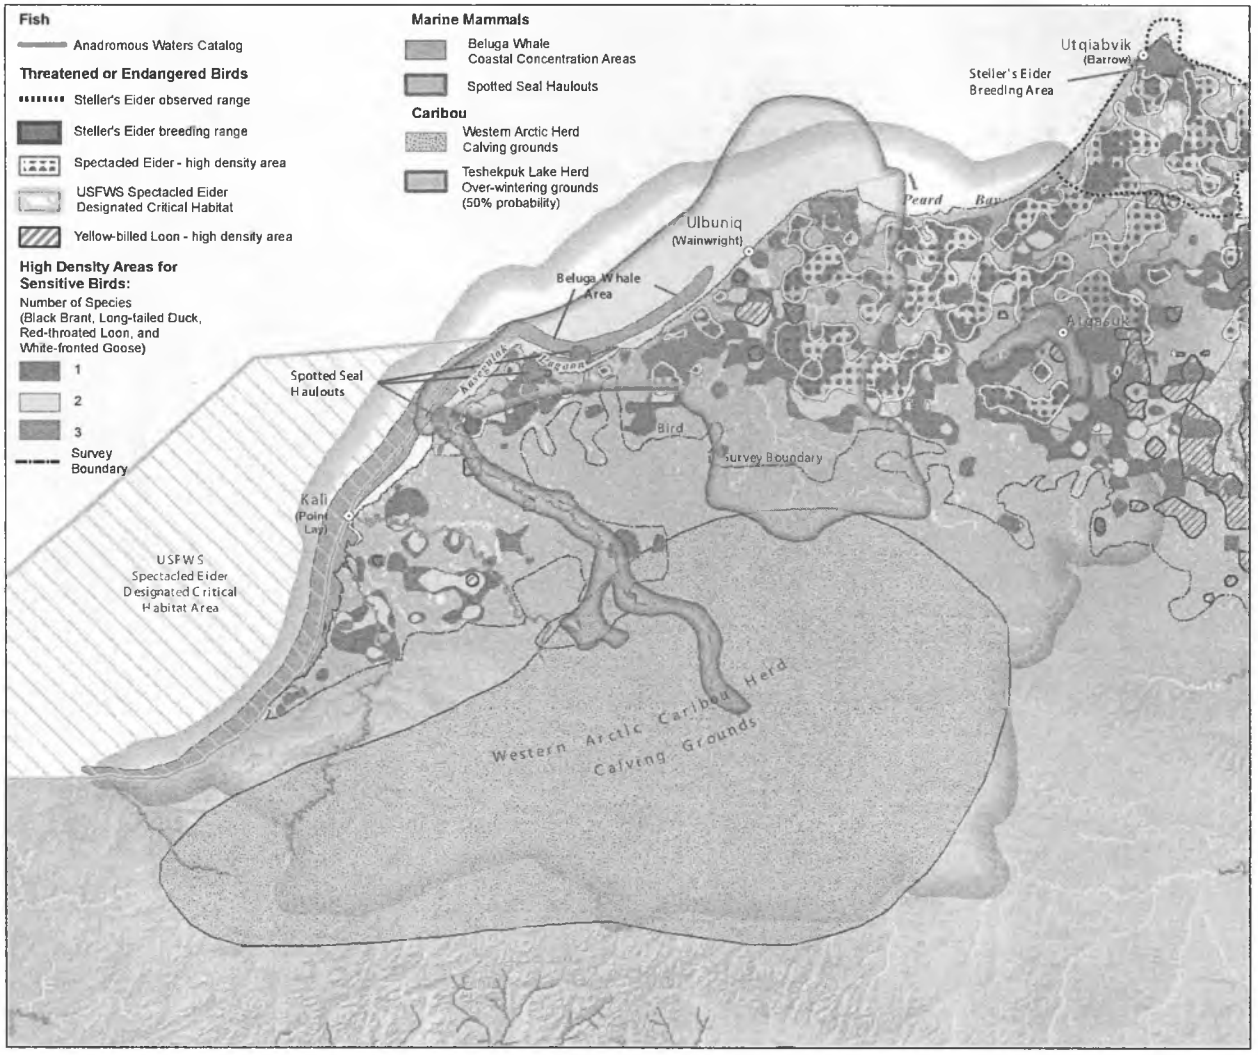
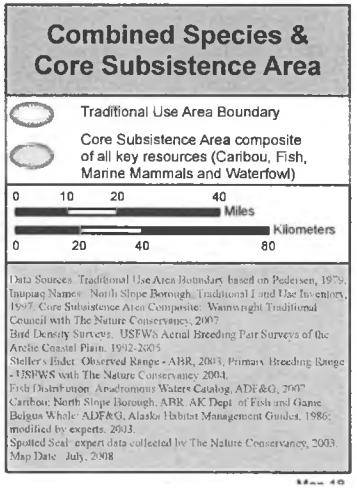
Despite the growing awareness and care that is taken to evaluate environmental impacts, there is still grave concern regarding the cumulative impacts to the environment as a whole and to native communities. This concern was voiced in a number of our structured discussion sessions (see appendix A).

Although there is a great deal of information on the Arctic Ocean, including the Chukchi and Beaufort Seas, the information is not synthesized and is not integrated. This has implications for impact analysis, but especially for cumulative impact analysis. The data and information also are not collected in a geospatially sufficient manner to provide as strong a data underpinning as we have on land (fig. 7–2).

There also is a body of knowledge regarding behavioral animal studies related to drilling activities (related to the full range of activities including impacts from boats, aircraft, noise, light, and more), but some studies are anecdotal and cite behavior of animals in certain circumstances, certain times of the year, with certain activities. It is unclear if there is any synthesis of cumulative impacts, especially of repeated behavior. Because there is not yet offshore development in the U.S. Arctic, now is the optimal time to develop studies to determine cumulative impact, which includes a full synthesis of the literature and studies that are available to determine what is already known and what remains uncertain. There is a great deal of literature on different species, activities, behavior, and a synthesis of these studies would likely show findings different than individual studies.





This map combines the core subsistence areas from Map 11 and the combined sensitive species habitat areas from Map 17. There is strong overlap between the combined core subsistence area and the important habitat for many sensitive and Threatened and Endangered species, demonstrating the biological and cultural importance of these areas. The importance of these habitats demonstrates the need for careful land use planning.

As land use decisions are made in the NPR-A, the information in this report can be used as a tool for crafting management recommendations that balance conservation and development. Well informed decisions that consider all available information can ensure that areas of high cultural and ecological value are conserved.

Figure 7–2. Map showing combined sensitive species habitat areas and core subsistence areas for onshore Arctic Alaska. Similar data and visualizations are yet not available at this level for the Arctic OCS. (The Nature Conservancy and Wainwright Traditional Council, 2008.)

7.03. Finding: There is a growing volume of scientific information for the Arctic and the Arctic OCS, more specifically, that is not synthesized and is not integrated. This has implications for confident impact analyses, but particularly for the development of rigorous cumulative impact analyses.

7.03. Recommendation: A thorough synthesis of the existing Arctic literature needs to be conducted to develop a body of knowledge about cumulative impacts. This analysis would point out where studies show consistency and where there is need for more robust analysis of cumulative impacts on certain species or during certain times of the year or during certain behaviors (breeding, feeding, migrating, molting, staging, for example). Significant mitigation measures are being planned and in many cases may be enough (temporary disturbance for certain species during certain times of the year). But a thorough analysis of the literature would give greater assurance of the scientific validity of such assumptions, especially since the literature is detailed and plentiful for some species and sparse and anecdotal for others. This literature synthesis and evaluation should be supplemented with local traditional knowledge. This baseline for cumulative impact analysis will also help in dealing with the effects of climate change on cumulative impact. The data reviewed in the synthesis need to be made digital, where appropriate, so as to facilitate combining data sets and providing a foundation upon which to add more data and to identify data gaps.

Through reviewing the literature and looking at the issues associated with industrial activity, this author compiled a list of just some of the issues that need to be evaluated and how they accumulate when considering a comprehensive cumulative impact evaluation of offshore development:

1. How the resource will be transported—pipeline or tanker?;
2. What onshore infrastructure will be needed to support offshore exploration and development?;
3. How this onshore infrastructure will impact current Alaska North Slope oil and gas development and the cumulative impacts of that development and the two (onshore and offshore) combined;
4. Whether or not offshore development will affect or be affected by the coastal erosion currently occurring at unprecedented rates;
5. Invasive species;
6. Potential from oil spills (not just from drilling activities, but from other factors, such as ships);
7. Socioeconomic changes to affected communities; and
8. Effect on or interaction with subsistence activities.

This is but a small list of factors that need to be considered, in addition to the others listed in this chapter (climate change effects and others) and the other chapters of this report (such as effect on marine mammals, ecosystems, and oil-spill risk).

Effects of Climate Change on Cumulative Impact Analysis

Climate change and resulting ecosystem changes complicate evaluating cumulative effects. Continued climate change effects will themselves accumulate and affect sea ice, plant and animal distribution (both terrestrial and marine), permafrost, human activities, and oil field operations.

The National Research Council (2003) found in their assessment that it appeared customary for practitioners to assume that the only source of environmental change in the evaluation of cumulative impacts is the action under study and that the environmental setting itself does not affect the analysis. Climate change, however, alters this assumption especially in Arctic Alaska, because the climate is changing rapidly and is affecting the landscape and environment itself, independent of, and in addition to, any potential petroleum activity. These factors must be taken into account when evaluating cumulative effects.

Climate change is only peripherally considered in most cumulative impact evaluations or assessments. Climate change can have significant effect on the ecosystem, which in turn will be additive to other impacts, although not directly related. An excellent example of this can be seen in figure 7–3, which illustrates the shift from benthic to pelagic ecosystems, which is already being documented in Arctic waters.

The conditions that are postulated to occur with climate change may have a profound effect on the environment even in the absence of development, and thus will have a profound effect on any cumulative impact analysis. Yet little is understood about how to incorporate these changes into a cumulative impact assessment.

7.04. Finding: Climate change considerations in cumulative impact evaluations are often peripherally handled with limited analytical rigor. Yet, climate change can significantly affect ecosystems, which in turn will be additive to other impacts under consideration.

7.04. Recommendation: A methodology needs to be developed to incorporate climate change effects into a cumulative effects analysis that is transparent, robust, and sufficiently structured to incorporate existing scientific uncertainty about future climate scenarios.

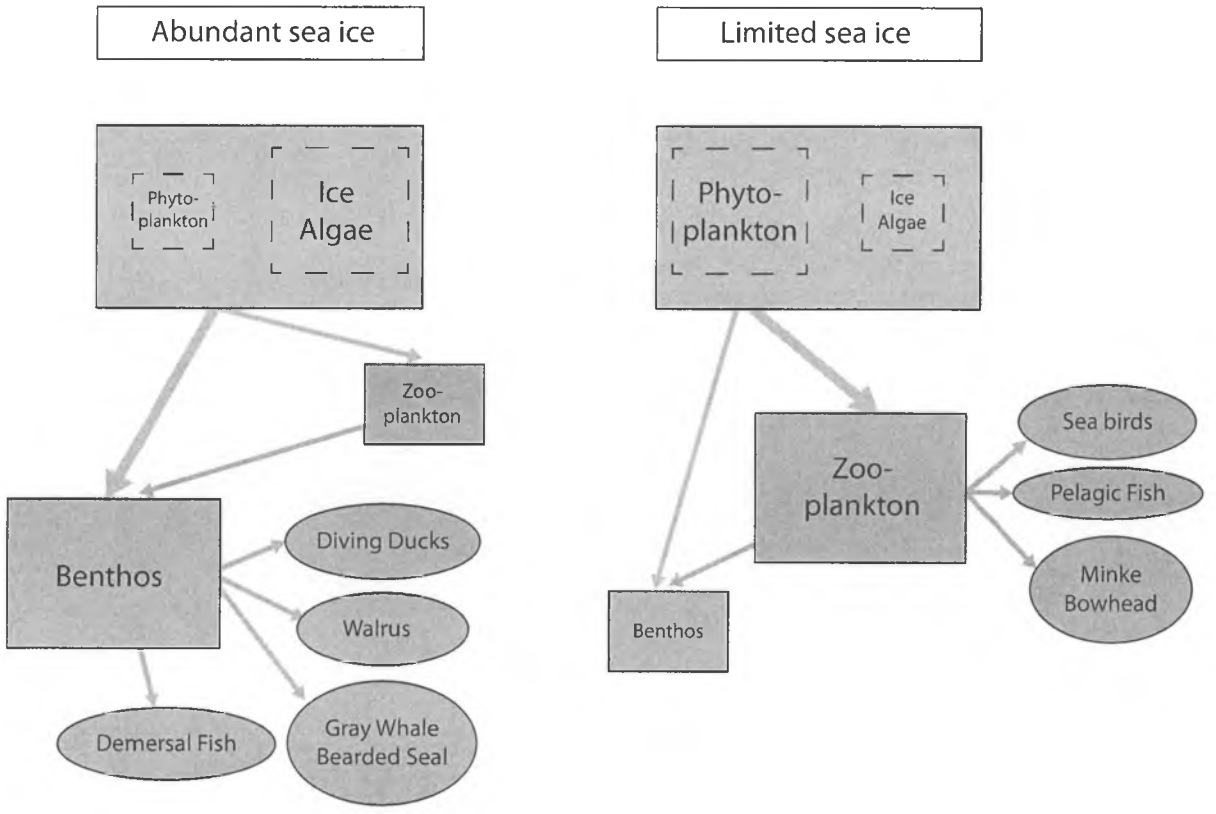


Figure 7–3. How different ice conditions may affect Arctic marine ecosystems (Bluhm and others, 2008).

Methodology for Cumulative Impact Analysis

No universally accepted framework or approach for cumulative effects analysis exists and, thus, there are different approaches to cumulative impact analysis. Further, each government agency handles it differently. This leads to the perception that cumulative impacts are ignored, or when not ignored, are met with confusion. This issue was voiced in each of the structured listening sessions. However, there are accepted general principles that need to be included in all cumulative effects analysis—the analysis needs to be conducted within a context of understanding the resources, ecosystem, and human community thresholds, that is, levels of stress beyond which the desired condition degrades (Council on Environmental Quality, 1997). Determining this threshold is often difficult and problematic. Cumulative impact analysis is complex and difficult, and impacted by a number of factors, but confusion is increased by the different approaches and scales. The different approaches make the results or findings very difficult to compare and contrast. A single methodology could be consistently applied to different areas, account for regional variables, and allow for a comparison of results. Different factors are currently counted in many different ways and words and terms are used differently by different groups: for example, what are threshold indicators; what mitigation measures are prompted when (what kind of threshold has been passed); what are acceptable impacts. A single Department of the Interior approach (1) could alleviate the perception that factors are not being weighed equally (either positive or negative impacts); (2) will resolve the issue of cumulative impact analysis being done differently in different planning areas by different agencies; and (3) will increase the clarity about what is really being considered. One approach also will address the perception that individual development projects are not being adequately addressed by cumulative impact analysis.

The National Research Council (2003) report was unable to attribute the absolute degree of importance to effects, so it attempted a descriptive approach to the importance of the effects. Since then, there have been efforts to develop standardized, quantitative approaches to cumulative effects [for example, Johnson and others (2005) and Halpern and others (2008)], but these have only described some of the impacts and no benefits of proposed activities. Another study that bears watching is the BP- and North Slope Borough-funded study at the University of California, Santa Barbara to develop an approach to quantitatively assess the cumulative impact of noise on marine mammals (namely gray whales and bowheads). These are excellent examples from which to build, but more work needs to be done.

What seems to be missing from many of the cumulative impact analyses is the consideration of future actions. This is very difficult to do, but in an area such as the Arctic where development is still relatively new, one must consider future development in order to account for cumulative impact. The challenge of trying to determine future development is exacerbated by the various oversight responsibilities of the different agencies. Consideration must be given to developing a consistent approach to "reasonably foreseeable future actions," to account for the various projects among and between the various agencies, geographic regions, and time frames, but not overestimate projects that may never be developed. What is considered reasonable and foreseeable is going to be different in each area, but guidelines, definitions, and thresholds need to be developed so they are common and consistent.

Monitoring is an important part of the iterative nature of cumulative impact analysis, to assess the accuracy of predictions of effects and to evaluate the success of mitigation. Consequences should be evaluated repeatedly in the cumulative impact analysis and a monitoring program should include the following (Council on Environmental Quality, 1997):

1. Measurable indicators of the magnitude and direction of ecological and social change;
2. Appropriate timeframe;
3. Appropriate temporal and spatial scales;
4. Means of assessing causality; and
5. Means of measuring mitigation.

It also is important to note that possible effects, both positive and negative, are perceived differently by different groups and individuals. It is not clear that there is a method to attribute a degree of importance to effects, so often the effects are descriptive or qualitative instead of quantitative.

Recently, ecosystem-based marine spatial planning (MSP) is being discussed as a possible tool for assessing and managing for cumulative effects of multiple activities (Foley and others, 2010) as well as a viable strategy for managing human activities in Federal waters. Marine spatial planning is a comprehensive, adaptive, integrated, ecosystem-based spatial planning process for analyzing current and anticipated uses of the oceans (National Ocean Council, 2010, accessed March 31, 2011, at http://www.whitehouse.gov/administration/eop/oceans/cmsp). MSP is a process that analyzes the spatial distribution of activities in the ocean so that ecosystem health and services can be protected and that existing and future uses can be maintained, reducing use conflict. Some MSP efforts, notably those in Norway, explicitly cover multiple sectors including oil and gas development (Olsen and others, 2007). Marine spatial planning takes into account two fundamental principles, namely those of context and uncertainty (Foley and others, 2010), as well as stakeholder input—all issues mentioned previously as important to consider when conducting cumulative impact analysis. Marine spatial planning, as outlined in a number of studies, many of which are described in Foley and others (2010), can be used to reduce the level of cumulative impacts in any one area, as well as the number of trade-offs and conflicts between users and between users and the ecosystem.

7.05. Finding: No universally accepted framework or approach for cumulative effects analysis exists, which leads to the perception among some stakeholders that cumulative effects are ignored. The lack of a clear structure and quantitative analytical process leads stakeholders to question the sufficiency of approaches taken and validity of resulting findings.

7.05. Recommendation: A methodology for comprehensive, quantitative cumulative impact analysis that is transparent, externally vetted, and adopted consistently across at least the Bureaus of the Department of the Interior should be developed. In order to help develop the methodology, an evaluation of the various approaches should be conducted, including marine spatial planning, to determine best practices of all agencies both domestic and international. A common language and a common set of metrics should be developed. One methodology that can take into account regional variables should be developed. The analysis should include more than single projects, and the scope of the analysis should be determined by an expert panel. The approach should define the information needed for a decision and what to do when a decision is required but there are no data. The methodology and resultant analysis should include a plan for the number and types of projects in the region and be able to account for both positive and negative tradeoffs. An approach must be developed to incorporate or predict reasonable future development and monitoring of impacts as development progresses.

Conclusion

The evaluation of cumulative impacts—the combined, incremental effects of human activity—has a basis in NEPA and is guided by CEQ guidelines. In practice, study of cumulative impacts is complex and difficult, especially when consideration is given to potential future development and the overprint of climate change. There is confusion among all parties interested in cumulative impacts regarding what they are and how to evaluate them. Several agencies and organizations evaluate cumulative effects, but there is little coordination of efforts or resultant findings. Furthermore, there is no universally accepted methodology for the study of cumulative impacts. Society's ability to judge the potential effects of oil, gas, and other development considerations in the Arctic would benefit greatly from the creation of a methodology for comprehensive cumulative impact analysis to be adopted consistently. To develop such a new methodology will require an evaluation of best practices across all agencies, domestic and international, and taking advantage of new analytical approaches emerging in fields outside of environmental sciences. A consistent national approach, with common language and a common set of metrics that can take into account regional variables, would allow for the scientific underpinning of an assessment for Arctic development to be viewed relative to actions elsewhere. Efforts to develop such a methodology should consider how best to incorporate more than single projects. Any new approach needs to define the amount of data needed for a decision and what to do when a decision is needed and there are few or no data. The methodology and resultant analysis should include a plan for the number and types of projects in the region and be able to account for both positive and negative tradeoffs. An approach must be developed that is flexible and robust enough to incorporate or predict reasonable future development and define essential monitoring of impacts as development progresses. Synthesis activities must be regularly conducted to document our growing understanding of ecosystems and effects. Development and implementation of cumulative impact analysis must include the various stakeholders in the Arctic. A thorough synthesis of the existing Arctic literature is needed to develop a body of knowledge about cumulative impacts from which to develop the cumulative impact assessment. This synthesis also will aid in incorporating climate change into the new cumulative impact assessment methodology. Only in this way will we start to appreciate what cumulative impacts, both positive and negative, will truly be associated with development in the Arctic.

Chapter 8

Conclusions

By Brenda Pierce and Leslie Holland-Bartels

The Arctic has had relatively little industrial development thus far, giving us a unique opportunity to determine the future land use and resource management of this area and "get it right." We have the chance to study the environment and all its components and how any changes (human-induced or natural, including climate change) will affect the Arctic. Specific and detailed USGS summaries of key existing scientific information, key knowledge gaps, and recommendations are found in each chapter. Those recommendations are important for understanding what the USGS discovered in the course of this study and to help inform and improve decision making. Within this conclusions section, we provide a higher level summary and synthesis of our findings to help inform the Secretary of the Interior's considerations of the right places and the right ways in which to develop oil and gas resources in the Arctic Outer Continental Shelf.

Impacting all Arctic components and affecting any resource management strategies will be climate change. Climate conditions in the Arctic have recently been undergoing a marked change, particularly during the last 20 years. Environmental changes include warmer air and ocean temperatures, earlier spring snowmelt, a marked decrease in the extent and thickness of sea ice, accelerated coastal erosion, permafrost degradation, an increase in shrubs on the Arctic coastal plain, and other habitat changes. These changes in the physical environment influence biological, human, and industrial systems in a number of ways:

- The distribution of some animal species (for example, walrus and polar bear) is responding to changes in, or the loss of, critical habitat (for example, sea ice) during parts of the year.
- This in turns impacts subsistence hunting.
- The number of days seismic exploration vehicles can operate on the tundra without causing environmental harm has decreased from 200 to 100 over the last 30 years.

Climate projections for the next 50–100 years produced by global climate models consistently show a pronounced warming over the Arctic, accelerated sea-ice loss, and continued permafrost degradation. Of all areas on Earth, the Arctic has the greatest sensitivity to changes in greenhouse gases, with some of the largest changes expected to occur in the Bering, Beaufort, and Chukchi Seas. If realized, these projected climate changes will ultimately affect nearly every aspect of the Arctic environment. This is a major concern from a biological standpoint because the indigenous plants and animals are so highly adapted to the specific extreme conditions that have been the norm in the Arctic.

The effects of climate change are anticipated to influence all components of the Arctic ecosystem, and Arctic Outer Continental Shelf energy activities may exacerbate those changes, unless careful analysis of risks and tradeoffs is conducted. By judiciously planning when energy activities occur, environmental risks associated with those activities may be reduced. For example, extreme cold is a contributing factor in drilling accidents and spills, and thus the significant warming of mean autumn and winter temperatures expected by mid-century will lessen the likelihood of accidents and spills. Although portions of the Chukchi and Beaufort Seas are expected to be ice-free for a greater period of time each year, the pack ice is predicted to be more dynamic at certain times, increasing the risk of accidents and making oil-spill response more

difficult during these times. Ice seasons of shorter duration and longer open-water seasons could have profound effects on many different components of the Arctic system, likely affecting Arctic ecosystems and the species within them, especially in areas of particularly high biological productivity and potentially allowing for longer seasons of energy development and transportation.

Climate change also may affect:

- clouds, which in turn affect visibility;
- icing conditions, which are a significant hazard in the Arctic, and can increase the potential for accidents and make response more difficult;
- precipitation, an increase of which would hinder spill response and increase the potential for accidents;
- storms (possibly increasing in frequency or intensity during certain parts of the year);
- sea-level rise, which can affect coastal areas and infrastructure;
- ocean acidification, which can significantly impact calcifying organisms due to the corrosive effect of the acid on their shells and would have reverberations throughout the Arctic food chain;
- ocean circulation patterns, which are likely to change, although what those changes would be and what their effects would be are highly uncertain.

Climate change also will impact organisms in the Arctic (including fish, birds, whales), pinnipeds (ice seals and walrus), and polar bears in many different ways including through the warming of Arctic waters from sea-ice declines and from changes in the food chain notably from the potential effects of acidification of the Arctic Ocean.

Understanding climate change is an important piece of any type of development in the Arctic. More research needs to be conducted on the proposed effects of climate change on factors such as storms and ocean circulation. Storminess will directly affect the safety of oil and gas development. Ocean circulation patterns are critical in shaping both the physical and biological environments of the Arctic Outer Continental Shelf. The science community is actively engaged in developing state-of-the-art global climate models, but these models currently lack the resolution needed to address many of the issues discussed in this report. The United States, as one of the Arctic Nations, would benefit greatly from participating in the development of fully integrated (atmosphere-ocean-land) regional climate modeling efforts. Continued and enhanced efforts in this arena, specifically for the Arctic region, will provide a fundamental tool needed to better understand the degree and nature of any consequences of climate change as it relates to decisions regarding energy development in the Arctic. Periodic Arctic climate impact assessments can help ensure that an up-to-date scientific understanding of climate is achieved.

This theme of fully integrated regional modeling and analysis resonated throughout every topic that we studied. Our analysis of the many different literature sources—scientific reports, public policy documents, workshop findings, web sites—and discussions with a diverse range of stakeholders has resulted in a recognition that in recent years there has been a concerted effort to obtain more data and information on and conduct more research in the Arctic, so there is a great deal of information existing about the Arctic. Yet, in many ways, relatively little is known about the Arctic in large part because many of the studies are targeted in focus and independently conducted with limited synthesis, even within studies on the same topics. There is a critical need for large-scale synoptic efforts that synthesize the many different studies on the full range of topics by the numerous researchers and organizations examining the Arctic. However, there also is a need for some very specific research to address the identified science gaps (in the previous chapters, specifically, and here in general).

Recent research and evaluation efforts in the Arctic have resulted in better understanding of Arctic geology, including the acquisition of geophysical data, offshore mapping, and successfully completing the first Arctic research drilling expedition. Such efforts also have enhanced our understanding of the tectonic and climatic history of the Arctic system, including carbon cycling, and delineating Arctic petroleum systems. Yet, there is a growing need for 3-D seismic data in the Arctic in order to better understand the geologic history of the area and its oil and gas potential (conventional and unconventional), to provide information regarding the safe development of these resources, and to support claims regarding the Outer Continental Shelf under Article 76 of the U.N. Convention on Law of the Sea.

Improved estimates of the oil and gas resources in the Arctic are needed to provide a better baseline for effective resource management. But characterization of the oil reservoir volume and pressure also is needed throughout the Arctic Outer Continental Shelf, as these parameters have direct bearing on oil-spill risk assessment and oil-spill contingency planning. Underpinning research in foundational geology and geophysics can provide an improved understanding of how oil and gas resources are formed and emplaced in reservoirs in the Arctic.

Information on the physical oceanography (such as circulation processes and wind) is critical for oil-spill modeling, oil-spill response, and cleanup efforts, as well as for understanding biological resources. The physical oceanography and meteorological Arctic Outer Continental Shelf characteristics that are inputs into this modeling are highly dynamic as a result of complex factors including ocean

source waters, freshwater inflows, and ice melt differences between the Chukchi and Beaufort planning areas. Such complexities are not yet well understood because of the challenge of instrumenting a remote ice-influenced system such as the Arctic Outer Continental Shelf. Thus, the physical understanding of the Arctic Outer Continental Shelf is not comparable with that of the Gulf of Mexico Outer Continental Shelf, nor is the circulation or weather modeling that informs oil-spill trajectory models yet of similar rigor. Outputs from such trajectory models also influence ecological effect analyses, as well as spill contingency planning and real-time response considerations. These analyses are limited by the accuracy and precision of the physical data that inform them. In addition, physical oceanographic and meteorological data help inform a wide variety of issues in the Arctic beyond trajectory modeling or contingency planning. The United States and Canada might benefit from the development of multi-purpose, multi-agency funded monitoring networks that could inform climate forecasting, aviation and shipping safety, and oil-spill response and mitigation plans. The visualization and serving of data through tools of the Alaska Ocean Observing System (AOOS) and (or) the Emergency Response Management Application under development for the Arctic (Arctic ERMA) would ensure efficient access to information and improved asset planning that is critical in the high cost instrumentation environment of the Arctic.

Development in the Arctic is challenging and complex because of the many unknowns and because of the inherent risks of working in frontier and relatively pristine environments. Beyond the focused question of "science gaps" the USGS Outer Continental Shelf Team was challenged with, we observed a need to evaluate all relevant information available to help develop guidelines, best practices, regulations, and policies. Lessons learned from all existing Arctic or sub-Arctic examples must be used to inform future decisions and optimize future actions. The *Exxon Valdez* oil spill in 1989 was the largest oil spill in United States waters until the *Deepwater Horizon* spill of 2010. The lessons learned from the *Exxon Valdez* oil spill are included in our report for the purposes of highlighting Alaska-based experience ranging from spill response through Natural Resource Damage Assessment components. Any Arctic Outer Continental Shelf evaluation and planning effort for oil development can benefit from the lessons learned from *Exxon Valdez* oil spill, which can better inform overall preparedness and particularly oil-spill prevention and response.

Current information and recent baselines developed for different components of the Arctic ecosystems need to be supplemented with ongoing monitoring so as to understand the changes in the ecosystem and monitor its health. Information is needed on all levels of species, from phytoplankton, microbes, and zooplankton, to fish and birds, to marine mammals. It is important to include not just those species that live in the Arctic year-round, but also migratory species as well.

A particular concern, voiced by many stakeholders and cited in the literature, is the impact of noise on marine mammals. Even with multiple studies conducted on ocean noise and marine mammals, large uncertainty still exists in understanding how impacts to individual animals may affect characteristics in the populations and research is needed on this topic. An inventory of seismic sound sources used in the Arctic Ocean does not exist. Such an inventory would provide standardized information about source, physical oceanographic conditions, and timing and duration of surveys. This database could be used to evaluate multiple sound sources that a marine mammal might hear in space and time, and help validate models that estimate sound propagation. The database may ultimately reduce the need for expensive or redundant acoustic modeling and monitoring, especially in sensitive or biologically significant habitats, as well as contribute to developing more effective mitigation strategies. Further, there is a need for an inventory of all non-natural noise in the Arctic Ocean, such as vessel noise, ship-induced icebreaking, and aircraft. Such databases will be important to distinguish between anthropogenic and natural sources of noise impacts to marine mammals and will point out where there are significant information gaps (there is relatively little information on any of these). Data gaps also include the overall ambient noise budgets of the Arctic and how these vary seasonally and spatially. These data are needed because substantial challenges remain for scientists to understand the magnitude and significance of potential effects of anthropogenic sound on marine mammals. Additional research is needed to discriminate between the effects of sound, other aspects of human activity, and environmental variation (natural background). A synthesis of existing data on whale population abundance, structure, and habitats would provide a framework for analyzing how sound impacts whales and help managers determine times and places where whales might be most impacted by anthropogenic sounds. Similarly, fundamental biologic and habitat information about ice-dependent species, such as ice seals, is lacking, as is any information on how anthropogenic sound impacts them. This information needs to be obtained and integrated into these anthropogenic effects databases. In addition, walrus reactions to anthropogenic sounds also need to be better documented and studied (there is even considerable uncertainty as to whether walrus reactions to anthropogenic activities are caused by sight, sound, or smell) and a better understanding and inventory of habitat needs for walrus are needed.

There is a continuing need to facilitate the collection, integration, and sharing of multi-scale data sets to advance our understanding of the Arctic as a complex, interdependent system. Such multidisciplinary data sets need to be used to develop comprehensive, holistic approaches to resource development and impact scenarios to inform planning. The multiple agencies, responsible for different parts of the system, make this task challenging, but it is a critical need. There must be a comprehensive approach taken to any type of industrial development in the Arctic. This comprehensive approach would benefit greatly from international cooperation and coordination. We share a border with Canada, which faces many of the same questions and challenges that we do, and other countries, particularly those of northern Europe, have experience from which we could benefit.

Also resonating throughout many of the issues examined was the challenge of relating the rapidly emerging science and technical information to the decision-making process. The level of information, the number of agencies and entities generating information, and the manner in which information from these sources is served is becoming more important as attention is turned towards the Arctic in general, and resource development in the Arctic more specifically. These information sources, while individually well structured, roll up to a complex information picture that is a challenge to interpret. It is difficult, if not impossible, in attempting to examine such information holistically, to know which needs are being addressed fully or partially, what new information needs or insights have emerged, how one weighs the relative importance of the information, and which new or continued investments are critical to reducing uncertainty among vested parties.

This information challenge is particularly important when it comes to evaluating cumulative impacts. Cumulative impacts are the combined, incremental effects of human activity. Cumulative impacts can result from factors which may be insignificant by themselves but significant when interacting and (or) accumulating over time and space, through repetition, or from a combination with other effects. When actions are considered individually or independently, their combined consequences—or cumulative impact—may not be fully considered or evaluated. This results in misunderstanding, and failure to consider the long range impact of multiple decisions over a large area or over time. Policy decisions are usually made at the regional or national level, but environmental effects are usually analyzed and assessed at the project level. Decisions about and permitting of industrial activities are often done on a case by case basis by multiple entities responsible for oversight of different aspects of the activity. These entities often operate without the benefit of a comprehensive plan or understanding of the scope, intensity, and consequences of the industrial activities, especially if overseen by another entity. Long-term decision making must take into account the cumulative nature and extent of the development benefits and challenges, and the costs and risks of both.

Cumulative effects analysis requires application of sophisticated geospatial technologies, regular synthesis of environmental data and information, ecological forecasting, and multidimensional evaluations of planned human developments. Thus, there is need for more coordination and comprehensive planning among the various stakeholders in the Arctic, including those with responsibility for resources, those that conduct research, and those that use resources. In order to conduct cumulative impact analysis, a thorough synthesis of the existing Arctic literature that builds on the initial work in this report needs to be conducted to develop a body of knowledge about cumulative impacts, a theme that resonates throughout this report. It is critical that this cumulative impact information synthesis and evaluation include local traditional knowledge. The indigenous, subsistence community is extremely knowledgeable about the environment, ecosystem, and changing conditions of the Arctic. Local traditional knowledge is a critical resource and should be incorporated into all of the above syntheses and databases described throughout this report.

Equally important is the critical need to develop a methodology for comprehensive, quantitative cumulative impact analysis that is transparent, externally vetted, and adopted consistently. An evaluation of the current approaches should be conducted, including marine spatial planning, to determine best practices and develop a common language and a shared set of metrics. An approach must be developed to incorporate or predict reasonable future development and the monitoring of impacts as development progresses.

The subsistence community and culture are an essential component of the Arctic and all of the issues studied in this report will have an impact on these people and their way of life. To predict with any degree of accuracy the future of Arctic subsistence, with or without energy exploration and development, will require a greater understanding of the potential changes in local environments and ecologies because subsistence patterns closely correlate to these factors. Thus, subsistence patterns are vulnerable to the effects of climate change and anthropogenic development (whether it be oil and gas development, shipping, tourism, or another). Additional information is needed to determine the potential hazard to native subsistence livelihoods from oil and gas exploration and development, since such development can impact all parts of the spectrum from the specific subsistence animals themselves through their food chain and ecosystem.

In discussions with individuals and groups in the course of our assignment, and to some degree in the literature, it became clear that evaluating the science and filling identified science gaps will not be enough to address the issues surrounding energy development in the Arctic. Opinions on development run the gamut from "there is already enough science" to "there will never be enough science." There are areas of significant scientific research that form a sound basis upon which to make decisions; there are areas where additional science is needed; but there also is an area in which more than science is needed. For that reason, we offer the appendix on Structured Decision Making (SDM), as an example of a type of tool that might be used to help inform decisions about energy development in the Arctic. SDM is a tool to help decision makers when a great deal of complex information and substantial uncertainty exists about the potential effects of development on the many resources of management interest. SDM consists of deconstructing decisions into their component parts, analyzing each part, and synthesizing the parts into a decision framework that can produce direct recommendations to decision makers about which decision is most likely to lead to attainment of their management objectives. This process helps the decision maker develop the fullest possible understanding of the complexities of the decision, including decision objectives, tradeoffs, uncertainties, and risks.

As stated in Chapter 1, Framing the Assignment and Process, our discussions and analyses highlighted that science sufficiency and science gaps are not absolutes but exist in large part in the eye of the beholder. As dynamic concepts, they are tied to an individual's or organization's held beliefs and what weighs most heavily in the decision process when complexity and uncertainty come into play. Whether to develop oil and gas resources, where they might be developed, when they might be developed, and what science is needed to inform those decisions are complex questions because Arctic Outer Continental Shelf development, particularly in the Chukchi Sea, would be a new, frontier activity with limited information and previous experience to guide the decisions being made. Positions about how to deal with any complex issue are informed by a mix of held and technically derived beliefs, and science influences those beliefs to different degrees. So, the questions become:

> How necessary does the vested party consider new information to its decision process? and
>
> How informative is the available science to be considered (uncertainty, applicability)?

Because of the complex nature and diversity that exist across human belief structures and the difficult-to-study and changing nature of Arctic ecological systems, development of full agreement about science sufficiency is a challenge.

Thus, while there is a growing base of scientific and technical information for the Arctic, which is synopsized in this report, as are critical science gaps to be addressed, many of the challenges emerging in Arctic oil and gas development decision making are beyond the ability of science alone to resolve. There is no "silver bullet." However, we believe a few strategic actions can better support decision making and make for a more transparent process for all vested parties to express, understand, and perhaps balance their respective views on tradeoffs associated with "inaction until more information is in hand" versus "action not sufficiently informed."

In conclusion, the use of SDM approaches brings vested and interested stakeholders into the decision process in a transparent and documented way. The process allows for learning and adaptation, which are critical concepts in a changing frontier environment like the Arctic and we encourage its use. Second, oil and gas development decision making occurs within the broader context of Arctic issues. A collaborative and comprehensive Arctic science planning process would bring great value to the decisions required to proceed with development of oil and gas and other strategic assets in the Arctic in a changing climate environment. Such a science plan and its implementation must be informed by an SDM-like process and the syntheses of information we discussed earlier. Third, the Arctic science and resource community, and particularly the Alaska community, is a model of collaboration. We found throughout our consultations an open and energized desire to understand different views on development and to find means to move forward. Thus, the development of integrated monitoring efforts and collaborative science efforts across governmental, industry, and nongovernmental entities can be accomplished. However, we believe focused attention is required to envision and implement such a fully collaborative environment. Finally, our study found many excellent examples of thoughtful analyses of science and technology needs to inform oil and gas development decisions in the Arctic. Our recommendations and findings add to those already in the literature. To move forward, we strongly recommend that a collaborative implementation process that includes appropriate measures of accountability for all responsible parties/entities be put in place. In our many discussions, we heard from managers, responders, scientists, and community members that they are willing to engage in discussing information needs but that they have a growing expectation that those needs will be considered and, if appropriate, addressed in a visible and traceable manner.

Appendix A. Expert Consultations

Table A–1. Input received during the five facilitated expert consultations and the North Slope Public Session.

