decision on certification within six months of receipt of the CMS Plan. If a regional CMS Plan does not meet certification requirements, the NOC would work with the regional planning body to address issues with the CMS Plan and could allow for approval of those parts of a CMS Plan that do meet such requirements. Upon certification by the NOC, a decision document adopting the CMS Plan would be co-signed by senior State officials (e.g., Governors), tribal representatives, as appropriate, and senior officials of the Federal agencies represented on the regional planning body. Upon signature by the partners, the CMS Plan would be considered "in effect" and implementation would begin.[12]

National CMSP Objectives, Performance Measures, and Guidance

The NOC would establish national objectives, national outcome-based performance measures, and guidance to promote national consistency in the development and implementation of CMS Plans. Because the intent of CMSP is integration across sectors, the NOC would develop a range of national objectives. These may include: economic, conservation, security, and social objectives. The NOC would also develop national performance measures to evaluate, monitor, and report on progress towards implementing national CMSP objectives. As specified in the *Essential Elements of the CMSP Process* and the *Essential Elements of the Plan*, regional planning bodies would develop region-specific objectives and associated performance measures, as part of the regional CMSP process. Regional performance measures developed by the regional planning bodies would be used to track improvements towards stated CMS Plan objectives. These regional measures and objectives would be consistent with the nationally established objectives and measures.

Regional and national performance measures should directly relate to the stated national and regional objectives established in the CMSP process. Performance measures would assess both conservation and socio-economic objectives of the CMS Plan. Measures of conservation may include, but are not limited to, indicators of ecosystem health such as the status of native species diversity and abundance, habitat diversity and connectivity, and key species (*i.e.*, species known to drive the structure and function of ecosystems). In addition, socio-economic measures would be developed and may include, but are not limited to: the economic value or productivity of certain economic sectors, such as commercial and recreational fisheries, aquaculture, and offshore energy; the number of recreation days; and the time

[12] If the NOC does not certify a plan, it would provide to the regional planning body the specific reasons for its decision. The regional planning body would then have continued opportunity to address the NOC's reasons and resubmit the plan.

required for permit applications to complete the regulatory process. Performance measures would provide a means of demonstrating results of and provide accountability for the CMSP process to stakeholders, the general public, and decision-makers.

The NOC would develop guidance in conjunction with the regional planning bodies for regional objectives and concomitant performance measures to ensure that they are cost-effective, measurable, interpretable, grounded in theory, responsive, and specific. The NOC would develop consistent guidance for these ecological and socio-economic approaches and tools to assist regional planning bodies in these efforts in order to provide for nationally applicable common scales of assessment. This will ensure that regional planning bodies are given the independence and flexibility to develop regionally meaningful objectives and measures, but also assure that regional measures and reporting are consistent with a national CMSP performance system.

XIII. Consistency with International Law

CMS Plans would be implemented in accordance with customary international law, including as reflected in the Law of the Sea Convention, and with treaties and other international agreements to which the United States is a party. Seaward of the baseline, development and implementation of CMS Plans are to be consistent with the extent to which the United States exercises its rights and jurisdiction and performs duties in its territorial sea, EEZ, and Continental Shelf. CMS Plans would not change the rights, duties, and jurisdiction of the United States under international law, including with respect to navigational rights and freedoms. Nothing in this document or in CMS Plans developed pursuant to it would create private rights of action or other enforceable individual legal rights regarding the meaning and applicability of international law.

XIV. Adherence to and Compliance with National Ocean Council-Certified Coastal and Marine Spatial Plans

Signatories and all NOC member agencies would adhere to a NOC-certified CMS Plan, within the limits of their existing statutory and regulatory authorities. If a signatory intends to take an action that does not substantially adhere to a certified CMS Plan, it would need to provide advance notice to the regional planning body and the NOC, including justification (e.g., new statutory requirement) for the non-adherence. The CMS Plan signatories and the NOC would periodically evaluate the reasons requiring deviation from a NOC-certified CMS Plan, and, as appropriate, develop recommendations for minimizing these deviations in the future, including CMS Plan modification or underlying regulatory or statutory changes. Disputes regarding agency interpretation of a CMS Plan would be resolved according to the dispute resolution process developed by the NOC, as described above.

Agencies would incorporate components of the CMS Plan into their respective regulations to the extent possible. Adherence with CMSP would be achieved through Federal and State agencies and tribal authorities incorporating CMS Plans into their pre-planning, planning, and permitting processes, to the extent consistent with existing laws and regulations. The CMS Plan signatories would periodically

review these processes, and where legal constraints are identified, would seek to remedy these constraints, including by working with the NOC to evaluate whether a legislative solution or changes to regulations are necessary and appropriate.

The effectiveness of the CMSP process depends, in-part, on the willingness and the ability of Federal, State, and tribal authorities to ensure that activities of third-parties are in compliance with relevant laws and regulations. The Nation would not achieve the benefits of comprehensive and integrated CMSP if there were inconsistent use or violation of the applicable laws and regulations. Successful enforcement, carried out by agencies exercising their individual enforcement authorities and responsibilities, must be based upon clear, concise, and easily understood requirements that reflect the practical realities of compliance and enforcement.

CMS Plans would provide a framework for improved coordination and cooperation among Federal, State, tribal, and local enforcement agencies as they work together to enforce existing regulations in accordance with their respective authorities in support of regional goals that often extend beyond individual agency jurisdictions. To the extent permitted by existing laws and regulations, this cooperative regional approach should build productive partnerships that encourage sharing of information and best practices, help foster mutually agreed upon enforcement priorities and strategies, and make more effective use of scarce enforcement resources by focusing those resources on the highest regional enforcement priorities. A cooperative enforcement approach for Federal, State, and tribal CMSP-related laws could also facilitate more consistent interpretation and application of regulations across agencies and jurisdictions, resulting in greater certainty and understanding for ocean, coastal, and Great Lakes users, which in turn could foster improved compliance and overall effectiveness. The NOC and CMS Plan signatories would periodically review enforcement effectiveness and seek to remedy any conflicts or gaps in existing Federal-State-tribal coordinated enforcement mechanisms.

XV. Scientific Knowledge and Data Integration, Research, Management, and Access

CMSP is fundamentally science-based and adaptive in response to new evidence, technology, and understanding. Essential to CMSP are scientific knowledge and data, collectively referred to here as *information.* Information is necessary to comprehensively, consistently, and continually investigate, assess, forecast, and analyze human uses, ecosystem conditions, management alternatives, information and data gaps, and CMS Plan effectiveness. Reflecting our long history of ocean science and exploration, the United States holds vast stores of natural and social science information about ocean, coastal, and Great Lakes ecosystems and their uses which can immediately be used to begin informing CMS Plan development. However, data and knowledge gaps, particularly regarding the complexities of these ecosystems, human use patterns, and the relationship between the two, indicate the need for continuing research to supplement existing information, especially in the context of changing environmental conditions and societal needs. Additional CMSP research will provide new information, including on specific and cumulative effects, ecosystems processes and resiliency, and the assessment and valuation of ecosystem services.

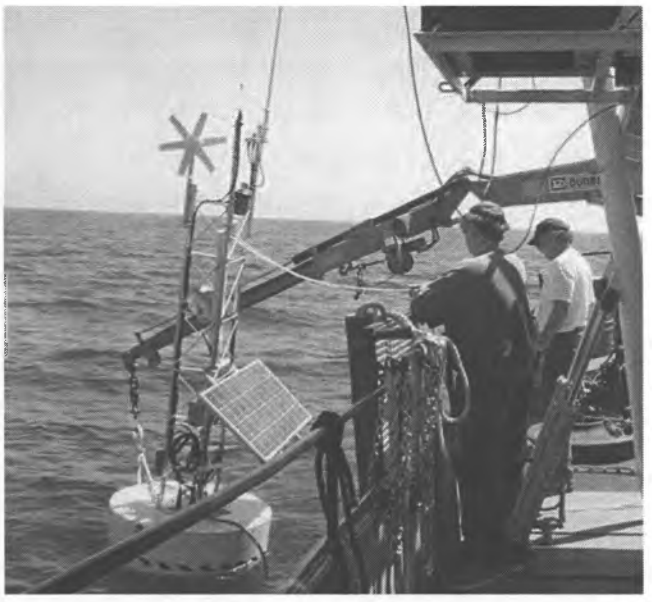
Relevant and credible information is critical for successful planning and, in turn, must be accessible to Federal, State, and local managers, tribes, academics, the private sector, and the public. A robust national information management system dedicated to coastal and marine scientific data and information products is required to meet the diverse data and application requirements of CMSP, and the varying technical capabilities of users. The NOC, working with the regional planning bodies, would create a system that is compatible with existing Federal information systems, captures relevant Federal information resources, has effective governance and accountability across agencies, and preserves data confidentiality, where appropriate. The NOC would leverage and build upon existing national data systems and initiatives (e.g., ocean observation), where appropriate. Within this construct, Federal agencies and the other regional partners would make relevant data, metadata, and derived products available and web accessible using recognized national and international standards and protocols to the extent permitted by law and regulation. In addition, State agencies, tribes, academia, the private sector, stakeholders, and other non-governmental sources would be encouraged to make their relevant information and knowledge, including local and traditional knowledge, available through this system. Exceptions would include sensitive but unclassified information that cannot be synthesized and modified into a format that is appropriate for broader distribution, pursuant to CMSP needs and information that is proprietary, statutorily confidential, or classified information.