[Participants were asked to identify issues/gaps under each of the four Issue Topics (Climate Change, Oil-Spill Response, Marine Mammals and Noise, and Cumulative Impacts) requiring scientific knowledge that will affect their ability to accomplish their jobs. Sessions often did not cover all four Issue Topics as noted by dark blue. EIS, Environmental impact statement; LTK, local traditional knowledge; NSB, North Slope Borough; OCS, Arctic Outer Continental Shelf]

Issue topics and detailed input	Industry session	North Slope session	Federal session	Non-regulatory session	State session	North Slope public session
Climate change						
Hardware for data collection, especially in shoulder seasons	X					
Lack of climate data	X					
Ability to down scale models to regional development	X			X		
Lack of data collection network/coordination of research (data sharing…)	X					
Issues created by multiple agencies' climate agendas	X					
Unknown biological response to climate change and adaptability			X	X		
Adequacy of physical models for climate change				X		
Baseline data for biological systems (spatial and temporal)				X		
Use of existing technology/resources to understand climate change in the Arctic				X		
Predictability of refugia in time and space				X		
Relationship between water chemistry and environmental changes due to climate change				X		
Human response to climate change (for example, ship traffic, noise, hunting patterns, fishing, subsistence)				X		X
Relationship between subsistence use/Native culture and changing environmental conditions				X		X
Construction must be sufficient to cover any range of conditions including climate change						X
What happens to platforms at the end of their productive life?						X
Oil-spill response						
Inability to conduct field tests	X					X
Secondary data are perceived as not applicable	X					
Inability to access gray literature (in electronic forms)	X					
Detection and tracking				X		
Mechanical response				X		
Risk assessment				X		
Ice management				X		
Non-mechanical response options—Dispersants				X	X	X
Ecosystems and human response to spill				X		
Impacts of spill response on ecosystems and human systems				X		
Capacity assessment				X		
Fate and effect of spill				X		X

Table A–1. Input received during the five facilitated expert consultations and the North Slope Public Session.—Continued

Issue topics and detailed input	Industry session	North Slope session	Federal session	Non-regulatory session	State session	North Slope public session
Oil-spill response—Continued						
Baseline for damage assessments				X		
Sensitivity mapping and response planning				X		
Planned response options				X		
Protocols and standards (damage assessment, restoration)				X		
Information availability				X		
Well safety/control					X	
Systems for humans monitoring wells and identifying issues, ability to reduce human error					X	
Regulations to prevent accidents					X	
Public perception on response capability					X	
Contaminant load in environment—baseline					X	
Ability to test response equipment and methods					X	
Decision making and critical time needs during response					X	
Length of time oil persists in the Arctic environment					X	
Oil spill response gap analysis						X
A combination Coast Guard Oil Spill Response Team						X
Toxicity of dispersant on Arctic ocean organisms						X
Timing of drilling of relief well(s) in case of blowouts						X
Closeness/locations of oil spill cleanup team and equipment						X
Drilling only during favorable times of the year, to mitigate the chance of a catastrophic event						X
Marine mammals and noise						
There is no standard for measuring underwater sounds (science)	X		X		X	
Acoustic propagation is not well understood	X	X				
Lack of understanding of what sound levels cause impacts (behavioral changes, fallout from behavior changes, and other considerations)	X					X
Context of received noise levels for marine mammals, feeding versus migrating, habitual versus naïve	X	X				
Mitigation/quieting technology	X					
Development of remote sensing technology	X					
Effects of anthropogenic sound on bowhead whales from multiple sources/projects	X	X	X			X
Baseline data for species other than bowhead whale, especially related to climate change and seismic noise	X	X			X	X
Knowledge of spatial/temporal distribution, use of satellite tagging/aerial surveys/acoustic surveys	X	X		X		
Baseline data for the current state of the Chukchi Sea and ability to track changes and new species		X	X			

Table A–1. Input received during the five facilitated expert consultations and the North Slope Public Session.—Continued

Issue topics and detailed input	Industry session	North Slope session	Federal session	Non-regulatory session	State session	North Slope public session
Marine mammals and noise—Continued						
Ability to translate impacts on individual bowhead whales to larger bowhead populations		X				
Ability for LTK to document changes in the area as well as identify new species		X				
Information sharing among groups to reduce the risk of redundancy (seismic)		X	X			
Baseline information on natural sound levels and anthropogenic sound levels	X	X				
Information on the ability of marine mammals to communicate function with increased anthropogenic noise (ship traffic from multiple sources) and animal health		X	X			
Information about climate change and ice		X				
Information on ship strikes/ship interactions/entanglements		X	X			
Amount of seismic information being collected		X				
Need for alternatives to seismic surveys		X				
Process for assessing the effects of multiple activities (for example, seismic) on marine mammals, information available for decision making	X	X				
Information on duration of deflection, on individual as well as populations, when/if marine mammals return after deflection		X				
Ability to access information about where and when proprietary seismic activities take place to access the impacts on bowhead whales, both on individuals and populations		X				
Information on the physiological effects of noise	X	X				
Baseline information about how animals use habitats			X	X		
Impacts on marine mammals by spills/leaks			X			
Population dynamics of species (birth, growth, death) and sensitivities to disturbances at these life stages, behavioral changes			X	X		
Behavioral changes of animals and impacts these changes have on humans who depend on them			X			
Data that reflect trends and variability in species baseline			X			
Ability to identify differences between adaptation from climate change and seismic activity			X			
Information on state-of-the-art seismic activity for on-ice and in-water use (what it is and how it is used)			X			
Data on functional relationship between seismic technology use and marine mammals			X			
Data on the thresholds for seismic impacts to marine mammals			X			
Cascading effects of impacts to marine mammals resulting from impacts to other species			X			

Table A–1. Input received during the five facilitated expert consultations and the North Slope Public Session.—Continued

Issue topics and detailed input	Industry session	North Slope session	Federal session	Non-regulatory session	State session	North Slope public session
Marine mammals and noise—Continued						
Efficacy of monitoring and mitigation efforts of seismic activities (180/190 Criteria)	X		X		X	
Sensitivity to noise and variation in time and space				X		
Cumulative impacts, acute and chronic, time and space				X		
Chronic effect at drilling structure				X		
Unique behavioral patterns in the Arctic				X		
Synthesis of existing science				X		
Unique acoustics in Arctic				X		
Cumulative impacts to behavior from industrial activities (not just noise)				X		
Ambient noise mapping				X		
Avoidance capabilities of wildlife				X		
Habituation potential				X		
Predictive models for wildlife impacts and climate change impacts to species				X	X	
Baseline environmental contaminant level for marine mammals					X	
Creation of a marine mammal co-association to help monitor and study the cumulative impacts on the marine mammals						X
Ability to detect marine mammals during the seismic activity						X
Plankton and noise						X
Ocean bathymetry/seafloor relief data for both Chukchi and Beaufort Seas from coast line to 200 mile area for NSB						X
Cumulative impacts						
Lack of updated guidelines on how cumulative impact activities for EISs are written and used (sufficiency and applicability)	X	X		X		
Outcomes of cumulative impact assessments are not functional for intended purposes	X	X			X	
Lack of clear indicators and standards for cumulative impact analysis, inconsistencies between agencies, how science is incorporated	X	X			X	
Coordinated effort among industry to reduce impacts (for example, sharing seismic equipment/data)	X				X	
Efforts to integrate current cumulative impacts data into industry planning	X					
Cumulative impacts of exploratory drilling on food availability, breeding, behavior, predator/prey relationships, and contaminant levels		X	X			X
Functional relationship between existing/historical data management decision-making needs		X				

Table A–1. Input received during the five facilitated expert consultations and the North Slope Public Session.—Continued

Issue topics and detailed input	Industry session	North Slope session	Federal session	Non-regulatory session	State session	North Slope public session
Cumulative impacts—Continued						
Access to information on activities in Russia and Canada that effect cumulative impacts on animals exposed at multiple locations along migratory routes or over multiple years		X				
Ability to link onshore and offshore activities in cumulative impacts assessment		X				
Connection between cumulative impacts on species and on human subsistence/traditional (cultural) uses and social structure		X			X	
Information on drilling muds, discharges and what effects it might have on subsistence food sources		X				
Meaningful analysis of impacts to human health		X				
Attribution of impacts and thresholds (impacts for oil production versus other sources) (thresholds for unacceptable impacts to species)			X			
Data on functional relationships between risk factors			X			
Lack of data to run integrated multi-variant models of cumulative impacts			X			
Cumulative effects: linking spatial and species Bayesian models			X			
Waste management				X		
Amount of scientific information on cumulative impacts			X	X		
Consideration of the time and space scales that cumulative impacts are assessed				X		
Relationship between technology and cumulative impacts				X		
Risk assessment/technology changes of various development scenarios				X		
Terrestrial/marine interaction				X		
Uncertainty in development levels and potential development, unlikely scenarios included in decision making				X	X	
Unknown mitigation efforts to respond to cumulative impacts					X	
Inability to identify independent and cumulative impacts				X	X	
Public perception of cumulative impacts					X	
Not equally weighing positive and negative outcomes					X	
Cumulative impacts of on-land infrastructure for OCS exploration, damage to the tundra, and abandonment of infrastructure with end of exploration						X
Sea currents and winds will carry the spilled oil all over the Arctic, chain reaction destruction of the food chain						X
Increased shipping in OCS resulting in black carbon/soot emissions-cumulative impacts ocean acidification, chemical sink						X
Permitting is issued on individual bases and does not account enough for multiple activities						X
Disposals of all leases–total of all permits issued						X

Issue topics and detailed input	Industry session	North Slope session	Federal session	Non-regulatory session	State session	North Slope public session
Other concerns						
Social impacts with new development; income, population, lifestyle, way of life, lack of privacy					X	X
Effectiveness of mitigation acts					X	
Efficiency of mitigation acts					X	
Utilize traditional knowledge, western science alone is a fraction of knowledge of what the Iñupiat know						X
Are studies being conducted to look at the socioeconomic effects on the people of the NSB?						X
Publicize all findings from ALL study groups						X

Table A–2. Information-Consideration Grid to organize science and issue needs used in the U.S. Geological Survey Arctic Outer Continental Shelf (OCS) Team's facilitated expert consultation sessions.

[This information was used to consider science sufficiency as illustrated in figure A–1]

How important is issue XX in your decision making associated with oil and gas leasing, development, and policy topics?				
Not a consideration	**Minimally important**	**Moderately important**	**Important**	**Critically important**
	Some consideration, but as an ancillary topic, not enough to result in accommodation in project design or policy topic	One of several main issues considered in project design or policy topic	One of a few issues that are considered in decision outcomes	Foundational to determining decision outcomes
0	1	2	3	4

Please assess the body of scientific information status for issue XX				
None	**Minimal body**	**Moderate body**	**Good body**	**Robust**
No information available at all	Information with high uncertainty or very limited in scope, scale, or applicability to Arctic OCS	Body of information expanding but with notable insufficiencies, functional in most cases	Good body of information across most aspects of issue with limited uncertainty, data gaps may exist for minor elements	Robust information directly applicable to Arctic OCS decision making
0	1	2	3	4

Table A–3. Example of science questions and assessment of sufficiency for one of the expert consultation sessions, the non-regulatory session.

[Information-Consideration Grid scores (see table A–2) for four respondents are provided; however, for some issues, not every respondent provided a score. General judgment of sufficiency is based on the definitions provided in table A–2 and placement of the score within the Grid Graphic (see figure A–1). Scores that fell generally within red and orange zones of the graphic were placed as a gap. Often individuals differed either in the value of the topic to their decision making or to their opinion about status of the body of scientific information on the topic. These are listed as "variable" responses in Sufficiency column]

Issue/gap	Information-Consideration Grid Score Importance, Information Status	Sufficiency
Climate change		
Unknown biological response to climate change (models), adaptability	2,2; 3,1; 4,1; 3,1	Gap
Adequacy of physical models for climate change	1,2; 3,2; 4,1; 3,3	Variable
Baseline data for biological systems (spatial and temporal)	3,2; 4,2; 4,1	Gap
The ability to link larger models to near shore processes/response (down scale)	0,1; 2,2; 3,1; 2,1	Variable
Use of existing technology/resources to understand climate change in the Arctic	2,3; 2,1; 2,2	Variable
Predictability of refugia in time and space	1,1; 4,1; 4,0; 2,1	Gap
Relationship between water chemistry and environmental change due to climate change	0,1; 2,2; 1,2; 1,1	Reassess
Human use response to climate change (for example, ship traffic, noise, hunting patterns, fishing, subsistence)	0,1; 3,2; 4,1; 4,2	Gap
Relationship between subsistence use and changing environmental conditions	1,2; 2,2; 4,1; 2,2	Variable
Relationship between human cultural changes and changing environmental conditions	0,1; 2,2; 2,1; 1,2	Reassess
Oil-spill response		
Detection and tracking	4,2; 4,1; 4,0; 4,1	Gap
Mechanical response	4,2; 4,2; 4,1; 4,2	Gap
Risk assessment	2,1; 4,2; 4,1; 4,2	Gap
Ice management (includes subcategories)	4,2; 4,1; 4,1	Gap
Non-mechanical response options	3,2; 3,1; 4,2	Gap
Ecosystems and human response to spill	4,2; 4,1; 4,1; 3,2	Gap
Impacts of spill response on ecosystems and human systems	4,1; 3,1; 2,1; 3,2	Gap
Capacity assessment	3,1; 4,3; 4,2; 4,2	Variable
Trajectory assessment/models	3,1; 4,0; 3,2	Gap
Fate and effects of spill	4,2; 4,1; 4,1; 3,1	Gap
Baseline for damage assessments	3,3; 3,1; 4,1; 4,1	Gap
Pre-identification of sensitive areas	2,3; 4,1; 4,1; 3,1	Gap
Sensitivity mapping and response planning	3,3; 4,1; 4,1; 3,1	Gap
Planned response options	3,3; 3,2; 2,2	Good
Protocols and standards (damage assessment, restoration)	3,2; 2,1; 3,1	Gap
Information availability	4,2; 3,1; 4,1	Gap

Table A–3. Example of science questions and assessment of sufficiency for one of the expert consultation sessions, the non-regulatory session.—Continued

Issue/gap	Information-Consideration Grid Score Importance, Information Status	Sufficiency
Marine mammals and noise		
Location/tracking (habitat use)	4,1; 4,1; 3,3	Variable
Sensitivity to noise and variation in time and space	4,2 ; 3,2	Gap
Cumulative impacts, acute and chronic, time and space	4,0; 4,2, 4,0; 4,1	Gap
Chronic effect at drilling structure	3,1; 4,1; 2,2	Gap
Unique behavioral patterns in the Arctic	3,2; 2,1; 2,2	Gap
Modeling wildlife impacts	3,1; 4,1; 2,1	Gap
Synthesis of existing science	4,1; 4,1; 4,2	Gap
Unique acoustics in Arctic	2,1; 1,1	Reassess
Relationship between changes in behavior and changes in sensitivity	3,1; 1,1	Variable
Cumulative impacts to behavior from industrial activities (not just noise)	3,1; 4,1; 3,1	Gap
Ambient noise mapping	2,0; 2,1	Gap
Avoidance capabilities of wildlife	3,1; 2,1; 2,1	Gap
Habituation potential	2,1; 2,1	Gap
Cumulative impacts		
Waste management	2,3; 2,1; 2,2	Variable
Amount of scientific information on cumulative impacts	4,1; 4,0; 4,1	Gap
Methods to conduct cumulative impacts assessments (sufficiency and applicability)	3,2; 4,1; 4,1	Gap
Knowledge of individual impacts	3,2; 3,1; 2,1; 3,2	Gap
Consideration of the time and space scales that cumulative impacts are assessed	3,1; 4,1; 4,2	Gap
Relationship between technology and cumulative impacts	1,1; 2,1; 3,2	Variable
Risk assessment/technology changes of various development scenarios	1,1; 4,1; 3,0; 2,1	Variable
Infrastructure development scenarios related to oil/gas development	1,1; 3,1; 4,0; 4,1	Variable
Terrestrial/marine interaction	2,2; 3,1; 4,1; 1,2	Gap
Uncertainty in resource condition	3,1; 2,1; 2,1	Gap
Uncertainty in development levels and potential development	3,1; 4,0; 3,1	Gap

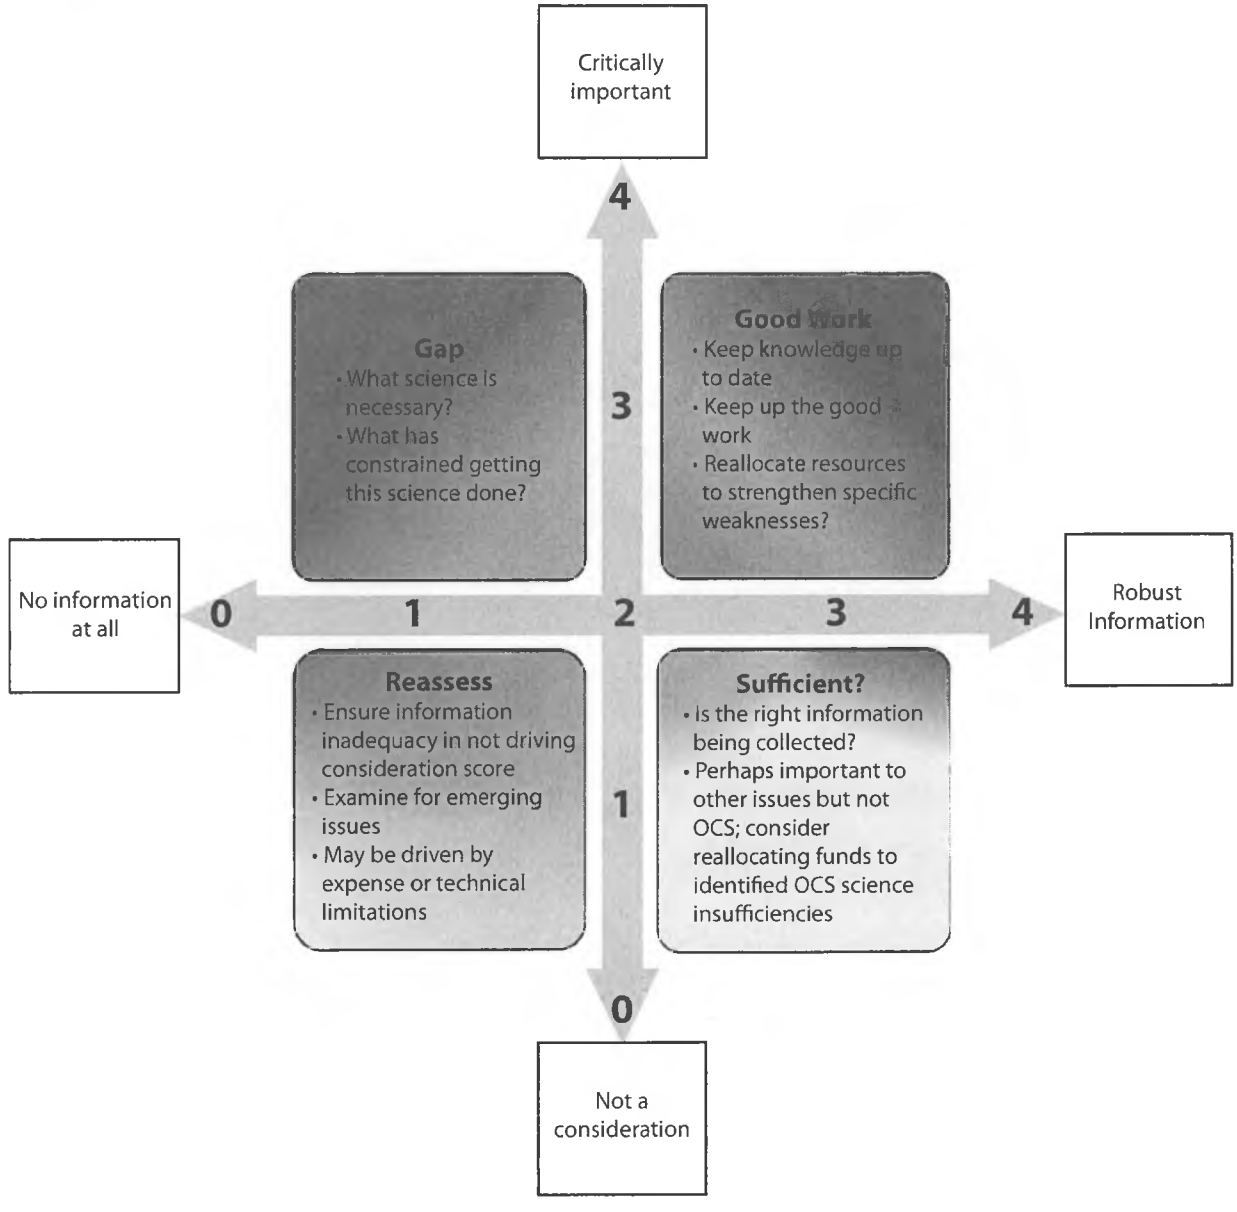

Figure A–1. Grid tool used in the first series of structured consultations sessions. *Y*-axis represents the importance of an issue to an individual's decision making associated with oil and gas development. *X*-axis represents the participant's view of the status of the body of scientific information for that issue. When scores (see table A–3) generally fell within a red or orange portion of the grid, the topic was considered a gap.

Appendix B. Science Workshop

As part of our series of expert consultations the USGS Outer Continental Shelf (OCS) Team participated in the January 2011 Alaska Marine Science Symposium in Anchorage, Alaska, to gain focused input from the science community on key topics that had arisen during our assignment. The USGS OCS Team participated in the Symposium's Poster Session to interact with participants and held a 3 hour facilitated technical workshop to obtain scientific input on areas of critical and fruitful investigation or approaches informative to the science gap analysis. The discussions were centered on four overarching scientific questions on topics that were consistently mentioned during our other expert consultations or in our literature assessments and that cross-cut the issues that are the focus of our science gap analysis (fig. 1–4). These topics were:

- What weather and oceanographic data are immediately needed to improve spill risk assessments, response planning, and spill response; what approaches are recommended to obtain such data?
- What supplements to agency monitoring and approaches to integrated ecological monitoring are needed for improved development impact assessment, including spill assessment (Natural Resource Damage Assessment, recovery, and restoration) efforts.
- Given gaps in spatial and temporal understanding of resources, how (methods, approaches) can the extensive industry site-specific monitoring be coupled with synoptic governmental efforts to improve broader scale understanding.
- What are the important differences in the physical and ecological conditions of the Beaufort and Chukchi Seas that need to be clearly understood to address the Secretary's commitment to OCS exploration in the "right place/right time."

The participants were provided background on the USGS OCS Team's assignment, context for each of the questions, and several discussion starter questions. They then were asked to self-select one of the four break-out groups to participate in. After 45 minutes of facilitated discussion, groups were disbanded and participants self-selected another break-out group to participate in. In this second series of discussions, participants started with the materials developed by the first group and continued discussion. At the end of these discussions, each break-out group reported out to the full workshop. Input from those break-out groups is summarized in appendix tables B–1 and B–2.

The following includes the materials that were provided to Symposium participants at the poster session in preparation for the January 21, 2011 USGS-sponsored 3-hour workshop.

Break-Out Topic One: What weather and oceanographic data are needed immediately to improve spill risk assessments, response planning, and spill response; what approaches are recommended to obtain such data?

Framing the Topic: Information, assumptions, and predictions of weather, ice, currents, and other physical oceanographic data occur throughout pre-decisional documents and implementation plans for oil and gas development. Such information and its uncertainty influence infrastructure design and placement decisions; spill risk probability determination; modeled spill trajectories and predicted ecological outcomes; and spill contingency planning, response gap estimates, and real-time spill response. The importance of these data to sound decision making is acknowledged and reflected in ongoing study efforts. For example, a recent Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE)-sponsored product by Weingartner and others (2010a) provides recommendations on physical oceanography studies for the Beaufort Sea. New technologies also are being assessed in BOEMRE- and industry-funded efforts as in Potter and Weingartner (2009) or Weingartner and others (2010b) who examine the use of a high-frequency radar system to map surface currents for improved spill trajectory models and spill response planning and how viable such systems are in partially ice-covered waters. However, what the potential fate and effect of oil might be from an accidental spill, the level of risk to be tolerated, and the sufficiency of science informing these topics remain points of discussion and disagreement among vested parties.

In this break-out group, we would like to know what is going well and needs to continue, what is a good start and needs enhancement, what has not been addressed and should be and WHY. In the latter two cases, we would appreciate your understanding of how proposed increases in existing efforts or new data would inform the decision process.

Discussion Starter Questions:

1. Are there proven technologies and sampling regimes that should be expanded temporally or spatially, or initiated? If so, how might that happen?
2. Logistics in the Arctic are challenging. Are there alternate technologies that should be investigated or whose use can be enhanced to obtain sufficient metocean data to support effective spill assessment, planning, and response?
3. The Arctic is not a static system, but is undergoing climate-driven change. What data collections and approaches should be considered to improve our ability to understand and forecast key weather and oceanography information to improve risk analyses over the multi-decade horizon of leasing decisions?
4. Are there different data needs or approaches that should be considered for the Chukchi Sea versus Beaufort Sea and vice versa?
5. What are some "low hanging fruit" opportunities, if any, that could be considered immediately?

Break-Out Topic Two: What supplements to agency monitoring and approaches to integrated ecological monitoring are needed for improved development impact assessment, including spill assessment (NRDA, recovery) efforts?

Framing the Topic: : Information and assumptions about the status and trends of ecosystem components occur throughout pre-decisional documents and implementation plans for oil and gas development. Such information and its uncertainty influence estimation of potential ecological impacts in Oil Spill Risk Assessment Models by providing likely resource intersections based on spill trajectory models. Spill contingency planning incorporates best understanding of ecologically sensitive areas to be protected during response. Status and trends in distribution, demographics, physiological condition, and the like provide the foundation for assessing damage under the National Resource Damage Assessment (NRDA) process and later inform restoration strategies, recovery goals, and progress towards those goals. In addition, experience from the 1989 *Exxon Valdez* Oil Spill restoration effort demonstrates the need for understanding of individual species to be coupled with a more holistic ecosystem framework in which to assess and judge recovery. Cumulative effects analyses also examine species and community perspectives. There is significant investment to develop improved species and system's knowledge. Various Federal and State agencies have ongoing mission-specific population-level sampling. The BOEMRE's Environmental Studies Program also funds key work across a wide spectrum of ecological components informative to the OCS planning process. Examples range from traditional knowledge as reported in Quakenbush and Huntington (2009) and satellite telemetry (Alaska Department of Fish and Game, 2010) collected to provide a broader understanding of single species such as bowhead whale, to studies of species groups such as shorebirds (Powell and others, 2009) to integrated biomonitoring/bioaccumulation sampling for nearshore areas (Neff, 2010). However, what the potential ecological consequences might be from oil and gas infrastructure or an accidental spill, the level of risk to be tolerated, and the sufficiency of science to inform these topics remain points of discussion and disagreement among vested parties.

In this break-out group, we would like to know what is going well and needs to continue, what is a good start and needs enhancement, what has not been addressed and should be and WHY. In the latter two cases, we would appreciate your understanding of how proposed increases or new data would inform the regulatory decision process.

Discussion Starter Questions:

1. Are there proven technologies and sampling regimes that should be expanded temporally or spatially, or initiated? If so, how might that happen?
2. Many different monitoring, population, and ecosystem studies and sampling efforts are ongoing within the BOEMRE, other Federal and State agencies, and academic and non-governmental organization communities within the Arctic OCS, both specifically to inform oil and gas development decisions and with other goals, informative to OCS decision making. Are there science frameworks or modeling approaches that might be fruitful to bring knowledge from such sources together in a transparent way to better inform annual study priority setting and determination of progress towards filling data gaps?
3. Logistics in the Arctic are challenging. It may not be feasible to sample all populations and communities of interest at the desired intensity to reduce uncertainty. Are there alternate metrics that could be added to existing population survey efforts as surrogates for population status?
4. The Arctic is not a static system, but undergoing climate-driven change. What data collections and approaches should be considered to improve our ability to understand and forecast key population and ecological functions to improve cumulative effects and risk analyses over the multi-decade horizon of leasing decision?
5. Are there different data needs or approaches that should be considered for the Chukchi Sea versus Beaufort Sea and vice versa?
6. What are some "low hanging fruit" opportunities, if any, that could be considered immediately?

Break-Out Topic Three: Given gaps in spatial and temporal understanding of resources, how (methods, approaches) can extensive industry site-specific monitoring be coupled with synoptic governmental efforts to improve broader scale understanding?

Framing the Topic: There are inherent uncertainties in estimates of undiscovered oil and gas resources and in economic conditions that define when and where development may occur as a result of a leasing program. From 5-year Lease Sale Plans through specific sale EIS documents, estimates of environmental effects must rely on assumed exploration and development scenarios. The question often asked is—how is what we know, at the scale we know it, applicable to environmental assessments. How much confidence should we have in that understanding.

In this break-out group, we would like to discuss your thoughts on mechanisms that could be considered to gain greater knowledge and improve scales of inference through strategic linkages of project or scale-specific studies or process studies by industry, academia and others with larger scale synoptic efforts.

Discussion Starter Questions:

1. What are the types of site-specific studies underway today? Process studies? Broader scale synoptic efforts?
2. Are there mechanisms in place to facilitate linkages among different scaled studies? If not, what would you like to see?
3. Could modeling and process study design approaches, such as those in the North Pacific Research Board-National Science Foundation Bering Sea Integrated Ecosystem Research Project, be fruitful to Arctic OCS decisions? Are there other such ecosystem-based "tactical" efforts that could be examined?
4. What are some "low hanging fruit" opportunities, if any, that could be considered immediately?

Break-Out Topic Four: What are the important differences in the physical and ecological conditions of the Beaufort and Chukchi Seas that need to be clearly understood to address the Secretary's commitment to OCS exploration in the "right place/right time."

Discussion Starter Questions:

1. Consider the other Break-out Topics (1) metocean data, (2) monitoring information, and (3) addressing scales of inference. Is there a difference in sufficiency or importance of specific science between the Beaufort and Chukchi Seas that need to be highlighted?
2. Are there particular ecological areas that need focus?
3. Are there unique socioeconomic considerations between the planning areas for which different science attention is warranted?

Table B–1. Listing of science concerns expressed by participants at the technical workshop held at the Alaska Marine Science Symposium on January 21, 2011, in Anchorage, Alaska.

Science concerns	Topic 1: Meteorological-ocean data needs	Topic 2: Monitoring efforts	Topic 3: Scaling issues
Climate down scaling has to be used to develop ranges of parameters not to expect precise results	X		
Distributed Biological Observatory (DBO)	X	X	X
DBO done on an ongoing basis where drilling may take place	X		
Make physical oceanographic models accessible to researchers, public, and oil-spill response. Combine on single interface (Alaska Ocean Observing System site?)	X		
Comprehensive ecological monitoring of subsurface phytoplankton, benthic ecology, substrate, diversity, production, ice seal stock, beluga stock, prey structure, cod, euphausiids, copepods, and identify biology	X	X	
Trace material flow through the ocean, including river melt water and sediment transport	X		
Monitoring for real-time met-ocean data and water-level observations	X		
Make sure ocean circulation data keep up with depth of oil exploration	X		
Ice thickness, scale of measurements needed, scale of time observations, ice gouging, met-forcing affects on ice-floe movement	X		
Understanding of the variations of the ocean from lease block to lease block	X		
Develop an incentive for public data (build and update database), publish raw data as it is collected, up-to-date data in GIS	X	X	
Make sure ocean/atmosphere models account for extreme events	X		
Coast Guard and oversight of spill cleanup	X		
Improve efficiency and collaboration between industry, academia, and government agencies including disciplines not used to collaborating	X	X	
Establish on-going consistent monitoring strategies done in a broad integrated manner that provides ability to quantitatively measure/predict impacts	X	X	X
Interactive online research assets map showing where instruments in field season exists, need to show this same information historically	X		
Determine when equipment cannot be deployed due to wind, waves, fog, cold, darkness	X		
Ranking of environmentally sensitive areas especially nearshore and shoreline, changes to priority protection sites based on projects	X	X	
Trajectory modeling particularly in ice conditions	X		
Physical oceanography effects on infrastructure seasonally and during storm events	X		
High resolution circulation patterns around sensitive areas, subsurface current information, seasonal variability of currents	X		
Greater focus on effects of potential submarine pipelines and onshore support facilities		X	
Fish species lists are slowly being developed, but population, total numbers, distribution, genetics, movement, and ice association are missing		X	
Effects of natural gas/methane on subsurface species		X	
Effects of gas blowout at depth		X	

Table B–1. Listing of science concerns expressed by participants at the technical workshop held at the Alaska Marine Science Symposium on January 21, 2011, in Anchorage, Alaska.—Continued

Science concerns	Topic 1: Meteorological-ocean data needs	Topic 2: Monitoring efforts	Topic 3: Scaling issues
Characterization of biological aspects of Barrow Canyon and other unique features that may be considered exempt from lease sales or need data at a higher resolution	X	X	
What compartment is the Chukchi/Beaufort biomass in during various seasons, years?		X	
National Resource Damage Assessment (NRDA) Process: how does monitoring relate, integration of historical and contemporary data, develop training [Shoreline Cleanup Assessment Technology (SCAT)], subsistence considerations in Bering Sea	X	X	
Conduct experiments including test spill with dye tracer, spill recovery methods, oil in water and oil in ice	X	X	
Consult with Norway and United Kingdom for their risk assessment and safety case planning as well as research on oil/ice interactions	X	X	
Local residents may be interested in working on compromises that determine right time/right place		X	
Use of models and datasets not representative of Arctic conditions may lead to incorrect conclusions and decisions		X	
Increase coordination for planning, lease sales, mitigation measures, permitting, on-going monitoring, and rehabilitation including oil-spill response		X	
Food web cycles are lacking adequate description especially low in food web, annual variability, and potential to disrupt these systems		X	
Develop oil vulnerability index for species in Beaufort/Chukchi		X	
Give emphasis for site-specific studies to sites located in areas likely to be effected, that is, lease areas		X	
Concern for cultural and resource impacts from development, need socio-economic baseline		X	
Better framing in terms of temporal/spatial – percent chance of occurrence		X	
First assess relative abundance/importance then prioritize areas for more in-depth studies		X	
Pair oceanographic observations with biological		X	
Data need for restoration of Arctic Ocean systems and populations		X	
Regular surveying of local communities for changes they are seeing		X	
How will we know the baseline data are representative given the potential changes occurring already due to climate change		X	
Marine mammal range extensions and response to ecosystem variability		X	
Incorporation of Alaska Ocean Observing System data into biological studies, especially for food web/prey structure/energy flow		X	
Continued development of autonomous underwater vehicles (AUVs) and unmanned aircraft, augment acoustic recorders with sensors to capture biological activity and develop new technologies to increase monitoring capabilities	X	X	
How is oil breakdown effected by dispersants in ice and ice-free environments		X	

Table B–1. Listing of science concerns expressed by participants at the technical workshop held at the Alaska Marine Science Symposium on January 21, 2011, in Anchorage, Alaska.—Continued

Science concerns	Topic 1: Meteorological-ocean data needs	Topic 2: Monitoring efforts	Topic 3: Scaling issues
Effects of oil containments and dispersants to the ecosystem, what is the adaptation of organisms to the oil		X	
Long-term carbon assessment in water [for example, chromophoric dissolved organic matter (CDOM)] as baseline assessment, seawater chemistry, locate natural seeps	X	X	
Successful monitoring of Boulder Patch (Beaufort) year-round could be considered for other significant habitats – (Chukchi?)		X	
Community-based monitoring and assessment as a framework for determining current status and future trends, include local communities for on-the-ground response	X	X	
Pre-identify in-state resources with appropriate and current training, publish roster at least within planning, response, and government and industry		X	
Pre-identify mechanisms to distribute response-related research funding		X	
Address unique Arctic logistical issues regarding chain of custody, such as sample storage/handling issues		X	
Pre-identify the process by which monitoring and sampling would be temporarily expanded or initiated		X	
What processes control the marine system, use this to help determine what to measure and monitor		X	
Scale at which things vary on benthos is much shorter than in water column		X	
Consider health impact, assessment and linking (and social parameters) human health with the ecosystem		X	
Necessary to identify what regions of the Arctic are important habitat for particular species		X	
Need migration/movement not just population for risk analysis		X	
More studies needed in microbiology (bacteria), bioremediation		X	X
Consider shifting baselines during monitoring programs and comparison to baselines		X	
Distinguish between monitoring of potential impacts of 'regular' operations versus those from 'spill' scenarios and monitor species recovery after a hydrocarbon release		X	X
Standardized studies need to be done to calculate locally meaningful correction factors for things like marine mammal density estimates.		X	
Gaps are seasonal, lacking early season and over winter so monitoring should include seasonal components, for example, winter oceanographic monitoring for circulation		X	X
Synthesis and integration of existing information including observations, model data, fate and effects of spilled oil, dispersant use, ecological data and baseline data	X	X	X
Under Ice system monitoring (including seasonality) = huge productivity	X	X	
Ice-edge tracking (underway; relationship to ecosystem)		X	
Species adaptation capability/capacity		X	
Expand buoy array		X	X

Table B–1. Listing of science concerns expressed by participants at the technical workshop held at the Alaska Marine Science Symposium on January 21, 2011, in Anchorage, Alaska.—Continued

Science concerns	Topic 1: Meteorological-ocean data needs	Topic 2: Monitoring efforts	Topic 3: Scaling issues
Transparency, quantitative/qualitative		X	
Recognize different monitoring needs/platforms/suitability to meet needs of the questions posed, proactive monitoring design		X	
Need time-sensitive sites (transect) that are spatially placed to capture upstream and downstream work			X
Transport models that incorporate key physical and biological parameters			X
Nested site selection			X
What is the type/discipline of ecosystems data received to understand that ecosystem			X
Longer comparable data sets from existing spatially distributed sampling stations, replicate Outer Continental Shelf Environmental Assessment Program (OCSEAP) studies		X	X
Fisheries—epibenthos abundance and distribution, species composition, ecological process, habitat association			X
Opportunistic opportunities to collect data and explore/analyze existing			X
Broader scope oceanographic understanding is needed for better understanding of smaller scale			X
Tiering of information/studies is an important technique			X
Do more research about planning to respond to oil spills in ice-infested Arctic waters, burning oil in ice, identify areas for pre-positioned protection	X		X
Propagation of sound through oceans			X
Passive acoustic monitors for mining data from other sounds			X
Seismic data – through water column			X
Spatial and temporal variability of ecology			X
Ecological asset inventory			X
Indices for keystone species			X
Model verification – especially validation			X
Process (in addition to coordination) for defining "sufficiency" across spectrum of data/understanding, different for different levels of activity		X	X

Table B–2. Differences in Beaufort and Chukchi Seas as noted by participants at the technical session held at the Alaska Marine Science Symposium on January 21, 2011, in Anchorage, Alaska.

Chukchi Sea
Cumulative impacts – shipping
Less infrastructure in place
Wave height, cold (affects weathering and clean up), visibility, wind driven leads
More complex, topographically, Barrow Canyon
Shoal habitat (Hanna and Harold)
Bering Sea influence; nutrients and carbon
Shallow sea with oil resource far offshore in deep water
Sea bottom very productive, hot spots
More shelf and areas of interest for exploration are ice free longer
Most development areas beyond coastal subsistence use areas
Spring whaling, seal hunting on shear ice, walrus and seal hunting in pack ice
Development farther offshore, greater risk?
More historical and ongoing work
Primarily ship provided transport, shorter transit from south, no road access
Walrus haulouts changing due to changing ice, modeling of walrus distribution
Critical feeding areas for migrating birds
Point Lay, Point Hope – very traditional village lifestyles
Beaufort Sea
Cumulative impacts – oil and gas in Canadian Beaufort
Ice-driven leads, land-fast ice
Current OSC exploration, more infrastructure
Nutrients and carbon from upwelling and shore, more complex circulation
Beaufort gyre influenced, longer sea ice in summer, river influenced
Deep sea with oil resource in shallow water
Flat shelf, sea bottom mostly barren, ice gouging, active gouging zone
Dissolved organic carbon terrestrial carbon utilization
Perhaps more viable, trending towards less ice cover
Lots of overlap between subsistence and development
Fall whaling, cisco/white fish
Importance of cod, 96 percent of fish abundance and biomass, keystone species
Need synthesis of existing data (census of marine life)
Multi-modal, road access to Prudhoe Bay, cargo aircraft, access to small vessels, used to heavy equipment, longer ship transport times
Much more subsistence, but perhaps not as traditional lifestyles

This page intentionally left blank.

Appendix C. Structured Decision Making for Energy Exploration and Development Decisions on the Arctic Outer Continental Shelf

By Sarah J. Converse

Background

Decisions facing the Department of the Interior (DOI) on behalf of the Federal Government about whether and where to permit oil and gas exploration and development on the Arctic Outer Continental Shelf (OCS) are challenging. The challenge arises primarily as a function of four characteristics. First, there are complex and potentially competing objectives associated with a diverse stakeholder contingent (for example, energy development, marine mammal protection, oil-spill prevention). Second, there are a wide variety of different decision alternatives available to the decision maker, including many possible combinations of temporal and spatial structures in development permitting. Third, there is an unknown array of decisions required of other agencies resulting from each possible oil and gas development decision alternative that could be selected by the DOI. Fourth, as demonstrated by the analyses outlined in the chapters of this report, there exists a great deal of complex information as well as substantial uncertainty about the potential effects of development on the myriad resources of management interest.

Structured decision making (SDM; sensu Clemen, 1996; Possingham and others, 2001; Williams and others, 2007) is the application of decision science to assist decision makers in the process of making decisions, and is especially important and applicable in the case of decisions that are both important (that is, high stakes) and challenging. SDM rests on the idea that decisions can be made more effectively (that is, more likely to lead to attainment of management objectives) if a structured analysis is conducted. This analysis consists of deconstructing decisions into their component parts, analyzing each part, and synthesizing the parts into a decision framework that can produce direct recommendations to decision makers about which decision is most likely to lead to attainment of management objectives. More generally, engagement in a formal decision-analytic process helps the decision maker to develop the fullest possible understanding of the complexities of the decision, such as decision objectives, tradeoffs, uncertainties, and risks.

Structured decision making is not appropriate in all cases. The use of the process requires that a decision maker can be identified and that the management objectives (potentially multiple and competing) of that decision maker can be articulated. In addition, the set of decision alternatives under consideration must be known or knowable, and there must be an ability to make predictions about how different alternatives would impact the objectives of interest; such predictions can arise from data or from expert judgment and may (and often do) involve substantial uncertainty. Finally, and most generally, the process requires transparency in development of all decision components.

Value of Structured Decision Making

A formal decision-analytic process can help most specifically by producing a recommended course of action most likely to lead to attainment of management objectives. More generally, however, the process is useful for informing a decision maker about the complexities of the decision. For instance, the process is useful in helping the decision maker to develop a clear articulation of the management objectives, to contemplate tradeoffs, to be aware of uncertainty and integrate risk attitudes into the decision (that is, the degree of risk the decision maker is willing to accept in order to obtain some potential benefit), and to develop a sense of what information is available and what uncertainties are relevant. When used appropriately, formal decision processes are designed to lead to decisions that are (Runge and others, 2009):

- Transparent—SDM is designed to produce transparency in the decision-making process, to remove the "black box" aspects of decision making, such that decisions can be understood and communicated.
- Explicit and Able to be Documented—The transparency required by the SDM process results in decision processes that are explicit in their treatment of decision components, which results in decisions that can be effectively documented within an administrative record.
- Deliberative—SDM encourages careful deliberation about the various components of the decision-making process. This is expected to lead to better decision outcomes because deliberation encourages more thorough identification of management objectives and tradeoffs, a wider search for creative decision alternatives, more complete use of scientific information in developing predictions of decision outcomes, and more thorough articulation of important uncertainties and risks in the decision.

- Robust—SDM recognizes that uncertainty and risk influence decision making. As such, SDM is designed to produce decision processes that fully recognize the type and magnitude of uncertainty and risk; such decision processes are designed to produce recommendations that are robust to the uncertainty and risk that exist; that is, decision processes that are most likely to lead to attainment of management objectives.

Stakeholders and Structured Decision Making

Within the public policy realm, consideration of the values of stakeholders is of paramount importance in framing decisions. In the U.S. Department of the Interior Adaptive Management Technical Guide, engagement with stakeholders is identified as the first step of the adaptive management process, which itself is recognized as a structured decision-making process (Williams and others, 2007). Stakeholders have multiple roles in developing decision processes, and should be effectively engaged in the development of each component of the process. Perhaps most critically, the objectives of stakeholders must be understood and integrated. The decision maker, in public policy decisions, has ultimate responsibility for understanding and articulating stakeholder objectives, and for weighing tradeoffs between competing objectives of diverse stakeholder groups. As such, we assume herein that the values of stakeholders are included as they are understood by and embodied in the objectives and tradeoffs of the decision maker.

Components of Structured Decision Making

Structured decision making consists, most basically, of deconstructing decisions into their component parts, analyzing the individual components, and synthesizing the components into an integrated decision framework that is designed to lead to recommended courses of action. As such, decision analysts recognize that every decision involves a consistent set of components (for example, Hammond and others, 1999). These components are:

Decision Problem.—The decision problem is a clear statement of the decision that is to be made. It includes information on the factors prompting the decision, the identity of the decision maker, the particular decision to be made, the spatial and temporal scope of the decision, the timing of the decision, and whether the decision will be repeated through time or is a one-time decision.

Objectives.—The objectives are the things that the decision maker wants to achieve in the context of the particular decision. They are representations of values, policy, and stakeholder objectives guiding the decision maker. In decision analysis, it is often useful to differentiate between fundamental and means objectives. Fundamental objectives reflect ultimate statements of values—in essence, the most basic values of the decision maker. Means objectives, by contrast, are objectives the decision maker would like to achieve because they are themselves means to achieving the fundamental objective(s). For example, if a fundamental objective, in the context of the OCS energy exploration and development decision, is to maintain the tourism value of the Arctic system, a means objective may be to minimize the construction of energy development infrastructure in critical viewsheds.

Alternatives.—The decision alternatives are the comprehensive set of alternative management actions available to the decision maker. The alternatives will depend on the particular decision to be made, and may have many elements (for example, spatial and temporal components).

Model.—The system model and predictions component is the component most familiar to scientists. This component encompasses all information available about the implications of different decision alternatives on the management objectives. That is, science in a decision-making context serves to link our decision alternatives to our objectives, such that we can make predictions of the form, "if we take action 'a', the result in terms of a given management objective will be 'b'." More specifically, we often make such predictions in a probabilistic framework, because we have substantial uncertainty about the functioning of complex systems.

Optimization.—The tradeoffs analysis, or optimization, is the final step necessary in identifying an optimal decision, and involves searching among the proposed set of decision alternatives for the option that is most likely to lead to the attainment of management objectives. In many cases, this means weighing tradeoffs among competing objectives. In addition, some decisions involve an additional component.

Monitoring and Feedback.—Monitoring and feedback are applicable when decisions are repeated through time. In these cases, monitoring data can be used to assess whether management objectives are met, to measure the state of the system for informing state-dependent decisions (that is, where the decision that one takes depends on some aspect of on-the-ground conditions), and to reduce uncertainty about how the system responds to management (Lyons and others, 2008). These monitoring data can then be used to update predictions about system responses to management, thus facilitating improved decision making through time (Nichols and Williams, 2006).

Prototyping of a Decision Framework

With the input of the U.S. Geological Survey (USGS) OCS Team, the broad outline of a decision framework to inform the DOI Arctic OCS energy exploration and development decision was developed. This framework was developed as an example of a more fully articulated framework that could be developed with the input of the decision maker or delegates. That is, this decision framework is both incomplete and not assumed to represent the true aspects of the decision as understood by the decision maker; instead it is intended as an illustration. This simple prototype demonstrates the basic process of SDM and how it could be applied to synthesize and analyze science and policy information to inform Arctic OCS energy exploration and development decisions.

Decision Problem.—The national strategy for energy and economic security defines the intent by the Administration to open certain OCS areas to exploration, set aside those areas deemed inappropriate for development, and increase oil and gas exploration in some frontier areas. The Arctic OCS is identified as one of the most promising frontier areas for consideration because of its high potential of oil and gas resources, a substantial portion of the global potential. This is evidenced by the fact that oil and gas leases already exist in the Arctic OCS. It also is an environment containing substantial ecological and social resources of high spatial and temporal complexity. Within this area, there exist federally mandated conservation requirements within the context of the National Environmental Policy Act, International treaty, and Endangered Species Act regulations. The DOI holds authority for decisions on energy exploration and development in the Arctic OCS.

There are two decisions facing the DOI—one short term and one long term. The short-term decision involves deciding what to do with current Arctic OCS leases that are on hold. The long-term decision involves deciding when and where to permit exploration, development, and production of oil and gas resources in the Arctic OCS; that process is nested within ongoing and repeated revision of the OCS 5-year planning process. There are decisions made at each stage (exploration, development, and production) that can be seen as linked decisions (that is, decisions made at one stage influence the decision alternatives available at the subsequent stage), and there are substantial stakeholder concerns related to the linked nature of these decisions. Concern in the conservation community is based on the perception that once exploration begins, it is inevitable that production will occur; the energy industry is concerned that any one of these linked stages can result in termination of exploration and development prior to production.

There are disparate stakeholders with vested interests and substantial influence through the congressional, judicial, and regulatory processes whose views must be considered and incorporated into the decision. Industry has made significant investments in the Arctic OCS. Other stakeholders include the subsistence community (who have invested generations in the region and whose culture is tied to the marine environment), the general public (who have a stake in the biodiversity, remoteness, the domestic energy resource, and the lease revenue), and the conservation community (who have a stake in the biodiversity and ecological function of the Arctic). Federal agencies with stakes in the decision include the Bureau of Ocean Energy Management, Regulation and Enforcement (BOEMRE) (regulatory authority over leases), the National Oceanic and Atmospheric Administration (NOAA) (regulatory authority over listed species), and the Coast Guard (ultimately responsible for spill response and safety).

There is substantial scientific uncertainty about the impacts of energy exploration and development on resources of interest. The DOI has recognized this uncertainty and has tasked the USGS with describing the state of scientific knowledge in order to inform decisions regarding the Arctic OCS; results of the USGS analyses are described in the chapters of this report. In addition, the linked nature of these decisions does have the effect of allowing monitoring data to inform future steps in the decision process, indicating the importance of well-designed and well-executed monitoring plans.

Objectives.—The USGS OCS team developed a draft objectives hierarchy consisting of fundamental objectives grouped in thematic areas, and linked to means objectives. This objectives hierarchy is expected to represent at least some of the objectives of the DOI in the context of the Arctic OCS energy exploration and development decision, but it is not expected to be a complete or necessarily accurate set of the DOI's objectives. The objectives are illustrated graphically in figures C–1 through C–3 and also are provided below. First tier elements are thematic areas (that is, groupings of fundamental objectives). There were three thematic areas identified: human communities, ecosystem values, and economic vitality. Second tier elements are fundamental objectives, of which 10 were identified. Third tier elements are means objectives.

The identified objectives are as follows:

1. Maintain Values of Human Communities
    a. Protect Human Health and Maintain Human Safety
    b. Protect and Maintain Subsistence Communities
        i. Maintain Populations of Subsistence-Hunted Species
        ii. Maintain Culturally Critical Components of Subsistence Hunting
    c. Meet Trust Responsibilities to Native Communities
2. Maintain Ecosystem Values
    a. Protect and Maintain Ecological Function
    b. Protect and Maintain Biological Diversity
        i. Maintain Populations of Endangered Species
        ii. Maintain Populations of Marine Birds
        iii. Maintain Populations of Marine Mammals
        iv. Maintain Populations of Fishes
    c. Protect Wilderness Values and Experience
3. Maintain Economic Vitality of Region
    a. Meet Energy Production Targets
    b. Meet Lease Revenue-Generation Targets
    c. Provide Employment Opportunities
    d. Maintain Tourism Value

Alternatives.—Decision alternatives will involve different spatial and temporal patterns of permitting. Spatial aspects include the particular blocks opened for permitting, such as whether to allow drilling inside the current exclusion area or to expand the exclusion area, and the physical location of permitted sites within permitted blocks, including the allowable proximity to resources of spatial interest. Temporal aspects include the timing of exploration and production activities within a permitted area (for example, drilling could be staggered through time) and whether to impose seasonal constraints on activities. Additional aspects include which mitigation measures to mandate (for example, such as constraints on the density and spacing of drill sites). Decision alternatives will be defined by various combinations of different spatial and temporal patterns of permitting, both with and without mandates for various mitigation measures.

Models.—The modeling stage is the stage during which scientific information is used to develop predictions of the impact of decision alternatives on the various management objectives. We note, however, that building predictive models can only commence after the preceding elements of the decision process are fully understood (that is, the decision problem, objectives, and decision alternatives).

To build predictive models, we would begin by developing conceptual models that link components of the system through logical relationships; these logical relationships are described in narrative form throughout the chapters of this report. Conceptual models must demonstrate links between alternatives and objectives, so the basis for predictions about the impacts of decision alternatives on objectives can be made. Development of conceptual flow diagrams is a useful precursor to development of quantitative predictions. An example can be seen in figure C–4, linking the spatial location of permitted sites to the objective of maintaining populations of marine mammals.

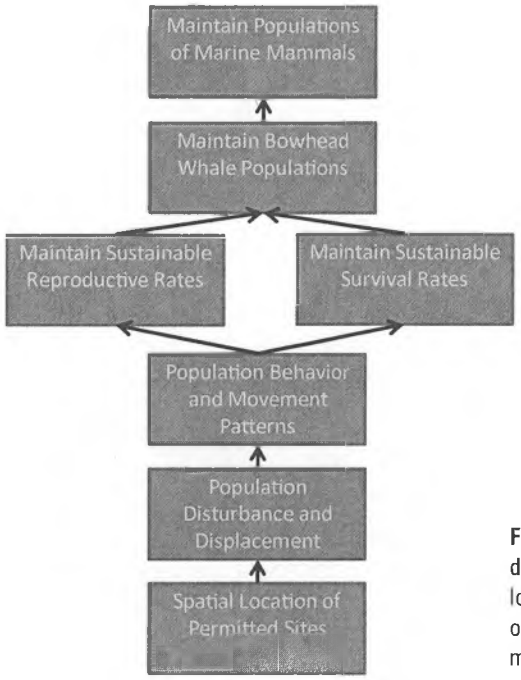

Figure C–4. An example logical flow diagram linking actions (the spatial location of permitted sites) to an objective (maintain populations of marine mammals).

Once such conceptual models are developed, they can be used to form the basis of quantitative predictions. Separate predictive models are needed for each of the fundamental objectives, where outputs of the models will be in units related to the objective (for example, for the objective "maintain populations of marine mammals," models for each species of interest would produce output in the form of numbers of individuals or probability of population viability). These models will make predictions, then, of the impact of each decision alternative on each of the identified management objectives.

One appropriate quantitative modeling tool for at least some of the objectives may be Bayesian Belief Networks (Marcot and others, 2006), which are graphical models that allow for propagation of uncertainty via conditional dependencies between model components. These are probabilistic models that frequently can be developed even with sparse scientific information. Much of the scientific information necessary to build the predictive models of interest may be in the form not of data but of expert knowledge. In this case, techniques for expert elicitation could be used to capture this information in a fashion appropriate for building quantitative models (Meyer and Booker, 1990; Ayyub, 2001).

Optimization.—Once predictions are made about the impact of each decision alternative on each management objective, a wide variety of formal techniques can be used to search among the decision alternatives to identify the optimal decision alternative. Given the complexity and multi-objective nature of the OCS energy exploration decision, it is likely that Multi-Criteria Decision Analysis (MCDA; Keeney and Raiffa, 1976) will be the source of appropriate optimization techniques. In multi-objective decisions, optimization consists of making tradeoffs among multiple objectives. That is, certain alternatives will perform best on some objectives, while different alternatives will perform best on other objectives. The task, then, is to consider these tradeoffs.

A variety of methods are available for tradeoff analysis in MCDA, but frequently the techniques involve developing, in concert with the decision maker or delegates, weights on objectives and then normalizing and summing the predicted outcomes across alternatives to develop "scores" for each alternative, where the alternative with the highest score is identified as the preferred alternative. A necessary final step, then, is sensitivity analysis to evaluate the impact of any uncertainty on the model predictions or the objective weights to inform the decision maker if the decision is highly sensitive to these elements. Sensitivity analyses may suggest places for improvement in the decision framework before final recommendations are developed.

Capacity for Structured Decision Making and Requirements of the Process

Capacity for supporting decision-analytic processes exists both within USGS and in academic and non-profit settings around the United States. Recommendations for conducting decision analysis include:

1. Designate a team coordinator who can act as the decision maker's representative in the decision-analytic process. The team coordinator should have an accurate understanding of the decision maker's objectives (which will integrate the objectives of stakeholders as described above).

2. The team coordinator should work directly with the decision analyst(s) to form a team consisting of experts with relevant knowledge on the different components of the decision, as well as relevant legal and administrative matters.

3. The decision analyst(s) should work with team members in a workshop setting to develop an initial sketch of the elements of the decision (this is known as rapid prototyping the decision framework).

4. Individual team members can then work individually to further develop different components of the decision framework, for example, complete development of relevant predictive models. This individual work should be done in close coordination and with regular input from other members of the team.

5. A final workshop may be held during which the final tradeoffs analysis can be conducted. This, paired with appropriate sensitivity analyses, can be used to complete the report on the decision-analytic process.

Summary Recommendations: Formal decision-analytic methods are useful for supporting decision making in challenging settings with multiple objectives, complex sets of available decision alternatives, and substantial uncertainty and risk. Using the collective knowledge of the USGS OCS team, we developed a Structured Decision Making framework as an example of what could be developed to inform decisions about energy exploration and development in the Arctic OCS. Although development of such a framework would require input of the decision maker or delegates in order to accurately represent management objectives and tradeoffs, we present this example to illustrate the process as well as the potential utility of SDM in this setting, wherein adoption of SDM could facilitate a more robust, transparent, and deliberative decision. We encourage careful consideration of SDM as a useful process in the Arctic Outer Continental Shelf energy exploration decision setting.

Appendix D. The *Exxon Valdez* Oil Spill Experience: Lessons Learned from a Cold-Water Spill in Sub-Arctic Waters

By Dede Bohn

Background

The March 24, 1989 *Exxon Valdez* Oil Spill (EVOS) was not related to oil and gas development activities, but was the result of the grounding of the tanker *Exxon Valdez* on Bligh Reef in Prince William Sound, Alaska, while outside of normal traffic shipping lanes to avoid icebergs. This accident was the largest oil spill in U.S. waters until the *Deepwater Horizon* spill of 2010. The lessons learned from the spill are included here for the purposes of highlighting Alaska-based experience ranging from spill response through Natural Resource Damage Assessment components that can help inform the U.S. Geological Survey (USGS) Arctic Outer Continental Shelf (OCS) Team assignment.

Most of the oil from the grounding of the *Exxon Valdez* was spilled in the first 6 hours as approximately 10.9 million of the 53 million gallons of North Slope crude oil aboard leaked into the water. Within 2 months, the spread of this oil had impacted more than 1,300 discontinuous miles of the 9,000-mi long coastline in the Prince William Sound and the Gulf of Alaska region (fig. D–1). Less than 1 of the 1,300 mi of oiled beaches was accessible by road (Hunt, 2009). Exxon was not prepared for a spill of this magnitude, nor was its pipeline service company and responder Alyeska, nor the Federal or State governments (Skinner and Reilly, 1989). Efforts were made to remove oil from the water, and included booms to collect oil, test areas of burning, surface dispersants to break up the oil into smaller concentrations, and mechanical skimming to remove oil on the surface. Once the oil had reached shorelines, chemical cleaners, hot water and high pressure, and manual removal by shovels, human hands and absorbent materials were used (Alaska Department of Environmental Conservation, 1993). For the past 20 years, the $900 million in civil settlement funds paid by Exxon have supported restoration, monitoring and research activities in the spill-impacted area (*Exxon Valdez* Oil Spill Trustee Council, 2011b).

The OCS Arctic evaluation and planning effort for oil development can benefit from the EVOS experience through two aspects: (1) improvements in oil-spill prevention and response made as a result of the EVOS, which have enhanced our protection capabilities; and (2) lessons learned from the EVOS, which can inform better preparedness and protection.

Improvements in Spill Prevention and Response Triggered by the EVOS Have Enhanced Our Preparedness

Significant progress has been made in oil-spill prevention and response as a direct consequence of lessons learned from the EVOS, applicable to both its spill area as well as spills elsewhere. Some of these improvements better prepare the OCS Arctic planning effort, and are listed below. The Federal Oil Pollution Act of 1990 (OPA 90), passed by Congress in response to the EVOS, established a procedure for assessing natural resource damages and establishing liability, and designates specific Federal, State and Tribal Government officials to act as trustees on behalf of the public to recover damages from the responsible parties to restore injured, destroyed, or lost natural resources. The OPA 90 also added "oil" to the other hazardous substances covered by the Comprehensive Environmental Response, Compensation, and Liability Act of 1980. In the EVOS area itself, specific advances include:

- Alyeska Pipeline Service Company (established in 1970 to oversee the Trans Alaska Pipeline System, and Exxon's first responder to the EVOS), now spends more than $60 million annually under the Ship Escort/Response Vessel System (SERVS) created in 1989, to plan, prepare, and enhance oil-spill prevention and response measures in Prince William Sound.
    - Alyeska oversees oil spill contingency plans such as those required by the State of Alaska for all tankers traveling in Prince William Sound, which must include scenarios for open-water, nearshore, and shoreline responses and support operations.

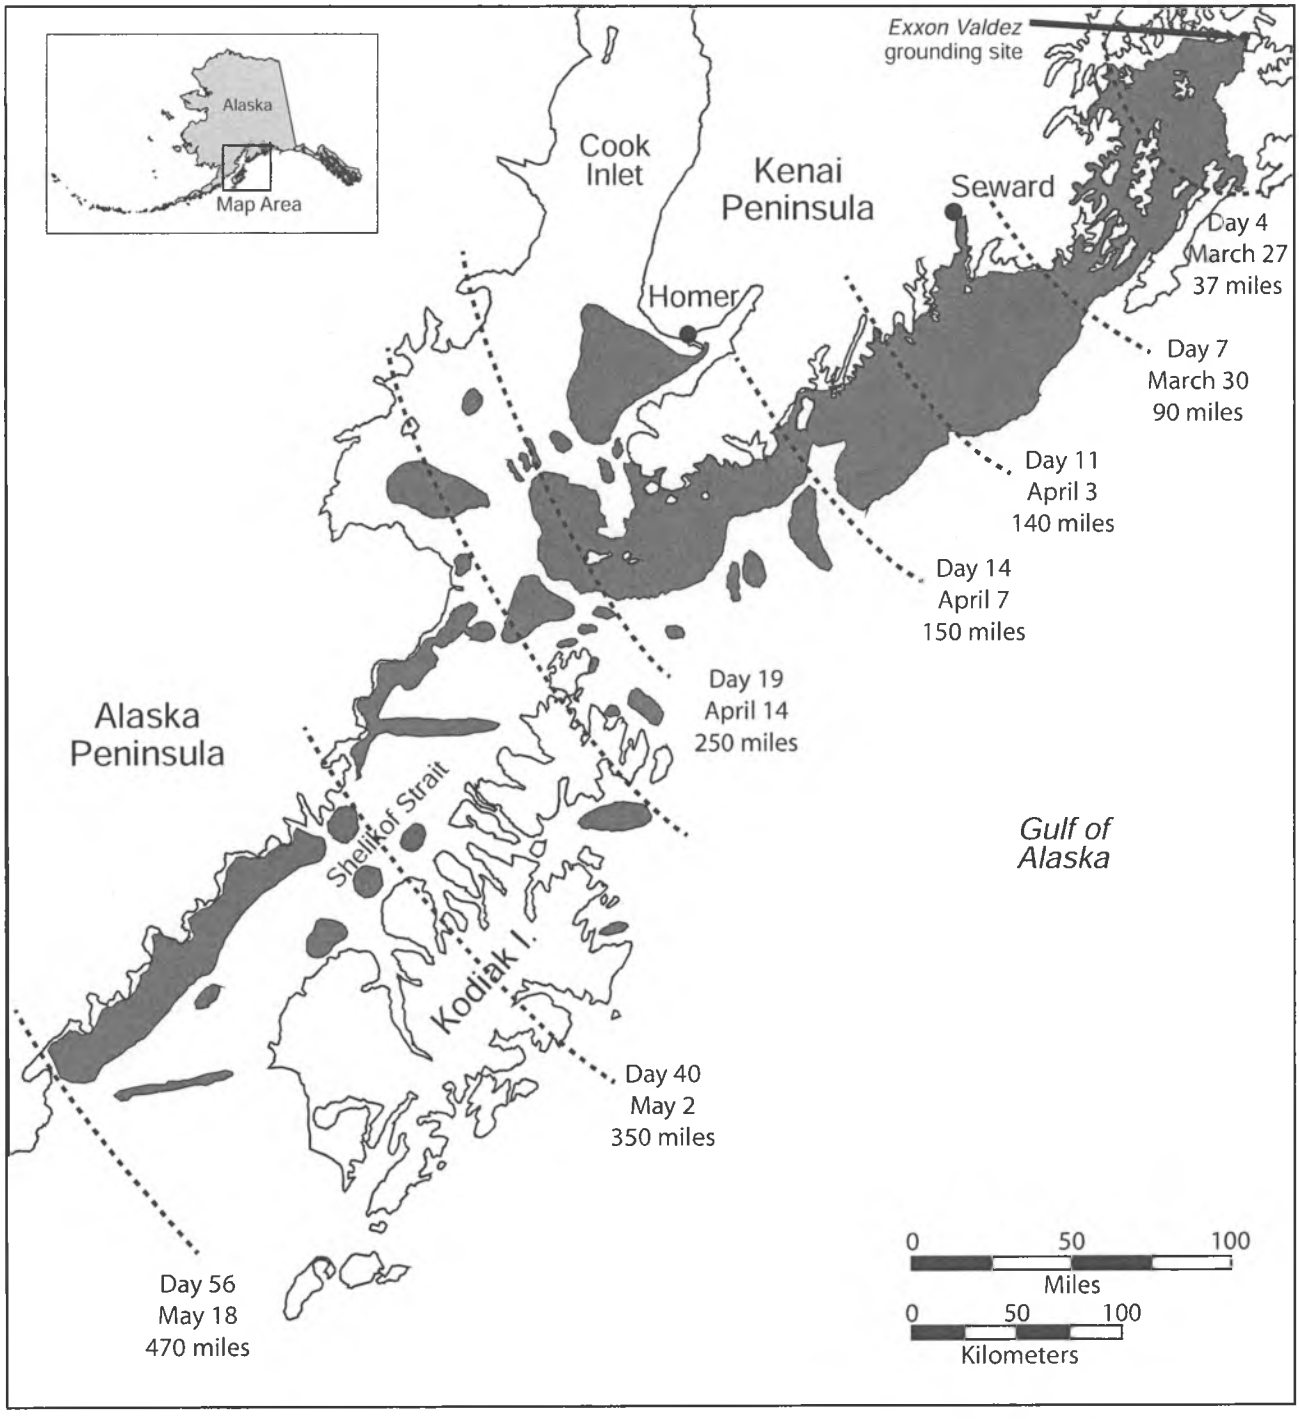

Figure D–1. Within 8 weeks after the spill, wind and currents had distributed the oil from the site of the accident at Bligh Reef in Prince William Sound into the Gulf of Alaska areas of Cook Inlet, Kodiak Island, and the Alaska Peninsula, a maximum distance of 470 miles. Source: 1993 State On-Scene Coordinator's Report (Alaska Department of Environmental Conservation, 1993).

  - Under Aleyska's SERVS program:
    - The design of skimming systems to separate and remove oil from the surface of water has been improved and is now 10 times greater than it was in 1989.
    - Seven barges, capable of holding 818,000 barrels of oil, have been made available in Prince William Sound. At the time of the spill, even if oil could have been collected, there was no holding facility.
    - Forty miles of containment boom is available in Prince William Sound, seven times as much as in 1989.
    - Dispersants are stockpiled for use and application systems via helicopters, airplanes, and boats have been designated.
    - Contingency planning for spills in Prince William Sound, held annually, must include a scenario for a spill of at least 12.6 million gallons.
- The U.S. Coast Guard, via satellite, has expanded the area where it monitors for icebergs and other potential hazards in the paths of tankers transporting oil across Prince William Sound.
- Two, rather than one, escort vessels now accompany and, if needed, assist each tanker while it is in the Sound, as directed by an executive order from the Alaska Governor soon after the EVOS.
- At the State level, a dozen new laws for oil-spill prevention, response, and oversight were passed by the Alaska Legislature between April 1989 and May 1990, including: (1) enlarging the State's emergency oil and hazardous substance response fund to 50 times its previous size; (2) revisions to the oil-spill prevention, response, contingency plan regulations; and (3) increased liabilities and penalties for polluters.
- Congress enacted legislation requiring double hulls on all oil tankers by 2015, including those traveling in Prince William Sound. A U.S. Coast Guard study estimated that, had the *Exxon Valdez* been double-hulled at the time of the spill, the amount of oil spilled would have been reduced by more than one-half (*Exxon Valdez* Oil Spill Trustee Council, 2011b).
- The OPA 90 established two oversight and monitoring programs, one in Prince William Sound, and one in Cook Inlet, to foster partnership of industry, government, and local communities in overseeing the environmental compliance for crude oil terminals (Cook Inlet Regional Citizens Advisory Council, 2011; Prince William Sound Regional Citizens' Advisory Council, 2011).
- The Oil Spill Recovery Institute, established by Congress in the OPA 90 after the spill, is charged with identifying and developing the best available techniques, equipment and materials for responding to oil spills in the Arctic marine environment and to complement Federal and State damage assessment efforts. The Institute is actively conducting research and educational and demonstration projects to carry out its mission, and is mandated through September 2012 (Prince William Sound Science Center Oil Spill Recovery Institute, 2011).

Planning for Preparedness in the Arctic OCS Region: Lessons Learned from the EVOS

Below we list in *italics* some of the lessons learned from the EVOS, which have bearing on the potential strengths and weaknesses of the scientific and technical understanding for Arctic OCS activities. Following each lesson is an explanation of the EVOS activities that comprised it.

Oil-Spill Response

Move quickly and be prepared to contain the oil to keep the situation from worsening.

The extent of injuries to natural resources and services resulting from a spill depends on the circumstances of the incident and the prevailing environmental conditions. Although the weather was calm for the first 3 days after the EVOS, Alyeska Pipeline Company, the designated first responder under the Prince William Sound contingency plan, had few pieces of equipment available and ready for use. In addition to Alyeska's contingency plan, National, regional, and local plans mandated by Federal regulation also had been developed, but the plans were not coordinated, had not established a response command hierarchy for responding to a spill, and lacked specific measures to address such problems as how to address spills in remote areas (Skinner and Reilly, 1989).

- Lightering, the process of unloading the remaining oil from the damaged tanker, took 11 days until the seepage of oil could be stopped. Underwater divers had located holes in 11 of the ship's holding tanks. (Skinner and Reilly, 1989).
- Only two skimmers and little or no containment boom were deployed initially (Skinner and Reilly, 1989).
- A small initial test burn successfully consumed 12,000 to 15,000 gal, but further tests were thwarted due to stormy weather (Skinner and Reilly, 1989).

- There were not enough dispersants available, nor enough vessels and equipment ready to deploy the dispersants. An initial trial application on the first day of the spill failed because of a lack of mixing energy (wind) and a later trial was inconclusive (Skinner and Reilly, 1989).
- A severe winter storm with wind gusts up to 73 mph arrived the evening of March 26 quickly dispersing the oil into patches, which spread to beaches up to 40 mi south of the site of the accident, at the same time temporarily grounding the response vessels.
- Eventually the oil reached as far as 470 mi away, to Chignik, on the Alaska Peninsula. Because the escaped oil was so widespread, it was necessary to continue cleanup efforts for four summers. Some oil lingers today, and cleanup efforts for it remain underway.

Spill response should aim to prevent oil from reaching streams, fine sediment beaches, and estuaries.

- Oil persisted in the sediments of streams, mussel beds, and estuaries, contaminating natal and nursery fish habitats for several years (Moles, 2001).

Damage and Injury Assessment

Fate of the oil, and thus the potential and nature of subsequent environmental effects, depends on a complex interaction of variables at the time of the spill, including chemistry, weather, shoreline characteristics, currents, temperature, and season.

- Estimates on the fate of the spilled oil are (Wolfe and others, 1994):
  - 20 percent evaporated,
  - 50 percent biodegraded either where it was deposited or in the water column,
  - 14 percent was recovered or disposed during the trial burning and dispersant treatments,
  - Less than 1 percent remained in the water column,
  - 2 percent remained on intertidal shorelines, and
  - About 13 percent remained in subtidal sediments, mostly as highly weathered residues.
- Within days, a winter storm had widely dispersed the oil slick both on the surface and subsurface of the seawater; oil droplets in the water column reached depths of at least 75 ft (Short and Harris, 1996); some mousse formed as the oil churned and mixed with water, and some tar balls formed as a result of evaporation (Payne and others, 1996).
- Wind, tide, and currents continued to redistribute the oil for at least 2 months, as shown in figure D–1.
- Spring tides were nearly 18 ft, stranding some oil high on shorelines, giving rise to a "bathtub ring" which was protected from wave action, resulting in no further dispersal (Spies, 2007).
- The total number of animals killed by the spill is unknown. The carcasses of more than 35,000 birds and 1,000 sea otters were found after the spill, but since most carcasses sink, this is a minimum estimate of the actual loss. The EVOS Trustee Council estimates are: 250,000 seabirds, 2,800 sea otters, 300 harbor seals, 250 bald eagles, up to 22 killer whales, and billions of salmon and herring eggs (*Exxon Valdez* Oil Spill Trustee Council, 2011c).
- Biologically, the end of March is particularly stressful for organisms because they have nearly depleted their stored energy and are beginning migration and reproduction cycles and the added impact of being oiled or having oiled prey takes a big toll. The populations of plankton and herring, which form the base of the food chain supporting much of the wildlife, were hard hit because the spring plankton bloom had just begun, and Pacific herring were entering the nearshore habitat of Prince William Sound in order to spawn. All age classes of herring and a significant portion of spawning habitats were contaminated by oil, and subsequently, lesions and elevated hydrocarbon levels were documented in some adult herring (Rice, 2010).

Emphasize preplanning: develop and maintain a regularly updated scientific sampling or biological response plan.

- Develop assessment approaches that do not require extensive baseline data, such as ecosystem models that identify pathways and processes at risk to oil injury; increase the accuracy of these models by running the models with parameters gleaned from pre-spill biological samples so that a baseline condition can be better established, and perturbations tested pre-spill. Monitor populations that can serve as surrogates for others, such as monitoring harlequin ducks as a surrogate for benthic-feeding birds (See, 2001).
- Develop a multi-species integrated approach to test mechanisms limiting recovery; an example in the nearshore environment included a study focused on the invertebrate-feeding sea otter and harlequin duck combined with the fish-feeding river otter and pigeon guillemot seabird (Peterson and Holland-Bartels, 2002).
- Pre-plan coordination and designate trained staff; maintain a scientific sampling or biologic response plan. Otherwise, collections can be haphazard, and data and specimens can be lost and unreported, inaccurate, and incomplete. Plan for a central data clearinghouse (See, 2001).

Obtain a geochemical signature of the spilled oil; not all of the oil encountered on the beaches of the spill area was sourced from the Exxon Valdez accident.

- Some of the oil residues found on some of the Prince William Sound shorelines were chemically distinct from the spilled oil (Kvenvolden, 1993).
- Flattened tar balls found throughout the northern and western parts of the Sound had carbon-isotopic and biomarker signatures of oil products used in Alaska before 1970, and are thought to have been created when storage facilities ruptured during the 1964 Alaska earthquake (Kvenvolden, 1995).

Cleanup

Cleanup was slow to get started, but eventually involved more than 11,000 workers. The combination of the presence of such a large workforce and its supporting infrastructure on sensitive coastal areas, coupled with effects from cleanup approaches, resulted in confounded impacts to the environment.

Detrimental effects of shoreline cleanup methods are complex and sometimes oversimplified.

- High-pressure, hot-water washing of the Prince William Sound shorelines effectively removed stranded oil, but damaged flora and fauna directly and indirectly, and received much public criticism, which caused it to be discontinued. Studies from the EVOS were among the first to document these impacts (Mearns, 1996).
- Response methodologies continue to include the high-pressure, hot-water washing techniques, but the National Oceanic and Atmospheric Administration (NOAA) Office of Response and Restoration now gives greater weight to evaluating the complexities and competing interests and the environmental tradeoffs before these methodologies are used (National Oceanic and Atmospheric Administration Office of Response and Restoration, 2011).

Restoration

A number of factors affected the ability of agencies to assess damage, define restoration goals, and judge progress towards those goals. Main among these was the lack of pre-spill data for potentially damaged natural resources and (or) the lack of current data. While, for example, significant data were available for seabirds and their prey, such data were collected in the 1970s prior to a decadal oceanic regime shift, which brought in different oceanic temperatures and salinities, resulting in changes to the food web, which triggered restructuring of the biological communities (Anderson and Piatt, 1999). Thus, the use of available pre-spill data such as seabird colony population surveys and demographic information as a pre-spill data set upon which to judge damage or recovery was confounded (Piatt and Anderson, 1996).

The United States Government and the State of Alaska settled their claims against Exxon Shipping Company and Exxon Corporation on October 9, 1991, with a settlement agreement comprised of a criminal plea agreement and fine of $150 million, criminal restitution for injuries to fish, wildlife, and land for $100 million, and a $900 million civil settlement fine. A Memorandum of Agreement between the Federal and State governments established the *Exxon Valdez* Oil Spill Trustee Council to manage the $900 million civil settlement for restoration activities. The Council is comprised of three Federal and three State Trustees.

Define restoration objectives and strategies to achieve the goal of recovering the oil spill area ecosystem.

- Since the EVOS, the OPA 90 Natural Resource Damage Assessment (NRDA) regulations have established that the restoration goal is achieved when the injured natural resources and services have returned to the condition they would have been, had the spill not occurred.
- In the 1994 EVOS Restoration Plan, some recovery objectives specified a return to pre-spill conditions or to stable or increasing population trends, which did not account for stressors other than oil, which became increasingly important as time went by.

Injury assessment of natural resources is complicated by a lack of pre-spill data and compounded by natural variation and will always involve uncertainties.

- In lieu of applicable pre-spill population data, animal carcass counts, a crude and minimal measure, had to be used in order to measure the extent of damages. Actual losses were higher than counted because some carcasses sank or were never discovered. For example, research studies have estimated the actual loss of the seabird murre population at 40 percent of its pre-spill level, or a loss of 250,000 murres, compared with the carcass recovery of 21,000 (Piatt and Ford, 1996). Such extrapolations are highly sensitive to the "observed versus not observed" ratio applied to calculate total loss, which in turn is affected by weather conditions that hamper the ability to make observations.
- Sources of uncertainty in assessing both the short- and long-term damage following a spill include variability in the available population estimates, lack of pre-spill data, ongoing changes to the ecosystem as a result of changing climate and other natural factors, emergence of new effects (for example, new contamination arising from contact with lingering oil), difficulty establishing causation (an unequivocal cause-and-

effect relationship between the biological resource and the oil), and comparing studies of differing spatial and temporal scales (Integral Consulting, Inc., 2006).

- Additional measures and approaches to measure damage in lieu of contemporary pre-spill baselines proved essential to developing an understanding of system recovery. Recovery status has been determined by evaluating the initial magnitude of oil impacts to a population through carcass counts, comparing the population demographics between oiled and unoiled areas, comparing the health of biological community members from oiled and unoiled areas, measuring to determine continued exposure to lingering oil through biomarker or tissue concentrations, establishing the persistence of sublethal or chronic injuries, evaluating the intrinsic ability of the population to recover, and accounting for other stressors from natural or anthropogenic sources (*Exxon Valdex* Oil Spill Trustee Council, 2006).

Track the status of recovery by updating the status of injury through monitoring.

- A list of natural resource and human service injuries caused by the EVOS helped guide the Restoration Plan adopted by the EVOS Trustee Council in 1994. The listings include the recovery status of individual species as well as sediments, subtidal and intertidal communities, commercial fishing, subsistence, recreation and tourism, archeological resources, and designated wilderness areas. The list has been instrumental to the EVOS Trustee Council in prioritizing the expenditure of public restoration funds received from the civil settlement with Exxon, ensuring that money was expended on resources needing attention. As restoration has proceeded and recovery statuses have changed, the list has been updated and re-published in 1996, 1999, 2002, 2006, and 2010. The list serves to track and document the status of recovery of the oil spill area; as of 2010, 2 resources have not recovered (Pacific herring, pigeon guillemots), 10 resources are recovering (Barrow's Goldeneyes, black oystercatchers, clams, designated wilderness areas, harlequin ducks, intertidal communities, killer whales, mussels, sea otters, sediments), 10 resources have recovered (archeological resources, bald eagles, common loons, common murres, cormorants, Dolly Varden fish, harbor seals, pink salmon, river otters, sockeye salmon), 3 resources are very likely recovered (cutthroat trout, rockfish, subtidal communities), and the recovery status of 2 resources (Kittlitz' and Marbled Murrelets) is unknown (*Exxon Valdez* Oil Spill Trustee Council, 1994, 2006, 2010).

Use an ecosystem perspective; examine food chains, and use ecosystem models to pinpoint pathways and processes at risk to oil injury. Do not ignore lower trophic levels.

- Multi-disciplinary, multi-species approaches increased the power to detect and evaluate recovery: the Sound Ecosystem Assessment project evaluated factors affecting productivity of Pacific herring and pink salmon; the Nearshore Vertebrate Predator program addressed factors affecting the recovery of four indicator species; and the Alaska Predator Ecosystem Experiment evaluated the productivity and recovery of seabirds based on the availability of forage fish (*Exxon Valdez* Oil Spill Trustee Council, 2011b). Recovery also will involve complex interactions, such as those associated with the dynamics of both microbial communities and food webs, which will cascade changes up to the largest predator.

Oil can remain toxic in the environment a surprisingly long time; oil degradation rates depend upon localized conditions (Michel and Esler, 2010, and citations therein).

- Some oil has persisted more than 2 decades in unexpected amounts and in toxic relatively unweathered forms, buried in the subsurface intertidal area of approximately 50 discontinuous beach sites, which put together, total a shoreline length of about 1.5 mi.
- The beaches with persistent oil have an upper, highly permeable layer and a lower layer of low permeability where the oil has remained trapped, physically protected from disturbance, oxygenation, and photolysis.
- The oiling history (high, medium, low) of the beaches, surveyed after the spill and again in 2001 and 2008, is one important indicator of predicting where oil persists.
- Biodegradation of the oil has been limited by a low concentration of dissolved oxygen as well as a nutrient concentration too small to sustain oil-consuming microorganisms. Bioremediation projects are being undertaken in 2011, 22 years after the spill.

Some of the lingering oil has been bioavailable to wildlife and has induced chronic exposure in nearshore species (Michel and Esler, 2010, and citations therein).

- Organisms that use the intertidal zone were severely impacted by initial oiling and cleanup and continued to show adverse impacts from continued exposure such as reduced survival rates and diminished populations. Studies have addressed and documented exposure to lingering oil in birds (harlequin ducks, Barrow's Goldeneyes, black oystercatchers, pigeon guillemots), sea otters, and fish (masked greenlings and crescent gunnels).
- Some harlequin ducks and sea otters in the nearshore environment have continued to exhibit signs of exposure to oil through 2006 and 2009, as measured through elevated oil biomarkers in blood and tissues or in gene expression. Studies are ongoing and awaiting the results of laboratory analyses of the most recent harlequin duck samples collected in March 2011 to see if oil exposure continues.

Long-term chronic exposure is now recognized as a major component of injury and may equal or exceed acute effects (Peterson and others, 2003).

- Effects of the EVOS have revised the paradigm for assessing ecological risks of oil in the ocean. Previously, it was assumed that acute mortality is the main impact to a population, but EVOS research has shown that chronic, delayed and indirect long-term risks and impact play a much larger role than previously envisioned. Risk assessment models that project biological injury need to be updated from treating species independently to instead provide for interacting variables.
- A delay in population reduction was caused, for example, by ingestion of oiled prey, by lower survival rates for harlequin ducks in the winters following the spill due to cumulative stress from encountering the lingering oil, and by damage to fish over time through oil exposure which increased embryo mortality and deformity and resulted in poor predator avoidance and low growth rates.
- Recovery was postponed as cascades of indirect effects, such as a food shortage of forage fishes as well as a reduction of high-quality forage fish prey reduced seabird populations of murres, puffins, and pigeon guillemots. Animal communities may experience delayed recovery depending on complex interactions, and communities may not soon return to their original configurations. For example, a loss of experienced breeders in seabird colonies disrupted the phenology of breeding for several years, imperiling late-fledging young, such as murres. On rocky shorelines, indirect interactions resulting from oiling and loss of the ubiquitous rockweed plant cover, as well as grazing and predatory gastropods, are thought to have delayed the recovery process for a decade or more, while opportunistic barnacles colonized the open rock spaces and disrupted the food chain.
- Injury to seabirds, mammals, fish, and invertebrates continues long term through chronic exposure from ingesting contaminated prey and through foraging in oiled sediments, and through disruption of reproduction. Long-term exposure of fish embryos to weathered oil has had population consequences through indirect effects on growth, deformities, and behavior (Rice, 2010, and citations therein).

Oil effects can be subtle, indirect, and long term.

- Long-term monitoring and research have been essential in identifying the full impacts of the spill, as evidenced particularly for sea otters and harlequin ducks. The EVOS Trustee Council has sponsored a multitude of projects to monitor the recovery of injured species, and final reports can be found on their website (*Exxon Valdez* Oil Spill Trustee Council, 2011b) as well as throughout the published literature. Long-term monitoring of the recovery of the nearshore environment, where patches of toxic oil still linger, is one such project which is ongoing, and which is being considered for 5 to 20 additional years of funding by the EVOS Trustee Council at its August 2011 meeting.
- Some injuries cannot be determined until years later, such as the significant long-term biological effects of lingering oil; studies are currently in progress for harlequin ducks and sea otters.
- Delays in the recovery of bird and mammal predators of fish and invertebrates resulted from chronic and indirect effects, such as the loss of their habitat due to oiling or cleanup activities and the subsequent spread of opportunistic species, such as algae or small intertidal fishes, which inhibited the return of the original fish and invertebrate food sources (Peterson, 2000).

- Sublethal exposures to oil caused mortalities due to compromised health, growth, or reproduction; for example, long-term exposure of the black oystercatchers that foraged on heavily oiled shores, documented up to 3 years post-spill, showed reduced breeding and smaller eggs than those that bred in unoiled areas; higher chick mortality occurred in areas where their diet consumption had included oiled mussels; and the oystercatcher parents gathering prey on oiled shores fed chicks more to achieve less growth than those on unoiled shores, at a higher energetic cost (Peterson and others, 2003).
- The acute, initial loss of killer whales following the spill has had a long-term impact on the recovery of the ecosystem because the species is long-lived with low reproductive rates, and, as the predator at the top of the food chain, significantly affects the structure of the ecosystem (Rice, 2010).
- Pacific herring, a primary forage fish for many seabird and marine mammals, still have not recovered. Despite numerous studies, the causes of this phenomenon are not well understood, but appear to include disease, predation, and poor recruitment (the survivability of juveniles) (*Exxon Valdez* Oil Spill Trustee Council, 2010).

Not much real (that is, direct) restoration can be done; so instead the environment must be restored.

- Lost services, such as commercial and sport fishing, recreation and tourism, and subsistence are assumed to be restored when the species upon which they were based are restored (*Exxon Valdez* Oil Spill Trustee Council, 1994).
- To date, because direct restoration opportunities are few, the $900 million civil settlement funds received from Exxon and managed by the EVOS Trustee Council have been allocated 24 percent to research, monitoring, and direct and indirect restoration; 37 percent to habitat protection and acquisition; 22 percent reimbursements for assessments and response; and 17 percent in an investment trust fund to increase the amount of funds available for future studies (*Exxon Valdez* Oil Spill Trustee Council, 2011b).
- Natural recovery was selected under the 1994 EVOS Restoration Plan as the preferred alternative for restoration, and research and monitoring were directed at tracking the status of recovery (*Exxon Valdez* Oil Spill Trustee Council, 1994).
    - Because natural recovery over the past 20 years has failed to remediate the 50 beach segments identified recently with the most significant persistent oil, bioremediation projects using oxygenation and nutrient enrichment techniques are being tested by the EVOS Trustee Council in 2011 as a way to clean up the remaining oil (*Exxon Valdez* Oil Spill Trustee Council, 2011a).
- Habitat acquisition to promote natural recovery of spill-injured resources, especially on lands under imminent threat of development, has been a significant and well-received component of the EVOS restoration program, and could be an effective tool elsewhere. As of 2006, the Council has protected more than 630,000 acres of habitat, including more than 1,400 mi of coastline and more than 300 streams valuable for salmon spawning and rearing (*Exxon Valdez* Oil Spill Trustee Council, 2010).

A Reopener clause, part of the 1991 legal settlement between Exxon and the State and Federal governments, provided for unanticipated injury.

- Some of the long-term injury from the spill was not identifiable initially, but has been established since, under research funded by the EVOS Trustee Council. Under the oil spill Reopener clause in the 1991 litigation settlement with Exxon, on August 31, 2006, the Federal and State governments submitted a demand letter to Exxon to pay up to $100 million for additional restoration work for the recovery of a population, habitat or species suffering a substantial loss or decline from an injury that could not have been known or reasonably anticipated on the date of the settlement. The plan focuses on the restoration of sites where lingering toxic oil persists (U.S. Department of Justice, 2006). Studies assessing the linkage of injury from the lingering oil to damage at the population level, particularly in sea otters and sea ducks, which inhabit the nearshore environment where the lingering oil occurs, are ongoing, and their outcome will help inform the Reopener claim. Trustee Council-sponsored research is underway to continue to identify lingering oil site locations, factors limiting the degradation of the oil, and to test pilot projects to remediate the pockets of lingering oil. Negotiations between the governments and Exxon to address this claim remain underway since September 2006.

Prepare for conflicting studies.

- Exxon Corporation has continued to fund its own damage assessment studies, and the resulting conclusions have consistently contrasted with those funded by the EVOS Trustee Council. The studies have differed in concept, statistical rigor, and choice of study sites and those differences have led to differing conclusions (Spies, 2007; Rice, 2010).

- Sampling design begets conclusions: Despite having common goals, four studies on the impact of the spill on intertidal biota involved different sampling efforts, analytical methodologies, and the choice of biological response variables that led to differing conclusions. Two of the studies were funded by Exxon Corporation, one by the EVOS Trustee Council, and one by the NOAA Hazmat program (Peterson and others, 2001).