Principles to Manage and Disseminate CMSP Information

- CMSP information is a national strategic asset and must be developed and managed on an ongoing basis to meet planning needs.
- CMSP information would be made available and accessible with nationally compliant "information about information" (i.e., metadata) to stakeholders.
- Federal agencies would improve metadata to make information easier to discover, retrieve, use, and manage.
- CMSP information that is collected, produced, or disseminated by Federal agencies, including information obtained from non-Federal sources, would meet government-wide information quality standards, and any other additional minimum standards adopted by the NOC.

To provide easy user access to agency CMSP-related information, a national information management system with either a central portal or regional portals that connect to CMSP information would be developed. The NOC would identify a Federal lead agency or collaborative entity to manage, implement, and update the CMSP portal(s) and components of the information management system. System interoperability, information exchange, and information and application technologies are intrinsically linked and would be developed and implemented together within the CMSP portal(s). To ensure national consistency, minimum data standards for CMSP information would be adopted and include standards for information quality. All information management and provision activities would be developed and updated with participation from existing and appropriate Federal data centers and initiatives. The NOC would ensure that the information is publicly available and easy-to-access

through computer readable files and web service formats that support a variety of CMSP and user needs. This could include web browsers, geospatial web services, and other web-based collaborative resources. The CMSP portal would leverage emerging web technologies, including private sector partnerships, to increase transparency and promote public engagement.

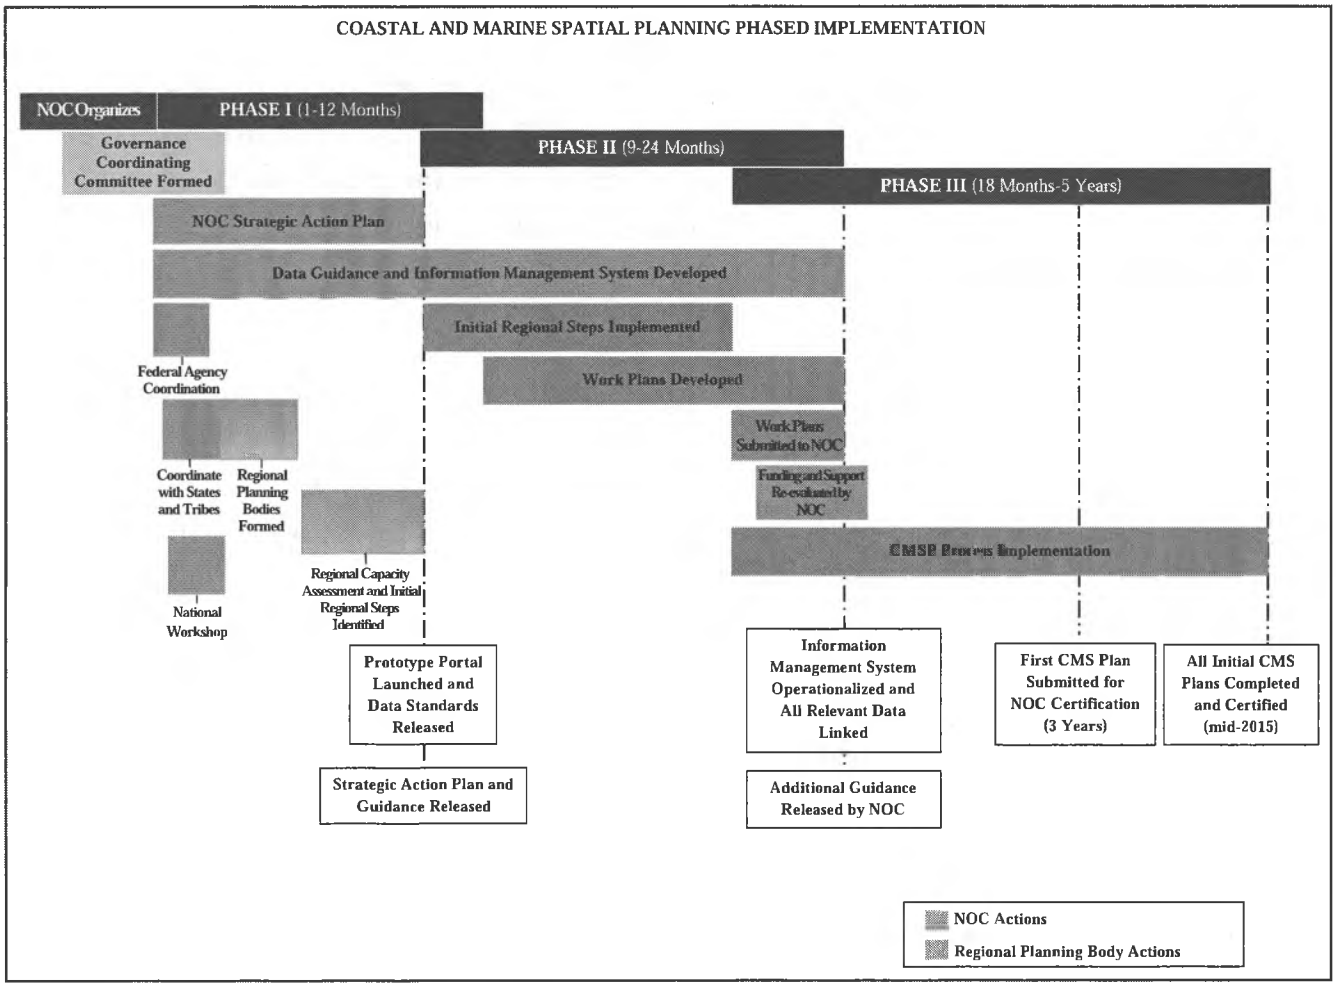


In order to build upon the existing CMSP scientific foundation, the NOC would establish mechanisms to identify and address priority CMSP science needs. This would include identification of priority CMSP research, data acquisition and information synthesis gaps, and new tools that would be required to apply science more effectively in the CMSP process. Identification of data, information, and research needs would be conducted on a regular basis as part of the adaptive and iterative process to improve the development and application of CMSP over time.

Additionally, nationally consistent, derived data products, ranging from consistent habitat maps as data layers to specialized decision-support tools, would be developed to provide a consistent framework for regional assessments and alternative future spatial management scenarios. The NOC may provide further guidance for using such information in decision-making, for example, how to decide which areas are of particular ecological importance or value. Designed or adapted specifically for CMSP, these science-based decision-support tools, including models, assessments, and visualization capabilities,

would enable the regional planning bodies to synthesize information most relevant to CMSP decisions in ways that produce robust comprehensive CMS Plans. These tools would offer a shared knowledge base for meaningful stakeholder engagement, objective assessment of alternative and future scenarios, identification of the types of uses that are consistent with societal objectives, and regular evaluation of CMS Plans. They would be developed and made accessible in a way that regional and State efforts could build upon or add regional specific data and information to leverage these efforts and analyze the regionally-specific aspects of their planning within the broader national framework.

XVI. Implementation



Implementation of this framework would occur in multiple phases through the NOC and among the regions. As a first step, the NOC would undertake initial actions to develop and build a foundation for the national CMSP efforts. Concurrently, the NOC would directly engage States and tribes to discuss cooperative strategies to move forward with CMSP. Recognizing the extensive scope of the task of developing and implementing CMSP, it is important for Federal, State, tribal, and other partners to prioritize efforts in this initial implementation period. Each of the regions could have different priorities and be at varying stages in the development of the data, analyses, and the relevant issues for

policy-makers. With these differences in mind, the phased approach outlined below would enable the NOC and the regions sufficient time to develop capacity, build on existing efforts, and leverage and gain efficiencies from lessons learned. In order to best achieve the completion of CMS Plans in all regions by 2015, the NOC would have the flexibility to make minor adjustments or modifications to this implementation schedule.

Phase I (1-12 months)

Many of the actions the NOC and State, tribal, and regional representatives commence in Phase I would serve as the foundation to implement CMSP on a national scale.

Develop NOC Internal Organization and Begin Strategic Action Plan (Months 1-9)

In the first month of Phase I, building on the initial establishment and organization period of the NOC, the NOC would determine how best to incorporate CMSP into the NOC governance structure (e.g., establish a CMSP Interagency Policy Sub-Committee), decide on the roles of individual agencies in implementing specific elements of the CMSP framework, including identification of a lead Federal agency for each regional planning body that would serve with non-Federal co-lead(s), and assess resource needs including personnel, financial, and technical CMSP support.

The NOC would then begin development of a strategic action plan to address specific areas that require additional consideration, analysis, and elaboration. The strategic action plan would be released in six to nine months and include: national objectives; national performance measures; guidance regarding the development of a national information management system, including identification of additional CMSP information and research needs; legal analysis and recommendations for legislative changes, if necessary; description of a dispute resolution mechanism, as described previously; and any additional guidance the NOC deems appropriate for CMSP. The NOC would also further assess the relationship between RFMCs and regional planning bodies and determine the most effective mechanism for engagement in the CMSP process, including whether representation on the regional planning bodies is the best method for such engagement. The NOC would ensure opportunity for the GCC, existing regional governance organizations, and public participation as it develops the strategic action plan for coastal and marine spatial planning. The NOC, in cooperation with the GCC, would provide for a mechanism for resolving disputes if they occur among the members of the regional planning bodies during the development of CMS Plans, as described in Section X of this Part.