Summary Points for the OCS Oil Planning Team Effort

Prevention is the principal defense against oil spills. Preparedness is the next best thing, with the caveat that no two oil spills are the same. Full recovery from the *Exxon Valdez* oil spill has not yet occurred, 22 years later. Keeping oil from reaching shorelines, where it is difficult to treat, may remain in a toxic form in the subsurface for up to 22 years—as in the EVOS—and takes an enormous toll on the food chain, must be a top priority in spill response. Not all species are equally affected, and not all species recover at the same rate. Initial wildlife mortalities from the EVOS were extreme, and likely understated due to lack of pre-spill population data and the difficulty in recovering carcasses. Studies of the long-term environmental and health effects on wildlife of acute and chronic exposure to oil have yielded surprising findings emphasizing the magnitude and complexity of the long-term impact. The effects of chronic oil exposure, delayed impacts, and sub-lethal impacts on growth, development, and reproduction have caused decreases at the population level; this finding is significant. An ecosystem-approach, allowing for the effects of indirect and cascading reactions, is imperative in evaluating restoration.

Appendix E. Arctic Marine Synthesis—Data Sources and Data Quality

The "Arctic Marine Synthesis: Atlas of the Chukchi and Beaufort Seas" by Audubon Alaska and Oceana (Smith, M.A., 2010, Arctic Marine Synthesis—Atlas of the Chukchi and Beaufort Seas: Audubon Alaska and Oceana, Anchorage) represents an emergent approach about data quality and sufficiency. Before the creation of this effort few others had assembled broad-scale information for this area. This broad synthesis utilizes spatial data from more than 100 sources plus literature and reports from another 400 sources, resulting in 44 thematic maps that cover six categories for the Chukchi and Beaufort Seas: Physical Oceanography, Water Column and Benthic Life, Fish, Birds, Mammals, and People. A listing of maps, data sources, and data quality ratings compiled from this synthesis is shown in table E–1.

Table E–1. Listing of maps, data sources, and data quality ratings as compiled from "The Arctic Marine Synthesis: Atlas of the Chukchi and Beaufort Seas" by Audubon Alaska in partnership with Oceana (Smith, 2010).

[**Good:** provides a complete geographic picture of the resource or species; data are consistent and of decent quality for mapping at the scale used (1:5,000,000); this rating does not indicate that fine-scale, project level data are available; **Fair:** provides a partial geographic picture of the resource or species; data are variable, some portions of the map are represented by reliable, high-quality data and data for other portions of the map are outdated, opinion-based, or missing data altogether; some key features, such as concentrations areas, may be missing. **Poor**: provides an incomplete geographic picture of the resource or species; information is missing, outdated, or deficient, but it is the best known data available (Smith, M.A., 2010, Arctic Marine Synthesis—Atlas of the Chukchi and Beaufort Seas: Audubon Alaska and Oceana, Anchorage)]

Map title	Data quality rating (Good, Fair, Poor)	Data sources for individual maps

Table E–1. Listing of maps, data sources, and data quality ratings as compiled from "The Arctic Marine Synthesis: Atlas of the Chukchi and Beaufort Seas" by Audubon Alaska in partnership with Oceana (Smith, 2010)—Continued

Good: provides a complete geographic picture of the resource or species; data are consistent and of decent quality for mapping at the scale used (1:5,000,000); this rating does not indicate that fine-scale, project level data are available; **Fair:** provides a partial geographic picture of the resource or species; data are variable, some portions of the map are represented by reliable, high-quality data and data for other portions of the map are outdated, opinion-based, or missing data altogether; some key features, such as concentrations areas, may be missing. **Poor**: provides an incomplete geographic picture of the resource or species; information is missing, outdated, or deficient, but it is the best known data available (Smith, M.A., 2010, Arctic Marine Synthesis—Atlas of the Chukchi and Beaufort Seas: Audubon Alaska and Oceana, Anchorage)]

Table E–1. Listing of maps, data sources, and data quality ratings as compiled from "The Arctic Marine Synthesis: Atlas of the Chukchi and Beaufort Seas" by Audubon Alaska in partnership with Oceana (Smith, 2010)—Continued

Good: provides a complete geographic picture of the resource or species; data are consistent and of decent quality for mapping at the scale used (1:5,000,000); this rating does not indicate that fine-scale, project level data are available; **Fair:** provides a partial geographic picture of the resource or species; data are variable, some portions of the map are represented by reliable, high-quality data and data for other portions of the map are outdated, opinion-based, or missing data altogether; some key features, such as concentrations areas, may be missing. **Poor**: provides an incomplete geographic picture of the resource or species; information is missing, outdated, or deficient, but it is the best known data available (Smith, M.A., 2010, Arctic Marine Synthesis—Atlas of the Chukchi and Beaufort Seas: Audubon Alaska and Oceana, Anchorage)]

Sea Grant
Alaska

Alaska Marine Policy Forum

Summary of Wednesday, May 25, 2011 call
Host: Molly McCammon mccammon@aoos.org

Alaska Marine Policy Forum: A bimonthly teleconference for Alaskans to network and share information about marine policy, budgets, and legislation at state, national, and international levels, sponsored by Alaska Sea Grant and the Alaska Ocean Observing System.

NOTES FROM THE May 25 CALL

Cheryl Rosa and John Farrell, Arctic Research Commission
As part of the National Ocean Council development of a National Ocean Policy, the Arctic Research Commission is co-lead with the Navy in developing an Arctic Strategic Action Plan (SAP). They have been working since February, and the draft outline will be public on June 1 (at www.whitehouse.gov/administration/eop/oceans/sap). The National Ocean Policy has 9 priority areas that include environmental response, ocean observing and coordination of data. The Arctic is the only geographic region called out for its own SAP. Two listening sessions will be held in Alaska: one in Barrow on June 9th at City Hall, and the other in Anchorage on June 10th at the Loussac Library (both 4-9 pm).

Arne Fuglvog, staff to AK Senator Lisa Murkowski
Senator Murkowski was very happy with her trip to Nuuk for the Arctic Council meeting with Secs. Clinton and Salazar. She is impressed with the administration's willingness to step up for Arctic issues, showing that the Arctic has reached a new level of priority. The new Search and Rescue (SAR) binding agreement is important and they now are moving toward an agreement on oil spill response.

Arne noted that more and more Arctic issues are coming up at the national level. Sen. Murkowksi gave a floor speech last week on the Arctic. She and Sen. Begich still want to see movement on the Law of the Sea Treaty. It needs 67 votes to pass the Senate, and it will probably take 7-8 days of "floor time" to get the vote scheduled.

Lawson Brigham suggested that the Arctic Council's oil spill response plan be written more openly using public and industry input, unlike how the SAR agreement was reached. Bob Pawlowski asked about the deep water port charrette in Anchorage last week. Arne mentioned that currently the US doesn't have any plans to build an Arctic port,, but with about 800 ongoing projects in the Arctic, that might make sense. He mentioned that the state and industry need to engage in the discussions about a deep water port. The fundamental question is "Is it in the nation's best interest to have a deep water port in the Arctic?"

Re: Budget – The House is marking up bills; the Senate is more focused on debt ceiling and isn't likely to mark up any individual bills this summer. It's possible that individual budget bills get passed, or that

there is an omnibus bill, or there could be another continuing resolution. Unfortunately, if a continuing resolution is passed late in the year, summer construction projects in Alaska get delayed.

Christine Hess, Staff to AK Legislature Rep. Reggie Joule (D-Kotzebue)
Re: the Alaska Coastal Management Program (ACMP) – the Alaska State Senate says that they have the votes to agree to come back for a special session for probably 2 days to address the Alaska Coastal Management Program. Senator Begich sent a letter to the governor which was very helpful. A 2/3 vote of the House is required for the Legislature to call itself into special session. The issues on the table are the inclusion of local and traditional knowledge in decision making, and 'removal for cause' from the Board. NOTE: Since the Marine Policy Forum teleconference, the Legislature decided not to hold the special session since they were not able to reach agreement on the legislation.

The Northern Waters Task Force will meet in Kotzebue on July 5 and 6, followed by Nome on July 7 and 8. The Task Force will take field trips to Red Dog Mine on the 6th, and to Wales, Diomede, and potential port sites, on the 9th. The Kotzebue visit will be concurrent with the local trade fair festival. Other trips on the docket include:

- Unalaska: Aug 24-26th
- September: potentially an additional meeting to wrap up loose ends or hear from presenters not available at other meetings, especially the Bethel meeting that was cancelled.

Cheryl Rosa, USARC (continued)
The Interagency Arctic Policy Committee (IARPC), part of the White House Office of Science and Technology Policy, has hired Alaskan Brendan Kelly for about 45% of his time. They are working on budget cross-cut planning for federal Arctic research which will allow them to get a handle on what is being spent on the Arctic. This cross cut has the support of OMB, and will be part of the 2014 budget. In the 5-year plan that IARPC is crafting, there is emphasis on collaboration, sustainability, and improved coordination.

Amy Holman, NOAA
Check the Federal Register for notification about a public hearing by the International Whaling Commission in Anchorage June 14. Also, NOAA and BOEMRE have developed an MOU so that they can work more closely together.

Ian Dutton, Alaska SeaLife Center
Several Alaskans recently attended the International Marine Conservation Congress in Victoria, BC. Ian can provide information if you are interested. June 8th is World Oceans Day and there will be two new statues unveiled at the ASLC, as well as 2 new exhibits. Tickets to the evening party are $20 (5-7pm on the 8th).

Cdr. Mark Everitt, USCG
USCG Rear Admiral Tom Ostebo was recently appointed Commander of the 17th USCG District replacing Chris Colvin. The Coast Guard will do a search and rescue exercise in Barrow next week. They will also do a towing experiment in the Bering Strait this summer, as well resume Arctic overflights. If you are interested in coming along on a flight, contact Shane Montoya or Mark Everitt at the USCG. Additionally, the Healy leaves Seattle next week, will stop in Hawaii, and then continue on to the Arctic until Dec 30th.

Kris Holdereid, Kachemak Bay NERR and Gary Freitag, Alaska Sea Grant MAP

Harmful algal blooms in Ketchikan and Juneau are significant right now. Gary noted that these are Alexandruim cells, so PSP and not domoic acid. Three very sick people have gone to the hospital in Ketchikan for digging clams on local beaches. He noted that with warm, sunny weather, conditions are just right.

Upcoming Events

June 8	World Ocean Day, events at the Alaska Sea Life Center
June 9	National Ocean Policy Listening Session, Barrow
June 10	National Ocean Policy Listening Session, Anchorage
June 11	Copper River Nouveau, Cordova
June 13	Cryosphere Hazards in Alaska workshop, Anchorage
June 14	NOAA Deputy Undersecretary Monica Medina has ocean observing discussion at AOOS
June 19-21	Arctic Imperatives conference, Girdwood, sponsored by Aspen Institute & AK Dispatch
June 20-25	"4th Symposium on Impacts of Ice Diminishing Arctic on Naval and Maritime Operations (Washington DC)
June 21-23:	National Ocean Policy's national CMSP meeting. Reps from Alaska are six fed agencies points of contact, Mark Robbins from the Governor's office, and some invitees from the Alaska Native community. Washington DC. (June 21st is open to public; the rest is invite-only.) Washington DC
June 26-29:	Solutions to Coastal Disasters national conference, Anchorage
July 18-22	Coastal Zone 2011 national conference, Chicago

Next Meetings

Dates for next two calls:

Wednesday July 20th, 1 pm Alaska time
Wednesday, September 21, 1 pm Alaska time

AOOS
www.aoos.org

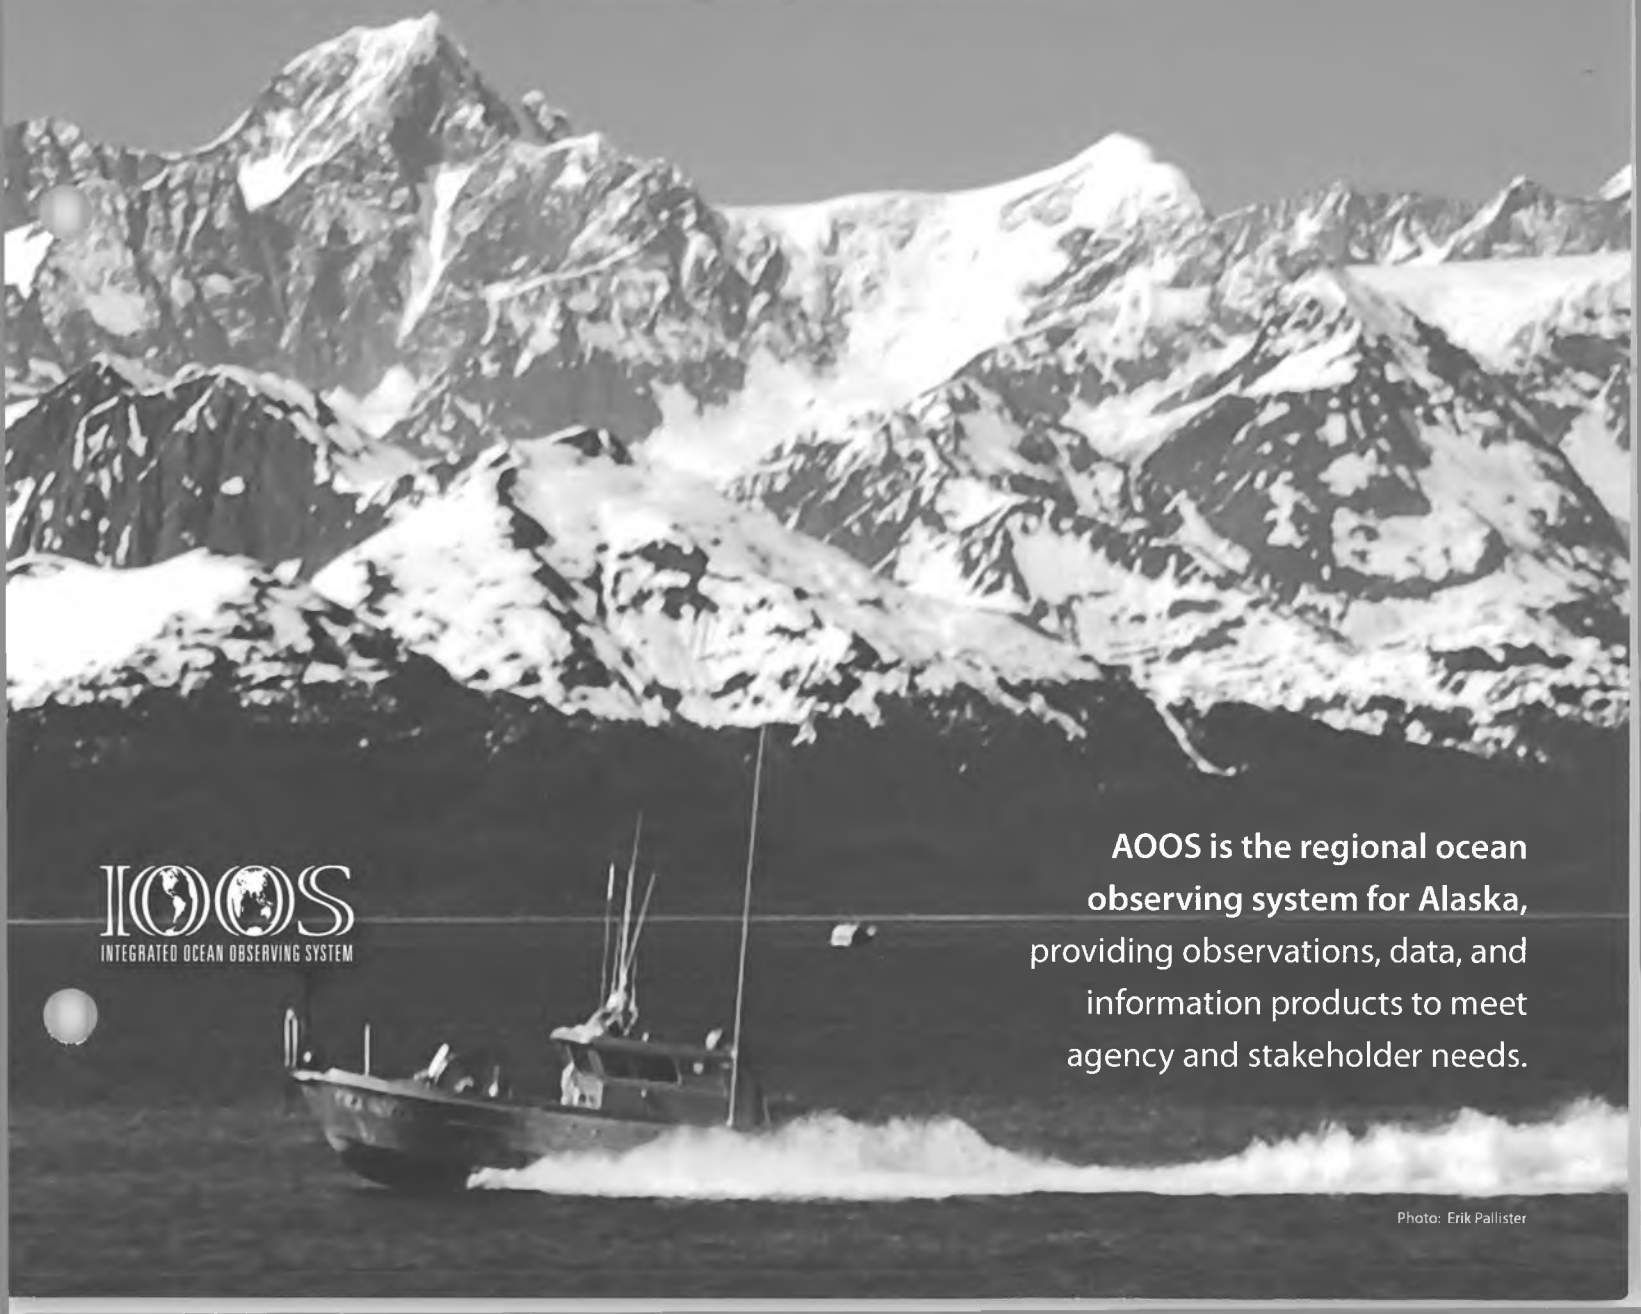
The eye on Alaska's coasts and oceans

We help improve

SAFETY: By ensuring the safety and security of Alaskans

ECONOMY: By helping unlock economic benefits of the ocean

ENVIRONMENT: By protecting our marine resources



IOOS
INTEGRATED OCEAN OBSERVING SYSTEM

AOOS is the regional ocean observing system for Alaska, providing observations, data, and information products to meet agency and stakeholder needs.

Photo: Erik Pallister

A tool for tracking, predicting, managing, and adapting to changes in our marine environment

AOOS

AOOS Members

State agencies
- Alaska Dept. of Environmental Conservation
- Alaska Dept. of Fish and Game
- Alaska Dept. of Natural Resources

Federal agencies
- Bureau of Ocean Energy Management, Regulation and Enforcement
- NOAA
- U.S. Coast Guard
- U.S. Geological Survey

State/federal entities
- Alaska Sea Grant Program

Research entities
- Alaska SeaLife Center
- Barrow Arctic Science Consortium
- NOAA Alaska Fisheries Science Center
- North Pacific Research Board
- Prince William Sound Science Center/ Oil Spill Recovery Institute
- University of Alaska
- U.S. Arctic Research Commission

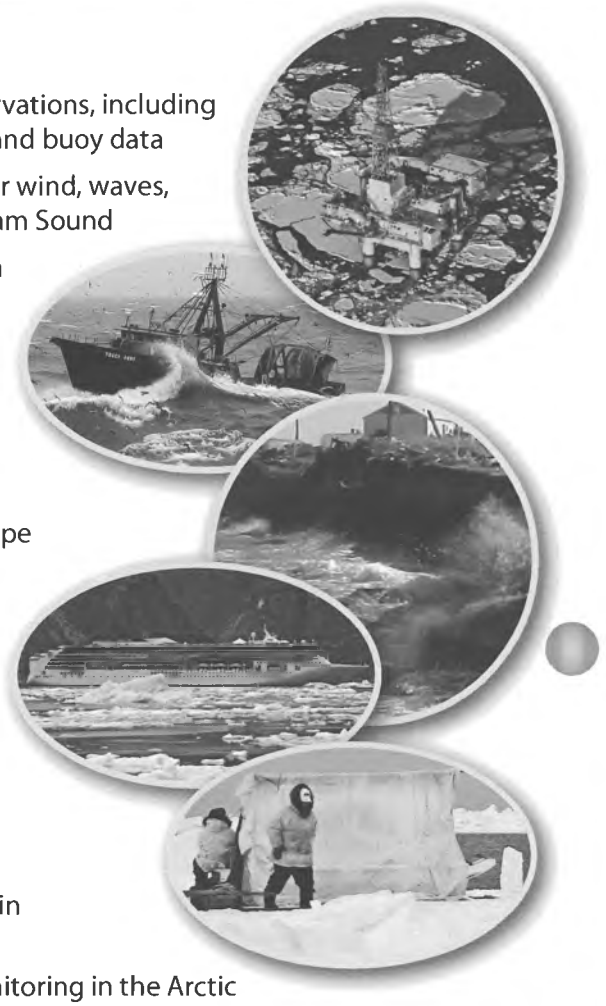
Non-profit NGO
- Marine Exchange of Alaska

AOOS Board Officers
- ***Chair: Denby Lloyd,*** Alaska Dept. of Fish and Game
- ***Vice Chair: Glenn Sheehan,*** Barrow Arctic Science Consortium
- ***Secretary: Ed Page,*** Marine Exchange of Alaska
- ***Treasurer: Doug DeMaster,*** NOAA Alaska Fisheries Science Center

AOOS Staff
- ***Molly McCammon,*** Executive Director
- ***Darcy Dugan,*** Program Manager for Partnerships and Outreach
- ***Rob Bochenek,*** Data Manager

What we do

- Give access to real-time observations, including web cams, weather stations, and buoy data
- Produce data and forecasts for wind, waves, and circulation in Prince William Sound
- Monitor ocean acidification in the northern Gulf of Alaska and Arctic
- Support glider observations in the Arctic to monitor climate change
- Support the Alaska Harbor Observation Network prototype system in Seward
- Track agency and industry research assets in the Arctic



Coming soon

- More wind, wave, and ocean circulation forecasts in Southcentral Alaska
- Real-time wave observations in Lower Cook Inlet
- More ocean acidification monitoring in the Arctic
- An annual ***State of Alaska's Oceans and Coasts*** **report**
- Water level sensors and wave buoys in western Alaska
- Marine forecasts and real-time data to vessels using Automatic Identification System (AIS) tracking
- An electronic Sea Ice Atlas for shippers and forecasters

With more funding, we would

- Improve storm surge forecasts for western Alaska statewide
- Develop coastal climate change monitoring program
- Expand an ocean acidification monitoring system statewide
- Expand glider observing program
- Expand real-time wind, water level and wave observations and forecasts

AOOS is part of national and global networks of ocean observing.

1007 W 3RD AVENUE, SUITE 100 • ANCHORAGE, AK 99501 • 907-644-6703 • WWW.AOOS.ORG

H.

Arctic Energy Network

INSTITUTE OF THE NORTH

The Arctic Energy Network

The Arctic Energy Network (AEN) is a community of interest focused on exploring policy and practice related to the Arctic's unique energy resources as well as the energy needs of arctic communities. Hosted by the Institute of the North, the AEN brings together stakeholders from across the Arctic to learn, teach and collaborate on arctic energy issues.

Vision

The exchange of knowledge results in the responsible development of Arctic energy resources and support and improve the economic, social and environmental conditions of Arctic communities, states and nations.

Mission

The AEN connects stakeholders in Arctic energy issues, building bridges and creating opportunities to learn, teach and collaborate on shaping the emerging and best practices in Arctic energy policies, technology, infrastructure and security.

The AEN meets its mission through:

- ⇨ Hosting networking and learning opportunities
- ⇨ Educating policy makers and administrators
- ⇨ Seeking out and sharing best practices
- ⇨ Supporting collaborative research opportunities
- ⇨ Convening around emerging energy issues
- ⇨ Conducting research projects
- ⇨ Encouraging groundbreaking thinking

As a part of its mission based activities, the AEN hosts a website that serves as an interactive forum to:

- Convene members & facilitate around specific topics.
- Create an archive of essential ideas, programming, speeches, reviews, and action plans that result from AEN functions.
- Promote collaborative research opportunities.
- Share upcoming events on a calendar dedicated to Arctic energy conferences, workshops, and presentations.
- Connect members to projects across the Arctic.

Membership

Membership is open to all stakeholders and parties interested in Arctic energy issues including private sector, indigenous groups, government agencies, non-governmental organizations, local, state & national governments, policy makers, energy experts and research institutions who share the following values:

1. Energy should be affordable, reliable and accessible.
2. Energy wealth should be invested to support community and economic development.
3. A balance of non-renewable and renewable energy sources is necessary.
4. Wise energy development is the cornerstone to economic sustainability in the Arctic.

Membership Benefits

The AEN offers the following benefits to all of its members:

- ⇨ Invitations to join educational technology and policy tours of neighboring nations, states, and provinces.
- ⇨ E-newsletter on energy news from across the Arctic.
- ⇨ Case studies of energy projects across the Arctic.
- ⇨ Chance to engage in cross-industry collaborations.
- ⇨ Coordination of fellowships and professional exchanges.
- ⇨ Opportunities to participate in AEN programs and initiatives.
- ⇨ Promotion of member's events in the shared-event calendar.
- ⇨ Access to the "Member's Only" section of the AEN website.
- ⇨ Membership directory.
- ⇨ Invitations to annual Arctic Energy Policy Forum.
- ⇨ Biannual Arctic Energy Summit.

The Arctic is in a state of change and there are great opportunities as well as challenges that face, collectively, Arctic communities. AEN member organizations work to address these challenges and develop opportunities by sharing expertise, experience and knowledge.

Membership Dues & Additional Benefits:

- Individual: $100
- Basic Organization: $250
- Supporting Organization: $1000
  - Discounts on registration for events such as policy tours and Arctic Energy Summit
- Sponsoring Organization: $5000
  - Discounts on registration for events such as policy tours and Arctic Energy Summit
  - Logo on AEN website & newsletters
  - Invitation to VIP receptions
  - Observer status on the Advisory Council

Member organizations may become sustaining member with an additional gift on top of dues. The additional contributions of sustaining members support the biannual conference and other networking and educational events throughout the year.

Governance

The AEN is led by an Advisory Council reflective the diversity of the membership of the AEN and diversity of the Arctic. Advisory Council members are responsible for evaluating new programs and initiatives, contributing their expertise to the current and future work of the AEN, providing leadership in the planning of the biannual Arctic Energy Summit and general guidance on the direction of the AEN. All Advisory Council meetings are open to the general membership.

Membership on the Advisory Council

Each of the eight Arctic nation governments may appoint one representative to the Advisory Council. Additional seats to the Advisory Council are elected from the membership and apportioned to ensure diverse experience and knowledge is contributed. Elected seats are apportioned as follows:

- Indigenous Organization (2)
- Resource Development (2)
- Energy Research (2)
- Non-governmental Organization (2)

Each of the elected members serves a two year term. Elections are held at the biannual Arctic Energy Summit and each member of the AEN has an equal vote. Select sponsors are also invited to participate in a non-voting Observer role.

Special Committees

The Advisory Council may elect to form special committees. The Chair of a committee shall be an advisory council member but other members of the AEN as well as subject matter experts may be invited to serve on committees.

Lead Organization

The AEN is hosted by the Institute of the North, and qualifies as a 501 (c)(3) organization under its umbrella. As a lead organization the ION houses AEN staff and administers the AEN's finances.

The Institute's mission and vision are strongly aligned with the work of the AEN. Governor Walter J. Hickel, founder of the Institute of the North, believed strongly that we must understand the reality, the richness and the responsibility of the North. Today, the Institute works to share that vision, specializing in how to utilize and care for the resource-rich commons for the benefit of those living in and on the commons. Areas of special study include Alaska, the many regions of the Arctic and other areas of the world that are wealthy in both human cultures and natural resources. The Institute has gained a wide reputation as a center for the study of commonly-owned lands, seas and resources using Alaska as a model.

Appendix A

Members of the AEN have indicated recommended the following areas of work for the Arctic Energy Network to focus their energy and attention on. The AEN Advisory Council will assist in prioritizing the most cutting edge issues, developing projects and promoting opportunities for members to engage each other, exchanging knowledge and pioneering new thoughts on these and many other critical arctic energy issues.

COMMUNITY ENERGY ISSUES

Arctic communities are consumers of energy that is not often affordable, reliable or accessible to them, greatly impacting their sustainability. In finding community energy solutions, topics of interest include improving the transportation, storage and transmission of energy, developing stranded renewable resources, improving energy efficiency, improving and developing new technology for community energy projects, financing research for development, testing and implementation of new technology, creating viable energy markets in remote and rural locations, reducing diesel consumption, and enhancing leadership development and training opportunities for local people to administer, develop and improve on community energy solutions.

RESOURCE DEVELOPMENT

Responsible development of extractive and renewable energy resources is a challenge and an opportunity in the Arctic. It is estimated that 25% of the undiscovered global oil and gas resources are in the Arctic as well as bountiful supply of renewable resources including bio-mass, wind and geothermal energy. Creating infrastructure to develop and transport these resources, addressing indigenous and other community concerns with resource development, the security of the projects being developed, evaluating new technologies that are being deployed, sharing best practices for development in sensitive Arctic environments, promoting technology exchange between the renewable and extractive energy sectors, and strengthening trust and facilitating better relationships are among the hot topics that the members of the AEN are interested in.

PUBLIC POLICY

Public policy for the Arctic has not necessarily kept pace with the changes in the Arctic. While Arctic environment has been the subject of much hotly contested policy work, the Arctic as a global commons, indigenous rights, stewardship, local, national and international standards for development, improvements in regulatory structures, disaster mitigation, public-private partnerships, projected increases in Arctic development particularly by non-Arctic nations, sovereign wealth funds, sustainability of communities, the effects of climate change, reducing black carbon, and other unique Arctic issues have received less attention.

DATA COLLECTION

Significant gaps still exist in the Arctic knowledge base that can be filled by the AEN from creating a comprehensive database of expertise, knowledge, best practices and current projects in the Arctic, to mapping energy use in the Arctic and proving assessments of resource wealth and renewable energy resources.

Introduction to Northern Waters Task Force

- The NWTF was created by HCR 22 during the 2010 legislative session.

- Warming trends have caused the perennial Arctic sea ice to be depleted by 9% per decade, scientist predict that the Arctic could be ice free in 20 to 30 years, which will open up a vast array of new challenges and opportunities for the communities that live along the seas, for the state, for the nation and the entire globe

- During the last legislature, Representative Alan Austerman from Kodiak brought to a group of legislators' attention something that had been bobbing around in the ether for some time: that the Alaska legislature lacks meaningful involvement in addressing issues related to the changing Arctic seas. After some discussion, what most of us knew but had not acted on was that the federal government and independent organizations are taking action to address the opportunities and challenges that are coming before us as the Arctic ice melts. We felt it was time to get involved, so together, we pushed to create the Task Force.

- During the course of our meetings in Juneau, we heard discussion of an Arctic waters commission being formed at the federal level. We felt that since the only reason the U.S. borders the Arctic is because of Alaska, Alaskans should have input in creating the body that the federal government planned to set up, so that our state and communities' interests would be adequately represented.

- This federal body has been created, so our thinking was timely. On July 19, 2010 President Obama signed an Executive Order establishing the first ever National Policy for the Stewardship of the Ocean, Our Coasts, and the Great Lakes, which adopts the Final Recommendations of the Interagency Ocean Policy Task Force and directs federal agencies to implement these recommendations.

- A high level National Ocean Council has been created to coordinate

federal agencies to implement the National Policy and to strengthen ocean governance. It will establish a Governance Coordinating Committee to formally engage with states, tribes and local governments. The Committee will consist of 18 members, including one designated seat for an Alaskan representative chosen in consultation with the governor. There may be other opportunities for Alaska representation, as there is a seat for one member of a state legislature, three tribal representatives, and three local government representatives.

- The National Ocean Council will immediately begin coastal and marine spacial planning to analyze current and anticipated uses of ocean and coastal areas. The NOC has created 9 regional planning bodies to develop the coastal and marine spacial plans. Alaska is a region unto itself.

- According to the resolution creating our Task Force, the duties of the task force are to:

(1) assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;
(2) facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;
(3) identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and
(4) conduct hearings in the Northern region of the state to fulfill its purpose;

The task force shall provide recommendations regarding the formation of the commission and shall deliver a preliminary report of its findings to the legislature by January 20, 2012, and deliver a final report to the legislature on January 30, 2012, together with legislative proposals for consideration.

- I thank you for taking time out of your extremely busy schedules to be part of this Task Force.

During Session:

Alaska State Legislature
REPRESENTATIVE REGGIE JOULE

To: Senator Stevens, Senate President
Representative Chenault, Speaker of the House

From: Representative Reggie Joule

Date: September 9, 2010

Re: Northern Waters Task Force

Thank you for your recent appointments to the Northern Waters Task Force. Recently, my fellow legislators have selected me to chair the task force. Our first hearing is tentatively scheduled for October 1st in Anchorage. As the chair, I am now seeking authority to spend the funds designated for the task force so that we can carry out the mission outlined in Legislative Resolve 54. Attached with this letter is a list of the members of the task force with their contact information so that the accounting department can assist us with arranging travel and reimbursing members for their expenses. By your signatures above you will authorize the chair to expend the funds for the task force. Thank you for your attention to this matter.

WORKING AGENDA

1. Welcome and organization 8-8:45 a.m.

   Introduce members
   Overview of task force and task force mission
   Travel and accounting procedures
   Possible schedules for future hearings and sites:

   - Alaska Federation of Natives (Oct. 20-22nd)
   - Nov. 15-18th Kotzebue and Nome
   - Dec. 1-2 Barrow with PNWER
   - End of Jan. Bethel

15 min. Break

2. Introduction and overview 9-9:15 a.m. (CLH)

Molly McCammon 644-6703/227-7643 (confirmed)
Director
Alaska Ocean Observing Systems

3. Science of the warming waters 9:15-10 am (CLH)

   Kate Moran 202-841-1566/ 202-456-6079
   kmoran@ostp.eop.gov
   Hajo Eicken 474-7280
   Hajo.eicken@gi.alaska.edu
   Mike Castellano

Break 10-10:15 am

4. NOAA/and what the feds are doing 10:15 to 11 am (CLH)

   Amy Holman NOAA 271-5334 call out

5. Overview of what the state is doing and the state federal executive roundtable (LH) 11-11:45 Commissioner Hartig 465-5065

15 min break to get food

12 to 1 p.m. International Lunchtime Panel: (EH)

Alaska Federation of Natives/ISER

United States Arctic Commission, Cheryl Rosa, Deputy Director

Consulate of Canada, Jennifer Loten

ICC

6. US Coast Guard/Marine Shipping 1:15 to 2pm (RE)

   Rear Admiral Christopher Colvin
   Michael.cerne@usdg.mil
   Capt. Carl Uchytil 463-2226/lead for Arctic

   Mike Straga/Lawson Bringham

7. United States Arctic Commission Report 2-2:45 pm (EH)(confirmed)

   Cheryl Rosa

Deputy Director of USARC and Anchorage Director,
Buck Sharpton

15 min break

8. Oil and Gas 3-3:45 (Linda Hay)

Marilyn Crockett/Judy Brady/ Shell/Jason Brune

4:15 to 5 pm wrap up

Video conferencing Rob

Molly McCammon, Alaska Ocean Observing Systems
Jackie Menge/Arctic report Card

7. Coast Guard:

Captain Carl Uchytil 463-2226 Carl.J.Uchytil@uscg.mil
Christopher Colvin, 17th District Commander for the Arctic
Mike Cerne co-chairing strategy development for the National Ocean policy Michael.Cerne@uscg.mil

8. States efforts: Governor's Climate change Subcabinet and four working groups and other state efforts:

Commissioner Hartig

9. Other possible for first hearing but not for village travel:

John Madden, DMVA abd HS&ER (increased capacity for emerging emergency needs in the Arctic)
Mike Coffey, AK DOT (transportation needs in the Arctic)
Mike Brubaker ANTHC (changing climate and health)
Phil Martine, USFWS, (coordinating Arctic landscape conservation cooperative)

STATE OF ALASKA
THE LEGISLATURE

2010

Source
CSHCR 22(FIN)

Legislative Resolve No.
54

Establishing and relating to the Alaska Northern Waters Task Force.

BE IT RESOLVED BY THE LEGISLATURE OF THE STATE OF ALASKA:

WHEREAS Alaska is the only Arctic state in the nation; and

WHEREAS recent warming trends have resulted in the depletion of Arctic perennial sea ice by nine percent a decade; and

WHEREAS, according to the National Aeronautics and Space Administration, the rate of depletion is accelerating because of the interaction among the ice, oceans, and atmosphere; and

WHEREAS rapidly retreating sea ice is altering fish and wildlife habitats and affecting the accessibility and viability of certain species on which many local communities rely for nutritional and cultural purposes; and

WHEREAS reduced sea ice is affecting polar route navigation by opening oceans previously frozen year-round; and

WHEREAS the new accessibility of the Northern waters is resulting in increased marine transportation, access to resources, tourism, fisheries, and the presence of United States government agencies in the North; and

WHEREAS the waters of Northern Alaska are of national security and strategic importance to the United States and the State of Alaska; and

WHEREAS, because of national security concerns, the United States Coast Guard is increasing its presence in the North and has plans to build new infrastructure to support its heightened activity, including housing and office facilities and possibly a deepwater port; and

WHEREAS Northern Alaska contains important mineral and other resources both in state waters and on the outer continental shelf; and

WHEREAS commercial activities, including resource development, and the revenue they generate for the state may be significantly affected by the changing Arctic waters; and

WHEREAS those changes will affect local communities, businesses, the state, and the natural resources on which they rely; and

WHEREAS there is no comprehensive state plan for Alaska's Northern waters; and

WHEREAS various federal agencies and international bodies are working together to form a commission to address the changing ocean patterns and the opportunities and problems that may arise as a result of those changing patterns; and

WHEREAS the State of Alaska should be involved in the process of forming the commission; and

WHEREAS a comprehensive plan to address the warming ocean, including the economic, ecological, and security effects, will benefit the state and its residents;

BE IT RESOLVED by the Alaska State Legislature that the Alaska Northern Waters Task Force is created in the legislative branch and shall consist of 11 members as follows:

(1) two senators appointed by the President of the Senate;

(2) two representatives appointed by the Speaker of the House of Representatives; and

(3) seven members appointed jointly by the President of the Senate and the Speaker of the House of Representatives, as follows:

(A) five public members, three of whom reside in coastal areas of the state;

(B) one member representing the executive branch of state government;

(C) one member representing the federal government; and be it

FURTHER RESOLVED that a vacancy on the task force shall be filled in the manner of the original appointment; and be it

FURTHER RESOLVED that the legislators on the task force shall select a chair from among themselves, and the chair may assign staff to provide support to the task force; and be it

FURTHER RESOLVED that the public members, and, if the member does not receive reimbursement for expenses from the federal government, the federal government member of the task force may receive per diem and travel expenses authorized for boards and commissions under AS 39.20.180; and be it

FURTHER RESOLVED that the task force may meet during and between legislative sessions, and the duties of the task force include the following:

(1) assess and facilitate creation of a state and federal commission responsible for overseeing the development of state and federal northern ocean waters;

(2) facilitate regional coordination, cooperation, and outreach regarding the creation of the commission to keep local stakeholders informed and to incorporate their input into the process;

(3) identify and coordinate efforts of mutual concern for federal, state, and local agencies, as well as international interests in the creation of the commission; and

(4) conduct hearings in the Northern region of the state to fulfill its purpose; and be it

FURTHER RESOLVED that the task force shall provide recommendations regarding the formation of the commission and shall deliver a preliminary report of its findings to the legislature by January 20, 2012, and deliver a final report to the legislature on January 30, 2012, together with legislative proposals for consideration; and be it

FURTHER RESOLVED that the task force shall be available for legislative hearings regarding its final report and recommendations; and be it

FURTHER RESOLVED that the continuation or termination of the task force shall be reevaluated during the Second Regular Session of the Twenty-Seventh Alaska State Legislature.

Russian Assn of Indigenous Peoples of the North (RAIPON) www.raipon.org

III. RESEARCH AND ACADEMIC ORGANIZATIONS

A. State of Alaska and US Federal Research

Interagency Arctic Research Policy Committee (IARPC)
www.nsf.gov/od/opp/arctic/iarpc/start.jsp
IARPC consists of fifteen-plus agencies, departments, and offices across the US Federal government and is chaired by the National Science Foundation.
IARPIC Departments:

the National Science Foundation www.nsf.gov
- **Office of Polar Programs** (OPP) www.nsf.gov/dir/index.jsp?org=OPP
  The key funder of Arctic and Antarctic research in the U.S.

the Department of Commerce
- **NOAA's National Marine Fisheries Service** (NMFS) www.nmfs.noaa.gov
- **NOAA's Office of Oceanic and Atmospheric Research** (OAR) www.oar.noaa.gov provides the research foundation for understanding the complex systems that support our planet. NOAA Research provides better forecasts, earlier warnings for natural disasters and a greater understanding of the Earth. Their role is to provide unbiased science to better manage the environment, nationally and globally.

the Department of Defense
- **US Army Cold Regions Research & Engineering Laboratory** **www.crrel.usace.army.mi**

the Department of State www.state.gov
the Department of Health and Human Services
- **National Institutes of Health** www.nih.gov/index.html
- **Indian Health Service** www.ihs.gov

the Department of Homeland Security
- **US Coast Guard** www.uscg.mil
- **US Coast Guard Research & Development Center** www.uscg.mil/acquisition/rdc/rdc.asp

the Office of Science and Technology Policy
www.whitehouse.gov/administration/eop/ostp
- **National Science and Technology Council**: This Cabinet-level Council is the principal means within the executive branch to coordinate science and technology policy across the diverse federal entities. By July 22, 2010 Presidential Memorandum, the NSTC now coordinates some IARPIC activities.

the Department of Agriculture www.usda.gov
the Department of Energy www.energy.gov
- **National Renewable Energy Lab** (NREL) www.nrel.gov

the Department of the Interior www.doi.gov
- **Bureau of Indian Affairs** www.bia.gov
- **US Fish & Wildlife Service** www.fws.gov

- **US Geological Survey** www.usgs.gov
- **Bureau of Ocean Energy Management** www.boemre.gov
  On May 19, 2010, Secretary Salazar began splitting the MMS into three bureaus: the Bureau of Ocean Energy Management, the Bureau of Safety and Environmental Enforcement, and the Office of Natural Resources Revenue.

the Department of Transportation www.dot.gov
- Maritime Administration: www.marad.dot.gov
- Federal Aviation Administration www.faa.gov

the National Aeronautics and Space Administration www.nasa.gov
the Environmental Protection Agency www.epa.gov
- Office of Research & development www.epa.gov/ORD

the Smithsonian Institution www.si.edu
the National Endowment for the Humanities www.neh.gov

United States Arctic Research Commission (USARC) www.arctic.gov
The Commission's main purpose is to establish the national policy, priorities, and goals necessary to construct a federal program plan for basic and applied scientific research with respect to the Arctic, including natural resources and materials, physical, biological and health sciences, and social and behavioral sciences and to recommend Arctic research policy, and to communicate our research and policy recommendations to the President and the Congress.

Arctic Research Consortium of the United States (ARCUS) www.arcus.org
The Arctic Research Consortium of the United States was formed in 1988 to identify and bring together the human and facilities resources of the Arctic research community in the United States. ARCUS is a non-profit corporation consisting of institutions organized and operated for educational, professional, or scientific purposes. The ARCUS headquarters and staff are located in Fairbanks, Alaska.

Alaska Fisheries Science Center (AFSC) www.afsc.noaa.gov
Barrow Arctic Science Consortium (BASC) www.arcticscience.org
North Slope Science Initiative (NSSI) www.northslope.org
US Army Corps of Engineers Cold Regions Research and Engineering Laboratory (CRREL) www.crrel.usace.army.mil
Office of Naval Research (ONR) www.onr.navy.mil
National Research Council (NRC) http://nationalacademies.org/nrc
Provides independent, expert advice to the Congress, Administration and public. Three boards of relevance: Polar Research Board; Marine Board; and Ocean Studies Board.

B. International Research

International Arctic Science Committee http://web.arcticportal.org/iasc
Comprised of national science organizations covering all fields of Arctic research, the International Arctic Science Committee (IASC) was established in 1990, began operations in 1991 and today involves 18 member countries. The IASC's mission is to encourage and facilitate cooperation in all aspects of Arctic research throughout the

region. Although IASC is not a funding agency, it supports science development by providing scientific advice as well as seed money. In general, IASC-supported activities are international or circumpolar in nature and thus of interest to several member countries. The organizational needs of IASC are served by a secretariat located in Stockholm. IASC is an international associate of the International Council for Science, and has observer status on the Arctic Council.

The International Union for Circumpolar Health http://iuch.net
Formally established in 1981, the International Union for Circumpolar Health (IUCH) is a non-governmental organization with members, adhering bodies and affiliates throughout the circumpolar region. Its focus is the health problems and needs of northern peoples. Its functions include disseminating medical knowledge, research findings and demonstrated solutions to the general and specific medical and health problems of Arctic communities. To support its members and affiliates, and the scientific and indigenous communities at large, the IUCH has established working groups that concentrate on specific health problems of importance to circumpolar populations, maintains several publications, and supports international efforts in telemedicine and health informatics.

International Polar Year 2007-2008 (IPY) www.ipy.org
The International Polar Year is a large scientific program focused on the Arctic and the Antarctic. An important aspect of its activities is the legacy of information and organization that it will leave in the polar regions. One of the most significant efforts in this regard is concerned with the creation of a Sustained Arctic Observation Network to meet scientific and societal needs.

Arctic Human Health Initiative (AHHI) www.arctichealth.org/ahhi (Arctic Council)
International Arctic Research Center (IARC) www.iarc.uaf.edu
International Study of Arctic Change (ISAC) www.arcticchange.org

C. Universities, Colleges, Institutes, Non-Profits and Think Tanks

University of the Arctic www.uarctic.org
The University of the Arctic is a cooperative network of universities, colleges and other organizations committed to higher education and research in the North.
Institute of Arctic Studies (Dartmouth)
http://dickey.dartmouth.edu/initiatives/arctic-studies
Scott Polar Research Institute (Cambridge) www.spri.cam.ac.uk
Institute of Arctic & Alpine Research University of Colorado
http://instaar.colorado.edu
North Pacific Research Board (NPRB) www.nprb.org
Institute of the North www.institutenorth.org
Anchorage-based think tank on Arctic and other issues. Worked on **the Arctic Marine Shipping Assessment**: www.institutenorth.org/servlet/content/maritime_news.html
The Northern Forum www.northernforum.org
The Northern Forum is a non-profit, international organization composed of sub-national or regional governments from eight northern countries.

2.

Summary of Proposed Federal Legislation

Senator Begich - Inuvikput Package

Introduced August 3, 2009, the *Inuvikput Package* consists of seven pieces of legislation:

S.1560 Arctic OCS Revenue Sharing Act - Alaska Natives who have subsisted on marine mammals and other arctic resources for thousands of years would bear the direct risks of increased commercial activity in their waters. This bill directs a portion of federal revenues from offshore oil and gas development - the same share Louisiana receives from drilling in the adjacent Gulf of Mexico - to the State of Alaska with a percentage of those funds directed to those most affected.

S.1561 Arctic Marine Shipping Assessment Implementation Act - As the polar icecap recedes, the Arctic region is increasingly accessible to shipping and tourism. This bill is designed to ensure safe and reliable maritime transportation in the Arctic and protect its waters. It would boost the nation's investment in needed infrastructure, including replacement of America's aging fleet of icebreakers and building new forward operating air bases for the Coast Guard to assert our national interest in the region.

S.1562 Arctic Science, Coordination and Integration Act - Numerous scientists and agencies conduct important and needed research into various aspects of the Arctic but concerns remain that these efforts are not well coordinated and leave gaps in our understanding of Arctic issues. This bill calls on the National Research Council to undertake a study toward a comprehensive strategy to coordinate Arctic research and make recommendations to Congress on a long-term Arctic Ocean research plan.

S.1563 Arctic Ambassador Act - Russia, Canada, Norway and other Arctic nations are represented at the ambassadorial level before the Arctic Council and U.S. interests would benefit from an enhanced diplomatic presence in Arctic matters. This bill is intended to strengthen U.S. representation before the Arctic Council and other international forums by appointment of a U.S. ambassador to the Arctic.

S.1564 Arctic Oil Spill Research and Recovery Act - Vast energy reserves are believed to lie beneath Arctic waters and it is vital that any development of such resources be conducted in a responsible manner that protects the environment upon which residents of the region depend. This bill directs the Secretary of Commerce to conduct research to improve oil spill prevention, response and recovery in Arctic conditions and requires the Coast Guard to assess and reduce risk from such development.

S.1565 Arctic Health Research Act - People of the Arctic suffer from increased rates of alcohol abuse, diabetes, high blood pressure, and death from injury and suicide. This act would initiate a study into the mental, behavioral and physical health problems in the Arctic, institute an Arctic health assessment program at the Centers for Disease Control and create an "Arctic desk" at the National Institute of Health that was called for in 1984 but has never been established.

S.1566 Arctic Climate Change Adaptation Act - Alaska villages and public infrastructure are already suffering from coastal erosion, flooding, permafrost melting and other impacts of climate change. This bill would help the State of Alaska, Alaska Native organizations, affected Arctic communities and the private sector adapt to the impacts of climate change and assist in dealing with habitat restoration, clean energy development and other economic development activities.

Senator Murkowski's Arctic Bills - August 5, 2010

Sen. Murkowski has introduced three Arctic bills in the 111th Congress. None are expected to move this Congress. According to her staff, she awaits a Coast Guard report due out in December to begin pushing these bills forward.

Senator Murkowski's website provides, "One [piece of legislation] would implement some of the recommendations of the Arctic Marine Shipping Assessment, including the authorization of a study to determine and develop the necessary infrastructure to support increased Arctic maritime transportation. The legislation also authorizes the construction of two new heavy icebreakers to replace the aging Polar Sea and Polar Star.

A second bill would amend the Hydrographic Services Improvement Act to authorize funding to get data and services to the Arctic for safe navigation, delineate the U.S. extended continental shelf and monitor coastal changes.

The third bill would direct the Department of Defense and the Department of Homeland Security to study the feasibility, location and resource needs for an Arctic deep water port. This study would determine whether it is in the strategic interest of the United States to build a port and where it might be located. A deep water port would not only serve our military and Coast Guard needs, but as we develop our offshore oil and gas reserves and see more shipping, tourism and vessel traffic in the Arctic, a deep water port could provide a crucial base of operations.

Sen. Murkowski is also a strong proponent of ratification of the United Nations Convention on the Law of the Sea, believing that it is crucial for the United States to be a party to this Treaty and be a player in the process, rather than an outsider hoping our interests are not damaged. As the only Arctic nation not a party to the treaty, failure to ratify continues to keep the United States at a disadvantage internationally and outside the process, without a seat at the table."

http://murkowski.senate.gov/public/index.cfm?p=Arctic

3.

United States Arctic Policy

NSPD-66 / HSPD-25

The White House
President George W. Bush

National Security Presidential Directive and Homeland Security Presidential Directive

January 9, 2009

NATIONAL SECURITY PRESIDENTIAL DIRECTIVE/NSPD -- 66
HOMELAND SECURITY PRESIDENTIAL DIRECTIVE/HSPD -- 25

MEMORANDUM FOR THE VICE PRESIDENT
THE SECRETARY OF STATE
THE SECRETARY OF THE TREASURY
THE SECRETARY OF DEFENSE
THE ATTORNEY GENERAL

DIRECTOR OF NATIONAL INTELLIGENCE
ASSISTANT TO THE PRESIDENT FOR NATIONAL SECURITY AFFAIRS
COUNSEL TO THE PRESIDENT
ASSISTANT TO THE PRESIDENT AND DEPUTY NATIONAL SECURITY ADVISOR FOR INTERNATIONAL ECONOMIC AFFAIRS
ASSISTANT TO THE PRESIDENT FOR HOMELAND SECURITY AND COUNTERTERRORISM
CHAIRMAN, COUNCIL ON ENVIRONMENTAL QUALITY
DIRECTOR OF THE OFFICE OF SCIENCE AND TECHNOLOGY POLICY
CHAIRMAN OF THE JOINT CHIEFS OF STAFF
COMMANDANT, U.S. COAST GUARD
DIRECTOR, NATIONAL SCIENCE FOUNDATION

SUBJECT: Arctic Region Policy

I. PURPOSE

A. This directive establishes the policy of the United States with respect to the Arctic region and directs related implementation actions. This directive supersedes Presidential Decision Directive/NSC-26 (PDD-26; issued 1994) with respect to Arctic policy but not Antarctic policy; PDD-26 remains in effect for Antarctic policy only.

B. This directive shall be implemented in a manner consistent with the Constitution and laws of the United States, with the obligations of the United States under the treaties and other international agreements to which the United States is a party, and with customary international law as recognized by the United States, including with respect to the law of the sea.

II. BACKGROUND

A. The United States is an Arctic nation, with varied and compelling interests in that region. This directive takes into account several developments, including, among others:

1. Altered national policies on homeland security and defense;

2. The effects of climate change and increasing human activity in the Arctic region;

3. The establishment and ongoing work of the Arctic Council; and

4. A growing awareness that the Arctic region is both fragile and rich in resources.

III. POLICY

A. It is the policy of the United States to:

1. Meet national security and homeland security needs relevant to the Arctic region;

2. Protect the Arctic environment and conserve its biological resources;

3. Ensure that natural resource management and economic development in the region are environmentally sustainable;

4. Strengthen institutions for cooperation among the eight Arctic nations (the United States, Canada, Denmark, Finland, Iceland, Norway, the Russian Federation, and Sweden);

5. Involve the Arctic's indigenous communities in decisions that affect them; and

6. Enhance scientific monitoring and research into local, regional, and global environmental issues.

B. **National Security and Homeland Security Interests in the Arctic**

1. The United States has broad and fundamental national security interests in the Arctic region and is prepared to operate either independently or in conjunction with other states to safeguard these interests. These interests include such matters as missile defense and early warning; deployment of sea and air systems for strategic sealift, strategic deterrence, maritime presence, and maritime security operations; and ensuring freedom of navigation and overflight.

2. The United States also has fundamental homeland security interests in preventing terrorist attacks and mitigating those criminal or hostile acts that could increase the United States vulnerability to terrorism in the Arctic region.

3. The Arctic region is primarily a maritime domain; as such, existing policies and authorities relating to maritime areas continue to apply, including those relating to law enforcement.[1] Human activity in the Arctic region is increasing and is projected to increase further in coming years. This requires the United States to assert a more active and influential national presence to protect its Arctic interests and to project sea power throughout the region.

4. The United States exercises authority in accordance with lawful claims of United States sovereignty, sovereign rights, and jurisdiction in the Arctic region, including sovereignty within the territorial sea, sovereign rights and jurisdiction within the United States exclusive economic zone and on the continental shelf, and appropriate control in the United States contiguous zone.

5. Freedom of the seas is a top national priority. The Northwest Passage is a strait used for international navigation, and the Northern Sea Route includes straits used for international navigation; the regime of transit passage applies to passage through those straits. Preserving the rights and duties relating to navigation and overflight in the Arctic region supports our ability to exercise these rights throughout the world, including through strategic straits.

6. Implementation: In carrying out this policy as it relates to national security and homeland security interests in the Arctic, the Secretaries of State, Defense, and Homeland Security, in coordination with heads of other relevant executive departments and agencies, shall:

a. Develop greater capabilities and capacity, as necessary, to protect United States air, land, and sea borders in the Arctic region;

b. Increase Arctic maritime domain awareness in order to protect maritime commerce, critical infrastructure, and key resources;

c. Preserve the global mobility of United States military and civilian vessels and aircraft throughout the Arctic region;

d. Project a sovereign United States maritime presence in the Arctic in support of essential United States interests; and

e. Encourage the peaceful resolution of disputes in the Arctic region.

C. **International Governance**

1. The United States participates in a variety of fora, international organizations, and bilateral contacts that promote United States interests in the Arctic. These include the Arctic Council, the International Maritime Organization (IMO), wildlife conservation and management agreements, and many other mechanisms. As the Arctic changes and human activity in the region increases, the United States and other governments should consider, as appropriate, new international arrangements or enhancements to existing arrangements.

2. The Arctic Council has produced positive results for the United States by working within its limited mandate of environmental protection and sustainable development. Its subsidiary bodies, with help from many United States agencies, have developed and undertaken projects on a wide range of topics. The Council also provides a beneficial venue for interaction with indigenous groups. It is the position of the United States that the Arctic Council should remain a high-level forum devoted to issues within its current mandate and not be transformed into a formal international organization, particularly one with assessed contributions. The United States is nevertheless open to updating the structure of the Council, including consolidation of, or making operational changes to, its subsidiary bodies, to the extent such changes can clearly improve the Council's work and are consistent with the general mandate of the Council.

3. The geopolitical circumstances of the Arctic region differ sufficiently from those of the Antarctic region such that an "Arctic Treaty" of broad scope -- along the lines of the Antarctic Treaty -- is not appropriate or necessary.

4. The Senate should act favorably on U.S. accession to the U.N. Convention on the Law of the Sea promptly, to protect and advance U.S. interests, including with respect to the Arctic. Joining will serve the national security interests of the United States, including the maritime mobility of our Armed Forces worldwide. It will secure U.S. sovereign rights over extensive marine areas, including the valuable natural resources they contain. Accession will promote U.S. interests in the environmental health of the oceans. And it will give the United States a seat at the table when the rights that are vital to our interests are debated and interpreted.

5. Implementation: In carrying out this policy as it relates to international governance, the Secretary of State, in coordination with heads of other relevant executive departments and agencies, shall:

   a. Continue to cooperate with other countries on Arctic issues through the United Nations (U.N.) and its specialized agencies, as well as through treaties such as the U.N. Framework Convention on Climate Change, the Convention on International Trade in Endangered Species of Wild Fauna and Flora, the Convention on Long Range Transboundary Air Pollution and its protocols, and the Montreal Protocol on Substances that Deplete the Ozone Layer;

   b. Consider, as appropriate, new or enhanced international arrangements for the Arctic to address issues likely to arise from expected increases in human activity in that region, including shipping, local development and subsistence, exploitation of living marine resources, development of energy and other resources, and tourism;

   c. Review Arctic Council policy recommendations developed within the ambit of the Council's scientific reviews and ensure the policy recommendations are subject to review by Arctic governments; and

   d. Continue to seek advice and consent of the United States Senate to accede to the 1982 Law of the Sea Convention.

D. **Extended Continental Shelf and Boundary Issues**

1. Defining with certainty the area of the Arctic seabed and subsoil in which the United States may exercise its sovereign rights over natural resources such as oil, natural gas, methane hydrates, minerals, and living marine species is critical to our national interests in energy security, resource management, and environmental protection. The most effective way to achieve international recognition and legal certainty for our extended continental shelf is through the procedure available to States Parties to the U.N. Convention on the Law of the Sea.

2. The United States and Canada have an unresolved boundary in the Beaufort Sea. United States policy recognizes a boundary in this area based on equidistance. The United States recognizes that the boundary area may contain oil, natural gas, and other resources.

3. The United States and Russia are abiding by the terms of a maritime boundary treaty concluded in 1990, pending its entry into force. The United States is prepared to enter the agreement into force once ratified by the Russian Federation.

4. Implementation: In carrying out this policy as it relates to extended continental shelf and boundary issues, the Secretary of State, in coordination with heads of other relevant executive departments and agencies, shall:

   a. Take all actions necessary to establish the outer limit of the continental shelf appertaining to the United States, in the Arctic and in other regions, to the fullest extent permitted under international law;

   b. Consider the conservation and management of natural resources during the process of delimiting the extended continental shelf; and

   c. Continue to urge the Russian Federation to ratify the 1990 United States-Russia maritime boundary agreement.

E. **Promoting International Scientific Cooperation**

1. Scientific research is vital for the promotion of United States interests in the Arctic region. Successful conduct of U.S. research in the Arctic region requires access throughout the Arctic Ocean and to terrestrial sites, as well as viable international mechanisms for sharing access to research platforms and timely exchange of samples, data, and analyses. Better coordination with the Russian Federation, facilitating access to its domain, is particularly important.

2. The United States promotes the sharing of Arctic research platforms with other countries in support of collaborative research that advances fundamental understanding of the Arctic region in general and potential Arctic change in particular. This could include collaboration with bodies such as the Nordic Council and the European Polar Consortium, as well as with individual nations.

3. Accurate prediction of future environmental and climate change on a regional basis, and the delivery of near real-time information to end-users, requires obtaining, analyzing, and disseminating accurate data from the entire Arctic region, including both paleoclimatic data and observational data. The United States has made significant investments in the infrastructure needed to collect environmental data in the Arctic region, including the establishment of portions of an Arctic circumpolar observing network through a partnership among United States agencies, academic collaborators, and Arctic residents. The United States promotes active involvement of all Arctic nations in these efforts in order to advance scientific understanding that could provide the basis for assessing future impacts and proposed response strategies.

4. United States platforms capable of supporting forefront research in the Arctic Ocean, including portions expected to be ice-covered for the foreseeable future, as well as seasonally ice-free regions, should work with those of other nations through the establishment of an Arctic circumpolar observing network. All Arctic nations are members of the Group on Earth Observations partnership, which provides a framework for organizing an international approach to environmental observations in the region. In addition, the United States recognizes that academic and research institutions are vital partners in promoting and conducting Arctic research.

5. Implementation: In carrying out this policy as it relates to promoting scientific international cooperation, the Secretaries of State, the Interior, and Commerce and the Director of the National Science Foundation, in coordination with heads of other relevant executive departments and agencies, shall:

a. Continue to play a leadership role in research throughout the Arctic region;

b. Actively promote full and appropriate access by scientists to Arctic research sites through bilateral and multilateral measures and by other means;

c. Lead the effort to establish an effective Arctic circumpolar observing network with broad partnership from other relevant nations;

d. Promote regular meetings of Arctic science ministers or research council heads to share information concerning scientific research opportunities and to improve coordination of international Arctic research programs;

e. Work with the Interagency Arctic Research Policy Committee (IARPC) to promote research that is strategically linked to U.S. policies articulated in this directive, with input from the Arctic Research Commission; and

f. Strengthen partnerships with academic and research institutions and build upon the relationships these institutions have with their counterparts in other nations.

F. **Maritime Transportation in the Arctic Region**

1. The United States priorities for maritime transportation in the Arctic region are:

   a. To facilitate safe, secure, and reliable navigation;

   b. To protect maritime commerce; and

   c. To protect the environment.

2. Safe, secure, and environmentally sound maritime commerce in the Arctic region depends on infrastructure to support shipping activity, search and rescue capabilities, short- and long-range aids to navigation, high-risk area vessel-traffic management, iceberg warnings and other sea ice information, effective shipping standards, and measures to protect the marine environment. In addition, effective search and rescue in the Arctic will require local, State, Federal, tribal, commercial, volunteer, scientific, and multinational cooperation.

3. Working through the International Maritime Organization (IMO), the United States promotes strengthening existing measures and, as necessary, developing new measures to improve the safety and security of maritime transportation, as well as to protect the marine environment in the Arctic region. These measures may include ship routing and reporting systems, such as traffic separation and vessel traffic management schemes in Arctic chokepoints; updating and strengthening of the Guidelines for Ships Operating in Arctic Ice-Covered Waters; underwater noise standards for commercial shipping; a review of shipping insurance issues; oil and other hazardous material pollution response agreements; and environmental standards.

4. Implementation: In carrying out this policy as it relates to maritime transportation in the Arctic region, the Secretaries of State, Defense, Transportation, Commerce, and Homeland Security, in coordination with heads of other relevant executive departments and agencies, shall:

   a. Develop additional measures, in cooperation with other nations, to address issues that are likely to arise from expected increases in shipping into, out of, and through the Arctic region;

   b. Commensurate with the level of human activity in the region, establish a risk-based capability to address hazards in the Arctic environment. Such efforts shall advance work on pollution prevention and response standards; determine basing and logistics support requirements, including necessary airlift and icebreaking capabilities; and improve plans and cooperative agreements for search and rescue;

   c. Develop Arctic waterways management regimes in accordance with accepted international standards, including vessel traffic-monitoring and routing; safe navigation standards; accurate and standardized charts; and accurate and timely environmental and navigational information; and

   d. Evaluate the feasibility of using access through the Arctic for strategic sealift and humanitarian aid and disaster relief.

G. **Economic Issues, Including Energy**

1. Sustainable development in the Arctic region poses particular challenges. Stakeholder input will inform key decisions as the United States seeks to promote economic and energy security. Climate change and other factors are significantly affecting the lives of Arctic inhabitants, particularly indigenous communities. The United States affirms the importance to Arctic communities of adapting to climate change, given their particular vulnerabilities.

2. Energy development in the Arctic region will play an important role in meeting growing global energy demand as the area is thought to contain a substantial portion of the world's undiscovered energy resources. The United States seeks to ensure that energy development throughout the Arctic occurs in an environmentally sound manner, taking into account the interests of indigenous and local communities, as well as open and transparent market principles. The United States seeks to balance access to, and development of, energy and other natural resources with the protection of the Arctic environment by ensuring that continental shelf resources are managed in a responsible manner and by continuing to work closely with other Arctic nations.

3. The United States recognizes the value and effectiveness of existing fora, such as the Arctic Council, the International Regulators Forum, and the International Standards Organization.

4. Implementation: In carrying out this policy as it relates to economic issues, including energy, the Secretaries of State, the Interior, Commerce, and Energy, in coordination with heads of other relevant executive departments and agencies, shall:

   a. Seek to increase efforts, including those in the Arctic Council, to study changing climate conditions, with a view to preserving and enhancing economic opportunity in the Arctic region. Such efforts shall include inventories and assessments of villages, indigenous communities, subsistence opportunities, public facilities, infrastructure, oil and gas development projects, alternative energy development opportunities, forestry, cultural and other sites, living marine resources, and other elements of the Arctic's socioeconomic composition;

   b. Work with other Arctic nations to ensure that hydrocarbon and other development in the Arctic region is carried out in accordance with accepted best practices and internationally recognized standards and the 2006 Group of Eight (G-8) Global Energy Security Principles;

   c. Consult with other Arctic nations to discuss issues related to exploration, production, environmental and socioeconomic impacts, including drilling conduct, facility sharing, the sharing of environmental data, impact assessments, compatible monitoring programs, and reservoir management in areas with potentially shared resources;

   d. Protect United States interests with respect to hydrocarbon reservoirs that may overlap boundaries to mitigate adverse environmental and economic consequences related to their development;

   e. Identify opportunities for international cooperation on methane hydrate issues, North Slope hydrology, and other matters;

   f. Explore whether there is a need for additional fora for informing decisions on hydrocarbon leasing, exploration, development, production, and transportation, as well as shared support activities, including infrastructure projects; and

   g. Continue to emphasize cooperative mechanisms with nations operating in the region to address shared concerns, recognizing that most known Arctic oil and gas resources are located outside of United States jurisdiction.

H. **Environmental Protection and Conservation of Natural Resources**

1. The Arctic environment is unique and changing. Increased human activity is expected to bring additional stressors to the Arctic environment, with potentially serious consequences for Arctic communities and ecosystems.

2. Despite a growing body of research, the Arctic environment remains poorly understood. Sea ice and glaciers are in retreat. Permafrost is thawing and coasts are eroding. Pollutants from within and outside the Arctic are contaminating the region. Basic data are lacking in many fields. High levels of uncertainty remain concerning the effects of climate change and increased human activity in the Arctic. Given the need for decisions to be based on sound scientific and socioeconomic information, Arctic environmental

research, monitoring, and vulnerability assessments are top priorities. For example, an understanding of the probable consequences of global climate variability and change on Arctic ecosystems is essential to guide the effective long-term management of Arctic natural resources and to address socioeconomic impacts of changing patterns in the use of natural resources.

3. Taking into account the limitations in existing data, United States efforts to protect the Arctic environment and to conserve its natural resources must be risk-based and proceed on the basis of the best available information.

4. The United States supports the application in the Arctic region of the general principles of international fisheries management outlined in the 1995 Agreement for the Implementation of the Provisions of the United Nations Convention on the Law of the Sea of December 10, 1982, relating to the Conservation and Management of Straddling Fish Stocks and Highly Migratory Fish Stocks and similar instruments. The United States endorses the protection of vulnerable marine ecosystems in the Arctic from destructive fishing practices and seeks to ensure an adequate enforcement presence to safeguard Arctic living marine resources.

5. With temperature increases in the Arctic region, contaminants currently locked in the ice and soils will be released into the air, water, and land. This trend, along with increased human activity within and below the Arctic, will result in increased introduction of contaminants into the Arctic, including both persistent pollutants (e.g., persistent organic pollutants and mercury) and airborne pollutants (e.g., soot).

6. Implementation: In carrying out this policy as it relates to environmental protection and conservation of natural resources, the Secretaries of State, the Interior, Commerce, and Homeland Security and the Administrator of the Environmental Protection Agency, in coordination with heads of other relevant executive departments and agencies, shall:

   a. In cooperation with other nations, respond effectively to increased pollutants and other environmental challenges;

   b. Continue to identify ways to conserve, protect, and sustainably manage Arctic species and ensure adequate enforcement presence to safeguard living marine resources, taking account of the changing ranges or distribution of some species in the Arctic. For species whose range includes areas both within and beyond United States jurisdiction, the United States shall continue to collaborate with other governments to ensure effective conservation and management;

   c. Seek to develop ways to address changing and expanding commercial fisheries in the Arctic, including through consideration of international agreements or organizations to govern future Arctic fisheries;

   d. Pursue marine ecosystem-based management in the Arctic; and

   e. Intensify efforts to develop scientific information on the adverse effects of pollutants on human health and the environment and work with other nations to reduce the introduction of key pollutants into the Arctic.

IV. Resources and Assets

A. Implementing a number of the policy elements directed above will require appropriate resources and assets. These elements shall be implemented consistent with applicable law and authorities of agencies, or heads of agencies, vested by law, and subject to the availability of appropriations. The heads of executive departments and agencies with responsibilities relating to the Arctic region shall work to identify future budget, administrative, personnel, or legislative proposal requirements to implement the elements of this directive.

GEORGE W. BUSH

Information on the Interagency Ocean Policy Task Force

White House Interagency Ocean Policy Task Force

On June 12, 2009, President Obama sent a memorandum to the heads of executive departments and federal agencies establishing an Interagency Ocean Policy Task Force, led by the White House Council on Environmental Quality. The Task Force is charged with developing a recommendation for a national policy that ensures protection, maintenance, and restoration of oceans, our coasts and the Great Lakes. It will also recommend a framework for improved stewardship, and effective coastal and marine spatial planning.

The oceans, our coasts, and the Great Lakes provide jobs, food, energy resources, ecological services, recreation, and tourism opportunities, and play critical roles in our Nation's transportation, economy, and trade, as well as the global mobility of our Armed Forces and the maintenance of international peace and security," President Obama wrote in the memorandum. "We have a stewardship responsibility to maintain healthy, resilient, and sustainable oceans, coasts and Great Lakes resources for the benefit of this and future generations."

"The challenges our oceans, coasts, and Great Lakes are facing are complex, and to meet these challenges we must have the participation of a wide spectrum of views from within the federal government," said Nancy Sutley, Chair of the White House Council on Environmental Quality. "The Task Force has a wealth of opportunity to make our oceans, coasts and Great Lakes healthier - both environmentally and economically."

The recommendations and frameworks developed by the Task Force will be cost effective and improve coordination across federal agencies. The Chair will terminate the Task Force upon the completion of its duties.

The time period to submit comments to the Task Force has closed, but you can read comments from others. The Task Force's Interim Framework is open for comment through Friday, February 12, 2010.

Read the President's Proclamation on National Oceans Month

Summary of Executive Order - Stewardship of the Ocean, Our Coasts, and the Great Lakes - and the Final Recommendations of the Interagency Ocean Policy Task Force

Distributed by Representative Joule - August 4, 2010

On July 19, 2010, President Obama signed an Executive Order establishing the first ever National Policy for the Stewardship of the Ocean, Our Coasts, and the Great Lakes ("National Policy"). The Order adopts the Final Recommendations of the Interagency Ocean Policy Task Force ("OPTF") and directs federal agencies to implement them. The Final Recommendations of the Task Force include:

1. Strengthening ocean governance and coordination, and establishing principles for ocean management.

2. Creation of a National Ocean Council to coordinate federal agencies to implement the National Policy and to strengthen ocean governance. It will hold its first meeting in late summer 2010. Co-chairs are chair of the Council on Environmental Quality and Director of the Office of Science and Technology Policy. Members are nine Secretaries; Attorney General; Administrators of EPA, OMB, NOAA, and NASA; Directors of National Intelligence and NSF; Chairman of the Joint Chiefs of Staff; National Security Advisor; Assistants to the President for Homeland Security, Domestic Policy, Energy and Climate Change, and Economic Policy; and a federal employee designated by the Vice President.

3. An implementation strategy with nine priority objectives for U.S. action. Within them, there are five Areas of Special Emphasis for implementing the National Policy, including "Changing Conditions in the Arctic: Address environmental stewardship needs in the Arctic Ocean and adjacent coastal areas in the face of climate-induced and other environmental changes. The National Ocean Council is responsible for developing and overseeing a strategic action plan for each priority within 6-12 months of its establishment.

4. An ecosystem-based framework for coastal and marine special planning ("CMSP") to address conservation, economic activity, user conflict and sustainable use. CMSP is "a comprehensive, adaptive, integrated, ecosystem-based, and transparent spacial planning process, based on sound science, for analyzing current and anticipated uses of ocean, coastal, and Great Lakes areas." Nine regional planning bodies consisting of federal, state, tribal and other representatives will develop the CMSPs. Alaska is a region unto itself. The National Oceans Council will commence the CMSP process immediately.

5. Establishment of a Governance Coordinating Committee to formally engage with states, tribes and local governments. It will consist of 18 members, including one designated seat for an Alaskan representative chosen in consultation with the Governor. There may be other opportunities for Alaska representation, as there is a seat for one member of a state legislature, three tribal representatives, and three local government representatives.

The Interagency Ocean Policy Task Force, formed in June 2009 at the President's request, included 24 senior policy officials from across the federal government and was led by the White House Council on Environmental Quality. The OPTF found that the complexity of the oceans governance structure, which included hundreds of domestic policies, laws & regulations, was leaving gaps in governance. Thus, it recommended the National Policy.

The National Policy does not establish new regulations or restrict any uses. It does not require new legislation in order to be implemented. The Policy is intended to provide a stronger framework from applying existing laws and agency authorities, but does not supersede them or alter their authorities.

To come to its recommendations, the OPTF reviewed federal, state and foreign policies, past and pending legislation, recommendations in two earlier Ocean Commission reports, and public comments through a robust public process (38 expert roundtables, 6 regional public meetings - in Anchorage on August 21, 2009 - and a website to accept public comments). It received over 5,000 public comments. The key themes the Task Force incorporated in the Final Recommendations are: the importance of science-based decision making, improved transparency and public participation, avoiding new layers and bureaucracy and unnecessary costs, and funding to implement the policy adequately.

The President has requested funding for the 2011 fiscal year: $12 million for CMSP and geospatial modernization, $20 million for regional ocean partnership grants, and $5 million for integrated ecosystem assessments. His budget requests also include investments across agencies to implement the National Policy.

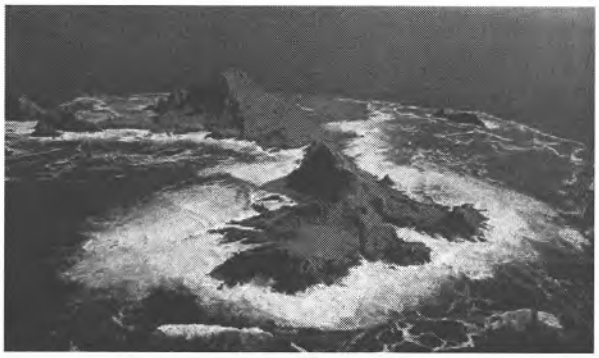
EXECUTIVE SUMMARY

I. Introduction



In order to better meet our Nation's stewardship responsibilities for the ocean, our coasts, and the Great Lakes, President Obama established the Interagency Ocean Policy Task Force (Task Force) on June 12, 2009. The Task Force is composed of 24 senior-level officials from executive departments, agencies, and offices across the Federal government and led by the Chair of the Council on Environmental Quality (CEQ). The President charged the Task Force with developing recommendations to enhance our ability to maintain healthy, resilient, and sustainable ocean, coasts, and Great Lakes resources for the benefit of present and future generations.

The Deepwater Horizon-BP oil spill in the Gulf of Mexico and resulting environmental crisis is a stark reminder of how vulnerable our marine environments are, and how much communities and our Nation rely on healthy and resilient ocean and coastal ecosystems. The ocean, our coasts, and the Great Lakes deeply impact the lives of all Americans, whether we live and work in the country's heartland or along its shores. America's rich and productive coastal regions and waters support tens of millions of jobs and contribute trillions of dollars to the national economy each year. They also host a growing number of important activities, including recreation, science, commerce, transportation, energy development, and national security and they provide a wealth of natural resources and ecological benefits.

Nearly half of the country's population lives in coastal counties, and millions of visitors enjoy our Nation's seashores each year. The ocean, our coasts, and the Great Lakes are vital places for recreation, including boating, fishing, swimming, nature watching, and diving. These activities not only help fuel our economy, but also are critical to the social and cultural fabric of our country. In addition, coastal ecosystems provide essential ecological services. Barrier islands, coral reefs, mangroves, and coastal wetlands help to protect our coastal communities from damaging floods and storms. Coastal wetlands shelter recreational and commercial fish species, provide critical habitat for migratory birds and mammals, and serve as a natural filter to help keep our waters clean.

Despite the critical importance of these areas to our health and well-being, the ocean, coasts and Great Lakes face a wide range of threats from human activities. Overfishing, pollution, coastal development and the impacts of climate change are altering ecosystems, reducing biological diversity, and

placing more stress on wildlife and natural resources, as well as on people and coastal communities. Compounding these threats, human uses of the ocean, coasts, and Great Lakes are expanding at a rate that challenges our ability to plan and manage significant and often competing demands. Demands for energy development, shipping, aquaculture, emerging security requirements and other new and existing uses are expected to grow. Overlapping uses and differing views about which activities should occur where can generate conflicts and misunderstandings. As we work to accommodate these multiple uses, we must also ensure continued public access for recreation and other pursuits, and sustain and preserve the abundant marine resources and healthy ecosystems that are critical to the well-being and prosperity of our Nation.

The challenges we face in the stewardship of the ocean, our coasts, and the Great Lakes lie not only within the ecosystems themselves, but also in the laws, authorities, and governance structures intended to manage our use and conservation of them. United States governance and management of these areas span hundreds of domestic policies, laws, and regulations covering international, Federal, State, tribal, and local interests. Challenges and gaps arise from the complexity and structure of this regime.

The time has come for a comprehensive national policy for the stewardship of the ocean, our coasts, and the Great Lakes. Today, as never before, we better comprehend the links among land, air, fresh water, ocean, ice, and human activities. Advances in science and technology provide better and timelier information to guide decision-making. By applying the principles of ecosystem-based management (which integrates ecological, social, economic, commerce, health, and security goals, and which recognizes both that humans are key components of ecosystems and also that healthy ecosystems are essential to human welfare) and of adaptive management (which calls for routine reassessment of management actions to allow for better informed and improved future decisions) in a coordinated and collaborative approach, the Nation will more effectively address the challenges facing the ocean, our coasts, and the Great Lakes and ensure their continued health for this and future generations.

II. Summary of the Final Recommendations of the Task Force

To develop its recommendations, the Task Force reviewed Federal, State, and foreign policies and models, past and pending legislation, the recommendations contained in the two earlier Ocean Commissions' reports, and public comments.

The Task Force also initiated a robust public engagement process to receive input from a diversity of voices across the country. On behalf of the Task Force, CEQ hosted 38 expert roundtables to hear from a broad range of stakeholder groups. The Task Force also hosted six regional public meetings, and created a website to accept public comments through CEQ. The Task Force received more than 5,000 public comments, with many of the groups commenting representing constituencies of hundreds or thousands of members.

The Task Force recommendations set a new direction for improved stewardship of the ocean, our coasts, and the Great Lakes. They provide: (1) our Nation's first ever *National Policy for the Stewardship of the*

Ocean, Our Coasts, and the Great Lakes (National Policy); (2) a strengthened governance structure to provide sustained, high-level, and coordinated attention to ocean, coastal, and Great Lakes issues; (3) a targeted implementation strategy that identifies and prioritizes nine categories for action that the United States should pursue; and (4) a framework for effective coastal and marine spatial planning (CMSP) that establishes a comprehensive, integrated, ecosystem-based approach to address conservation, economic activity, user conflict, and sustainable use of ocean, coastal, and Great Lakes resources.

National Policy for the Stewardship of the Ocean, Our Coasts, and the Great Lakes

It is the Policy of the United States to:

- Protect, maintain, and restore the health and biological diversity of ocean, coastal, and Great Lakes ecosystems and resources;
- Improve the resiliency of ocean, coastal, and Great Lakes ecosystems, communities, and economies;
- Bolster the conservation and sustainable uses of land in ways that will improve the health of ocean, coastal, and Great Lakes ecosystems;
- Use the best available science and knowledge to inform decisions affecting the ocean, our coasts, and the Great Lakes, and enhance humanity's capacity to understand, respond, and adapt to a changing global environment;
- Support sustainable, safe, secure, and productive access to, and uses of the ocean, our coasts, and the Great Lakes;
- Respect and preserve our Nation's maritime heritage, including our social, cultural, recreational, and historical values;
- Exercise rights and jurisdiction and perform duties in accordance with applicable international law, including respect for and preservation of navigational rights and freedoms, which are essential for the global economy and international peace and security;
- Increase scientific understanding of ocean, coastal, and Great Lakes ecosystems as part of the global interconnected systems of air, land, ice, and water, including their relationships to humans and their activities;
- Improve our understanding and awareness of changing environmental conditions, trends, and their causes, and of human activities taking place in ocean, coastal, and Great Lakes waters; and
- Foster a public understanding of the value of the ocean, our coasts, and the Great Lakes to build a foundation for improved stewardship.

The recommended National Policy establishes a comprehensive national approach to uphold our stewardship responsibilities; ensures accountability for our actions; and serves as a model of balanced,

productive, efficient, sustainable, and informed ocean, coastal, and Great Lakes use, management, and conservation within the global community. The National Policy recognizes that America's stewardship of the ocean, our coasts, and the Great Lakes is intrinsically and intimately linked to environmental sustainability, human health and well-being, national prosperity, adaptation to climate and other environmental change, social justice, foreign policy, and national and homeland security. It sets forth overarching guiding principles for United States management decisions and actions affecting the ocean, our coasts, and the Great Lakes.

Policy Coordination Framework to Improve the Stewardship of the Ocean, Our Coasts, and the Great Lakes

No single agency can successfully resolve the complex and pressing problems facing the ocean, our coasts, and the Great Lakes. Successful stewardship will require an effective governance structure with sustained leadership and broad interagency coordination to effectively manage the many uses of these resources. A coordinated Federal effort, proactively guided by a senior-level interagency body, will ensure that the hundreds of domestic policies, laws, and regulations governing the management of the ocean, our coasts, and the Great Lakes are implemented in a meaningful way.

The Task Force recommends a combination of modifications to the structure of the existing Committee on Ocean Policy[1], a stronger mandate and direction, and renewed and sustained high-level engagement. Subject to later refinements, the Task Force recommends:

1. Establishing a new National Ocean Council (NOC) which consolidates and strengthens the Principal- and Deputy-level components of the existing Committee on Ocean Policy within a single structure;

2. Strengthening the decision-making and dispute-resolution processes by defining clear roles for the NOC and the NOC leadership;

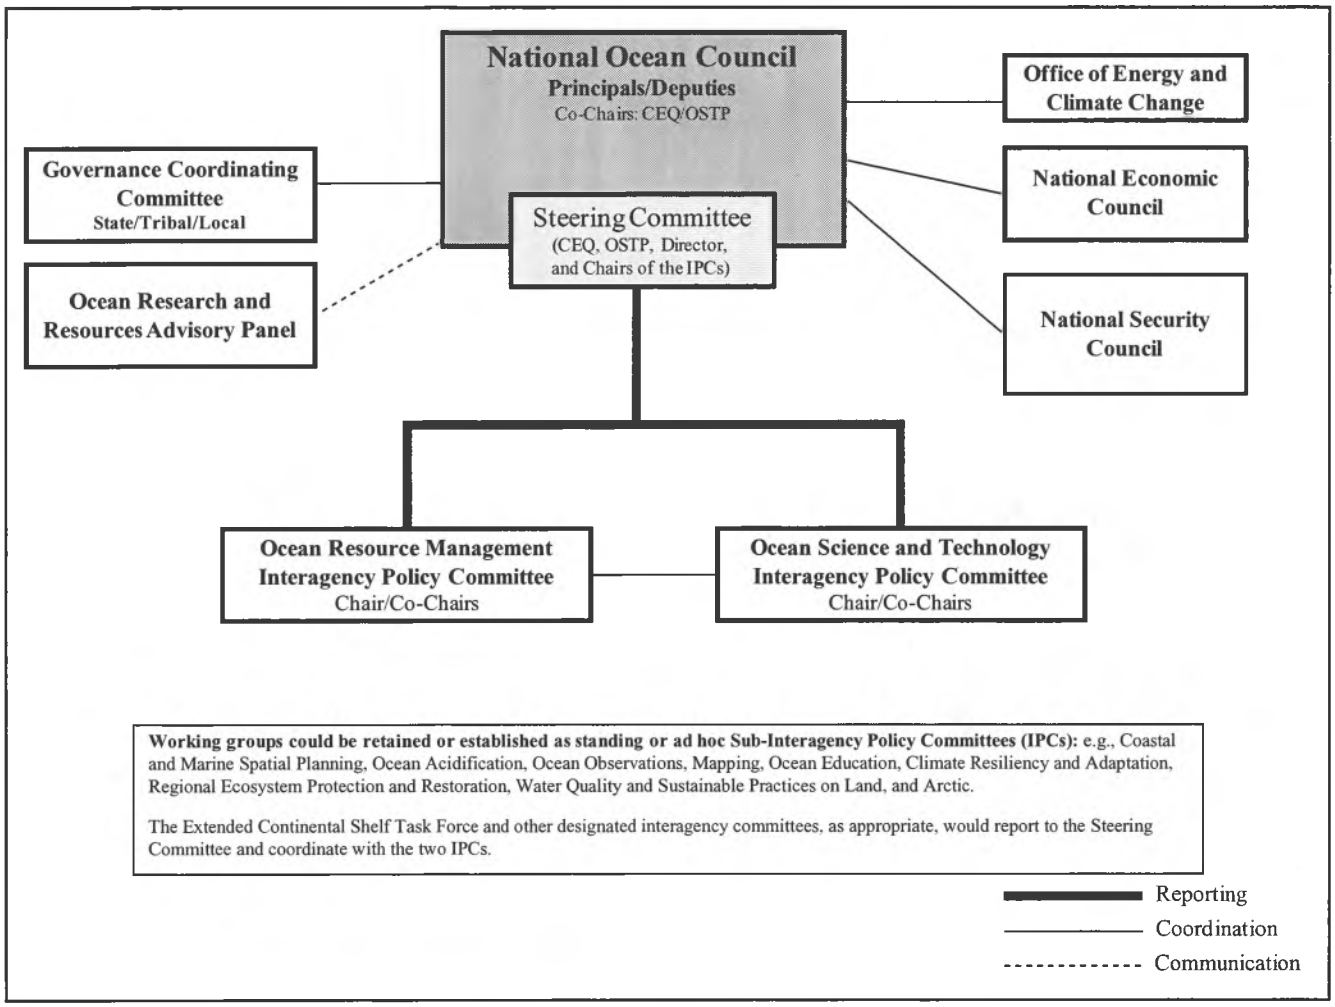
3. Formally engaging with State, tribal, and local authorities to address relevant issues through the creation of a new committee comprised of their designated representatives;

4. Strengthening the link between science and management through a new NOC Steering Committee; and

5. Strengthening coordination between the NOC, the National Security Council, the National Economic Council, the Office of Energy and Climate Change, the Council on Environmental Quality, the Office of Science and Technology Policy, the Office of Management and Budget, and other White House entities.