Develop and Implement Public and Stakeholder Engagement

Early and meaningful steps to facilitate public and stakeholder outreach and education regarding CMSP and its implementation are vital to advance national CMSP efforts. As discussed above, the NOC would ensure substantial opportunity for public participation as it develops all nine strategic action plans, including the strategic action plan for coastal and marine spatial planning. Also, to better inform all participants and the public, the NOC would work with Federal agencies and the regional planning bodies, when established, to guide the drafting and production of educational materials, guidebooks,

manuals, and other materials. These materials would be developed keeping in mind that the content should reflect the issues, language, and methods that would be meaningful in a particular region. These materials would include a glossary of key CMSP terms in order to reduce potential misunderstandings that could result in an inconsistent or ineffective CMSP process. The NOC, in coordination with the regional planning bodies, when established, would hold additional informational workshops for stakeholders to discuss the CMSP process and potential ways stakeholder participation would take place. Additional stakeholder engagement would be conducted by the regional planning bodies throughout the CMSP process.

National Objectives and National Performance Measures

As part of the strategic action plan, the NOC would establish national objectives for CMSP consistent with, and in furtherance of, the National Policy, CMSP goals and principles, and other relevant national goals and priorities. These national objectives would serve as additional direction for the development of regional objectives and to help to maintain national and regional consistency of CMSP. Along with these objectives, national outcome-based performance measures would be established to help define success and measure results.

Guidance Regarding the Development of a National Information Management System

While overarching objectives and measures would help direct CMSP efforts, guidance on data, technology, and tools would also be developed. During the first six to nine months, initial actions to coordinate, integrate, and manage data would be necessary. The NOC would begin development of a national information management system and CMSP portal(s), adopt minimum data standards consistent with government-wide information quality standards, identify a Federal lead agency or entity to manage, implement, and update the CMSP portal(s), identify and begin development of any new standard tools or models needed for CMSP in all regions, and identify additional CMSP information and research needs. At the end of nine months, guidance on these fundamentals would be released as part of the strategic action plan and a prototype CMSP portal(s) would be operational. However, building the information management system and linking the relevant data may take up to two years and would be ongoing as new information becomes available.

Legal Analysis and Recommendations of Legislative Changes, if Necessary

Also, as part of the strategic action plan, the NOC would oversee efforts to identify gaps and conflicts in Federal authorities and recommend potential steps to reconcile them. This effort would examine how various statutory authorities of particular agencies can be harmonized in order to support comprehensive, integrated CMSP. Further, the NOC would consider how legal authorities of Federal, State, tribal, and local entities might collectively be used to support implementation of regional CMSP efforts. In doing so, the NOC should identify objective priorities and existing grant or other assistance programs that can support CMSP, consistent with relevant authorities.

Convene and Organize Federal Agency Representatives in the Regions (Months 1-2)

National and regional Federal agency representatives would convene to discuss current and improved methods for communicating, sharing data and products, exploring regulatory efficiencies, and determining how best to work with State and tribal partners to achieve a CMS Plan. Due diligence is necessary on the part of the Federal community to self organize and coordinate among agencies before engaging State and tribal partners to ensure that a service is being provided in a way that meets considerations unique to each region.

Develop Model Agreement (Months 1-3)

During the first three months of Phase I, the NOC would create and make available a model development agreement to be used by the regional planning bodies. This model would be used to foster efficiency and consistency in forming the regional planning bodies. As described in Section X of this Part, the development agreement would be an express commitment to work cooperatively to engage in CMSP and develop eventual CMS Plans, identify the lead representatives for each of the partners, and define ground rules, roles, and responsibilities of the partners.

Organize and Convene a National Workshop(s) and CMSP Simulation Exercise (Months 2-4)

Within the initial two to four months of Phase I, the NOC would also organize and convene, with input from the GCC, one or more workshops and a CMSP process simulation exercise for potential regional planning body representatives. The workshop(s) would be a forum to directly engage Federal, State, and tribal representatives, to give an overview of CMSP and the national framework, to demonstrate and test how this framework would work in a planning exercise, and to discuss collaborative strategies to move forward. The NOC would identify lessons learned and additional operational issues that were brought to light from the workshop(s) and exercise within two months of workshop completion.

Determine Composition of and Establish Regional Planning Bodies (Months 4-6)

After the workshop and exercise are held, the NOC, with advice from the GCC, would determine the additional types of representation needed for the composition of the regional planning bodies. Once the composition of the regional planning bodies is determined, the NOC would coordinate with the appropriate State authorities (e.g., Governors) and tribal representatives to establish regional planning bodies for each of the nine regions, identify specific members, and enter into a development agreement.

Capacity Assessment and Identification of Initial Regional Steps (Months 6-12)

During the latter six to twelve months of Phase I, the regional planning bodies would conduct a regional CMSP capacity assessment. The assessment would evaluate capabilities, expertise, and resources in each region available to develop and implement CMSP. In addition, the assessment would help to identify and prioritize initial regional steps described below in Phase II. The NOC, in coordination with the regional planning bodies, would make a determination on how best to meet the needs identified in the capacity assessment and to support the initial regional steps through existing mechanisms, and possibly new resources and/or funding mechanisms.

Develop Stakeholder and Scientific Participation Process (Months 6-18)

During Phase I, each regional planning body would begin to identify key stakeholders, scientific and technical experts, non-governmental organizations, and other partners to engage in the CMSP process. A formal mechanism for regular stakeholder, scientific, and technical input would be established and incorporated into the process. Additionally, regional planning bodies, in conjunction with the NOC, would establish procedures and methods to ensure transparency, participation, and collaboration in the planning process, such as public meetings, document availability, and timely public notification.

Phase II (9-24 months)

Building on Phase I's initial foundational steps of CMSP implementation, Phase II focuses on building capacity and testing specific issues or elements of the process.

Initial Regional Steps (Months 9-18) and Work Plan Development (Months 12-24)

During Phase II, the NOC would enable the regions to focus during the initial work plan development period on those issues that are of highest regional priority. In this way, these early steps in each region can serve as a test for the other regions for specific issues. For example, a region may select to begin CMSP efforts by organizing, gathering, and analyzing data, whereas another region may select to focus on developing regional CMS Plan objectives. The focus for each region's initial steps should be agreed upon after the capacity assessment is completed at the end of Phase I. After the initial regional steps are underway, the regional planning bodies would begin development of a full CMSP work plan, as detailed in Section X of this Part. In development of its work plan, each regional planning body should integrate the lessons learned from its and other regions' initial steps and also consider how to best integrate relevant ongoing regional planning initiatives.

Work Plan Submittal and Planning Process Preparation (Months 18-24)

Once initial regional steps are completed or in tandem with their completion, the regional planning bodies would submit to the NOC a package consisting of the proposed work plan. Once the work plan is submitted, the NOC would re-evaluate how best to support the regional CMSP effort through existing mechanisms, and possibly new resources or funding mechanisms to build on the lessons learned from the initial regional CMSP steps. For example, support might involve individual agencies

contributing staff or technical expertise to efforts coordinated through the NOC, or identifying existing grant programs to help support CMSP and achieve mutually agreed upon outcomes.

Phase III (18 months to 5 years)

While continuing to advance the actions and steps of Phases I and II, regional planning bodies would build out and scale up their efforts to establish a comprehensive CMSP process during Phase III to develop, multi-objective, multi-sectoral CMS Plans in all regions.

Develop and Carry Out CMSP Process and Provide Feedback from Initial Regional Steps (Months 18 and beyond)

After the initial regional steps are undertaken by each region, the regional planning bodies would transition into Phase III, developing and carrying out a CMSP process using the initial regional steps and the work of the NOC as a foundation. There is recognition that some regions' planning processes might be longer or more complicated than others. The timeframes for completion of the CMSP process are intended to be flexible to account for differing levels of resources, capacity, and other factors. During this process, regional planning bodies, in coordination with the NOC, would develop a mechanism for providing feedback and status reports to the NOC and appropriate State and tribal leadership to share lessons learned, best practices, and ensure routine and frequent communication nationally and among the regions. The regional planning bodies, in coordination with the NOC, would also ensure consistency, address questions and concerns, and adaptively manage the effort as appropriate. Although there would be flexibility in the framework to allow for variable CMSP process timeframes, regional planning bodies are encouraged to have final CMS Plans completed in three years and all regions would be expected to have final CMS Plans certified and implementation started by mid-2015. These final CMS Plans are intended to be iterative and are expected to be modified through the adaptive process beyond 2015.

XVII. Priorities for Financial and Other Support

Recognizing the reality of the limited availability of new resources, each of the Federal agencies engaged in this bold mission of developing and implementing CMSP would re-evaluate how resources are allocated in light of their statutory and regulatory mandates. Agencies would use the implementing actions of the President to recommend adjustments to their respective agency priorities to better align with the approved National Policy and CMSP goals. As CMSP is developed and implemented over time, the NOC would consider any additional resource needs through the budget prioritization process described earlier. Various Federal agencies would have differing roles to support the scientific basis and governance structures necessary to develop and implement CMSP. The following four areas should receive initial priority consideration for financial and other support for CMSP.

1. National Workshop(s) and Simulation Exercise

Priority: Hold a national workshop(s) and simulation exercise.

Rationale: The first step towards a constructive process for CMSP would be for the participants to engage in a forum that creates a common vision for implementing CMSP, to identify challenges and solutions for regional CMSP development, and to enhance the capacity of regions to implement CMSP. This priority also would include support to ensure widespread involvement of Federal, State, and tribal representatives.

2. Initial Support for Regional CMSP Processes

Priority: Support the development of regional CMSP, including the capacity for regional planning bodies and the NOC to carry out initial CMSP activities.