[1] The Committee on Ocean Policy was established by Executive Order 13366 in 2004 and has only been moderately effective in establishing forums for bringing Federal agencies together to coordinate on ocean-related matters.

Policy Coordination Framework



These recommendations establish high-level direction and policy guidance from a clearly designated and identifiable authority. They also call for more consistent and sustained senior-level participation and attention on ocean-related issues from all member agencies and departments essential to effective management. The Task Force is confident that this combination of improvements provides a framework for more successful policy coordination to improve the stewardship of the ocean, our coasts, and the Great Lakes.

Implementation Strategy

The Task Force recommends an implementation strategy that identifies nine priority objectives (i.e., categories for action) that our Nation should pursue. These priority objectives provide a bridge between policy and specific actions, but do not prescribe in detail how individual entities will undertake their responsibilities, leaving those details to be determined through the development of strategic action plans. The Task Force recommends the following nine priority objectives:

National Priority Objectives

1. **Ecosystem-Based Management:** Adopt ecosystem-based management as a foundational principle for the comprehensive management of the ocean, our coasts, and the Great Lakes.
2. **Coastal and Marine Spatial Planning:** Implement comprehensive, integrated, ecosystem-based coastal and marine spatial planning and management in the United States.
3. **Inform Decisions and Improve Understanding:** Increase knowledge to continually inform and improve management and policy decisions and the capacity to respond to change and challenges. Better educate the public through formal and informal programs about the ocean, our coasts, and the Great Lakes.
4. **Coordinate and Support:** Better coordinate and support Federal, State, tribal, local, and regional management of the ocean, our coasts, and the Great Lakes. Improve coordination and integration across the Federal Government, and as appropriate, engage with the international community.
5. **Resiliency and Adaptation to Climate Change and Ocean Acidification:** Strengthen resiliency of coastal communities and marine and Great Lakes environments and their abilities to adapt to climate change impacts and ocean acidification.
6. **Regional Ecosystem Protection and Restoration:** Establish and implement an integrated ecosystem protection and restoration strategy that is science-based and aligns conservation and restoration goals at the Federal, State, tribal, local, and regional levels.
7. **Water Quality and Sustainable Practices on Land:** Enhance water quality in the ocean, along our coasts, and in the Great Lakes by promoting and implementing sustainable practices on land.
8. **Changing Conditions in the Arctic:** Address environmental stewardship needs in the Arctic Ocean and adjacent coastal areas in the face of climate-induced and other environmental changes.
9. **Ocean, Coastal, and Great Lakes Observations, Mapping, and Infrastructure:** Strengthen and integrate Federal and non-Federal ocean observing systems, sensors, data collection platforms, data management, and mapping capabilities into a national system, and integrate that system into international observation efforts.

The NOC would develop strategic action plans for each of the priority objectives, focusing on key areas identified by the Task Force. Each strategic action plan would identify specific and measurable near-term, mid-term, and long-term actions, with appropriate milestones, performance measures, and outcomes to meet each objective. In addition, each plan would explicitly identify key lead and participating agencies; gaps and needs in science and technology; potential resource requirements and efficiencies; and steps for integrating or coordinating current and out-year budgets. This strategy would allow adequate time to fully consider the necessary details for implementation, and, as appropriate, to coordinate and collaborate with States, tribal, and local authorities, regional governance structures, academic institutions, non-governmental organizations, recreational users, and private enterprise.

Framework for Effective Coastal and Marine Spatial Planning

As called for in President Obama's June 12, 2009 memorandum, the Task Force recommendations provide a framework for CMSP that offers a new, comprehensive, integrated, regionally-based approach to planning and managing uses and activities. The recommended framework places sound science and the best available information at the heart of decision-making and would bring Federal, State, and tribal partners together in an unprecedented manner to cooperatively develop coastal and marine spatial plans (CMS Plans). This process is designed to decrease user conflict, improve planning and regulatory efficiencies, decrease associated costs and delays, engage affected communities and stakeholders, and preserve critical ecosystem functions and services. The recommendations emphasize

The National Goals of Coastal and Marine Spatial Planning

1. Support sustainable, safe, secure, efficient, and productive uses of the ocean, our coasts, and the Great Lakes, including those that contribute to the economy, commerce, recreation, conservation, homeland and national security, human health, safety, and welfare;
2. Protect, maintain, and restore the Nation's ocean, coastal, and Great Lakes resources and ensure resilient ecosystems and their ability to provide sustained delivery of ecosystem services;
3. Provide for and maintain public access to the ocean, coasts, and Great Lakes;
4. Promote compatibility among uses and reduce user conflicts and environmental impacts;
5. Improve the rigor, coherence, and consistency of decision-making and regulatory processes;
6. Increase certainty and predictability in planning for and implementing new investments for ocean, coastal, and Great Lakes uses; and
7. Enhance interagency, intergovernmental, and international communication and collaboration.

the importance of frequent and robust stakeholder, scientific, and public engagement throughout the planning process.

The recommended framework includes a unified definition of CMSP, identifies the reasons for engaging in the process, and describes the proposed geographic scope of the planning areas. The framework articulates national goals and guiding principles that would be followed in CMSP efforts and the development and implementation of CMS Plans. Under this framework, the United States will be subdivided into nine regional planning areas: Northeast, Mid-Atlantic, South Atlantic, Great Lakes, Caribbean, Gulf of Mexico, West Coast, Pacific Islands, and Alaska/Arctic regions. Each region will have a corresponding regional planning body consisting of Federal, State, and tribal representatives to develop regional goals, objectives, and ultimately regional CMS plans. To provide for national consistency and support, the framework establishes and describes planning steps and elements, a process by which the NOC would guide and certify the development of regional CMS Plans, a method to address CMS Plan adherence and compliance, a robust information management system to allow easy access to and transparency of data and information necessary for planning, and mechanisms for frequent stakeholder and public input. In addition, the framework describes an implementation approach that maximizes flexibility among the regions, addresses regional capacity, and aims to have CMS Plans for all regions by 2015.

III. Support for Joining the Law of the Sea Convention

The Task Force strongly and unanimously supports United States accession to the Convention on the Law of the Sea and ratification of its 1994 Implementing Agreement. The Law of the Sea Convention is the bedrock legal instrument governing activities on, over, and under the world's oceans. United States accession to the Convention will further our national security, environmental, economic, and diplomatic interests.

Key reasons for accession include:

- The Convention has garnered the unequivocal support of our national security leadership under both Republican and Democratic administrations, because, among other things, it codifies essential navigational rights and freedoms upon which our Armed Forces rely.
- The Convention sets forth the rights and responsibilities of nations to prevent, reduce, and control pollution of the marine environment and to protect and preserve resources off their shores.
- By becoming a party to the Convention, U.S. legal rights to our extended continental shelf can be put on the strongest legal foundation.
- As a party to the Law of the Sea Convention, the United States would have the ability to participate formally and more effectively in the interpretation and development of the Convention.

- Joining the Law of the Sea Convention would reaffirm and enhance United States leadership in global ocean affairs.

IV. Conclusion

In response to President Obama's June 12, 2009 memorandum, and after careful consideration of thousands of valuable comments from political leaders, public and private organizations, and citizens, the Task Force is pleased to submit these final recommendations. Once implemented, these final recommendations will provide the first-ever comprehensive national policy of the United States to improve stewardship of the ocean, our coasts, and the Great Lakes.

The Task Force is unanimous in its call for the Nation to set a new course for improved stewardship of the ocean, our coasts, and the Great Lakes. This must include a comprehensive, integrated, transparent, science-based, and ecosystem-based planning process to achieve the sustainable use of the ocean, our coasts, and the Great Lakes. The Task Force is mindful that these recommendations may create a level of uncertainty and anxiety among those who rely on these resources and may generate questions about how they align with existing processes, authorities, and budget challenges. The NOC will address questions and specifics as implementation progresses. Meaningful and frequent opportunities for stakeholder and public engagement throughout the implementation of the National Policy and implementation of coastal and marine spatial planning will be an essential component of cooperatively addressing these uncertainties head-on, and the Task Force recommendations embrace this approach. The Task Force is confident that the investments and improvements described in these final recommendations will advance the economic interests of the United States through sustainable and productive ocean uses; significantly improve our capacity to address the long-term challenges and impacts of climate and environmental changes; and provide a lasting foundation for improving the stewardship of and further enhancing the many vital benefits our Nation can derive from these resources.

With a clear National Policy and a revitalized, empowered, unified, and comprehensive framework to coordinate efforts set forth in these recommendations, we can achieve an America whose stewardship ensures that the ocean, our coasts, and the Great Lakes are healthy and resilient, safe and productive, and understood and treasured so as to promote the well-being, prosperity, and security of present and future generations.

RECOMMENDATIONS

PART ONE. NATIONAL POLICY FOR THE STEWARDSHIP OF THE OCEAN, OUR COASTS, AND THE GREAT LAKES

I. Vision

An America whose stewardship ensures that the ocean, our coasts, and the Great Lakes are healthy and resilient, safe and productive, and understood and treasured so as to promote the well-being, prosperity, and security of present and future generations.

II. National Policy Context

The Value of the Ocean, Our Coasts, and the Great Lakes

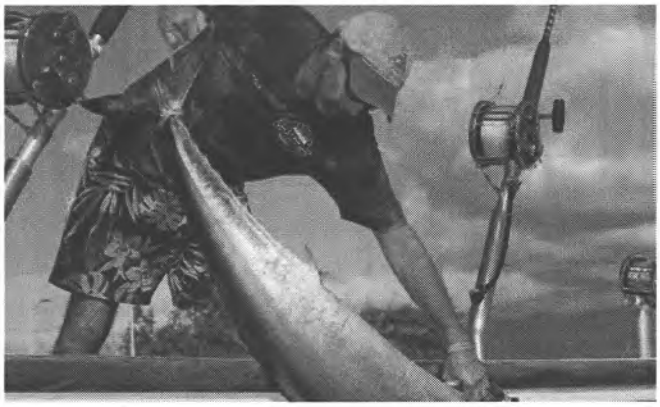
America is intricately connected to and directly reliant on the ocean, our coasts, and the Great Lakes. Each of us – whether living and working in the country's heartland or along its coasts – affects and is affected by these places. Their beauty inspires us, and their bounty contributes to our national well-being and security. Nearly half of our population is located in coastal counties. Our rich and productive coastal regions and waters account for the great majority of the national economy, totaling trillions of dollars each year, and support distant communities that may not even be aware of the connection between the land and sea. Millions of visitors enjoy our Nation's seashores each year, contributing not only to the economy, but also to personal and communal satisfaction and fulfillment. The sea is both a refuge for spiritual reflection and a powerhouse of excitement for educating students of all ages and interests.

With over 95,000 miles of coastline and the largest Exclusive Economic Zone (EEZ) in the world, our Nation benefits from a wealth of goods and services derived from the ocean, our coasts, and the Great Lakes. They provide food, fresh water, minerals, energy, and other natural resources and ecological benefits. They support tens of millions of jobs and

play a critical role in our Nation's transportation, economy, and trade, as well as in the global mobility and readiness of our Armed Forces and the maintenance of international peace and security. They are also vital places for recreation, including boating, fishing, swimming, nature watching, and diving, which are critical to the economic, social, and cultural fabric of our country.

The ocean supports human health and well-being in myriad ways, including as a source of healthy foods, pharmaceuticals, and other beneficial compounds. The ocean is a source of existing energy and offers numerous opportunities for renewable energy, which can help to secure our energy independence and mitigate climate change.

The ocean and Great Lakes exert significant influence over how our planet functions. Covering over 70 percent of the Earth, the ocean plays a primary role in our planet's environment and natural operations, including weather and climate. The ocean's ability to absorb and store heat from the atmosphere and transport it to other parts of the globe keeps daily temperatures within a livable range. The Great Lakes are the largest freshwater system on Earth, with 10,000 miles of shoreline and some 95 percent of the Nation's fresh surface water. While we commonly refer to different oceans (Atlantic, Pacific, Arctic, etc.), it is important to recognize that all of these bodies of water are connected and influenced by each other. These linkages require our Nation to recognize that we benefit from and affect one global ocean.



The ocean shapes and sustains all life on Earth. We are dependent on the ocean for the air we breathe, the food we eat, and the water we drink. Though we may not think about it, processes on land and in the water, including biological processes, are intricately linked so that changes in one can have profound effects on the other. The ocean is both the beginning and the end of the Earth's water cycle. Water that evaporates from the surface of the ocean becomes rain that falls on our fields and fills our aquifers. Much of this precipitation eventually finds rivers which flow back to the sea, starting the cycle once more. Half of the oxygen we breathe comes from microscopic plants living in the ocean. Coastal barrier islands, coral reefs, mangroves, and wetlands serve as buffers between coastal communities and damaging floods and storms. Coastal wetlands are a nursery for many recreational and commercial fish species, provide essential habitat for many migratory birds and mammals, and serve as a natural filter helping to keep our waters clean. Ocean and coastal ecosystems absorb and detoxify many pollutants,

recycle nutrients, and help control pests and pathogens. Marine ecosystems house biological diversity exceeding that found in the world's rain forests.

Challenges Facing the Ocean, Our Coasts, and the Great Lakes

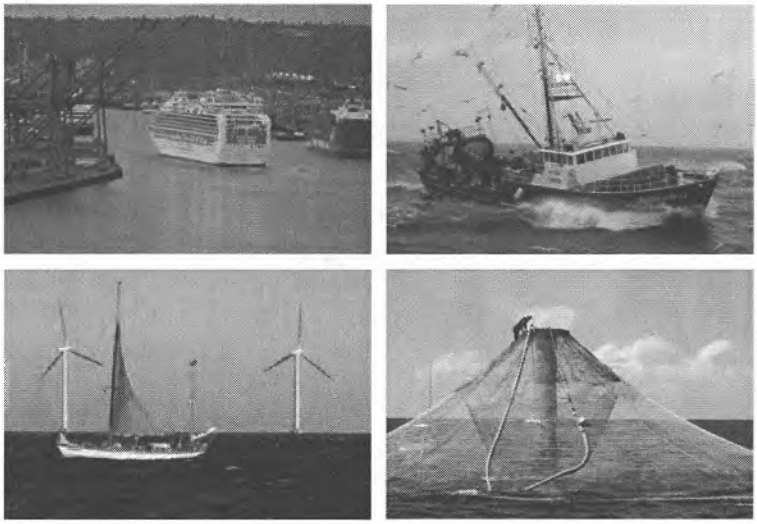
The importance of ocean, coastal, and Great Lakes ecosystems cannot be overstated; simply put, we need them to survive. It is clear that these invaluable and life-sustaining assets are vulnerable to human activities and, at the same time, human communities are rendered more vulnerable when these resources are degraded. Yet ocean, coastal, and Great Lakes ecosystems are experiencing an unprecedented rate of change due to human activities. We are only now beginning to understand the full extent of the direct and indirect consequences of our actions on these systems.

Climate change is impacting the ocean, our coasts, and the Great Lakes. Increasing water temperatures are altering habitats, migratory patterns, and ecosystem structure and function. Coastal communities are facing sea-level rise, inundation, increased threats from storms, erosion, and significant loss of coastal wetlands. The ocean's ability to absorb carbon dioxide from the atmosphere buffers the impacts of climate change, but also causes the ocean to become more acidic, threatening not only the survival of individual species of marine life, but also entire marine ecosystems. The ocean buffers increased global temperatures by absorbing heat, but increasing temperatures are causing sea levels to rise by expanding seawater volume and melting land-based ice. Increased temperatures may eventually reduce the ocean's ability to absorb carbon dioxide. Conversely, climate change is predicted to lower the water levels of the Great Lakes, thereby altering water cycles, habitats, and economic uses of the lakes.

Along many areas of our coasts and within the Great Lakes, biological diversity is in decline due to overfishing, introduction of invasive species, and loss and degradation of essential habitats from coastal development and associated human activities. The introduction of non-native species can carry significant ecological and economic costs. Human and marine ecosystem health are threatened by a range of challenges, including increased levels of exposure to toxins from harmful algal blooms and other sources, and greater contact with infectious agents. Areas in numerous bays, estuaries, gulfs, and the Great Lakes are now consistently low in or lacking oxygen, creating dead zones along our bays and coasts. Unsustainable fishing (e.g., overfishing) remains a serious concern with consequences for marine ecosystems and human communities. In the Arctic, environmental changes are revealing the vulnerability of its ecosystems. These changes are increasing stressors and impacts on the ecosystems, people, and communities in the region and are presenting new domestic and international management challenges.

Many of these concerns are attributable not only to activities within ocean, coastal, and Great Lakes ecosystems, but also to actions that take place in our Nation's interior. For example, our industries, agricultural and transportation operations, cities, and suburbs generate various forms of pollution. Industrial operations emit pollutants, such as nitrogen and mercury, into the atmosphere that often find their way into the ocean and Great Lakes. Rain washes residues, chemicals, and oily runoff from our roadways into our estuaries and coastal waters. Heavy rainfall events can wash sediment, pesticides, debris, and nutrients from our fields, lawns, and agricultural operations into our waters. Urban and suburban development, including the construction of roads, highways, and other infrastructure, as well as modification to rivers and streams, can adversely affect the habitats of aquatic and terrestrial species.

Demands on the ocean, our coasts, and the Great Lakes are intensifying, spurred by population growth, migration to coastal areas, and economic activities. Human uses of the ocean, coasts, and the Great Lakes are expanding at a rate that challenges our ability to plan and manage them under the current sector-by-sector approach. New and expanding uses—including energy development, shipping, aquaculture, and emerging security requirements—are expected to place increasing demands on our ocean, coastal, and Great Lakes ecosystems. There is also increasing demand for access to these places for recreational, cultural, and other societal pursuits. As these demands increase, overlapping uses and differing views about which activities should occur where can generate conflicts and misunderstandings. At the same time, there is an overarching need to sustain and preserve abundant marine resources and healthy ecosystems that are critical to the well-being and continued prosperity of our Nation.



The State of the National Framework for Policy Coordination

The challenges we face in the stewardship of the ocean, our coasts, and the Great Lakes lie not only within the ecosystems themselves, but also in the laws, authorities, and governance structures intended to manage our use and conservation of them. United States governance and management of these areas span hundreds of domestic policies, laws, and regulations covering international, Federal, State, tribal, and local interests. These issues range from stewardship and resource use, to maritime safety and commerce, national security, water quality, ports and other transportation infrastructure, and energy. Challenges and gaps arise from the complexity and structure of this regime.

These challenges are not limited to our domestic governance and management regimes. Our Nation, as a major maritime power and coastal State, has a large stake in the development and interpretation

of international law and policy applicable to the ocean, our coasts, and the Great Lakes. Our national security interests are tightly linked to navigational rights and freedoms, as well as to operational flexibility. Our national security and economic interests are also linked to our ability to secure U.S. sovereign rights over resources in extensive marine areas off our coasts, to promote and protect U.S. interests in the marine environment, and to ensure that our maritime interests are respected and considered internationally. The Administration's support for accession to the 1982 United Nations Convention on the Law of the Sea (the Law of the Sea Convention) reflects several important objectives, including strengthening our Nation's ability to participate in and influence international law and policy related to the ocean.

Time to Act

The time has come for a national policy to uphold our stewardship responsibilities, ensure accountability for our actions, and serve as a model of balanced, productive, efficient, sustainable, and informed ocean, coastal, and Great Lakes use, management, and conservation within the global community. Today, as never before, we better comprehend the linkages among land, air, fresh water, ocean, ice, and human activities. We recognize that change is occurring rapidly and must be addressed. Advances in science and technology provide better and timelier information and understanding to guide decision-making. By applying the principles of ecosystem-based management (in which we integrate ecological, social, economic, commerce, health, and security goals, and recognize humans as key components of the ecosystem and healthy ecosystems as essential to human well-being) and adaptive management (whereby we routinely assess management actions to allow for better informed and improved future decisions) in a coordinated and collaborative approach, the Nation can improve its response to environmental, social, economic, and security challenges. With a clear national policy and a revitalized, empowered, unifying, and comprehensive framework to coordinate efforts among Federal, State, tribal, and local authorities, including regional governance structures, non-governmental organizations, the private sector, and the public, we can work together toward the changes needed to secure the health and prosperity of the ocean, our coasts, and the Great Lakes.

III. Policy

America's stewardship of the ocean, our coasts, and the Great Lakes is intrinsically and intimately linked to environmental sustainability, human health and well-being, national prosperity, adaptation to climate and other environmental changes, social justice, international diplomacy, and national and homeland security. Therefore, it is the policy of the United States to:

1. Healthy and Resilient Ocean, Coasts, and Great Lakes

   - Protect, maintain, and restore the health and biological diversity of ocean, coastal, and Great Lakes ecosystems and resources;

   - Improve the resiliency of ocean, coastal, and Great Lakes ecosystems, communities, and economies;

- Bolster the conservation and sustainable uses of land in ways that will improve the health of ocean, coastal, and Great Lakes ecosystems; and

- Use the best available science and knowledge to inform decisions affecting the ocean, our coasts, and the Great Lakes, and enhance humanity's capacity to understand, respond, and adapt to a changing global environment.

2. Safe and Productive Ocean, Coasts, and Great Lakes

- Support sustainable, safe, secure, and productive access to, and uses of, the ocean, our coasts, and the Great Lakes;

- Respect and preserve our Nation's maritime heritage, including our social, cultural, recreational, and historical values; and

- Exercise rights and jurisdiction and perform duties in accordance with applicable international law, including respect for and preservation of navigational rights and freedoms, which are essential for the global economy and international peace and security.

3. Understood and Treasured Ocean, Coasts, and Great Lakes

- Increase scientific understanding of ocean, coastal, and Great Lakes ecosystems as part of the global interconnected systems of air, land, ice, and water, including their relationships to humans and their activities;

- Improve our understanding and awareness of changing environmental conditions, trends, and their causes, and of human activities taking place in ocean, coastal, and Great Lakes waters; and

- Foster a public understanding of the value of the ocean, our coasts, and the Great Lakes to build a foundation for improved stewardship.

The United States will promote the objectives of this policy by:

- Ensuring a comprehensive and collaborative framework for the stewardship of the ocean, our coasts, and the Great Lakes that facilitates cohesive actions across the Federal Government, as well as participation of State, tribal, and local authorities, regional governance structures, non-governmental organizations, the public, and the private sector;

- Cooperating and exercising leadership at the international level, including by joining the Law of the Sea Convention; and

- Supporting ocean stewardship in a fiscally responsible manner.

IV. Principles

1. United States management decisions and actions affecting the ocean, our coasts, and the Great Lakes will be guided by the following stewardship principles to further this policy:

   a. As responsible environmental stewards we will protect, maintain, and restore the health, productivity, and resiliency of ocean, coastal, and Great Lakes ecosystems (including their waters and resources). Policies, programs, and activities of the United States should be

managed and conducted in a manner that seeks to prevent or minimize adverse environmental impacts to the ocean, our coasts, and the Great Lakes ecosystems and resources, including cumulative impacts, and to ensure and improve their integrity. They should be managed and conducted in a manner that does not undermine efforts to protect, maintain, and restore healthy and biologically diverse ecosystems and the full range of services they provide;

b. Decisions affecting the ocean, our coasts, and the Great Lakes should be informed by and consistent with the best available science. Decision-making will also be guided by a precautionary approach as reflected in the Rio Declaration of 1992, which states in pertinent part, "[w]here there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation;" and

c. Actions taken to protect the ocean, our coasts, and the Great Lakes should endeavor to promote the principles that environmental damage should be avoided wherever practicable and that environmental costs should be internalized, taking into account the approach that those who cause environmental damage should generally bear the cost of that damage.

2. Human activities that may affect ocean, coastal, and Great Lakes ecosystems should be managed using ecosystem-based management and adaptive management, through an integrated framework that accounts for the interdependence of the land, air, water, ice, and the interconnectedness between human populations and these environments. Management should include monitoring and have the flexibility to adapt to evolving knowledge and understanding, changes in the global environment, and emerging uses.

3. Current and future uses of ocean, coastal, and Great Lakes ecosystems and resources should be managed and effectively balanced in a way that:

   a. Maintains and enhances the environmental sustainability of multiple uses, including those that contribute to the economy, commerce, recreation, security, and human health;

   b. Harmonizes competing and complementary uses effectively;

   c. Integrates efforts to protect, maintain, and restore the health, productivity, and resiliency of ocean, coastal, and Great Lakes ecosystems and the services they provide; and

   d. Recognizes environmental changes and impacts, including those associated with an increasingly ice-diminished Arctic, sea-level rise, and ocean acidification.

4. The United States should support disciplinary and interdisciplinary science, research, monitoring, mapping, modeling, forecasting, exploration, and assessment to continually improve understanding of ocean, coastal, and Great Lakes ecosystems. These efforts should include improving understanding of physical, biological, ecological, and chemical processes and changes,

their interconnectedness with other parts of the Earth system and with human populations, and the potential social and economic consequences of management decisions on the long-term health and well-being of the population, including human health and safety. This knowledge, along with traditional knowledge, should be applied through ecosystem-based management and adaptive management. Information resulting from these efforts should be easily accessible to the public.

5. The United States should develop an improved awareness of changing environmental conditions and trends, and their causes, and of human activities that take place in the ocean, coastal, and Great Lakes environments.

6. United States policies, programs, and activities should enhance formal and informal education about the ocean, our coasts, and the Great Lakes and their uses to build a foundation for greater understanding and improved stewardship, and build capacity to produce future scientists, managers, and members of a dynamic and innovative workforce.

7. The United States should cooperate and provide leadership internationally in the protection, management, and sustainable use of the world's ocean, coastal regions, and the Great Lakes in keeping with applicable conventions and agreements, and with customary international law, as reflected in the Law of the Sea Convention.

8. United States programs, policies, and activities that may impact ocean, coastal, or Great Lakes ecosystems, or engage the use of their resources, should be designed to meet measurable benchmarks in support of clear goals and objectives related to stewardship of these ecosystems.

    a. These goals and objectives of programs and activities should be periodically reevaluated and their effectiveness assessed. This information should be used to adjust management priorities and guide future management and resource decisions; and

    b. The United States should develop appropriate standards and methods for measurement and assessment of parameters associated with the health of ocean, coastal and Great Lakes ecosystems.

9. United States policies, programs, and activities that may impact ocean, coastal, or Great Lakes ecosystems, or engage the use of their resources, should be assessed and conducted within an integrated and comprehensive interagency planning framework that:

a. Considers and addresses the full suite of impacts on resources, biological diversity, and ecosystems;

b. Is based on the best available scientific knowledge;

c. Considers and addresses potential use conflicts;

d. Ensures and advances coordination and collaboration across federal, state, tribal, and local jurisdictional lines, and with regional governance structures, the private sector, foreign governments, and international organizations, as appropriate;

e. Is coordinated and promotes consistency with our homeland and national security and foreign policy interests;

f. Is coordinated and promotes consistency with other national strategies that include environmental stewardship components relevant to the ocean, our coasts, and the Great Lakes;

g. Considers and respects our nation's maritime heritage, including our social, cultural, historical, recreational, and aesthetic values;

h. Aims to maximize long-term net benefits to society by considering a range of reasonable alternatives that balance potential economic, environmental, public health and safety, and other advantages; distributive impacts; and social justice and equity;

i. Operates through an open and transparent approach that encourages broad public participation;

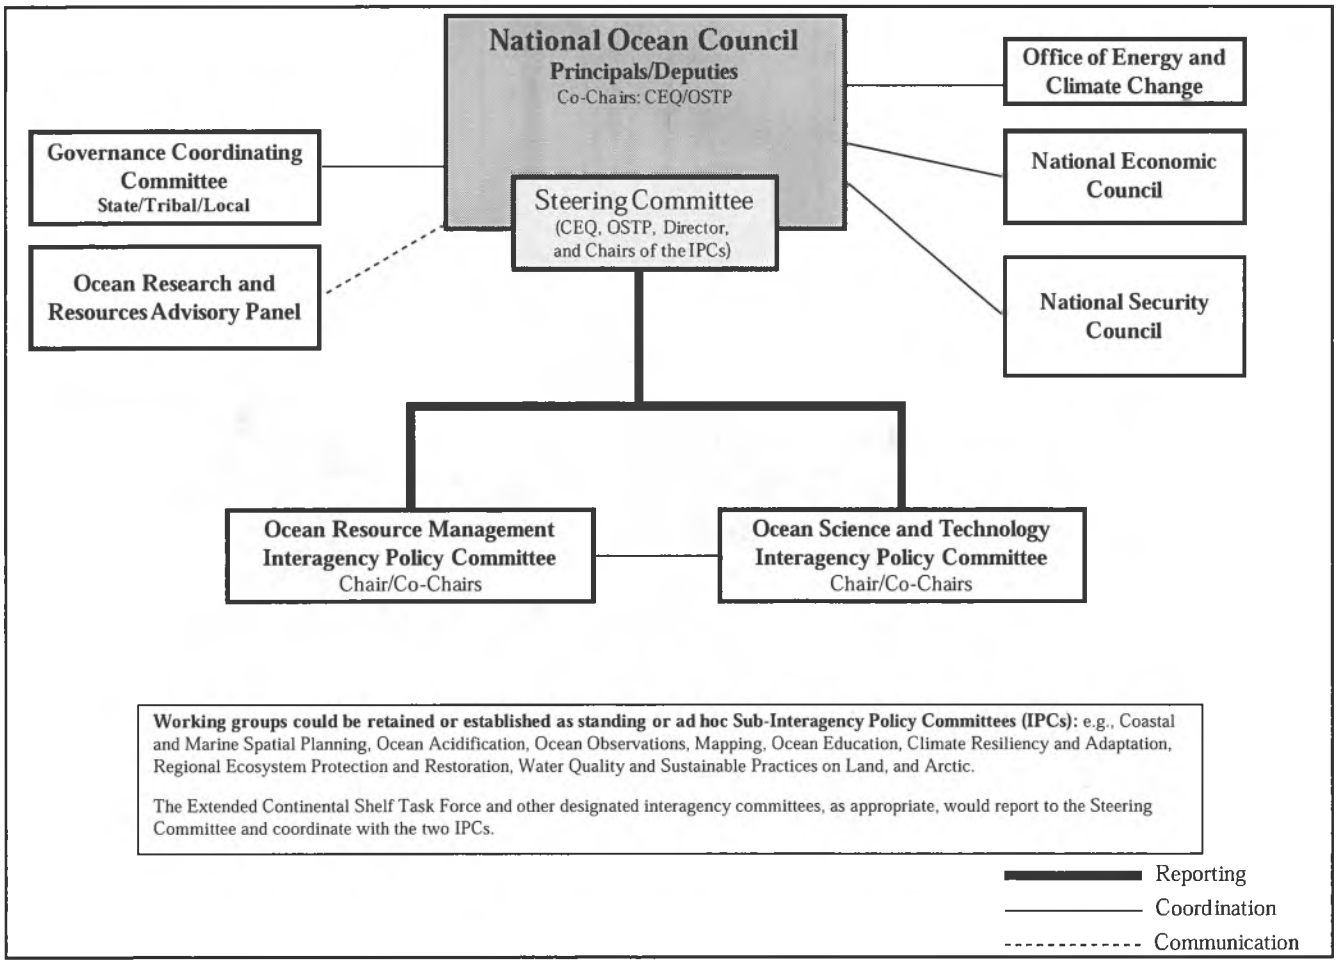
j. Ensures consistency with management and budgetary goals and compliance with relevant legal requirements;

k. Seeks to eliminate redundancy and encourage efficiencies and synergies; and

l. Includes a reporting and accountability mechanism.

Implementing a number of the policy elements and principles directed above will require appropriate resources and assets. Departments and agencies shall work to identify future budgetary, administrative, regulatory, or legislative proposal requirements to implement these elements within the budgetary and management guidelines of the President's budget.

PART TWO. POLICY COORDINATION FRAMEWORK



The recommended policy coordination framework provides a combination of modifications to the structure of the existing Committee on Ocean Policy, a stronger mandate and direction, and renewed and sustained high-level engagement. This combination of improvements provides a framework for more successful policy coordination to improve the stewardship of the ocean, our coasts, and the Great Lakes. The recommended policy coordination framework would provide a reinvigorated structure that would strengthen ocean governance and coordination by providing clear and visible leadership and sustained high-level engagement within the Federal Government. Additionally, the structure would provide for greater participation by, and coordination of State, tribal, and local authorities, and regional governance structures. The linkage between management and science would be strengthened, as would coordination with other senior level entities on relevant economic, climate, and security matters. This combination of improvements would enhance the stewardship of the ocean, our coasts, and the Great Lakes.

I. National Ocean Council

Structure

The National Ocean Council (NOC) would be a dual Principal- and Deputy-level committee. Membership of the NOC would include: the Secretaries of State, Defense, the Interior, Agriculture, Health and Human Services, Commerce, Labor, Transportation, Energy, and Homeland Security; the Attorney General; the Administrator of the Environmental Protection Agency; the Chair of the Council on Environmental Quality (CEQ); the Director of the Office of Management and Budget (OMB); the Administrator of the National Aeronautics and Space Administration; the Director of National Intelligence; the Director of the Office of Science and Technology Policy (OSTP); the Director of the National Science Foundation; the Chairman of the Federal Energy Regulatory Commission;[2] the Chairman of the Joint Chiefs of Staff; the Assistants to the President for National Security Affairs, Homeland Security and Counterterrorism, Domestic Policy, Energy and Climate Change, and Economic Policy; an employee of the United States designated by the Vice President; the Under Secretary of Commerce for Oceans and Atmosphere (NOAA Administrator); and such other officers or employees of the United States as the Co-Chairs may from time to time designate.

Co-Chairs

The NOC would be co-chaired by the Chair of the CEQ and the Director of OSTP. This construct would provide the NOC with the balance of equities at the most senior level of its leadership and better facilitate interagency cooperation and collaboration.

Function

Subject to the direction of the President and unless as otherwise provided for by law, the NOC would perform the following functions:

1. **Tier-one functions of the NOC (Principal-level).** The NOC has overall responsibility for implementation of the National Policy, including coastal and marine spatial planning. Functions

[2] Federal Energy Regulatory Commission and other independent regulatory agencies participate on the NOC by invitation of the Co-Chairs.

would include: (1) periodically update and set national priority objectives; (2) review and provide annual direction on National Policy implementation objectives based on Administration priorities and recommendations from the Deputy-level; and (3) be a forum for dispute resolution and decision-making of issues that could not be resolved at the Deputy-level. The NOC would be required to meet a minimum of twice per year, but the Co-Chairs could call additional meetings as necessary for dispute resolution or other purposes.

2. **Tier Two (Deputy-level) functions would include**: (1) ensure execution of National Policy implementation objectives; (2) ensure implementation of coastal and marine spatial planning; (3) transmit Administration priorities to the Ocean Resource Management Interagency Policy Committee (ORM-IPC) and Ocean Science and Technology Interagency Policy Committee (OST-IPC); (4) ensure activities of and products from the ORM-IPC and OST-IPC are consistent with Administration policy; (5) coordinate with the National Security Council (NSC), National Economic Council (NEC),[3] Office of Energy and Climate Change (OECC), and other offices, as appropriate; (6) provide direction and feedback to, and receive external input and advice from, its advisory bodies; and (7) assist with dispute resolution and decision-making, and if unable to do so, to forward the issues to the Principal-level. This group would also assume the duties of the statutorily mandated National Ocean Research Leadership Council (NORLC) under 10 U.S.C. § 7902.

The Deputies would be required to meet a minimum of quarterly.

II. Authorities and Responsibilities of the National Ocean Council Co-Chairs

1. Advise the President on the Implementation of the National Policy for the Stewardship of the Ocean, Our Coasts, and the Great Lakes

The Co-Chairs would advise the President on matters regarding implementation of the *National Policy for the Stewardship of the Ocean, Our Coasts, and the Great Lakes* (National Policy), consistent with the consensus views of the NOC. If consensus cannot be achieved, the Co-Chairs would provide their own views equally with the views of each member of the NOC.

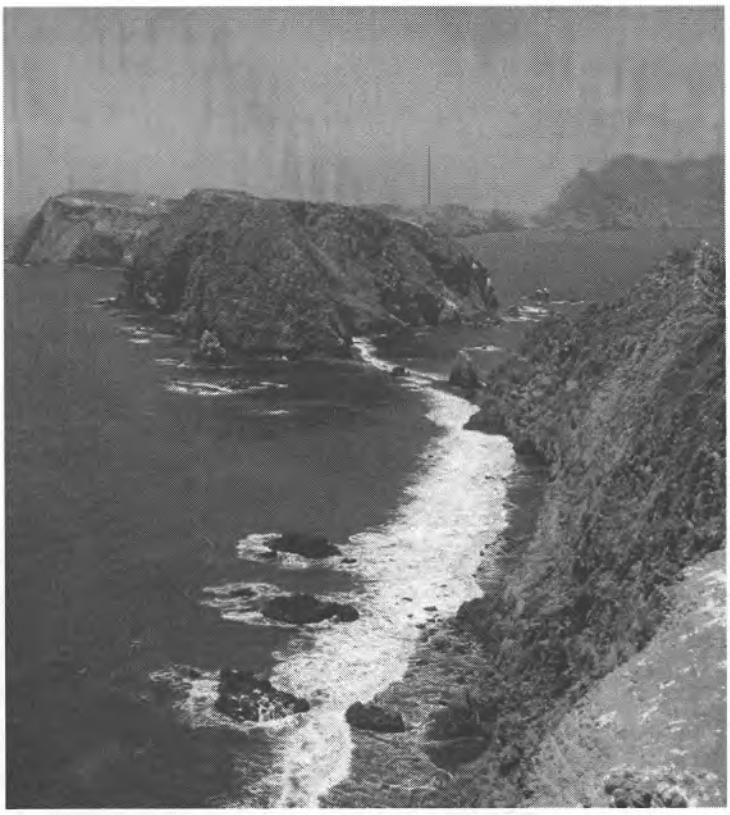
2. Implementation of the National Policy

On behalf of the NOC, the Co-Chairs would have overall responsibility for coordinating and facilitating the implementation of the National Policy, subject to the direction of the NOC and the President, including the following:

- **Development of Strategic Action Plans** – The Co-Chairs would facilitate development by the NOC of strategic action plans to further the National Policy and identify progress

[3] The existing Committee on the Marine Transportation System's coordination with the NOC governance structure would be done through the National Economic Council, at both the Principal-level and Deputy-level. Coordination with the ORM-IPC and OST-IPC would also be developed, as appropriate.

toward meeting defined goals and objectives.



- **Implementation of Coastal and Marine Spatial Planning** – The Co-Chairs would facilitate implementation of coastal and marine spatial planning in accordance with Part 4 below.

- **Reporting and Accountability** – The Co-Chairs would be responsible for: (1) coordinating interagency reporting on implementation and progress; (2) monitoring and ensuring effective implementation of policy decisions; (3) providing oversight and accountability for document preparation; and (4) coordinating and expediting interagency review and clearance of documents and reports within the NOC purview.

- **Budget** – The Co-Chairs would coordinate the development of an annual budget guidance memorandum on ocean priorities consistent with the goals and objectives of the National Policy. While it is understood that the Co-Chairs' authority would not be construed to impair or otherwise affect the function of the Director of OMB, they would work with OMB to issue interagency budget guidance consistent with annual priorities, develop crosscuts to inform the annual priorities on ocean, coastal, and Great Lakes stewardship, and consult with OMB and the NOC to identify programs that contribute significantly to the National Policy. The Co-Chairs also would work with OMB to coordinate preparation of the biennial Federal Ocean and Coastal Activities Report mandated by Section 5 of the Oceans Act of 2000.

- **Emerging Issues** – The Co-Chairs would bring any Presidential ocean actions or priorities to the NOC, as appropriate, for action and implementation and would coordinate proper management of and response to emerging issues of relevance to the National Policy.

- **International** – In implementing this policy, the Co-Chairs would coordinate with the Secretary of State and the heads of other relevant agencies on matters related to the policy issues that arise within the Intergovernmental Oceanographic Commission, International Whaling Commission, Arctic Council, International Maritime Organization, regional fishery management organizations, and other similar international organizations.

3. Co-Chairs of the NOC

- The Co-Chairs shall have authority to call NOC meetings, draft the agenda, prioritize issues, and call Deputies' meetings.

4. Coordination and Integration

   - The Co-Chairs would be the point of contact to coordinate with the National Security Advisor (NSA), NEC Director, and Assistant to the President for Energy and Climate Change (APECC), and other senior White House officials, as appropriate. The Co-Chairs would have authority to request meetings with these entities for the purposes of coordination and resolution of issues of overlapping responsibility.

5. Decision-Making and Dispute Resolution

   - The Co-Chairs would seek to encourage decisions and recommendations based on consensus of the NOC.

   - Disputes that could not be resolved at the Deputy-level would be referred to the Co-Chairs. The Co-Chairs would facilitate resolution among the Principals.

   - With respect to those matters in which resolutions or consensus could not be reached, the Co-Chairs would coordinate with the APECC, NEC Director, and NSA, as appropriate, to frame the disputed issue or issues for decision by the President.

   - The establishment of the NOC would not be construed to impair or otherwise affect: (1) authority granted by law to an executive department or agency or the head thereof; or (2) functions assigned by the President to the NSC (or subordinate bodies) relating to matters affecting foreign affairs, national security, homeland security, or intelligence – any of these matters that are not resolved by consensus within the NOC will be forwarded to the NSC for resolution.

III. Steering Committee

Structure

The Steering Committee would be a high-level, streamlined body of five members from OSTP, CEQ, and one Chair each of the ORM-IPC and OST-IPC, and the Director of the NOC Staff. The Steering Committee would meet at least every other month, but more often as issues require, and work in consultation with NSC, NEC, and OMB to ensure their respective input on relevant matters, as appropriate. NOC staff would attend these meetings and be responsible for ensuring the implementation of agreed-upon actions.

Function

The Steering Committee would be the key forum for ensuring integration and coordination on priority areas within the NOC. In particular, it would ensure that there is coordination of management and science issues and that the activities of the ORM-IPC and OST-IPC are aligned to fully support implementation of the National Policy and priorities agreed upon by the NOC. The Steering Committee would identify key issues and assist in developing the agenda for the NOC. The NOC staff would be responsible for ensuring the implementation of agreed upon actions. In addition, the Extended Continental Shelf Task Force and other designated interagency committees, as appropriate, would report to the Steering Committee.

IV. National Ocean Council Staff Leadership and Support

Structure

Two senior-level staff members, a Director of the NOC Staff, and a Deputy Director, would support the Co-Chairs in the implementation of the National Policy. On a day-to-day basis they would be responsible for ensuring the execution of the functions of the full-time staff supporting the NOC. They would be charged with ensuring the effective operation of the NOC, and the efficient implementation of the National Policy, under the guidance of the Co-Chairs. In addition, the NOC would initially be supported by an ocean policy office consisting of a minimum of six to eight dedicated staff comprised of interagency representatives on staggered two-year assignments from departments, agencies, and offices represented on the NOC. These full-time NOC staff personnel would report to the staff Director and Deputy Director.

Function

The staff Director and Deputy Director, as appropriate, would represent the Co-Chairs at policy-level meetings and forums, external events, and interaction with Congress. They would work with the IPC Co-Chairs to also ensure policy coordination and integration of the IPCs and facilitate close coordination between the NOC and its Ocean Research and Resources Advisory Panel (ORRAP) and Governance Coordinating Committee (GCC). They would oversee the NOC staff on a day-to-day basis and serve as the points of contact to coordinate at a staff level with CEQ, NSC, NEC, OSTP, OECC, and other offices, as appropriate. The staff Director, Deputy Director, and other NOC staff personnel would serve as the core support to the NOC in its operations and in implementation of the National Policy. Each member of the NOC staff would be required to have programmatic experience and analytical skills. Each staff member would work to provide administrative support to, and ensure coordination among, the NOC and the IPCs, GCC, and other appropriate entities.

V. Ocean Resource Management Interagency Policy Committee

Structure

The ORM-IPC is the successor to the current Subcommittee on Integrated Management of Ocean Resources. Chairs of the ORM-IPC are designated by the NOC. The group would consist of Deputy Assistant Secretaries or comparable representatives, or appropriate senior-level representatives with decision-making authority from departments, agencies and offices represented on the NOC. The ORM-IPC reports to the NOC. The ORM-IPC may establish Sub-IPCs as necessary, as approved by the NOC.

Function

The ORM-IPC would function as the ocean resource management body of the NOC, with an emphasis on ensuring the interagency implementation of the National Policy, national priority objectives, and other priorities defined or approved by the NOC. This would include the development of strategic plans, in coordination with the OST-IPC, for the implementation of priority management objectives,

with clear outcomes, milestones, deadlines, designated agencies, and performance measures with an adaptive review process. The ORM-IPC Chairs would develop a charter for the operation of the body, to be approved by the NOC, including, but not limited to, membership, meetings (e.g., requiring that it meet at least every two months), development of a new or updated work plan based on direction from the NOC, and a process for external input (e.g., State, tribal, local, regional, and the public).

VI. Ocean Science and Technology Interagency Policy Committee

Structure

The National Science and Technology Council's (NSTC) Joint Subcommittee on Ocean Science and Technology (JSOST) would serve as the OST-IPC. Chairs of the OST-IPC would be appointed through NSTC procedures in consultation with the NOC. The group would consist of Deputy Assistant Secretaries or comparable representatives, or appropriate senior-level representatives with decision-making authority from departments, agencies, and offices represented on the NOC. The NSTC would direct the OST-IPC to advise and assist the NOC in consonance with this National Policy and to work with associated bodies (e.g., the ORM-IPC) accordingly.

Function

The OST-IPC would function as the ocean science and technology body of the NOC, with an emphasis on ensuring the interagency implementation of the National Policy, national priority objectives, and other priorities for science and technology objectives. This would include the development of strategic

plans (e.g., the Ocean Research Priorities Plan and Implementation Strategy), in coordination with the ORM-IPC, for interagency implementation of priority science and technology objectives, with clear outcomes, milestones, deadlines, designated agencies, and performance measures with an adaptive review process. The OST-IPC Chairs, in close coordination with the NOC, would develop a charter for the operation of the body, to be approved by the NSTC, and would include, but not be limited to, membership, meetings (e.g., requiring that it meet at least every two months), development of a new or updated work plan based on input from the NOC, and a process for external input (e.g., State, tribal, regional, and public). The OST-IPC would also retain the legislatively mandated functions of JSOST, report to the NSTC's Committee on Environment and Natural Resources, and maintain a close operational relationship with the NOC. It would continue to adhere to the rules and regulations of the NSTC. The OST-IPC may establish Sub-IPCs, as necessary, and will do so under NSTC procedures and in close coordination with the NOC.

VII. Governance Coordinating Committee

Structure

The NOC, in consultation with the White House Office of Intergovernmental Affairs, would establish the GCC that would consist of eighteen members from States, federally-recognized tribes, and local governments. Members would be chosen by the NOC and would be comprised of: (1) one State representative each from the Great Lakes Region, Gulf of Mexico Region, Mid-Atlantic Region, Northeast Region, South Atlantic Region, and West Coast Region, chosen in consultation with the Governors represented on the existing regional governance structures;[4] (2) one State representative each from Alaska, the Pacific Islands,[5] and the Caribbean,[6] chosen in consultation with respective Governors; (3) two at-large representatives from inland States, chosen in consultation with the National Governors Association; (4) one State legislative representative, chosen in consultation with the National Conference of State Legislatures; (5) three at-large tribal representatives, chosen in consultation with tribal councils, national and regional tribal organizations (e.g., the National Congress of American Indians); and (6) three local government representatives from coastal States (i.e., two mayors and one county official), chosen in consultation with the U.S. Conference of Mayors, the National League of Cities, and the National Association of Counties. Representatives would serve for staggered two-year terms. These representatives would select a Chair and Vice-Chair from their members. In addition, the GCC may establish subcommittees chaired by representatives of the GCC. These subcommittees would include additional representation, as appropriate, from State, tribal, and local governments, respectively, to provide for greater collaboration and expanded exchange of views. The GCC would be supported by the NOC staff.

---

[4] Existing regional governance structures include the Great Lakes Commission, the Governors' South Atlantic Alliance, the Gulf of Mexico Alliance, the Mid-Atlantic Regional Council on the Ocean, the Northeast Regional Ocean Council, and the West Coast Governors' Agreement on Ocean Health.

[5] For purposes of this section "Pacific Islands" include Hawaii, Guam, the Commonwealth of the Northern Mariana Islands, and American Samoa.

[6] For purposes of this section "Caribbean" includes the Commonwealth of Puerto Rico and the U.S. Virgin Islands.

Function

The role of the GCC would be to serve as a formal body for State, tribal, and local government representatives to deliberate and coordinate with the NOC on issues of inter-jurisdictional collaboration and cooperation on the National Policy and related matters. These matters would include coordinating on the development of a uniform procedure to facilitate resolution at the regional level of disputes regarding the development of coastal and marine spatial plans (CMS Plans) prior to elevation to the NOC and providing advice on long-term strategic management and research priorities. The GCC would submit to the IPCs and the Steering Committee ocean and coastal related issues for potential discussion by the NOC and provide input on issues at the request of the Steering Committee. The GCC would also have regular and continued communication with the IPCs, via the NOC Steering Committee, throughout the development of the strategic action plans and implementation of the National Policy.

The United States has a unique legal relationship with federally recognized American Indian and Alaska Native tribal governments (tribes) as set forth in United States treaties, statutes, Executive Orders, and court decisions. These instruments establish a framework for the Federal Government's recognition of and support for tribal sovereignty and tribal self-government and self-determination, consistent with applicable Federal law, but not necessarily with State law. While the GCC includes three tribal representatives, the function of the GCC and these representatives would not replace Government-to-Government consultations with tribes under existing authorities.

VIII. Ocean Research and Resources Advisory Panel

Structure

The ORRAP is a legislatively established body that advises the NORLC under the Federal Advisory Committee Act (FACA).

Function

The ORRAP would provide independent advice and guidance to the NOC. Current membership is comprised of individuals from the National Academies, State governments, academia, and ocean industries, representing marine science, marine policy, and other related fields. However, ORRAP membership would be reviewed to determine whether to include additional representatives to broaden the level of expertise in support of the goals of the National Policy. The NOC would routinely provide guidance and direction on the areas for which it seeks advice and recommendations from the ORRAP.

IX. Review and Evaluation

After 12 months of operation, the NOC would conduct a review of the governance structure to evaluate its effectiveness and make any necessary changes or improvements.

PART THREE. IMPLEMENTATION STRATEGY

National Priority Objectives

HOW WE DO BUSINESS

1. **Ecosystem-Based Management:** Adopt ecosystem-based management as a foundational principle for the comprehensive management of the ocean, our coasts, and the Great Lakes.
2. **Coastal and Marine Spatial Planning:** Implement comprehensive, integrated, ecosystem-based coastal and marine spatial planning and management in the United States.
3. **Inform Decisions and Improve Understanding:** Increase knowledge to continually inform and improve management and policy decisions and the capacity to respond to change and challenges. Better educate the public through formal and informal programs about the ocean, our coasts, and the Great Lakes.
4. **Coordinate and Support:** Better coordinate and support Federal, State, tribal, local, and regional management of the ocean, our coasts, and the Great Lakes. Improve coordination and integration across the Federal Government and, as appropriate, engage with the international community.

AREAS OF SPECIAL EMPHASIS

1. **Resiliency and Adaptation to Climate Change and Ocean Acidification:** Strengthen resiliency of coastal communities and marine and Great Lakes environments and their abilities to adapt to climate change impacts and ocean acidification.
2. **Regional Ecosystem Protection and Restoration:** Establish and implement an integrated ecosystem protection and restoration strategy that is science-based and aligns conservation and restoration goals at the Federal, State, tribal, local, and regional levels.
3. **Water Quality and Sustainable Practices on Land:** Enhance water quality in the ocean, along our coasts, and in the Great Lakes by promoting and implementing sustainable practices on land.
4. **Changing Conditions in the Arctic:** Address environmental stewardship needs in the Arctic Ocean and adjacent coastal areas in the face of climate-induced and other environmental changes.
5. **Ocean, Coastal, and Great Lakes Observations, Mapping, and Infrastructure:** Strengthen and integrate Federal and non-Federal ocean observing systems, sensors, data collection platforms, data management, and mapping capabilities into a national system and integrate that system into international observation efforts.

I. Introduction

The National Policy would provide our Nation with a comprehensive approach, solidly based on science and technology, to uphold our stewardship responsibilities, and ensure accountability for our actions to present and future generations. Furthermore, the United States intends, through the National Policy, to serve as a model of balanced, productive, efficient, sustainable, and informed ocean, coastal, and Great Lakes use, management, and conservation within the global community. This implementation strategy recommends a clear set of priority objectives that our Nation should pursue to further the National Policy.

Overview of National Priority Objectives

This implementation strategy recommends nine priority objectives. The first four, which together frame *How We Do Business,* represent overarching ways in which the Federal Government must operate differently or better to improve stewardship of the ocean, our coasts, and the Great Lakes. The implementation of ecosystem-based management embodies a fundamental shift in how the United States manages these resources, and provides a foundation for how the remaining objectives would be implemented. Within that construct, the implementation of coastal and marine spatial planning and management would mark the beginning of a new era of comprehensive, integrated techniques to address conservation, economic activity, user conflict, and sustainable use of ocean, coastal, and Great Lakes resources. The other overarching objectives – to better inform decisions and improve understanding by the public through a strengthened ability to obtain and use science and information and to better coordinate and support science-based management across various authorities and governance structures are, in and of themselves, not new concepts. However, these efforts have suffered from the lack of a clear National Policy and a comprehensive framework within which to achieve desired outcomes.

The implementation strategy also identifies five *Areas of Special Emphasis,* each of which represents a substantive area of particular importance to achieving the National Policy. These priority areas of work seek to address some of the most pressing challenges facing the ocean, our coasts, and the Great Lakes. For many years, scientists, resource managers, private industry, and others have been wrestling with these issues with a variety of existing Federal Government programs in place to address them. While those efforts have delivered their share of results, in each of these critical areas more can – and must –

be done. In many cases, we have lacked the capability and understanding – both scientific and technical – to affect the type of change required. In the last several years, however, science has significantly evolved and advanced, and our capacity to respond to environmental and technological changes in these five areas has improved substantially. With this strategy, these specific areas of work should be viewed as national priorities with a renewed and coordinated effort at finding and implementing solutions. Over time, the NOC will assess the progress on these areas and also identify other areas to be addressed.

Planning

Together, these nine priority objectives provide a bridge between the National Policy and action on the ground and in the water, but do not prescribe in detail how individual entities would undertake these responsibilities. For each priority objective, the NOC would be responsible for, and oversee development of, a strategic action plan within six to twelve months from its establishment. The NOC's ORM-IPC and OST-IPC would be charged with developing these plans. The plans would address the *Obstacles* and *Opportunities* identified for each objective and would focus on, but not be limited to, the key areas identified under each objective. In addition, each plan would:

- Identify specific and measurable near-term, mid-term, and long-term actions, with appropriate milestones, performance measures, and outcomes to fulfill each objective;
- Consider smaller-scale, incremental, and opportunistic efforts that build upon existing activities, as well as more complex, larger-scale actions that have the potential to be truly transformative;
- Explicitly identify key lead and participating agencies;
- Identify gaps and needs in science and technology; and
- Identify potential resource requirements and efficiencies; and steps for integrating or coordinating current and out-year budgets.

The plans would be adaptive to allow for modification and addition of new actions based on new information or changing conditions. Their effective implementation would also require clear and easily understood requirements and regulations, where appropriate, that include enforcement as a critical component. Implementation of the National Policy for the stewardship of the ocean, our coasts, and the Great Lakes will recognize that different legal regimes, with their associated freedoms, rights, and duties, apply in different maritime zones. The plans would be implemented in a manner consistent with applicable international conventions and agreements and with customary international law as reflected in the Law of the Sea Convention. The plans and their implementation would be assessed and reviewed annually by the NOC and modified as needed based on the success or failure of the agreed upon actions. Upon identification and finalization of plans, the NOC Co-Chairs, in collaboration with OMB, would develop an annual interagency ocean budget guidance memorandum. Recognizing the reality of the limited availability of new resources, each of the Federal agencies engaged in the implementation

of strategic action plans would re-evaluate how resources should best be allocated in light of their statutory and regulatory mandates.

While these plans are under development, any agency that is conducting an activity that supports or furthers one of the objectives would bring them to the attention of the NOC. The NOC – working with the agency – would review the activity to determine how it might best contribute to overall implementation of the priority objectives, including being incorporated into the relevant strategic action plan.

Transparency and Collaboration

Transparency in developing strategic action plans and implementing the National Policy is critical. As the NOC develops and revises the plans, it will ensure substantial opportunity for public participation. Final plans, revisions, and reports of how well plan performance measures are being met would be made publicly available.

The effective implementation of this far-reaching and comprehensive National Policy would require active collaboration of the Federal Government with State, tribal, and local authorities, regional governance structures, academic institutions, non-governmental organizations, recreational interests, and private enterprise. In developing and revising the plans, the NOC would reach out to these interested parties, as appropriate, through the NOC's GCC, the ORRAP, workshops, and by other means. Furthermore, international collaboration on a broad range of ocean issues is an important component of these objectives. The Nation plays a leadership role in various international forums that deal with these issues, such as the Arctic Council, the International Maritime Organization, the Intergovernmental Oceanographic Commission, regional fisheries management organizations, and the International Whaling Commission. By joining the Law of the Sea Convention now, we can reaffirm and enhance United States leadership in the development and interpretation of international law applicable to the ocean. The Convention's provisions are highly favorable to the national security, environmental, and economic interests of the United States. Becoming a party would give the United States the ability to participate formally and more effectively in the interpretation and development of the Convention.

II. National Priority Objectives

How We Do Business

1. **Ecosystem-Based Management: Adopt ecosystem-based management as a foundational principle for the comprehensive management of the ocean, our coasts, and the Great Lakes.**

Obstacles and Opportunities

Traditional management of resource use and other activities in the ocean, along our coasts, and in the Great Lakes has focused on individual species, resources, areas, or actions with limited consideration for how the management practices of one might impact the sustainability of another. This has often led to disjointed management approaches resulting in loss of resources, economic hardship, and environments at risk. To ensure healthier, more resilient, and productive ocean, coastal, and Great Lakes environments, comprehensive management systems are needed that fully integrate ecological, social, economic, and security goals into decisions. Embedding ecosystem-based management, grounded in science, as an overarching principle would be a fundamental shift in the traditional way the Federal Government approaches management of the ocean, our coasts, and the Great Lakes. It would provide the opportunity to ensure proactive and holistic approaches to better manage the use and conservation of these valuable resources. This broad-based application of ecosystem-based management would provide a framework for the management of our resources, and allow for such benefits as helping to restore fish populations, control invasive species, support healthy coastal and Great Lakes communities and ecosystems, restore sensitive species and habitats, protect human health, and rationally allow for emerging uses of the ocean, including new energy production.

The Plan Should Address:

- "Best practices" for developing and implementing effective ecosystem-based management systems;
- Identification and prioritization of geographic areas of special sensitivity or in greatest need for ecosystem-based management;
- Establishment of a process for working with States, tribal, and local authorities and regional governance structures to apply the most successful approaches in these areas of the greatest need; and
- Measures to ensure that decisions about ocean, coastal, and Great Lakes activities, uses, and goals are made based on the best available science and incorporate principles of ecosystem-based management.

2. **Coastal and Marine Spatial Planning: Implement comprehensive, integrated, ecosystem-based coastal and marine spatial planning and management in the United States.**

Obstacles and Opportunities

The ocean, our coasts, and the Great Lakes are host to countless commercial, recreational, scientific, energy, and security activities, which often occur in or near areas set aside and managed for

conservation and resource protection goals. Overlapping uses and differing views, about what activities should occur and where, can generate conflicts and misunderstandings. Coastal and marine spatial planning (CMSP) that fully incorporates the principles of ecosystem-based management will provide a means to objectively and transparently guide and balance allocation decisions for use of ocean, coastal, and Great Lakes waters and resources. It would allow for the reduction of cumulative impacts from human uses on marine ecosystems, provide greater certainty for the public and private sector in planning new investments, and reduce conflicts among uses and between using and preserving the environment to sustain critical ecological, economic, recreational, and cultural services for this and future generations.

The Plan Should Address:

- Implementation and expansion of the Framework for Effective Coastal and Marine Spatial Planning as described later in this document.

3. **<u>Inform Decisions and Improve Understanding:</u> Increase knowledge to continually inform and improve management and policy decisions and the capacity to respond to change and challenges. Better educate the public through formal and informal programs about the ocean, our coasts, and the Great Lakes.**

Obstacles and Opportunities

A broad program of basic and applied disciplinary and interdisciplinary scientific research, mapping, monitoring, observation, and assessment, coupled with development of forecasts, models, and other decision-support tools, is required to build knowledge of ocean, coastal, and Great Lakes ecosystems and processes and ensure that management and policies are based on sound science. Increased understanding of watershed processes and the linkages with our coasts will be necessary to develop better decision-support tools to adequately manage human uses, human impacts, including disproportionate impacts on minority or low income populations, and watershed conservation activities that affect our ocean and coasts. In addition, increased scientific knowledge and a more comprehensive awareness and a detailed understanding of current and emerging human activities taking place in and around our waters are essential to sound ocean planning and management. However, there are significant gaps in our understanding of ocean ecosystem dynamics, ocean conditions and trends, and the complex links between these conditions and human health, economic opportunities, national and homeland security, and social justice. There is significant opportunity to improve how and what information we gather to better understand change and respond

to challenges, better integrate current scientific knowledge (natural, social and traditional/ cultural) and real-time data into decision-making, improve the management and integration of data supporting science and decision-making, and identify and close knowledge gaps necessary to adequately understand the impacts of human activities on the ocean, our coasts, and the Great Lakes. A diverse, interdisciplinary, ocean-literate workforce that has the appropriate skills and training to capitalize on these opportunities is needed. In addition, formal and informal education programs developed and implemented to target grades K-12 and beyond would create opportunities for enhanced appreciation of coastal and ocean issues, and better prepare the workforce of the future. Robust education programs already exist in many NOC member agencies and can serve as the foundation for increasing knowledge on ocean, coastal, and Great Lakes issues. Success in building our knowledge and applying it to improve management also relies on an engaged and informed public. Many Americans do not realize the importance of the ocean, our coasts, and the Great Lakes to their daily lives, the benefits they provide, or the possibilities they present for further discovery. There is great opportunity to raise awareness and identify ways we can help protect our waters and their resources.

Inform and Improve

The Plan Should Address:

- Identification of priority issues in addressing emerging topics and changes in ocean, coastal, and Great Lakes ecosystems and processes;

- Specific scientific requirements and research needs, including the need for reconciling inconsistent standards, physical infrastructure, research platforms, organizations, and data management, to identify critical gaps, ensure high quality data, and provide information necessary to inform management, including mechanisms to transition research results into information products and tools for management;

- The development of a more comprehensive awareness of environmental conditions and trends and human activities that take place in the ocean, coastal, and Great Lakes environments; and

- Requirements for routine integrated ecosystem assessments and forecasts, including impacts related to climate change, to address vulnerability, risks, and resiliency, and inform tradeoffs and priority-setting.

Educate

The Plan Should Address:

- Challenges, gaps, opportunities, and effective strategies for training and recruiting the current and next generation of disciplinary and interdisciplinary scientists, technicians, operators, managers, and policy-makers, with a particular focus on the needs of disadvantaged or under-served communities; and

- Identification of successful formal and informal education and public outreach approaches, including their application toward a focused nation-wide campaign to build public awareness, engagement, understanding, and informed decision-making, with specific emphasis on the state of ecosystems.

4. **Coordinate and Support: Better coordinate and support Federal, State, tribal, local, and regional management of the ocean, our coasts, and the Great Lakes. Improve coordination and integration across the Federal Government and, as appropriate, engage with the international community.**

Obstacles and Opportunities

One of the significant obstacles to effective management of the ocean, our coasts, and the Great Lakes is the complex set of Federal, State, tribal, and local laws, authorities, mandates, and governance structures intended to manage their use and conservation. Consistent approaches to the management of resources, including ecosystem-based and adaptive management, are difficult to achieve given this shared, piece-meal, and overlapping jurisdictional model. Furthermore, the United States is party to numerous international agreements and subject to customary international law regarding use and protection of the ocean and the Great Lakes. The United States should engage with international partners bilaterally and multilaterally to achieve increased cooperation and coordination on ocean issues. Through increased communication, coordination, and integration across all levels of government, we can streamline processes, reduce duplicative efforts, leverage resources, resolve disparities, and enhance synergy. A set of shared principles and objectives coordinated among all levels of government would translate into effective outcomes consistent with the National Policy.

Coordinate

The Plan Should Address:

- Identification of gaps, inconsistencies, and duplications in statutory authorities, policies, and regulations, and taking necessary and appropriate actions to address them;

- Procedures to identify and align mutual and consistent management objectives and actions across jurisdictions;

- Tangible tools and procedures to prevent and resolve conflicts across jurisdictions and disagreements concerning jointly managed ocean, coastal, and Great Lakes resources; and
- Opportunities for engaging the international community to further the objectives of the policy, as appropriate.

Support

The Plan Should Address:

- Actions to assist the States in advancing the network of regional alliances to protect ocean, coastal, and Great Lakes health;
- Evaluation of existing or new funding sources and options to protect, maintain, and restore ocean resources; and
- Legislative or regulatory changes necessary to simplify the sharing and transfer of resources among Federal, State, tribal, and local agencies.

Areas of Special Emphasis

1. **Resiliency and Adaptation to Climate Change and Ocean Acidification: Strengthen resiliency of coastal communities and marine and Great Lakes environments and their abilities to adapt to climate change impacts and ocean acidification.**

Obstacles and Opportunities

The ocean plays a central role in shaping the Earth's climate and influencing climate variability. Because of this important relationship and the ecosystem services that the ocean, our coasts, and Great Lakes provide, global climate change and its associated impacts as well as ocean acidification pose some of the most serious threats to these ecosystems and coastal communities. Warming ocean temperatures have a profound impact on the distribution of rainfall over land, the melting of ice sheets, and the distribution and productivity of species. Sea-level rise, increased severe storm events, rapid erosion, and salt water intrusion threaten low-lying coastal communities with the destruction of infrastructure, flood inundation, the potential displacement of millions of people, and the loss of key species and habitats. At the same time, climate change is predicted to lower the water levels of the Great Lakes, thereby altering water cycles and supply, habitat, and economic uses of the Lakes. In addition, ocean acidification is expected to have significant and largely negative impacts on the marine food web, ocean ecosystems as a whole, and biological diversity in general. Since climate change and ocean acidification may have widespread impacts,

increased coordination of monitoring and mapping efforts and improved understanding of the changes in the ocean are vital to minimizing these impacts on our marine and Great Lakes ecosystems and coastal communities. We have an opportunity and a responsibility to develop strategies for reducing the vulnerability, increasing the resilience, and improving adaptation of human and natural systems to climate change impacts, as well as for mitigating the effects of climate change itself.

The Plan Should Address:

- Research, observations and modeling needed to forecast regional and local scale climate change impacts and related vulnerabilities for natural resources, health, infrastructure, and livelihoods, including social and economic impacts;
- Better integration of ocean and coastal science into the broader climate dialogue and measures to improve understanding of the connections among land, water, air, ice, and human activities;
- Evaluation of potential social and economic costs related to sea-level rise, such as accelerating erosion, increased saltwater intrusion, and more severe coastal and inland flooding;
- Adaptive actions to identified climate change impacts and related vulnerabilities, such as ocean acidification, and the development of ecological and economic resilience strategies and priorities for research and monitoring to address these strategies;
- Changes to local and regional ocean and lake management systems that incorporate changing climate risks and elements of resilient systems; and
- A comprehensive approach to understanding human health implications of policies for the ocean, our coasts, and Great Lakes, and for identifying opportunities for the protection and enhancement of human health.

2. **Regional Ecosystem Protection and Restoration: Establish and implement an integrated ecosystem protection and restoration strategy that is science-based and aligns conservation and restoration goals at the Federal, State, tribal, local, and regional levels.**

Obstacles and Opportunities

Along our coasts and the Great Lakes, essential habitats continue to suffer significant losses and degradation due to coastal development, sea-level rise, and associated human activities. Impacts on these ecosystems and the people and communities in these areas are presenting new management challenges. Additionally, external stressors, including invasive species, are impacting native species and habitat. While progress has been made in addressing some of these challenges through ecosystem-based management, the threat of critical habitat loss and degradation of ecosystem services is still apparent in the Gulf Coast, the Chesapeake Bay, Puget Sound, South Florida, San Francisco Bay, and the Great Lakes. By addressing coastal and ocean challenges that cross jurisdictional boundaries and sectors on a regional and ecosystem scale, we can more effectively manage these resources. Because climate change is impacting our coastlines, it has become even more important to assess and place priorities on ecosystem restoration projects. These experiences provide valuable lessons for other coastal ecosystems.

The Plan Should Address:

- Prioritization of the locations and geographic scope of coastal and Great Lakes ecosystem restoration projects, including implementation of the Great Lakes Restoration Initiative;
- Interim and longer term goals and mechanisms to facilitate collaboration among stakeholders to implement projects;
- Best practices for collaborative science-based planning to achieve ecosystem restoration goals building on the lessons learned in ongoing ecosystem restoration efforts;
- Impacts of invasive species on ocean, coastal, and Great Lakes ecosystems, and a range of methodologies for control and prevention of these species; and
- Protection, maintenance, and restoration of populations and essential habitats supporting fisheries, protected species, ecosystems, and biological diversity.

3. **Water Quality and Sustainable Practices on Land: Enhance water quality in the ocean, along our coasts, and in the Great Lakes by promoting and implementing sustainable practices on land.**

Obstacles and Opportunities

Nonpoint source pollution (pollution that comes from diffuse sources instead of one specific point), caused by poor land management practices, is the leading cause of water quality problems in the United States and a major cause of rapidly declining ocean and coastal ecosystem health. Runoff from suburban streets and lawns, agricultural and industrial uses, transportation activities, and urban development – even hundreds of miles away – negatively impacts water quality, resulting in deleterious effects on ocean, coastal, and Great Lakes systems as evidenced by harmful algal blooms, expansive dead zones, marine debris, and increased incidents of human illness. Areas with particularly poor water quality are known to experience frequent beach closures, massive fish kills, and areas of toxic sediments. Since this pollution comes from many diffuse sources throughout the country, addressing it requires a strong commitment to coordination and cooperation between multiple sectors and among Federal, State, tribal, local authorities, and regional governance structures. Fortunately, a number of point and non-point source prevention programs are available to Federal, State, tribal, local, regional, and private entities to reduce the amount of pollutants that are transported from our Nation's watersheds and into our coastal waters. There are opportunities to achieve significant reductions in these inputs to our coasts and ocean through concrete mechanisms that integrate and coordinate land-based pollution reduction programs.

The Plan Should Address:

- The major impacts of urban and suburban development and agriculture, including forestry and animal feedlots, on ocean, coastal, and Great Lakes waters;
- The relative contributions of significant land-based sources of pollutants, sediments, and nutrients to receiving coastal waters and ways to address them, including recommendations of how to integrate and improve existing land-based conservation and pollution programs;
- Best management practices, use of conservation programs, and other approaches for controlling the most significant land-based sources of nutrients, sediments, pathogens, toxic chemicals, solid waste, marine debris, and invasive species; and
- The establishment of a comprehensive monitoring framework and integration with State monitoring programs.

4. **Changing Conditions in the Arctic: Address environmental stewardship needs in the Arctic Ocean and adjacent coastal areas in the face of climate-induced and other environmental changes.**

Obstacles and Opportunities

Climate change is having a disproportionally greater impact on polar regions than elsewhere, and the Arctic region is faced with serious problems. Permafrost is thawing at an accelerated rate, which leads to the release of large amounts of methane. Multi-seasonal sea ice is rapidly deteriorating. Much of the Alaskan Arctic seashore is threatened by coastal erosion and other environmental challenges. Increased human activity in the area is bringing additional stressors to the Arctic environment, with serious implications for Arctic communities and ecosystems. At the same time, the diminishing ice presents opportunities and pressures for increased development of living and non-living resources and for increased commerce and transportation. Working with all of the stakeholders, including the indigenous communities, we have the opportunity to develop proactive plans, informed by the best science available, to manage and encourage use while protecting the fragile Arctic environment.

The Plan Should Address:

- Better ways to conserve, protect, and sustainably manage Arctic coastal and ocean resources, effectively respond to the risk of increased pollution and other environmental degradation on humans and marine species, and adequately safeguard living marine resources;

- New collaborations and partnerships to better monitor and assess environmental conditions and devise early warning and emergency response systems and procedures to be prepared for and respond to emerging events in the Arctic region, such as environmental disasters;

- Consistency and coordination with the implementation of United States Arctic Region Policy as promulgated in National Security Presidential Directive 66/Homeland Security Presidential Directive 25 (2009); and

- Improvement of the scientific understanding of the Arctic system and how it is changing in response to climate-induced and other changes.

5. **Ocean, Coastal, and Great Lakes Observations, Mapping, and Infrastructure: Strengthen and integrate Federal and non-Federal ocean observing systems, sensors, data collection platforms, data management, and mapping capabilities into a national system and integrate that system into international observation efforts.**

Obstacles and Opportunities

Our ability to understand weather, climate, and ocean conditions, to forecast key environmental processes, and to strengthen ocean management decision-making at all levels is informed by a sound knowledge base. Efficient and effective coordination of the many available tools, continued development of new tools and infrastructure, and integration of them into a cohesive, unified, robust system is becoming increasingly difficult as an ever increasing number of data collection and processing systems come on line. New ground-breaking observation technologies give us the ability to observe and study global processes at all scales. These new tools, if fully integrated, will significantly advance our knowledge and understanding of the ocean, our coasts, and the Great Lakes. Furthermore, successful integration of new tools and data will improve our ability to engage in science-based decision-making and ecosystem-based management by ensuring that biological, ecological, and social data and processes are included in the calculus.

The Plan Should Address:

- A nationally integrated system of ocean, coastal, and Great Lakes observing systems, comprised of Federal and non-Federal components, and cooperation with international partners and organizations, as appropriate;

- Regional and national needs for ocean information, to gather specific data on key ocean, coastal, and Great Lakes variables that are required to support the areas of special emphasis and other national needs;

- The use of unmanned vehicles and remote sensing platforms and satellites to gather data on the health and productivity of the ocean, our coasts, and the Great Lakes;

- The capabilities and gaps of the National Oceanographic Fleet of ships and related facilities; and

- Data management, communication, access, and modeling systems for the timely integration and dissemination of data and information products.

PART FOUR. THE FRAMEWORK FOR EFFECTIVE COASTAL AND MARINE SPATIAL PLANNING

I. Introduction

Coastal and marine spatial planning is one of the nine priority objectives in the recommendations. This framework for CMSP in the United States provides a definition of CMSP, identifies the reasons for engaging in CMSP, and describes its geographic scope. It articulates national CMSP goals and guiding principles that would be adhered to in CMSP efforts and the eventual development and implementation of coastal and marine spatial plans. In addition, this framework describes how CMSP and CMS Plans would be regional in scope and developed cooperatively among Federal, State, tribal, local authorities, and regional governance structures, with substantial stakeholder and public input.

II. What is Coastal and Marine Spatial Planning?

CMSP is a comprehensive, adaptive, integrated, ecosystem-based, and transparent spatial planning process, based on sound science, for analyzing current and anticipated uses of ocean, coastal, and Great Lakes areas. CMSP identifies areas most suitable for various types or classes of activities in order to reduce conflicts among uses, reduce environmental impacts, facilitate compatible uses, and preserve critical ecosystem services to meet economic, environmental, security, and social objectives. In practical terms, CMSP provides a public policy process for society to better determine how the ocean, coasts, and Great Lakes are sustainably used and protected - now and for future generations.

III. Why Coastal and Marine Spatial Planning?

The Nation's interests in the ocean, our coasts, and the Great Lakes support a growing number of significant and often competing uses and activities, including commercial, recreational, cultural, energy, scientific, conservation, and homeland and national security activities. Combined, these activities profoundly influence and benefit coastal, regional, and national economies and cultures. However, human uses of our ocean, coasts, and the Great Lakes are expanding at a rate that challenges our ability to plan and manage them under the current sector-by-sector approach. While many existing permitting processes include aspects of cross-sectoral planning (through, for example, the process governed by the National Environmental Policy Act), most focus solely on a limited range of management tools and outcomes (e.g., oil and gas leases, fishery management plans, and marine protected areas). Missing from this picture is a more integrated, comprehensive, ecosystem-based, flexible, and proactive approach to planning and managing these uses and activities. This new approach would be national in scope to address national interests, but also scalable and specific to regional and local needs. Without such an improved approach, we risk an increase in user conflicts, continued planning and regulatory inefficiencies with their associated costs and delays, and the potential loss of critical economic, ecosystem, social, and cultural services for present and future generations.

Traditional, New, and Expanding Ocean, Coastal, And Great Lakes Uses

The ocean, our coasts, and the Great Lakes are home to and support myriad important human uses. CMSP provides an effective process to better manage a range of social, economic, and cultural uses, including:

- Aquaculture (fish, shellfish, and seaweed farming)
- Commerce and Transportation (e.g., cargo and cruise ships, tankers, and ferries)
- Commercial Fishing
- Environmental/Conservation (e.g., marine sanctuaries, reserves, national parks, and wildlife refuges)
- Maritime Heritage and Archeology
- Mining (e.g., sand and gravel)
- Oil and Gas Exploration and Development
- Ports and Harbors
- Recreational Fishing
- Renewable Energy (e.g., wind, wave, tidal, current, and thermal)
- Other Recreation (e.g., boating, beach access, swimming, surfing, nature and whale watching, and diving)
- Scientific Research and Exploration
- Security, Emergency Response, and Military Readiness Activities
- Subsistence Uses
- Tourism
- Traditional Hunting, Fishing, and Gathering
- Working Waterfronts

Recent scientific and ocean policy assessments have demonstrated that a fundamental change in our current management system is required to achieve the long-term health of our ocean, coasts, and Great Lakes in order to sustain the services and benefits they provide to society. The present way we

manage these areas cannot properly account for cumulative effects, sustaining multiple ecosystem services, and holistically and explicitly evaluating the tradeoffs associated with proposed alternative human uses.

Scientific understanding and information are central to achieving an integrated and transparent planning process. Natural and social sciences can inform decisions about how to achieve societal objectives from the Nation's ocean, coastal, and Great Lakes waters, both now and into the future, while maintaining ecosystem integrity. Built on this foundation of sound science, this new system for planning should facilitate maintenance of essential ecosystem services, encourage compatible uses, minimize conflicts, evaluate tradeoffs in an open and transparent manner, and include significant and meaningful stakeholder involvement.

CMSP can facilitate sustainable economic growth. For instance:

In the Netherlands-
A "preferred sand mining area" has been identified within its territorial sea. This use allocation through marine spatial planning will allow sand extraction closer to shore at less cost to both the private sector and the government, especially in the next 20 years when it is used for coastal adaptation to anticipated climate change.

In Germany-
An environmental assessment for a wind farm permit costs about €1 million (US$1.5 million) to prepare. Because the federal government has already prepared a Strategic Environmental Assessment for its marine spatial plan that includes priority areas for wind farms, costs of preparing and reviewing an environmental assessment for every permit proposed in a "Priority Wind Farm Area" will be reduced or avoided.

The Benefits of CMSP

As recommended in this framework, CMSP is intended to yield substantial economic, ecological, and social benefits. To do so, it must fully incorporate the principles of sound science for ecosystem-based and adaptive management, be transparent, and be informed by stakeholders and the public. Many have raised concerns regarding whether CMSP would result in additional layers of regulatory review or delays in decision-making. To the contrary, CMSP is intended to build upon and significantly improve existing Federal, State, tribal, local, and regional decision-making and planning processes. Thus, while the development of CMSP would require significant initial investments of both human and financial resources, these investments are expected to result in substantial benefits. Several States, regions, and other nations have already recognized the many advantages of marine spatial planning, undertaken the planning process, and are eager to take positive steps to realize those advantages.

CMSP is intended to facilitate sustainable economic growth in coastal communities by providing transparency and predictability for economic investments in coastal, marine, and Great Lakes industries, transportation, public infrastructure, and related businesses. CMSP could promote national objectives such as enhanced national energy security and trade and provide specific economic incentives (e.g., cost savings and more predictable and faster project implementation) for commercial users.

CMSP allows proactive planning to integrate a wide range of ecosystem services. For instance:

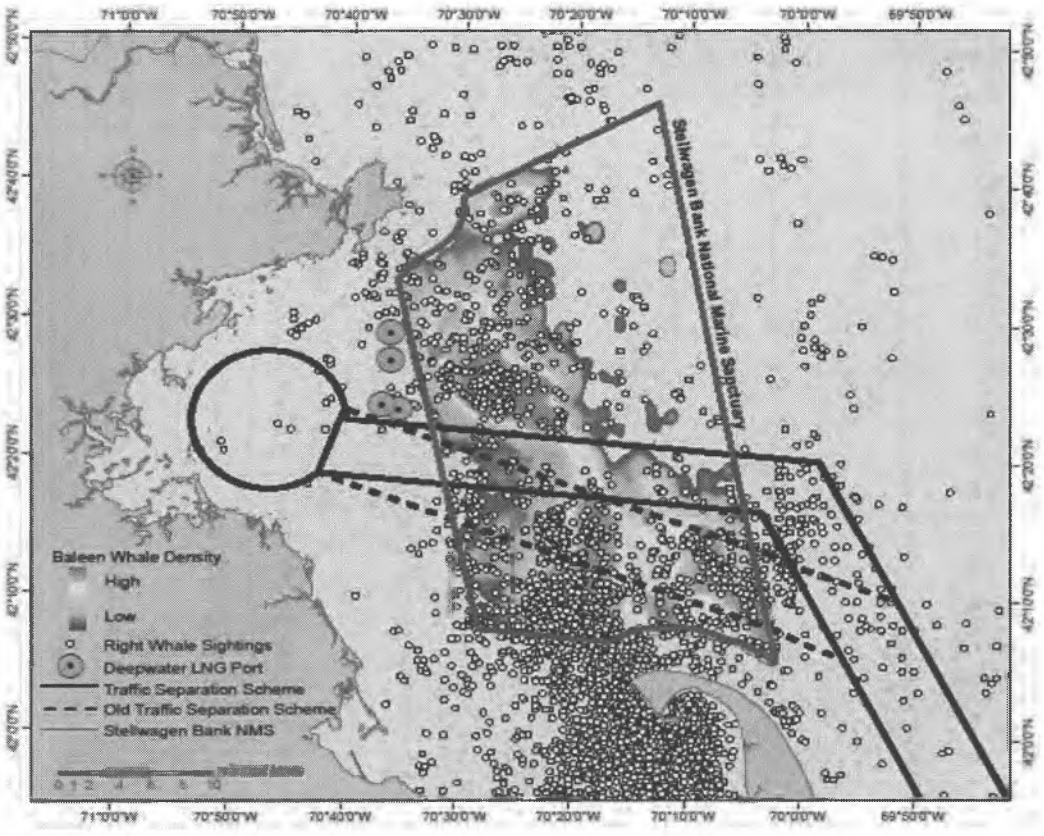
Provisioning
Energy, Seafood, Biomedical

Regulating and Supporting
Flood Prevention, Biological Diversity Maintenance, Climate Regulation, Erosion Control, Control of Pests and Pathogens, Nutrient Recycling, and Primary Production

Cultural Services
Education, Recreational, Heritage, and Spiritual

CMSP is intended to improve ecosystem health and services by planning human uses in concert with the conservation of important ecological areas, such as areas of high productivity and biological diversity; areas and key species that are critical to ecosystem function and resiliency; areas of spawning, breeding, and feeding; areas of rare or functionally vulnerable marine resources; and migratory corridors. Enhanced ecosystem services and benefits can be attained through CMSP because they are centrally incorporated into the CMS Plan as desired outcomes of the process and not just evaluated in the context of individual Federal or State agency action. CMSP allows for a comprehensive look at multiple sector demands which would provide a more complete evaluation of cumulative effects. This ultimately is intended to result in protection of areas that are essential for the resiliency and maintenance of healthy ecosystem services and biological diversity, and to maximize the ability of marine resources to continue to support a wide variety of human uses.