Rationale: A comprehensive and inclusive approach for regional CMSP planning processes would be based on each region engaging Federal, State, and tribal representatives to form the regional planning bodies. An effective process to sustain initial CMSP activities would necessitate regional planning bodies to organize and establish the necessary CMSP coordination (e.g., partnerships, interagency teams, and technical support staffing). To attain national and regional objectives, regional planning bodies would assess capacities, target resources, and begin implementing initial regional steps (e.g., stakeholder engagement, information acquisition, and CMS Plan development). This priority would also include support for the NOC to establish and carry out the necessary national CMSP steps (e.g., national objectives, national guidance, and building regional capacities), as described in Section XVI of this Part.

3. National Data and Information Management System, Prototype CMSP Portal(s) and Initial Development of Science and Information Needs

Priority: Improve and integrate the information (i.e., data and knowledge) used to inform CMSP; and identify additional scientific research to support CMSP information needs.

Rationale: Effective CMSP would utilize the best available data and objective analyses. Such information would be nationally consistent, publicly available, and easily accessible to promote public engagement and allow for a consistent framework for regional implementation. Priority would be given to developing the national information management system and a prototype CMSP data portal(s). Subsequent efforts would identify and fill key national information needs,[13] and develop CMSP decision-support tools and derived data products, including visualization tools, forecasting, and routine integrated ecosystem assessments. Additionally, scientific understanding is central to make informed CMSP decisions that reflect an integrated and transparent planning framework. To achieve this end would require a robust research foundation.

[13] Identification and filling information gaps, as previously presented in the framework, is an ongoing and iterative process. This framework recognizes that the acquisition of data and knowledge would proceed in tandem with developing CMS Plans using sound science and the best available information.

4. Public Outreach and Stakeholder Engagement

Priority: Build the knowledge, skills, and understanding of CMSP through regional planning bodies and stakeholder workshops, blogs, webinars, and other outreach methods.

Rationale: An informed and engaged public and stakeholder community is critical to the effective implementation of the CMS Plans. Effective CMSP is predicated on the building of knowledge, skills, and understanding of CMSP through a range of robust outreach approaches.

PART FIVE. CONCLUSION

In response to President Obama's June 12, 2009 memorandum, and after careful consideration of thousands of valuable comments from political leaders, public and private organizations, and citizens, the Task Force is pleased to submit these final recommendations for a comprehensive national ocean policy, an improved governance structure, a targeted implementation strategy, and a framework for effective coastal and marine spatial planning. Once implemented, these final recommendations will provide the first-ever comprehensive national policy of the United States to improve stewardship of the ocean, our coasts, and the Great Lakes.

The Task Force is unanimous in its call for the Nation to set a new course for improved stewardship of the ocean, our coasts, and the Great Lakes. This must include a comprehensive, integrated, transparent, science-based, and ecosystem-based planning process to achieve the sustainable uses of the ocean, our coasts and the Great Lakes. The Task Force is mindful that these recommendations may create a level of uncertainty and anxiety among those who rely on these resources and may generate questions about how they align with existing processes, authorities, and budget challenges. The NOC will address questions and specifics as implementation progresses. Meaningful and frequent opportunities for stakeholder and public engagement throughout the implementation of the National Policy and implementation of coastal and marine spatial planning will be an essential component of cooperatively addressing these uncertainties head-on, and the Task Force recommendations embrace this approach. The Task Force is confident that the investments and improvements described in these final recommendations will advance the economic interests of the United States through sustainable and productive ocean uses; significantly improve our capacity to address the long-term challenges and impacts of climate and environmental changes; and provide a lasting foundation for further enhancing the many vital benefits our Nation can derive from these areas.

With a clear National Policy and a revitalized, empowered, unified, and comprehensive framework to coordinate efforts set forth in these recommendations, we can achieve an America whose stewardship ensures that the ocean, our coasts, and the Great Lakes are healthy and resilient, safe and productive, and understood and treasured so as to promote the well-being, prosperity, and security of present and future generations.

APPENDIX A.
PRESIDENTIAL MEMORANDUM ON A NATIONAL POLICY FOR THE OCEAN, OUR COASTS, AND THE GREAT LAKES

THE WHITE HOUSE

Office of the Press Secretary

For Immediate Release June 12, 2009

June 12, 2009

MEMORANDUM FOR THE HEADS OF EXECUTIVE DEPARTMENTS AND AGENCIES

SUBJECT: NATIONAL POLICY FOR THE OCEANS, OUR COASTS, AND THE GREAT LAKES

The oceans, our coasts, and the Great Lakes provide jobs, food, energy resources, ecological services, recreation, and tourism opportunities, and play critical roles in our Nation's transportation, economy, and trade, as well as the global mobility of our Armed Forces and the maintenance of international peace and security. We have a stewardship responsibility to maintain healthy, resilient, and sustainable oceans, coasts, and Great Lakes resources for the benefit of this and future generations.

Yet, the oceans, coasts, and Great Lakes are subject to substantial pressures and face significant environmental challenges. Challenges include water pollution and degraded coastal water quality caused by industrial and commercial activities both onshore and offshore, habitat loss, fishing impacts, invasive species, disease, rising sea levels, and ocean acidification. Oceans both influence and are affected by climate change. They not only affect climate processes but they are also under stress from the impacts of climate change. Renewable energy, shipping, and aquaculture are also expected to place growing demands on ocean and Great Lakes resources. These resources therefore require protection through the numerous Federal, State, and local authorities with responsibility and jurisdiction over the oceans, coasts, and Great Lakes.

To succeed in protecting the oceans, coasts, and Great Lakes, the United States needs to act within a unifying framework under a clear national policy, including a comprehensive, ecosystem-based framework for the longterm conservation and use of our resources.

In order to better meet our Nation's stewardship responsibilities for the oceans, coasts, and Great Lakes, there is established an Interagency Ocean Policy Task Force (Task Force), to be led by the Chair of the Council on Environmental Quality. The Task Force shall be composed of senior policy-level officials from the executive departments, agencies, and offices represented on the Committee on Ocean Policy established by section 3 of Executive Order 13366 of December 17, 2004. This Task Force is not meant to duplicate that structure, but rather is intended to be a temporary entity with the following responsibilities:

more

(OVER)

1. Within 90 days from the date of this memorandum, the Task Force shall develop recommendations that include:

a. A national policy that ensures the protection, maintenance, and restoration of the health of ocean, coastal, and Great Lakes ecosystems and resources, enhances the sustainability of ocean and coastal economies, preserves our maritime heritage, provides for adaptive management to enhance our understanding of and capacity to respond to climate change, and is coordinated with our national security and foreign policy interests. The recommendations should prioritize upholding our stewardship responsibilities and ensuring accountability for all of our actions affecting ocean, coastal, and Great Lakes resources, and be consistent with international law, including customary international law as reflected in the 1982 United Nations Convention on the Law of the Sea.

b. A United States framework for policy coordination of efforts to improve stewardship of the oceans, our coasts, and the Great Lakes. The Task Force should review the Federal Government's existing policy coordination framework to ensure integration and collaboration across jurisdictional lines in meeting the objectives of a national policy for the oceans, our coasts, and the Great Lakes. This will include coordination with the work of the National Security Council and Homeland Security Council as they formulate and coordinate policy involving national and homeland security, including maritime security. The framework should also address specific recommendations to improve coordination and collaboration among Federal, State, tribal, and local authorities, including regional governance structures.

c. An implementation strategy that identifies and prioritizes a set of objectives the United States should pursue to meet the objectives of a national policy for the oceans, our coasts, and the Great Lakes.

2. Within 180 days from the date of this memorandum, the Task Force shall develop, with appropriate public input, a recommended framework for effective coastal and marine spatial planning. This framework should be a comprehensive, integrated, ecosystem-based approach that addresses conservation, economic activity, user conflict, and sustainable use of ocean, coastal, and Great Lakes resources consistent with international law, including customary international law as reflected in the 1982 United Nations Convention on the Law of the Sea.

3. The Task Force shall terminate upon the completion of its duties.

The Task Force's recommendations and frameworks should be cost effective and improve coordination across Federal agencies.

This memorandum covers matters involving the oceans, the Great Lakes, the coasts of the United States (including its

more

territories and possessions), and related seabed, subsoil, and living and non-living resources.

This memorandum is not intended to, and does not, create any right or benefit, substantive or procedural, enforceable at law or in equity by any party against the United States, its departments, agencies, or entities, its officers, employees, or agents, or any other person. Nothing in this memorandum shall be construed to impair or otherwise affect the functions of the Director of the Office of Management and Budget relating to budgetary, administrative, regulatory, and legislative proposals.

The Chair of the Council on Environmental Quality is hereby authorized and directed to publish this memorandum in the *Federal Register*.

APPENDIX C. PUBLIC ENGAGEMENT

Below is a description of the methods and summary results from the Task Force's public engagement process. In addition, included is a summary of key public comments and how they were addressed by the Task Force in the Final Recommendation.

I. Overview

The Task Force carried out a public engagement process throughout the 180-day period to receive input for consideration as it developed these recommendations. This builds on the comprehensive reports of the U.S. Commission on Ocean Policy and the Pew Oceans Commission, which were based on significant scientific, public, and stakeholder input. CEQ, on behalf of the Task Force, organized and hosted thirty-eight expert roundtables to hear from a broad range of stakeholders and interest groups. The roundtables included representatives from sectors including energy, conservation, recreational fishing, commercial fishing, transportation, agriculture, human health, State, tribal, and local governments, ports, recreational boating, business, and national and homeland security. Task Force representatives attended each roundtable. There was robust participation and the Task Force received many valuable comments and perspectives for its consideration during each session.

On behalf of the Task Force, CEQ also set up a website to accept public comments. The Task Force received approximately five thousand comments from a range of affected parties, including academia, citizens, commercial and recreational interests, non-governmental organizations, and States, tribes, and regional governance structures. Many of the groups commenting represented constituencies of hundreds or thousands of members.