Example of the Potential Benefits of CMSP: Stellwagen Bank National Marine Sanctuary



Comprehensive planning enabled NOAA, the United States Coast Guard, and several other government agencies and stakeholders to examine shipping needs, proposed deepwater liquefied natural gas port locations, and endangered whale distribution in a successful effort to reconfigure the Boston Traffic Separation Scheme (TSS) to reduce the risk of whale mortality due to collisions with ships in the Stellwagen Bank National Marine Sanctuary. The reconfigured TSS reduced risk of collision by an estimated 81% for all baleen whales and 58% for endangered right whales. Industry TSS transit times increased by only 9 – 22 minutes (depending on speed) and conflict with deepwater ports was eliminated. In addition, the new route decreased the overlap between ships using the TSS, commercial fishing vessels, and whale watch vessels, thereby increasing maritime safety. CMSP has the significant potential of applying this integrated, multi-objective, multi-sector approach on a broader and sustained scale.

Diagram Courtesy of NOAA/Stellwagen Bank National Marine Sanctuary

From a societal perspective, CMSP would improve opportunities for community and citizen participation in open planning processes that would determine the future of the ocean, our coasts, and the Great Lakes. For example, the CMSP process would recognize the social, economic, public health, and conservation benefits of sustainable recreational use of ocean, coastal, and Great Lakes resources (e.g., fishing, boating, swimming, and diving), by providing improved coordination with recreational users to ensure consideration of continued access and opportunities to experience and enjoy these activities consistent with safety and conservation goals. Integrated engagement and coordination should result in stronger and more diverse ocean, coastal, and Great Lakes stewardship, economies, and communities. Moreover, CMSP can assist managers in planning activities to sustain cultural and recreational uses, human health and safety, and the continued security of the United States. For

instance, CMSP would help to ensure that planning areas identified as important for public use and recreation are not subject to increased risk of harmful algal blooms, infectious disease agents, chemical pollution, or unsustainable growth of industrial uses.

IV. Integration, Cooperation, and Coordination

Strong partnerships among Federal, State, tribal, and local authorities, and regional governance structures would be essential to a truly forward-looking, comprehensive CMSP effort. One of the significant benefits of CMSP is to improve the ability of these authorities to seamlessly coordinate their objectives with broader planning efforts by participating in the CMSP process for areas within and beyond their jurisdictional waters. Many States and regional governance structures have already engaged in some form of comprehensive marine planning and CMSP would build upon and incorporate these efforts. Also, the United States has a unique legal relationship with federally-recognized American Indian and Alaska Native tribal governments. These tribal governments, and the indigenous populations in Hawaii and the United States Commonwealths and Territories, are integrally linked to the maritime realm and would play an important role in CMSP.

The United States shares maritime and Great Lakes boundaries with a number of countries and has the world's largest EEZ and an extensive Continental Shelf. The development of CMSP provides opportunities for engagement with other countries, in coordination with the Department of State and other relevant agencies. The views and decisions of relevant international fora should be taken into account, where appropriate, in CMSP and the development of CMS Plans.

The ability for States and tribes to participate in the CMSP process for areas within and beyond their respective jurisdictions can afford the following potential opportunities and incentives:

- Encourage and inform the Federal government to better manage resources or address processes that transcend jurisdictional boundaries;
- Define local and regional objectives and develop and implement CMSP in a way that is meaningful to regionally specific concerns;
- Leverage, strengthen, and magnify local planning objectives through integration with regional and national planning efforts;
- Proactively address concerns over proposed activities impacting State and tribal interests and minimize use conflicts before they escalate;
- Leverage support from the Federal government to build CMSP capacity, access CMSP data, and acquire scientific, technical, and financial assistance;
- Access data through CMSP portal(s) and utilize science tools developed, established, and maintained for CMSP efforts;
- Benefit from sustained Federal participation on the regional planning bodies that consist of representatives empowered to make decisions and commitments on behalf of their respective agencies, in turn helping to integrate and improve decision-making;
- Provide a clearer and easier point of access for all Federal agencies with regard to ocean, coastal, and Great Lakes issues; and
- Achieve regulatory efficiencies, reduction in administrative delays, and cost savings.

Similarly, as the United States is a leader in various international fora that deal with marine issues, the United States should introduce relevant aspects of CMSP for consideration by such bodies.

V. Public and Stakeholder Engagement

In addition to coordination and cooperation among all levels of government, robust public and stakeholder engagement is integral to a successful CMSP process. Given the multi-objective nature of CMSP it is critical to ensure there are numerous opportunities for a broad range of input to gain a better understanding of the human uses and influences on the planning area, and expectations, interests, and requirements for the future. Including a broad range of interests throughout the planning and implementation of CMSP is necessary to strengthen mutual and shared understanding about relevant problems and opportunities and will better inform the process and its outcomes.

VI. The Authority for Coastal and Marine Spatial Planning

Federal statutes often include authorizing language that explicitly gives agencies the responsibility to plan and implement the objectives of the statutes. Moreover, several Federal statutes specifically authorize agency planning with respect to the ocean, coastal, and Great Lakes environments. Federal agencies and departments also administer a range of statutes and authorized programs that provide a legal basis to implement CMSP. These statutory and regulatory authorities may govern the process for making decisions (e.g., through Administrative Procedure Act rulemaking and adjudications) and not just the ultimate decisions made. The processes and decision-making CMSP envisions would be carried out consistent with and under the authority of these statutes. State, tribal, and local authorities also have a range of existing authorities to implement CMSP, although this will vary among and within regions. This framework for CMSP is to provide all agencies with agreed upon principles and goals to guide their actions under these authorities, and to develop mechanisms so that Federal, State, tribal, and local authorities, and regional governance structures can proactively and cooperatively work together to exercise their respective authorities.

An agency or department's capacity to internalize the elements of any particular CMS Plan would vary depending on the nature of applicable statutes. CMSP is intended to provide a better framework for application of these existing laws and agency authorities, but is not intended to supersede them. Where pre-existing legal constraints, either procedural or substantive, are identified for any Federal agency, the NOC would work with the agency to evaluate necessary and appropriate legislative solutions or changes to regulations to address the constraints. In the interim, agencies would comply with existing legal requirements but should endeavor, to the maximum extent possible, to integrate their actions with those of other partners to a CMS Plan.

VII. The National Goals of Coastal and Marine Spatial Planning

For CMSP to be successful, it must be based on clear, broad-based goals that define the desired outcomes to be achieved. CMSP in the United States would be developed and implemented to further the following goals:

1. Support sustainable, safe, secure, efficient, and productive uses of the ocean, our coasts, and the Great Lakes, including those that contribute to the economy, commerce, recreation, conservation, homeland and national security, human health, safety, and welfare;

2. Protect, maintain, and restore the Nation's ocean, coastal, and Great Lakes resources and ensure resilient ecosystems and their ability to provide sustained delivery of ecosystem services;

3. Provide for and maintain public access to the ocean, coasts, and Great Lakes;

4. Promote compatibility among uses and reduce user conflicts and environmental impacts;

5. Improve the rigor, coherence, efficiency, and consistency of decision-making and regulatory processes;

6. Increase certainty and predictability in planning for and implementing new investments for ocean, coastal, and Great Lakes uses; and

7. Enhance interagency, intergovernmental, and international communication and collaboration.

VIII. The National Guiding Principles for Coastal and Marine Spatial Planning

In order to achieve the national goals of CMSP, planning efforts are to be guided by the following principles:

1. CMSP would use an ecosystem-based management approach that addresses cumulative effects to ensure the protection, integrity, maintenance, resilience, and restoration of ocean, coastal, and Great Lakes ecosystems, while promoting multiple sustainable uses.

2. Multiple existing uses (e.g., commercial fishing, recreational fishing and boating, subsistence uses, marine transportation, sand and gravel mining, and oil and gas operations) and emerging uses (e.g., off-shore renewable energy and aquaculture) would be managed in a manner that reduces conflict, enhances compatibility among uses and with sustained ecosystem functions and services, provides for public access, and increases certainty and predictability for economic investments.

3. CMSP development and implementation would ensure frequent and transparent broad-based, inclusive engagement of partners, the public, and stakeholders, including with those most impacted (or potentially impacted) by the planning process and with underserved communities.

4. CMSP would take into account and build upon the existing marine spatial planning efforts at the regional, State, tribal, and local level.

5. CMS Plans and the standards and methods used to evaluate alternatives, tradeoffs, cumulative effects, and sustainable uses in the planning process would be based on clearly stated objectives.

6. Development, implementation, and evaluation of CMS Plans would be informed by

sound science and the best available information, including the natural and social sciences, and relevant local and traditional knowledge.

7. CMSP would be guided by the precautionary approach as reflected in Principle 15 of the Rio Declaration, "Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation."

8. CMSP would be adaptive and flexible to accommodate changing environmental conditions and impacts, including those associated with global climate change, sea-level rise, and ocean acidification; and new and emerging uses, advances in science and technology, and policy changes.

9. CMSP objectives and progress toward those objectives would be evaluated in a regular and systematic manner, with public input, and adapted to ensure that the desired environmental, economic, and societal outcomes are achieved.

10. The development of CMS Plans would be coordinated and compatible with homeland and national security interests, energy needs, foreign policy interests, emergency response and preparedness plans and frameworks, and other national strategies, including the flexibility to meet current and future needs.

11. CMS Plans would be implemented in accordance with customary international law, including as reflected in the Law of the Sea Convention, and with treaties and other international agreements to which the U.S. is a party.

12. CMS Plans would be implemented in accordance with applicable Federal and State laws, regulations, and Executive Orders.

IX. Geographic Scope of Coastal and Marine Spatial Planning

The geographic scope of the planning area for CMSP in the United States includes the territorial sea, the EEZ, and the Continental Shelf. The geographic scope of the planning area would extend landward to the mean high-water line. The geographic scope for the Great Lakes would extend from the ordinary high-water mark and include the lakebed, subsoil, and water column to the limit of the United States and Canada international boundary, as maintained by the International Boundary Commission, and includes Lake St. Clair and the connecting channels between lakes. Privately owned lands as defined by law would be excluded from the geographic scope.

The geographic scope would include inland bays and estuaries in both coastal and Great Lakes settings. Inclusion of inland bays and estuaries is essential because of the significant ecological, social, and economic linkages between these areas with offshore areas. Additional inland areas may be included in the planning area as the regional planning bodies, described in Section X of this Part, deem appropriate. Regardless, consideration of inland activities would be necessary to account for the significant interaction between upstream activities and ocean, coastal, and Great Lakes uses and ecosystem health. Likewise, consideration would also be given to activities occurring beyond the EEZ and continental shelf that may influence resources or activities within the planning area.

The Great Lakes and CMSP

Great Lakes resources are governed in part by a body of law, treaties, and regional policy that is distinct from our ocean and other coastal areas. Of paramount significance is the Great Lakes Water Quality Agreement (GLWQA) with Canada and its implementation under various Federal laws that commit each country to restore and maintain the chemical, physical, and biological integrity of the Great Lakes through use of ecosystem-based management. However, while various Federal regulatory authorities apply in the United States Great Lakes, the submerged lands underlying them are largely under the jurisdiction and ownership of the Great Lakes States.

CMSP efforts in the Great Lakes would be complementary to and closely coordinated with the GLWQA and other Great Lakes initiatives and authorities, such as the President's Great Lakes Restoration Initiative and Executive Order 13340, which established a cabinet-level Great Lakes Interagency Task Force, its Regional Working Group, and a multi-stakeholder Great Lakes Regional Collaboration.

Land-based Activities and Their Relation to CMSP

Although the geographic scope of the CMSP area in the United States would not include upland areas unless a regional planning body determines to include them, the health and well-being of the ocean, our coasts, and the Great Lakes are in large part the result of the interrelationships among land, water, air, and human activities. Effective management of environmental health and services, maritime economies, commerce, national and homeland security interests, and public access necessitate connecting land-based planning efforts with ocean, coastal, and Great Lakes planning. Thus, successful implementation of CMSP would ultimately depend upon a better integration of coastal planning that considers influences from, and activities within, coastal watersheds and other contributing land areas. Land-based watershed planning efforts (e.g., components of the Great Lakes Restoration Initiative Action Plan) should inform and influence CMSP within each region. Similarly, ocean, coastal, and Great Lakes activities that affect land-based ecosystems should be considered and accounted for during CMSP efforts using the existing State and Federal programs including the Coastal Zone Management Act (CZMA), Clean Water Act, Clean Air Act, and other relevant authorities. It is the intent of the CMSP process to better understand how current mandates and programs interact towards the common goals of CMSP and, in doing so, to better coordinate, and where appropriate, strengthen their collective

benefits. In addition, watershed monitoring, terrestrial observation activities, and ocean, coastal, and Great Lakes observation systems should be linked to provide the necessary information on interactions and impacts across the land-sea boundary.

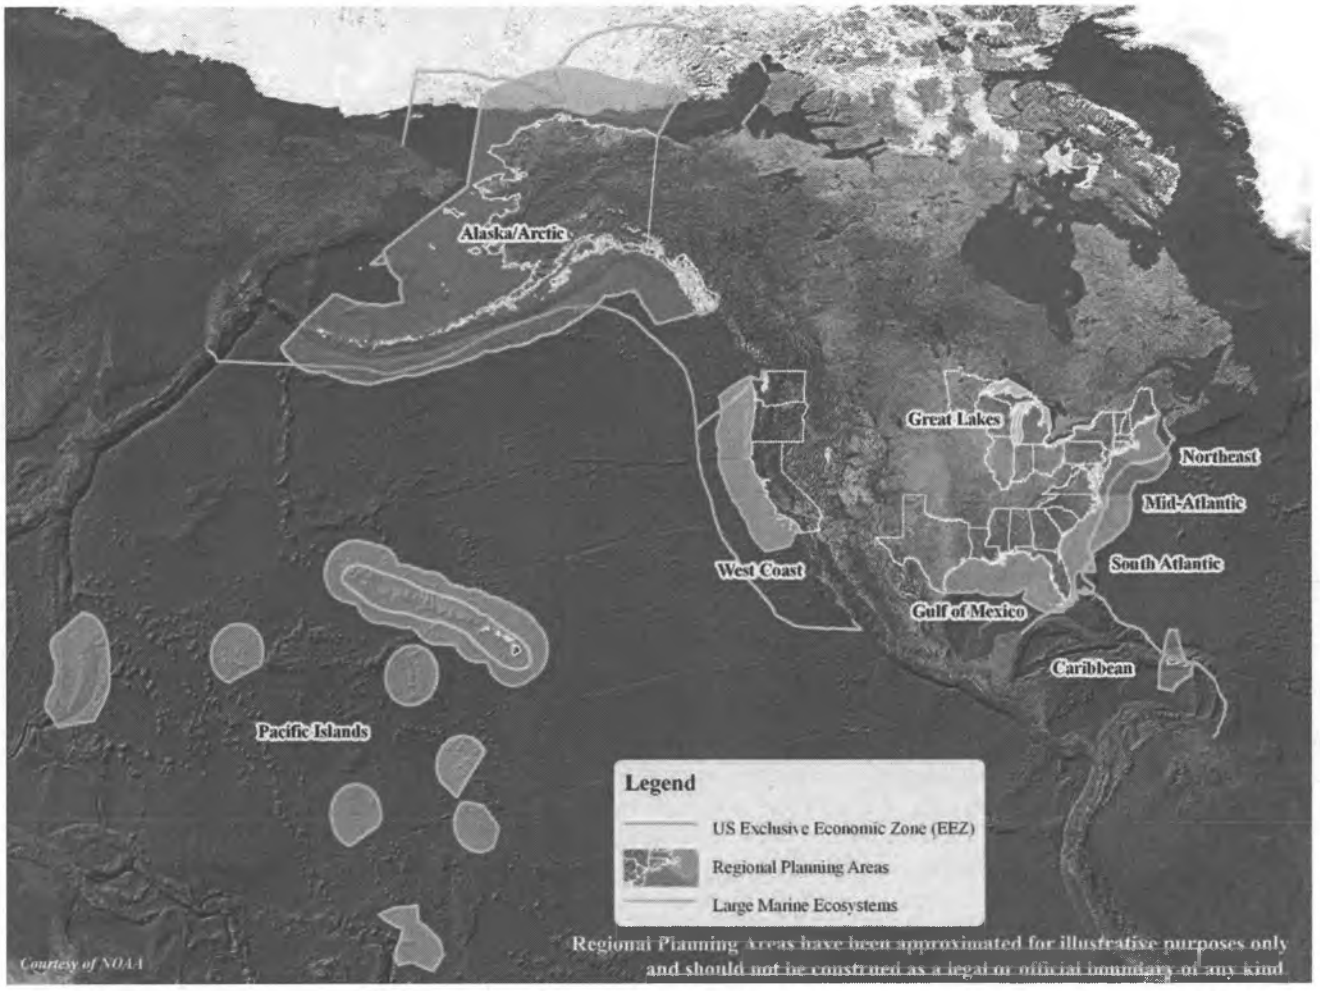
X. Development and Implementation of Coastal and Marine Spatial Planning

CMSP would be developed and implemented using a regional approach to allow for the variability of economic, environmental, and social aspects among different areas of the United States. This section describes the regional approach, recommended steps, and the essential elements to be included in the development and implementation of CMSP.

Given the importance of conducting CMSP from an ecosystem-based perspective, combined with the likely involvement of existing regional governance structures in developing plans, a consistent planning scale with which to initiate CMSP is at the large marine ecosystem (LME) scale.[7] These recognized LMEs were defined on the basis of consistent ecological conditions and other factors. Overall, the boundaries of regional governance structures for the Northeast, Mid-Atlantic, South Atlantic, Gulf Coast, and West Coast lie within LME boundaries. This regional approach, consistent with the LMEs, would also be applied to the Great Lakes, Alaska, the Pacific Islands, and the Caribbean. Therefore, for CMSP purposes, the United States would be subdivided into nine regional planning areas based on LMEs, with modifications as necessary to ensure inclusion of the entire U.S. EEZ and Continental Shelf and to allow for incorporation of existing state or regional ocean governance bodies. The NOC would facilitate the development of regional CMS Plans for those areas.

[7] The U.S. ocean and coastal waters hold all or parts of eleven LMEs: the West Bering Sea, East Bering Sea, Chukchi Sea, Beaufort Sea, Gulf of Alaska, California Current, Gulf of Mexico, Southeast U.S. Continental Shelf, Northeast U.S. Continental Shelf, Insular Pacific-Hawaiian, and the Caribbean Sea. For representational purposes only, the five Alaskan LMEs are depicted as a single complex in the map on page 52. Although, as a large fresh-water system, the Great Lakes are not usually considered an LME, they do represent a large regional ecosystem of similar scale and are considered as such for this framework. Further detail on LMEs can be found at: http://www.lme.noaa.gov.

Large Marine Ecosystems and Regional Planning Areas



Regional Planning Body

The NOC would work with the States[8] and federally-recognized tribes, including Alaska Native Villages, to create regional planning bodies – coinciding with the regional planning areas – for the development of regional CMS Plans. The membership of each of the nine regional planning bodies would consist of Federal, State, and tribal authorities relevant to CMSP for that region (e.g., resource management, including coastal zone management and fisheries management, science, homeland and national security, transportation, and public health). Members would be of an appropriate level of responsibility within their respective governing body to be able to make decisions and commitments throughout the process. Each regional planning body would identify Federal and non-Federal co-leads.[9] Appropriate State and tribal representation would be determined by applicable States and tribes, consistent with the types of representation described by the NOC per Section XVI of this Part. Regional planning bodies would develop a mechanism to engage other indigenous community representatives

[8] For purposes of this framework, "States" also include the Commonwealth of Puerto Rico, the U.S. Virgin Islands, Guam, the Commonwealth of the Northern Mariana Islands, and American Samoa.

[9] Each regional planning body would have one Federal co-lead, one State co-lead, and, as appropriate, one tribal co-lead. The co-leads would be responsible for guiding and facilitating the timely progress of the CMSP process, but would not have final decision-making authority.

with jurisdictional responsibilities or interests relevant to CMSP, as well as coordinate with appropriate local authorities throughout the CMSP process. In addition, the regional planning bodies would provide a formal mechanism for consultation with the Regional Fishery Management Councils (RFMCs) across their respective regions on fishery related issues given their unique statutory responsibilities under the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) and quasi-regulatory role in fisheries management.[10] The NOC would prepare guidance for regional planning bodies in meeting these consultative process requirements in order to ensure consistency across regions. In the future, if other statutorily-mandated or quasi-regulatory groups are identified, the NOC would determine whether a formal mechanism for consultation should be developed for such groups and, if necessary, provide guidance for regional planning bodies on the development of such a process.

Nine Proposed Regional Planning Areas and Corresponding Minimum State Representation

1. **Alaska /Arctic Region:** Alaska
2. **Caribbean Region:** Puerto Rico and U.S Virgin Islands
3. **Great Lakes Region:** Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, and Wisconsin
4. **Gulf of Mexico Region:** Alabama, Florida, Louisiana, Mississippi, and Texas
5. **Mid-Atlantic Region:** Delaware, Maryland, New Jersey, New York, Pennsylvania, and Virginia
6. **Northeast Region:** Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont
7. **Pacific Islands Region:** Hawaii, Commonwealth of the Northern Mariana Islands, American Samoa, and Guam
8. **South Atlantic Region:** Florida, Georgia, North Carolina, and South Carolina
9. **West Coast Region:** California, Oregon, and Washington

Each regional planning body[11] should make every effort to ensure representation from all States within a region, ideally through, or as part of, the existing regional governance structures created by or including the States to address cross-cutting issues, including regional planning. Given that activities that happen outside of the planning area of each regional planning body may affect CMSP decisions in that area, ex officio membership on these bodies could be extended to adjacent coastal States to help integrate and enhance consistency among regions. Inland States may also be afforded membership, as determined appropriate by the regional planning body. It is also recognized that the United States shares maritime boundaries with other nations (e.g., Canada and Mexico) and the regional planning bodies for those respective areas may include ex officio representatives or observers from these nations.

[10] There are no Regional Fishery Management Councils in the Great Lakes Region, but the Great Lakes regional planning body should work with the Great Lakes Fishery Commission and other relevant entities, as appropriate.

[11] The Task Force based the State membership of the nine regional planning areas in part on the membership of the existing regional governance structures, where they exist, with the following one exception: Pennsylvania was added to the Mid-Atlantic Region, in addition to the Great Lakes Region, because Pennsylvania has a coastline on the Delaware River that would, under the defined geographic scope, be included in the CMSP regional planning area.

Furthermore, there would be flexibility to develop sub-regional plans provided that these plans are encompassed in an overarching regional CMS Plan and overseen by the regional planning body. This construct may be particularly useful in the Alaska/Arctic and Pacific Islands Regions given the geographic breadth, the logistical constraints of coordinating resources across a region that spans the international dateline, and that multiple LMEs are encompassed by the Alaska/Arctic Region.

CMSP Development Agreement

The members of each regional planning body (the "partners") would prepare and execute a CMSP Development Agreement, a model of which the NOC would develop as described in Section XVI of this Part. The Development Agreement would be an express commitment to work cooperatively to engage in CMSP and develop eventual CMS Plans, identify the regional planning body members for each of the partners, and define ground rules, roles, and responsibilities of the partners.

Dispute Resolution Process

CMSP would provide a process for resolving conflicts should members of the regional planning bodies disagree during the development or modification of CMS Plans and in the interpretation of NOC-certified CMS Plans. The NOC would develop this process, in cooperation with the GCC, to ensure consistency from region to region. This process would be designed in a way to ensure that most disputes would be resolved at the regional level. If a conflict cannot be resolved at the regional level, the regional planning body leads would elevate the issue to the NOC for resolution, via the NOC resolution process outlined earlier. In those instances in which such a conflict reflects a dispute between Federal and non-Federal members at the regional level, the NOC would consult with the GCC as part of this process. Disputes regarding a specific agency's decisions pursuant to its statutory authority would be addressed through the various procedures and mechanisms available under that authority or other relevant authorities (e.g., Administrative Procedure Act).

Work Plan

Each regional planning body would develop a formal regional work plan that describes the agreed-upon process for CMSP and development of CMS Plans (including all essential elements), specifies members, identifies co-leads, establishes key milestones, identifies resources, specifies time frames, and addresses the essential elements required for the planning process, as defined below. The work plan would allow flexibility to account for the particular circumstances of a given region (e.g., if a region has existing State plans). In addition, each work plan would specify a formal mechanism for consultation to engage the RFMCs within the region as well as a mechanism to engage the indigenous community representatives. The work plan should also describe how the regional planning body would coordinate with appropriate local authorities. The NOC would review and approve each regional work plan prior to its implementation.

Essential Elements of the CMSP Process

Essential Elements of the CMSP Process

- Identify Regional Objectives
- Identify Existing Efforts that Should Help Shape the Plan throughout the Process
- Engage Stakeholders and the Public at Key Points throughout the Process
- Consult Scientists and Technical and Other Experts
- Analyze Data, Uses, Services, and Impacts
- Develop and Evaluate Alternative Future Spatial Management Scenarios and Tradeoffs
- Prepare and Release for Public Comment a Draft CMS Plan with Supporting Environmental Impact Analysis Documentation
- Create a Final CMS Plan and Submit for NOC Review
- Implement, Monitor, Evaluate, and Modify (as needed) the NOC-certified CMS Plan

The CMSP process consists of a series of steps that would eventually lead to the development of a comprehensive, multi-sectoral, and multi-objective CMS Plan. Although the CMSP process envisions optimum flexibility among and within regions, the following essential elements – and how the partners plan to accomplish them – would need to be addressed in the work plan in order to ensure a level of national consistency across regions. The process would be adaptive and refined as regions gain experience with CMSP.

- **Identify Regional Objectives:** Each region would define and agree upon a set of specific and measurable regional objectives that provide clear direction, outcomes, and timeframes for completion. These regional objectives would be consistent with the national goals and principles identified in this framework and with any national objectives the NOC has articulated for purposes of CMSP. These objectives would serve as a statement of purpose and need for action to guide the planning process and eventual development of an ecosystem-based, comprehensive, integrated CMS Plan.

- **Identify Existing Efforts that Should Help Shape the Plan throughout the Process:** The regional planning body would identify existing efforts (e.g., State and Federal ocean plans, data management efforts, and CMSP decision products) that would allow the regional plan to build on existing work. This work should be leveraged and expanded to enable a more

organic and holistic approach that would advance the region as a whole while not duplicating or hindering existing and ongoing efforts. These existing efforts can include those that are region-wide, State focused, or more site-specific marine spatial plans or efforts (e.g., Great Lakes Restoration Initiative Action Plan, Massachusetts Ocean Plan, Rhode Island Ocean Special Area Management Plan, or National Marine Sanctuary management plans), as well as issue-specific plans that seek to incorporate some aspects of CMSP approaches and principles (e.g., ocean energy and fishery management plans), as appropriate.

- **Engage Stakeholders and the Public at Key Points throughout the Process:** The regional planning body would ensure there is frequent and regular stakeholder engagement throughout all phases of the CMSP process, including development, adoption, implementation, evaluation, and adaptive management phases. To better ensure all concerns and ideas are considered, stakeholder engagement should be emphasized with those most impacted (or potentially impacted) by the planning process. Considerations should also be given to ensuring inclusion of underserved communities. Regions would establish an inclusive and transparent process for stakeholder participation (or, if applicable, utilizing an existing process) that ensures engagement with a representative balance of major social, cultural, economic, environmental, recreational, human health, and security interests. The regional planning body should also identify previous stakeholder input to regional or State CMSP efforts including the existing documentation on their input and needs. Stakeholder and public participation would be sought through a variety of robust participatory mechanisms that may include, but are not limited to, workshops, town halls, public hearings, public comment processes, and other appropriate means. Stakeholder and public engagement would be consistent with existing requirements for public notice and input under applicable laws. Additionally, regional planning bodies would operate with the maximum amount of transparency, participation, and collaboration to the extent permissible by law. The NOC would provide guidance on such operating procedures including methods that ensure effective public and stakeholder participation, encourage diversity of opinions, and contribute to the accountability of the CMSP process (e.g., public meetings, document availability, and timely public notification).

- **Consult Scientists and Technical and Other Experts:** The regional planning body would consult scientists, technical experts, and those with traditional knowledge of or expertise in coastal and marine sciences and other relevant disciplines throughout the process to ensure that CMSP is based on sound science and the best available information. To this end, the regional planning body would establish regional scientific participation and consultation mechanisms to ensure that the regional planning body obtains relevant information. Such consultation could take the form of regional private-public technology and science partnerships. In addition, the regional planning bodies would work with existing science and technical entities, such as the regional ocean observation organizations, and other organizations with relevant physical, biological, ecological, and social science expertise. Scientific participation and consultation mechanisms would provide scientific and technical oversight and support to the regional planning body throughout the CMS Plan development, implementation, and evaluation phases.

- **Analyze Data, Uses, Services, and Impacts:** With assistance from scientific and technical experts, the regional planning body would investigate, assess, forecast, and analyze the following:

  - Important physical and ecological patterns and processes (e.g., basic habitat distributions and critical habitat functions) that occur in the planning area, including their response to changing conditions;

  - The ecological condition and relative ecological importance or values of areas within the planning area, including identification of areas of particular ecological importance, using regionally-developed evaluation and prioritization schemes that are consistent with national guidance provided by the NOC;

  - The economic and environmental benefits and impacts of ocean, coastal, and Great Lakes uses in the region;

  - The relationships and linkages within and among regional ecosystems, including neighboring regions both within and outside the planning area, and the impacts of anticipated human uses on those connections;

  - The spatial distribution of, and conflicts and compatibilities among, current and emerging ocean uses in the area;

  - Important ecosystem services in the planning area and their vulnerability or resilience to the effects of human uses, natural hazards, and global climate change;

  - The contributions of existing placed-based management measures and authorities; and

  - Future requirements of existing and emerging ocean, coastal, and Great Lakes uses.

  This analysis would form the basis of the Regional Assessment described in the Essential Elements of the CMS Plan below. The regional planning body would identify and leverage existing approaches and efforts to collect information as well as clearly identify where there are gaps in data and information and what assumptions are made in the assessments, forecasts, and analyses to 'compensate' for lack of information and data.

- **Develop and Evaluate Alternative Future Spatial Management Scenarios and Tradeoffs:** The regional planning body would identify a range of alternative future spatial management scenarios based upon the information gathered on current, emerging, and proposed human uses, ecosystem conditions, and ecosystem services. Comparative analyses would assess, forecast, and analyze the tradeoffs and cumulative effects and benefits among multiple human use alternatives. The alternatives and the supporting analyses would provide the basis for a draft CMS Plan.

- **Prepare and Release for Public Comment a Draft CMS Plan with Supporting Environmental Impact Analysis Documentation:** Once a draft CMS plan and supporting environmental impact analyses, including alternatives, are completed, the regional planning body would release it for

appropriate public review and comment. During the development of a CMS Plan and before formal adoption of a final CMS Plan, regional planning bodies would also have the flexibility to move forward with CMSP efforts and agreements to address ongoing issues and regional coordination. It is recognized that these agreements would likely become part of the final CMS Plan. In drafting the CMS Plan, the regional planning body would resolve disputes using the process developed by the NOC, as discussed above in this Section.

- **Create a Final CMS Plan and Submit for NOC Review:** Based on public review of the draft plan and alternatives, the regional planning body would develop the final CMS Plan and environmental impact analysis that includes elements detailed in the Essential Elements of the Plan. The regional planning body would submit the final CMS Plan to the NOC for national consistency certification, as described in Section XII of this Part. Certification by the NOC would not occur until after release of the final CMS Plan for 30 days of public notice. These CMS Plans are intended to be iterative and are expected to be modified through the adaptive process described below.

- **Implement, Monitor, Evaluate, and Modify (as needed) the NOC-Certified CMS Plan:** The regional planning body would have an ongoing responsibility to monitor and assess the effectiveness of the CMS Plan. The regional planning body would adapt the CMS Plan, as necessary, based on relevant changes in ecological, economic, human health, safety, security, or social conditions and information. During implementation, each region would integrate new data and scientific findings to refine regional objectives and their respective goals. As new technologies are developed to observe and monitor ocean, coastal, and Great Lakes environments and their uses, they would be considered for application in regional CMSP monitoring and evaluation efforts.

Essential Elements of the CMS Plan

Essential Elements of the CMS Plan

- Regional Overview and Scope of Planning Area
- Regulatory Context
- Regional Assessment
- Objectives, Strategies, Methods, and Mechanisms for CMSP
- Compliance Mechanisms
- Monitoring and Evaluation Mechanisms
- Incorporation of the Dispute Resolution Process

CMS Plans are expected to vary from region to region according to the specific needs, capacity, and issues particular to each region. A completed CMS Plan would contain the following essential elements in order to ensure national consistency across regions and certification by the NOC. Scientific data, information, and knowledge, as well as relevant traditional knowledge would underpin each of these essential elements.

- **Regional Overview and Scope of Planning Area:** The CMS Plan would include a regional overview of the planning area. This overview would include a description of the planning area's ecosystems and their biological, chemical, and physical environments; social, recreational, human health, safety, security, and economic uses; ecological and conservation considerations, including identification of important ecological areas, habitats, flora, and fauna; and other concerns of the region. The overview would describe how the CMS Plan relates to and furthers the National Policy, CMSP national goals and principles, any national objectives developed by the NOC, regional objectives, and other relevant national, regional, State, and other policies. The CMS Plan would also define the geographic scope of the planning area.

- **Regulatory Context:** The CMS Plan would describe the statutes, rules, and regulations relevant to implementing CMSP throughout all levels of government. It would also describe, as appropriate, the principal existing planning processes (e.g., Great Lakes Restoration Initiative Action Plan or State marine spatial plans) that may be relied on or incorporated as part of the regional CMS Plan.

- **Regional Assessment:** The CMS Plan would include a regional assessment, based on environmental, social, economic, and other necessary data and knowledge, describing the existing and predicted future conditions, uses, and characteristics of the ocean, coastal, or Great Lakes areas covered in the CMS Plan. The regional assessment would include: relevant biological, chemical, ecological, physical, cultural, and historical characteristics of the planning area; ecologically important or sensitive species/habitats/ecosystems; and areas of human activities. The assessment would also include an analysis of ecological condition or health and of cumulative risks as well as forecasts and models of cumulative impacts. The regional assessment would explain the information obtained and analyses conducted during the planning process and how they were used to help determine management decisions and plan alternatives.

- **Objectives, Strategies, Methods, and Mechanisms for CMSP:** This section would describe the regional objectives and proposed strategies, methods, and mechanisms for CMSP for the region. It would provide the analysis, evaluation of options, and the basis for the conclusions made in the CMS Plan. It would describe the spatial determinations for conservation and uses, at the appropriate scale, and include any necessary visual representations. The CMS Plan would describe the strategies, methods, and mechanisms for integrated or coordinated decision-making, including addressing use conflicts. The CMS Plan would further describe the continuing processes by which implementation would proceed, including mechanisms to ensure that individual partner and collaborative decision-making are reviewed for consistency with plan priorities and objectives. The CMS Plan would describe continued opportunities for stakeholder and public engagement. It would provide the flexibility needed to accommodate activities and operations in preparation for and response to disasters, emergencies, and similar incidents. The CMS Plan would also consider a regional process for requesting variances and amendments.

- **Compliance Mechanisms:** The CMS Plan would specify mechanisms to enhance coordination and cooperation among decision-makers and promote consistency in each agency's interpretation and application of its respective existing laws and regulations used for implementation and enforcement of CMS Plans.

- **Monitoring and Evaluation Mechanisms:** The CMS Plan would specify the monitoring and evaluation mechanisms, including a reporting mechanism, to be employed to assess the effectiveness of the CMS Plan and identify where and when changes need to be considered. As part of monitoring and evaluation, regional planning bodies would define a clear set of regional performance measures to be used to assess whether or not the region is meeting national and regional objectives and goals.

Additionally, regional planning bodies would participate in the periodic execution of regional ecosystem assessments to evaluate impacts of management actions from economic, ecological, and social perspectives in order to inform the CMS Plan. Monitoring and evaluation will follow from and build upon the original regional assessment, consistent with national guidance provided by the NOC.

- **Incorporation of the Dispute Resolution Process:** The CMS Plan would incorporate the dispute resolution process, as described in Section X of this Part.

XI. The Nature of the Planning Process and National Ocean Council-Certified Coastal and Marine Spatial Plans

CMSP is intended to provide Federal, State, tribal, and regional bodies, stakeholders, and the public with a meaningful forum within which to develop a plan to better manage multiple sustainable uses, resolve conflicts, and support ecosystem-based management of the ocean, coasts, and Great Lakes in accordance with shared goals, guiding principles, and applicable legal authorities. In this way, regional objectives and national objectives, goals, and guiding principles can be considered in a single, comprehensive, and integrated process. In order to be successful, the outcome of CMSP would have to result in meaningful improvements in the way that Federal, State, tribal, local, and regional bodies, stakeholders, and the public participate in the use and conservation of these areas.

While the goal of this framework is to move toward comprehensive, integrated, flexible, proactive, ecosystem-based CMSP, this would not happen instantaneously. CMSP must be initiated and developed thoughtfully, allowing for time to address the myriad complexities and challenges that would undoubtedly arise as the process moves forward. Moreover, while this framework identifies some of the incentives and benefits for a coordinated Federal, State, tribal, and regional effort and envisions a fully coordinated planning process, there would be substantial flexibility to determine how best to develop and implement CMSP for each particular region. In the event that a particular State or tribe opts not to participate in the development or implementation of a CMS Plan, the development or implementation of the CMS Plan would continue. While this is not optimal because it would not result in a fully integrated CMS Plan, the benefits of coordinated planning among the participating partners warrant its completion.

Development and implementation of CMS Plans would be an iterative process leading to a comprehensive, multi-objective, multi-sectoral plan within the first five years. Since each region may have different drivers and capabilities for CMSP, regions may choose to prioritize initial development and implementation steps. While CMSP should help resolve many use conflicts, it is not realistic to expect that all such conflicts would be resolved. Further, partners might agree not to resolve certain issues in a CMS Plan at a particular time, but rather to acknowledge these issues and indicate how the parties would continue to work on them as part of the iterative CMSP process. Such issues may be resolved as data gaps are filled, new information is developed, or as State or Federal legal authorities are enacted, changed, or updated.

To ensure that CMSP is effective and has a positive overall impact, each partner participating in CMSP would need to commit in good faith to: (1) a cooperative, open, and transparent CMSP process leading to the development and implementation of CMS Plans, acknowledging that each partner may have different authorities and non-discretionary mission objectives that must be fully addressed; (2) ensure that consideration of the National Policy, national CMSP goals, objectives, and principles, and regional CMSP objectives are incorporated into the decision-making process of all the partners consistent with existing statutory, regulatory, and other authorities, and the critical needs of emergency response, and homeland and national security activities; and (3) dispute resolution processes that enable concerns and issues not resolved through the cooperative planning process to be resolved quickly, rationally, and fairly.

Signing onto the CMS Plan would be an express commitment by the partners to act in accordance with the CMS Plan, within the limits of applicable statutory, regulatory, and other authorities, and respecting critical emergency response and homeland and national security needs. Thus, State and Federal regulatory authorities would adhere to, for example, the processes for improved and more efficient permitting, environmental reviews, and other decision-making identified in the CMS Plan to the extent these actions do not conflict with existing legal obligations. State and Federal authorities with programs relevant to the CMS Plan would in a timely manner review and modify programs, as appropriate, to ensure their respective activities, including discretionary spending (e.g., grants and cooperative agreements), adhere to the CMS Plan to the extent possible. State and Federal agencies

would also be expected to formally incorporate relevant components of the CMS Plan into their ongoing operations or activities consistent with existing law. This may be implemented in a variety of ways. For example, agencies could enter into memoranda of understanding (MOUs) to coordinate or unify permit reviews and decision-making processes. Where existing regulatory or statutory requirements impose constraints on the ability of an agency to fully implement the CMS Plan, the agency would seek, as appropriate, regulatory or legislative changes to fully implement the CMS Plan.

Relationship of CMSP to Existing Authorities

CMSP under this framework would not vest the NOC or regional planning bodies with new or independent legal authority to supersede existing Federal, State, or tribal authorities. Rather, the NOC would facilitate the development of CMSP and provide national context and guidance within which bottom-up, flexible, regionally-based CMS Plans would be developed and implemented. Regional planning bodies would function as convening and planning bodies that comprise Federal, State, and tribal representatives responsible for implementing existing authorities to create a process, and ultimately a plan, to better apply such existing authorities to achieve agreed upon regional goals and objectives.

In and of themselves, CMS Plans, would not be regulatory or necessarily constitute final agency decision-making. However, they are intended to guide agency decision-making and agencies would adhere to the final CMS Plans to the extent possible, consistent with existing authorities, as described in Section XIV of this Part. Adherence to and implementation of the CMS Plan would be the result of a multi-year planning process by which regional planning body members would openly discuss their respective legal authorities, requirements, and processes and how they can be better applied in the CMSP context. Once a CMS Plan is approved, Federal, State, and tribal authorities would implement them through their respective legal authorities. Thus, for example, State permitting decisions remain within the purview and are the responsibility of the relevant State agency, not the NOC, regional planning body, or any of its other members. Also, as described earlier, disputes regarding a specific agency's decisions pursuant to its statutory authority would be addressed through the various procedures and mechanisms available under that authority or other relevant authorities (e.g., Administrative Procedure Act).

One example of the potential relationship between CMSP and existing authorities is the application of CZMA Federal consistency. Since there will be multiple Federal agencies and States involved in any one CMS Plan, the Federal agencies would need to determine how CZMA review would occur as

Federal agencies adopt the plan. For example, if a State works with the Federal agencies to develop a CMS Plan, the CMS Plan could include measures to ensure that it is consistent to the maximum extent practicable with the enforceable policies of a State's CZMA program. The relevant State could consider potential changes to the State's enforceable policies to achieve agreed upon regional CMSP objectives. Also, a CMS Plan might include CZMA Federal consistency administrative efficiencies so that CZMA review would not be needed for some activities. Finally, if a State incorporates a CMS Plan into its federally approved CZMA program, then it is likely that the CMS Plan would not need a CZMA Federal consistency review.

Relationship of CMSP to Existing Regional Entities

As mentioned above, the regional planning bodies would build upon the efforts of the existing regional governance structures. The regional planning bodies in conjunction with the NOC and the GCC would establish formal mechanisms or consultative processes to engage entities with statutorily-mandated or quasi-regulatory bodies that have an express role in the management and regulation of ocean, coastal, and Great Lakes resources. Specifically, as discussed earlier in Section X, a formal mechanism for consultation with the RFMCs would be incorporated into the CMSP process. In addition, regional planning bodies would coordinate with other existing regional entities and bodies such as Harbor Safety Committees, Regional Aquatic Nuisance Species Panels, and Area Maritime Security Committees, as appropriate.

Relationship of CMSP to Existing Plans and Projects

CMSP is not meant to delay or halt existing or pending plans and projects related to marine and Great Lakes environments or their uses. However, those responsible for making decisions on such plans and projects would be expected to take into account the national CMSP goals and principles, national policies, and any identified national and regional CMSP objectives in future decision-making to the extent possible under existing law. Once a CMS Plan is put into effect following NOC certification, its implementation would be phased in to avoid undue disruption or delay of projects with pending permits or other applications. The NOC would provide additional guidance on how best to accomplish this phased-in approach.

XII National Consistency

Certification by the NOC for National Consistency

The NOC would review each regional CMS Plan to ensure it is consistent with the National Policy, CMSP goals and principles as provided in this framework, any national objectives, performance measures, or guidance the NOC has articulated, and any other relevant national priorities. The NOC's review would ensure that the CMS Plans include all the essential elements described in this framework. The NOC would also consider the CMS Plan's compatibility with an adjacent region's CMS plan regarding issues that cross regional boundaries. Certification by the NOC would not occur until after release of the final CMS Plan for 30 days of public notice. The NOC would review and make a