Additionally, the Task Force hosted six regional public meetings with over two thousand public participants, in which Task Force members were available to answer questions and the public was able to voice their concerns and opinions. These meetings took place in the following regions: Alaska (held in Anchorage, Alaska, August 21, 2009); West Coast (held in San Francisco, California, September 17, 2009); East Coast (held in Providence, Rhode Island, September 24, 2009); Pacific Islands (held in Honolulu, Hawaii and via satellite link, September 29, 2009); Gulf Coast (held in New Orleans, Louisiana, and via interactive video link October 19, 2009); and Great Lakes (held in Cleveland, Ohio, October 29, 2009).

The public meetings, roundtables, and website showcased a strong desire and enthusiasm among participants for a national policy that provides clarity and direction regarding how the Nation will better care for the ocean, our coasts, and the Great Lakes. A valuable and wide diversity of interests were represented, and several key themes emerged. While not exhaustive, these include:

- Support for adopting ecosystem-based management as a guiding principle, acknowledging regional differences, and practicing adaptive management in light of concerns about competing uses and growth of industrial uses;

- Support for embracing science-based decision-making and investing in ecosystem-based science, research, ocean observations, and mapping including comprehensive research on the linkages among ecosystem health, human health, economic opportunity, national and homeland security, social justice, and environmental change, including climate change;
- Desire for improved coordination and collaboration across Federal, State, tribal, and local governments, and regional governance structures, and for improved transparency and public participation, while avoiding new layers of bureaucracy and unnecessary costs;
- Support for improving both formal and informal education about the ocean, our coasts, and the Great Lakes;
- Support for ensuring that policies are adequately funded; and
- Support for joining the 1982 United Nations Convention on the Law of the Sea (the Law of the Sea Convention).

II. Summary of Public Comments on the Interim Report of the *Interagency Ocean Policy Task Force* and on the *Interim Framework for Effective Coastal and Marine Spatial Planning*

The Task Force reviewed the public comments received in response to the *Interim Report* and *Interim Framework* and determined whether substantive comments were adequately addressed, merited further consideration and resulting changes, or were more suited for further consideration by the National Ocean Council (NOC), if established, as it implements the National Policy, if adopted.

Comments on the Interim Report of the Interagency Ocean Policy Task Force

Substantive comments on the Interim Report ranged from general support for a national policy and improved Federal coordination, to concerns over the process, and concerns that the Interim Report did not adequately account for economic uses of the ocean, our coasts, and the Great Lakes, or specifically mention the benefits of certain types of activities. There also were comments on governance, and numerous specific comments on the nine priority objectives of the implementation strategy, and other specific recommendations (e.g., reauthorize certain laws). The following summarizes some of the key substantive comments received and how the Task Force addressed them:

1. Overall Tone and Balance

   Comments have suggested that the balance between conservation and ocean uses in the report was skewed too much toward stewardship, and failed to emphasize certain types of uses such as recreational fishing, aquaculture, or renewable energy. The Task Force determined that the overall tone and balance of the recommendations were consistent with the President's direction to recommend a stewardship policy for the ocean, our coasts, and the Great Lakes. Improved stewardship will support not only healthier and more resilient ocean, coastal, and Great Lakes ecosystems and services, but also benefit the economies (e.g., commercial and recreational activities) and communities that rely on them. The Task Force recognizes the

05-05-10 DELIBERATIVE PRE-DECISIONAL COMMUNICATION
NOT ADMINISTRATION POLICY -- DO NOT RELEASE

significant role of recreation and other existing and emerging sustainable uses (e.g., renewable energy, aquaculture) of ocean, coasts, and Great Lakes resources. However, it did not single out individual sectors for discussion in the recommendations. Rather, the recommendations discuss better managing all uses of the ocean, coasts, and Great Lakes in a sustainable manner.

2. Recreational Users

Comments expressed a concern that recreational fishing interests and the unique distinction between recreational and commercial fishing were not adequately represented in the *Interim Report.* Additionally, the Task Force received comments to recognize that recreational users (e.g., anglers, boaters, and other outdoor enthusiasts) not only use and rely on the health of ocean, coastal, and Great Lakes resources, but have a long history of actively participating in their conservation and stewardship.

The Task Force made several changes in the recommendations to distinguish recreational and commercial fishing and to more expressly recognize the importance of access to the ocean, our coasts, and the Great Lakes for recreation. The Task Force recognizes the importance of recreation, including sustainable recreational fishing, and that Americans should continue to enjoy such outdoor experiences, which are also critical to the economic, social, and cultural fabric of our country. Recreational users have a long history of actively participating in the stewardship of the ocean, coastal, and Great Lakes resources. Ensuring healthier oceans, coasts, and Great Lakes will benefit all recreational activities and the communities and economies that rely on them.

3. Ecosystem-Based Management

A range of comments were received concerning the use of ecosystem-based management in the *Interim Report.* Some suggested that the language regarding ecosystem-based management be strengthened while others would like to ensure that ecosystem-based management, while a good principle, not be mandated. The Task Force determined that this principle, which was articulated in the President's June 12, 2009 memorandum, is critical to how we govern and manage our ocean, coasts, and Great Lakes and should remain as one of the nine priority objectives. How ecosystem-based management will be defined and implemented would be further addressed by the NOC as it develops a strategic action plan for this priority objective.

4. Precautionary Approach

A range of comments were received concerning the use of the precautionary approach as one of the National Principles. Application of a precautionary approach, as defined in the recommendations ("[w]here there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation"), is consistent with and essential for improved stewardship. Moreover, the United States has already affirmed this exact wording in the 1992

Rio Declaration on Environment and Development. Many comments supported its inclusion while others were concerned it would be used to prevent activities from occurring. These latter comments, however, may have misinterpreted the precautionary approach here as mandating, for example, the prohibition of activities that present an uncertain potential for significant harm unless the proponent of the activity shows that it presents no appreciable risk of harm. The Task Force has retained the precautionary approach as reflected in the Rio Declaration in its final recommendations, as it believes that we must be able to avail ourselves of timely, cost-effective stewardship measures, consistent with the approach articulated in the Rio Declaration. Some comments used the term "precautionary principle," but the United States has long taken the position that precaution is a tool or approach rather than a "principle," given the lack of a single definition or agreed formulation and the differing implications of its various forms.

5. National Ocean Council Membership

Comments were received on the role of the National Oceanic and Atmospheric Administration (NOAA) in the recommended governance structure, particularly that it should have a more prominent role on the NOC. The Department of Commerce would have a seat on the NOC. However, the Task Force recognizes that NOAA (an agency within the Department of Commerce) plays a particularly important role in coastal and ocean research, planning, and management. While the Task Force had always envisioned that NOAA would have a substantial role within the NOC and in the implementation of these recommendations, the Task Force has determined that the final recommendations should be more explicit by clarifying that the NOAA Administrator should also be added as a member of the NOC.

6. State, Tribal, and Local Government Role

A variety of comments were received pertaining to the role of State, tribal, and local governments in the recommended governance structure. Comments advocated for a greater role for State, tribal, and local governments and for more detail regarding the interplay of the Governance Advisory Committee with other entities in the NOC structure. The Task Force addressed these comments in five main areas: (1) changing the name of the Governance Advisory Committee to the Governance Coordinating Committee (GCC) to more accurately reflect its function; (2) modifying the composition of the GCC to include representation from local governments and State legislatures; (3) expressly acknowledging the unique legal relationship with federally recognized American Indian and Alaska Native tribal governments; (4) clarifying GCC functions and its relationship to other governance structure entities; and (5) strengthening coordination and collaboration between the GCC and various levels of the NOC.

7. Transparency and Public Input

   Comments suggested adding more detail on how the NOC will incorporate public input and keep the public informed about its actions. The Task Force addressed these comments throughout the recommendations, including adding new text that expressly identifies the need for the NOC to ensure substantial opportunity for public participation as it develops strategic action plans.

8. Additional Priority Objectives and Specificity of Implementation Strategy

   Comments suggested a range of additional priority objectives, including Community and Cultural Access, Protection of Culture and Traditions, Caribbean and the Pacific Islands, Antarctica, Coral Reefs, Marine Aquaculture, Recreational Fishing, Fisheries Management, Renewable Energy, Marine Transportation Safety, and Collaborative Environmental Problem Solving in Underserved Coastal Communities. While the Task Force strongly considered a wide array of priority objectives, the Task Force determined that the nine priority objectives, with some minor modifications, set out in these recommendations were the most appropriate initial priorities of the NOC. In addition, the NOC may always identify additional or different priority objectives in years to come. In fact, the functions of the NOC include updating and setting national priority objectives, as well as providing National Policy implementation objectives. Comments also advocated for more specificity in the implementation strategy, but the Task Force determined that further clarity and detail is best determined by the NOC and its component bodies.

Comments on the Interim Framework for Effective Coastal and Marine Spatial Planning

Substantive comments on the *Interim Framework* ranged from questioning the overall need for coastal and marine spatial planning (CMSP) to general support for a new, more efficient, ecosystem-based approach to managing sustainable uses of the ocean, our coasts, and the Great Lakes. Some comments also advocated for ensuring that CMSP provides a balance between economic uses and stewardship, while others raised questions or concerns over the relationship of CMSP to existing processes and authorities and specifics of how the process will work. Some comments were similar to those received on the *Interim Report* and are addressed in the previous section. The following summarizes some of the additional key substantive comments received on the Interim Framework and how the Task Force addressed them.

1. Why Coastal and Marine Spatial Planning

   Comments raised a variety of issues regarding the general nature of this effort. For example, it was suggested that the *Interim Framework* did not provide an adequate description of the problem trying to be solved; that existing processes are sufficient and only require improved coordination rather than a new top-down bureaucracy with too much authority vested in the National Ocean Council. Other comments strongly supported the need for CMSP and

the benefits to be derived from more proactive, multi-objective, multi-sectoral planning. Some comments raised concern that many processes in the *Interim Framework* were vague and required greater clarity and definition of terms (e.g., ecosystem-based management).

The recommendations describe a flexible, regionally based approach for the development of CMSP. The NOC would facilitate development of coastal and marine spatial plans (CMS Plans) and provide national guidance to ensure national consistency, as appropriate. The Task Force has made a number of changes to better clarify the processes described in the recommendations. The recommendations also describe that the NOC would provide further clarity through the development of a strategic action plan and national guidance documents, which would be developed with public and stakeholder input.

2. Overarching Goals, Principles, and Nature of Coastal and Marine Spatial Planning

Comments suggested that the *Interim Framework* should have as its primary overarching goal "protection, maintenance, and restoration" as this is a fundamental goal that supports all others (e.g., healthy ecosystems support the full range of ecosystem services). Other comments suggested that the *Interim Framework* should recognize benefits of commercial and recreational uses, and the significant economic benefits to be derived from the responsible production of energy resources, and other economic activities in Federal offshore waters.

The Task Force agrees that healthy ecosystems provide the foundation for the full range of ecological services the ocean, coasts, and Great Lakes provide, including economic, environmental, and societal benefits. CMSP is intended to result in better management of and planning for sustainable multiple uses (e.g., energy, recreation, and commercial and recreational fishing) across sectors as well as to improve conservation of the ocean, coasts, and Great Lakes. The Task Force believes that the recommendations adequately discuss the multi-objective nature of CMSP and the potential economic, environmental, and societal benefits.

3. Integration, Cooperation, and Coordination

Comments requested that the Task Force clarify that CMSP is intended to build off of and incorporate existing plans, processes, and authorities. Comments also requested that the Task Force recognize that certain decisions should be left to, or deference be given to, State decision-makers. There are a number of places throughout the *Interim Framework* (e.g., "Essential Elements of the CMSP Process") that expressly discuss the relationship of CMSP to existing processes. The Task Force has made additional clarifying changes to address these comments.

4. Geographic Scope

There were a number of comments on various aspects of the geographic scope for CMSP, including the treatment of private lands, inland areas, and bays and estuaries. The recommendations exclude private lands from the CMSP planning area; clarifying that the

exclusion applies to all private lands, not only private submerged lands. The Task Force decided to leave the regional planning bodies with the flexibility to include inland areas within the geographic scope, but has recommended that the NOC, in coordination with the GCC, develop guidance for the regional planning bodies to help determine whether to include inland areas. Finally, the Task Force determined to maintain the requirement to include bays and estuaries due to the strong linkages with ocean, coastal, and Great Lakes areas.

5. Development and Implementation of Coastal and Marine Spatial Planning

A number of comments raised questions regarding the role, composition, and operation of the regional planning bodies. The Task Force has maintained the core composition of regional planning bodies to include State, Federal, and tribal authorities, and has further articulated the types of representatives to be considered for inclusion. The Task Force did not add local governments to the regional planning bodies due to the numerous and wide variety of local authorities that could result in very disparate participation and representation across regions. However, the recommendations require regional planning bodies to coordinate with local governments, as appropriate, throughout the process.

Some comments suggested adding a Regional Fishery Management Council (RFMC) representative to the regional planning bodies given their unique quasi-regulatory role under the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act). The Task Force is interested in finding the most effective opportunity for sustained and meaningful engagement with the RFMCs as it is their statutory responsibility to develop fishery management plans and management measures for fisheries which NOAA then reviews and, if approves, implements through regulation. While the Task Force acknowledges the relatively unique role that RFMCs play, it did not want to prescribe a particular method for how RFMCs should be included in the CMSP process without more thoughtful consideration and analysis. The recommendations describe that the regional planning bodies would provide a formal mechanism for consultation with the RFMCs across their respective regions on fishery related issues and that the NOC would further assess if representation on the regional planning bodies is the best method for this engagement. In the future, if other statutorily-mandated or quasi-regulatory groups are identified, the NOC would determine whether a formal mechanism for consultation should be developed for such groups and, if necessary, provide guidance for regional planning bodies on the development of such a process.

Comments questioned how the regional planning bodies would operate, who would lead them, and how decisions would be made. Comments also suggested clarifying that the regions could create sub-regional planning bodies. The Task Force has clarified that the work plan to be developed by each regional planning body would specify the participants, Federal and non-Federal co-lead(s), timing, milestones, etc. The Task Force also clarified that there would be flexibility to develop sub-regional plans provided that these plans are encompassed in the

regional planning body's final CMS Plan. The Task Force recognized that this flexibility may be particularly useful in the Alaska/Arctic and Pacific Islands Regions.

There were a number of comments regarding strengthening involvement of stakeholders, the public, and scientific and technical experts in the CMSP process. The recommendations clarify and strengthen their role in CMSP, including requiring the development of inclusive and transparent stakeholder and scientific participation and consultation mechanisms in each region.

6. Nature of Planning Process and CMS Plans and Adherence to CMS Plans

Comments raised questions about whether CMS Plans would be comprehensive, multi-objective, and multi-sectoral. The Task Force has clarified that while there is flexibility as part of the CMSP process to address different priority issues at certain times, the final CMS Plans would be required to achieve this level of comprehensiveness in order to receive NOC certification. The Task Force also clarified that while it is recognized that CMSP is an iterative process and initial CMS Plans would likely identify gaps in understanding that may limit the ability to make informed decisions at a particular time, these gaps would be identified in the CMS Plan along with an implementation approach to how they would be addressed in future iterations of the CMS Plan.

A number of comments raised questions regarding the binding or non-binding nature of CMS Plans and the requirements to adhere to them. Comments also questioned the scope of the allowance for deviations from CMS Plans. The Task Force has clarified the language regarding the binding nature of CMS Plans to be consistent throughout the document. As it relates to deviations, the existing language allows for deviations from CMS Plans, but requires periodic reviews to determine why they are occurring and to identify remedies to minimize such deviations. The Task Force expects that as agencies gain experience with this process, any deviations would be minimized. The Task Force does not intend this language to be a broad exemption to CMS Plans.

Comments also expressed that the *Interim Framework* does not clearly establish the relationships between CMS Plans and existing regulatory authorities, including the Magnuson-Stevens Fishery Conservation and Management Act, Coastal Zone Management Act, and Outer Continental Shelf Lands Act. The Task Force has added language to better clarify the relationship between CMSP and existing authorities.

Comments suggested that the Task Force consider adding language that addresses what happens if a State opts out or a regional plan does not meet NOC certification requirements. The Task Force has added language clarifying that even if some States or tribes opt out of the CMS Process, the Federal, and participating State and tribal authorities would continue to develop and implement a regional CMS Plan.

7. National Consistency

Comments raised concerns that with nine different regions there could be different standards applied to the same activities (e.g., ballast water), or potential for other significant inconsistencies regarding commerce and other socio-economic sectors. The recommendations make clear that the NOC would develop national guidance and objectives to ensure national consistency and seek to minimize inconsistencies and conflicts across regions for cross-cutting or national issues. Development of this guidance would include opportunities for robust public and stakeholder participation.

8. Scientific Knowledge and Data Integration, Research, Management, and Access

Comments raised concerns over the complexities and resources needed to create a new information management system and encouraged adapting an existing system or search tool as an alternative. Comments also requested that the Interim Framework make clear that State, local, and other data would be included in the system, not only Federal data. Other comments requested a greater emphasis on local and traditional knowledge as data/information sources. These issues have been addressed in the recommendations.

9. Implementation

Comments on the length of the implementation process varied from the timeframe for development of CMS Plans being too short to excessively long. The Task Force determined that given the varied range of comments the phased, flexible approach recommended in the document provides an ambitious, but achievable timeline to develop CMSP in the United States.

10. Resources

While the Task Force is mindful of the national economic situation and budgetary challenges, it is confident that making the investments and improvements in these recommendations will advance the economic interests of the United States and facilitate greater efficiencies across the Federal Government. Recognizing the reality of the limited availability of new resources, Federal agencies would re-evaluate how resources are allocated in light of their statutory and regulatory mandates to further the recommended National Policy. Also, the President's Fiscal Year 2011 Budget Request includes funding that would support priority activities identified in these recommendations, such as coastal and marine spatial planning, geospatial modernization, regional ocean partnerships, water quality improvement, habitat restoration, integrated ecosystem assessments, coastal and estuarine land protection, research and development of ocean sensor technology, and environmental tools to support resilient coastal communities.

5.

Information on the National Ocean Council

THE WHITE HOUSE

Office of the Press Secretary

For Immediate Release July 19, 2010

EXECUTIVE ORDER

- - - - - - -

STEWARDSHIP OF THE OCEAN, OUR COASTS, AND THE GREAT LAKES

By the authority vested in me as President by the Constitution and the laws of the United States of America, it is hereby ordered as follows:

Section 1. Purpose. The ocean, our coasts, and the Great Lakes provide jobs, food, energy resources, ecological services, recreation, and tourism opportunities, and play critical roles in our Nation's transportation, economy, and trade, as well as the global mobility of our Armed Forces and the maintenance of international peace and security. The Deepwater Horizon oil spill in the Gulf of Mexico and resulting environmental crisis is a stark reminder of how vulnerable our marine environments are, and how much communities and the Nation rely on healthy and resilient ocean and coastal ecosystems. America's stewardship of the ocean, our coasts, and the Great Lakes is intrinsically linked to environmental sustainability, human health and well-being, national prosperity, adaptation to climate and other environmental changes, social justice, international diplomacy, and national and homeland security.

This order adopts the recommendations of the Interagency Ocean Policy Task Force, except where otherwise provided in this order, and directs executive agencies to implement those recommendations under the guidance of a National Ocean Council. Based on those recommendations, this order establishes a national policy to ensure the protection, maintenance, and restoration of the health of ocean, coastal, and Great Lakes ecosystems and resources, enhance the sustainability of ocean and coastal economies, preserve our maritime heritage, support sustainable uses and access, provide for adaptive management to enhance our understanding of and capacity to respond to climate change and ocean acidification, and coordinate with our national security and foreign policy interests.

This order also provides for the development of coastal and marine spatial plans that build upon and improve existing Federal, State, tribal, local, and regional decisionmaking and planning processes. These regional plans will enable a more integrated, comprehensive, ecosystem-based, flexible, and proactive approach to planning and managing sustainable multiple uses across sectors and improve the conservation of the ocean, our coasts, and the Great Lakes.

more

(OVER)

Sec. 2. Policy. (a) To achieve an America whose stewardship ensures that the ocean, our coasts, and the Great Lakes are healthy and resilient, safe and productive, and understood and treasured so as to promote the well-being, prosperity, and security of present and future generations, it is the policy of the United States to:

(i) protect, maintain, and restore the health and biological diversity of ocean, coastal, and Great Lakes ecosystems and resources;

(ii) improve the resiliency of ocean, coastal, and Great Lakes ecosystems, communities, and economies;

(iii) bolster the conservation and sustainable uses of land in ways that will improve the health of ocean, coastal, and Great Lakes ecosystems;

(iv) use the best available science and knowledge to inform decisions affecting the ocean, our coasts, and the Great Lakes, and enhance humanity's capacity to understand, respond, and adapt to a changing global environment;

(v) support sustainable, safe, secure, and productive access to, and uses of the ocean, our coasts, and the Great Lakes;

(vi) respect and preserve our Nation's maritime heritage, including our social, cultural, recreational, and historical values;

(vii) exercise rights and jurisdiction and perform duties in accordance with applicable international law, including respect for and preservation of navigational rights and freedoms, which are essential for the global economy and international peace and security;

(viii) increase scientific understanding of ocean, coastal, and Great Lakes ecosystems as part of the global interconnected systems of air, land, ice, and water, including their relationships to humans and their activities;

(ix) improve our understanding and awareness of changing environmental conditions, trends, and their causes, and of human activities taking place in ocean, coastal, and Great Lakes waters; and

(x) foster a public understanding of the value of the ocean, our coasts, and the Great Lakes to build a foundation for improved stewardship.

(b) The United States shall promote this policy by:

(i) ensuring a comprehensive and collaborative framework for the stewardship of the ocean, our coasts, and the Great Lakes that facilitates cohesive actions across the Federal Government, as well as participation of State, tribal, and local authorities, regional governance structures, nongovernmental organizations, the public, and the private sector;

(ii) cooperating and exercising leadership at the international level;

(iii) pursuing the United States' accession to the Law of the Sea Convention; and

(iv) supporting ocean stewardship in a fiscally responsible manner.

Sec. 3. Definitions. As used in this order:

(a) "Final Recommendations" means the *Final Recommendations of the Interagency Ocean Policy Task Force* that shall be made publicly available and for which a notice of public availability shall be published in the *Federal Register*.

(b) The term "coastal and marine spatial planning" means a comprehensive, adaptive, integrated, ecosystem-based, and transparent spatial planning process, based on sound science, for analyzing current and anticipated uses of ocean, coastal, and Great Lakes areas. Coastal and marine spatial planning identifies areas most suitable for various types or classes of activities in order to reduce conflicts among uses, reduce environmental impacts, facilitate compatible uses, and preserve critical ecosystem services to meet economic, environmental, security, and social objectives. In practical terms, coastal and marine spatial planning provides a public policy process for society to better determine how the ocean, our coasts, and Great Lakes are sustainably used and protected -- now and for future generations.

(c) The term "coastal and marine spatial plans" means the plans that are certified by the National Ocean Council as developed in accordance with the definition, goals, principles, and process described in the Final Recommendations.

Sec. 4. Establishment of National Ocean Council. (a) There is hereby established the National Ocean Council (Council).

(b) The Council shall consist of the following:

(i) the Chair of the Council on Environmental Quality and the Director of the Office of Science and Technology Policy, who shall be the Co-Chairs of the Council;

(ii) the Secretaries of State, Defense, the Interior, Agriculture, Health and Human Services, Commerce, Labor, Transportation, Energy, and Homeland Security, the Attorney General, the Administrator of the Environmental Protection Agency, the Director of the Office of Management and Budget, the Under Secretary of Commerce for Oceans and Atmosphere (Administrator of the National Oceanic and Atmospheric Administration), the Administrator of the National Aeronautics and Space Administration, the Director of National Intelligence, the Director of the National Science Foundation, and the Chairman of the Joint Chiefs of Staff;

(iii) the National Security Advisor and the Assistants to the President for Homeland Security and Counterterrorism, Domestic Policy, Energy and Climate Change, and Economic Policy;

(iv) an employee of the Federal Government designated by the Vice President; and

(v) such other officers or employees of the Federal Government as the Co-Chairs of the Council may from time to time designate.

(c) The Co-Chairs shall invite the participation of the Chairman of the Federal Energy Regulatory Commission, to the extent consistent with the Commission's statutory authorities and legal obligations, and may invite the participation of such other independent agencies as the Council deems appropriate.

(d) The Co-Chairs of the Council, in consultation with the National Security Advisor and the Assistant to the President for Homeland Security and Counterterrorism, shall regularly convene and preside at meetings of the Council, determine its agenda, direct its work, and, as appropriate to address particular subject matters, establish and direct committees of the Council that shall consist exclusively of members of the Council.

(e) A member of the Council may designate, to perform committee functions of the member, any person who is within such member's department, agency, or office and who is (i) an officer of the United States appointed by the President, (ii) a member of the Senior Executive Service or the Senior Intelligence Service, (iii) a general officer or flag officer, or (iv) an employee of the Vice President.

(f) Consistent with applicable law and subject to the availability of appropriations, the Office of Science and Technology Policy and the Council on Environmental Quality shall provide the Council with funding, including through the National Science and Technology Council or the Office of Environmental Quality. The Council on Environmental Quality shall, to the extent permitted by law and subject to the availability of appropriations, provide administrative support necessary to implement this order.

(g) The day-to-day operations of the Council shall be administered by a Director and a Deputy Director, who shall supervise a full-time staff to assist the Co-Chairs in their implementation of this order.

Sec. 5. Functions of the Council. (a) The Council shall have the structure and function and operate as defined in the Final Recommendations. The Council is authorized, after the Council's first year of operation, to make modifications to its structure, function, and operations to improve its effectiveness and efficiency in furthering the policy set forth in section 2 of this order.

(b) To implement the policy set forth in section 2 of this order, the Council shall provide appropriate direction to ensure that executive departments', agencies', or offices' decisions and actions affecting the ocean, our coasts, and the Great Lakes will be guided by the stewardship principles and national priority objectives set forth in the Final Recommendations, to the extent consistent with applicable law. The Council shall base its decisions on the consensus of its members. With respect to those matters in which consensus cannot be reached, the National Security Advisor shall coordinate with the Co-Chairs and, as appropriate, the Assistants to the President for Energy and Climate Change, and Economic Policy, and the employee of the United States designated by the Vice President, subject to the limitations set forth in section 9 of this order, to present the disputed issue or issues for decision by the President.

Sec. 6. Agency Responsibilities. (a) All executive departments, agencies, and offices that are members of the Council and any other executive department, agency, or office whose actions affect the ocean, our coasts, and the Great Lakes shall, to the fullest extent consistent with applicable law:

(i) take such action as necessary to implement the policy set forth in section 2 of this order and the stewardship principles and national priority objectives as set forth in the Final Recommendations and subsequent guidance from the Council; and

(ii) participate in the process for coastal and marine spatial planning and comply with Council certified coastal and marine spatial plans, as described in the Final Recommendations and subsequent guidance from the Council.

(b) Each executive department, agency, and office that is required to take actions under this order shall prepare and make publicly available an annual report including a concise description of actions taken by the agency in the previous calendar year to implement the order, a description of written comments by persons or organizations regarding the agency's compliance with this order, and the agency's response to such comments.

(c) Each executive department, agency, and office that is required to take actions under this order shall coordinate and contribute resources, as appropriate, to assist in establishing a common information management system as defined in the Final Recommendations and shall be held accountable for managing its own information assets by keeping them current, easily accessible, and consistent with Federal standards.

(d) To the extent permitted by law, executive departments, agencies, and offices shall provide the Council such information, support, and assistance as the Council, through the Co-Chairs, may request.

Sec. 7. Governance Coordinating Committee. The Council shall establish a Governance Coordinating Committee that shall consist of 18 officials from State, tribal, and local governments in accordance with the Final Recommendations. The Committee may establish subcommittees chaired by representatives of the Governance Coordinating Committee. These subcommittees may include additional representatives from State, tribal, and local governments, as appropriate to provide for greater collaboration and diversity of views.

Sec. 8. Regional Advisory Committees. The lead Federal department, agency, or office for each regional planning body established for the development of regional coastal and marine spatial plans, in consultation with their nonfederal co-lead agencies and membership of their regional planning body, shall establish such advisory committees under the Federal Advisory Committee Act, 5 U.S.C. App., as they deem necessary to provide information and to advise the regional planning body on the development of regional coastal and marine spatial plans to promote the policy established in section 2 of this order.

Sec. 9. General Provisions. (a) Nothing in this order, the establishment of the Council, and the Final Recommendations shall be construed to impair or otherwise affect:

(i) authority granted by law to an executive department or agency or the head thereof; or

(ii) functions assigned by the President to the National Security Council or Homeland Security Council (including subordinate bodies) relating to matters affecting foreign affairs, national security, homeland security, or intelligence.

(b) Nothing in this order shall be construed to impair or otherwise affect the functions of the Director of the Office of Management and Budget relating to budgetary, administrative, or legislative proposals.

(c) In carrying out the provisions of this order and implementing the Final Recommendations, all actions of the Council and the executive departments, agencies, and offices that constitute it shall be consistent with applicable international law, including customary international law, such as that reflected in the Law of the Sea Convention.

(d) This order is not intended to, and does not, create any right or benefit, substantive or procedural, enforceable at law or in equity by any party against the United States, its departments, agencies, or entities, its officers, employees, or agents, or any other person.

Sec. 10. Revocation. Executive Order 13366 of December 17, 2004, is hereby revoked.

BARACK OBAMA

Obama Administration Establishes National Policy to Protect Oceans, Coasts, and Great Lakes and Creates National Ocean Council to Oversee and Implement New Policy

By Emily Pitlick, John Clements, John Burnes, John Iani, and Jon Simon

On July 19, 2010, President Obama issued an Executive Order creating a national policy to promote stewardship of the ocean, coasts, and Great Lakes, to be implemented by federal agencies under the guidance of a new National Ocean Council (Council). The Order provides for the development of coastal and marine spatial plans (CMS Plans) based on ecosystem management to analyze current and future uses of ocean, coastal, and Great Lakes areas. The CMS Plans would identify areas most suitable for various types of activities and could impact existing and future commercial uses of these areas, such as oil and gas recovery and renewable wind and hydrokinetic projects, commercial and recreational fisheries, and those land-based industries that may degrade water quality and the ocean ecosystem through industrial runoff. The national policy emphasizes the need to provide for enhanced sustainability of the ocean, coastal and Great Lakes ecosystems and resources through science and adaptive management, and emphasizes understanding of the ecosystems' response to climate change and ocean acidification, as well as national security and foreign policy interests.

BACKGROUND

Although the Executive Order refers to the recent Deepwater Horizon oil spill in the Gulf of Mexico, its major driver appears to be the Final Recommendations of the Interagency Ocean Policy Task Force (Task Force), released simultaneously with the Executive Order and which the Executive Order adopts in full. The Task Force is a multi-agency entity led by the Council on Environmental Quality (CEQ) that was created by Executive Order in June 2009 to develop a national policy that ensures the protection, maintenance, and restoration of the health of ocean, coastal, and Great Lakes ecosystems and resources, including coastal and marine spatial planning (CMSP). Task Force members included two-dozen federal agencies and offices, including the Departments of Agriculture, Commerce, Defense, Justice, the Interior, and Energy, as well as the Environmental Protection Agency (EPA) and the Federal Energy Regulatory Commission (FERC).

The Council, which was recommended by the Task Force, will supersede the existing Committee on Ocean Policy that was created by President George W. Bush in 2004. It will be co-chaired by the Chair of CEQ and the Director of the White House Office of Science and Technology Policy. The Council's other members include the Secretaries of most cabinet-level agencies, such as State, Defense, the Interior, Agriculture, Commerce, Transportation, and Energy, and the heads of independent agencies such as EPA and the National Science Foundation (NSF). FERC, an independent agency in the Executive Branch of the federal government, is invited to participate consistent with its statutory authorities and legal obligations. The Executive Order directs all Council members, or other Executive branch offices whose actions affect the ocean, the coasts and the

Great Lakes, to participate in the CMSP process. Each implicated department, agency or office is also required to prepare an annual report describing its actions over the previous year to implement the Executive Order that includes a description of received written comments regarding that agency's compliance and its response to such comments.

COASTAL AND MARINE SPATIAL PLANNING

The purpose of the CMSP process is to identify areas most suitable for various types or classes of activities in order to reduce conflicts among uses, reduce environmental impacts, facilitate compatible uses, and preserve critical ecosystems to meet economic, environmental, security and social objectives. The planning process would broaden the scope of considerations in existing permitting for competing offshore uses (e.g., commercial fishing, and oil and gas exploration and development, and recreational purposes like boating and beach access) to permit a more integrated, comprehensive, ecosystem-based, flexible and proactive approach to planning managing these uses and activities.

The planning area includes the territorial sea, the United States' Exclusive Economic Zone (EEZ), and the Continental Shelf, as well as inland bays and estuaries. To make the task more manageable, the entire planning area is divided into nine regional planning areas based on large marine ecosystems: Alaska/Arctic, Caribbean, Great Lakes, Gulf of Mexico, Mid-Atlantic, Northeast, Pacific Islands, South Atlantic, and West Coast. Each of these regions would have a CMS Plan based on region-specific objectives to be developed by a regional planning body composed of federal, state, and tribal authorities relevant to the region, in consultation with the public and scientific and technical experts. The Council would oversee all regions' CMS Plan development and provide a dispute resolution process should conflicts arise. Each CMS Plan would then be certified by the Council for national consistency. Agencies intending to take an action inconsistent with a certified CMS Plan will be required to provide advance notice to the regional planning body and the Council, including justification for non-adherence to the plan.

RELATIONSHIP OF CMS PLANS TO EXISTING AUTHORITIES

The Executive Order creates no new or independent legal authority. CMS Plans will not be considered to be regulations and will not constitute final agency decision-making. Rather, the Council is intended to work within existing authority. The CMS Plans it certifies are intended to *guide* agency decision-making. However, the federal, state, and tribal authorities are anticipated to incorporate components of the CMS Plan into their respective regulations to the extent possible and enforce their regulatory programs consistent with their statutory authorities and the CMSP goals.

TIMELINE FOR IMPLEMENTATION

The new national policy will be developed in four phases, lasting through 2015 at the earliest. A preliminary phase is organization of the Council. During Phase I, the Council is expected to create Strategic Action Plans for CMSP over a year-long period while coordinating with federal agencies, states and federally recognized tribes, and while gathering data for science-based planning. Phase II, expected to begin nine months after the Council is organized and to consist of continued data gathering, initial regional step implementations, and work plan development. Full implementation of the CMSP process, Phase III, could take up to five years after the Council is organized. While Strategic Action Plans are being developed, Federal agencies are to continue to use

their existing processes for project development, but can begin to consider CMSP principles in their decision-making.

IMPLICATIONS

At this preliminary stage of development, the impact of the new national policy and the process to be implemented by the Council is uncertain. Much will depend on the substantive content of the regional CMS Plans that will be adopted, and how well the process works. The goal of the Executive Order is to establish a framework for a better coordinated and informed process for assessing the increasing and often competing uses of the nation's ocean, coastal, and Great Lakes water resources. That process envisions substantial stakeholder, scientific, and public input. On the one hand, increasing input can improve the process by developing a more complete record on which decisions can be based. On the other hand, the determination of which activities are suitable for specific areas may be controversial, and unless reasonable rules are established, the process can easily become more complex and lengthy, or bogged down by disputes that may delay the ultimate decision. Depending on how the Executive Order is implemented, these plans could have substantial impacts on a broad range of coastal development activities including entities operating existing energy projects or proposing to build new projects, fisheries, aquaculture, and commerce and transportation. These may include:

- A need to participate in the public and stakeholder engagement processes that will be used to develop regional CMS Plans, as well as in federal, state, or local rulemaking proceedings to implement regional CMS Plans;

- Additional consultation and data gathering requirements for initial permitting and permit renewals at the federal, state, and local level, including expanded emphasis on potential cumulative effects on "large marine ecosystems;" and

- New restrictions on energy development activities, commercial and recreational fisheries and aquaculture, as well as commerce and transportation, such as the establishment of zones where specific activities are prohibited, and new additional ongoing environmental impact analysis requirements.

FOR ADDITIONAL INFORMATION

For clients with business interests impacted by ongoing federal regulatory and policy developments relating to the use of U.S. waterways and coastal areas, Van Ness Feldman offers significant depth of experience and capabilities. Over half of the firm's 80 lawyers and policy advisors have worked as congressional staff, or at the U.S. Departments of the Interior and Energy, the U.S. Environmental Protection Agency, the Federal Energy Regulatory Commission, and the White House. Our professionals monitor federal regulatory and policy developments on a daily basis, and provide strategic advice to a range of clients. For more information, please contact any of the authors listed on this alert, or your usual Van Ness Feldman point of contact at 202.298.1800 in Washington, D.C. or 206.623.9372 in Seattle, WA.

Information on the Climate Change Adaptation Task Force

White House Climate Change Adaptation Task Force

In 2009, the White House Council on Environmental Quality (CEQ), the Office of Science and Technology Policy (OSTP), and the National Oceanic and Atmospheric Administration (NOAA) initiated the Interagency Climate Change Adaptation Task Force, which includes representatives from more than 20 Federal Agencies. When the President signed the Executive Order on Federal Leadership in Environmental, Energy, and Economic Performance, on October 5, 2009, he called on the Task Force to develop, within one year, Federal recommendations for adapting to climate change impacts both domestically and internationally.

Interim Progress Report

On March 16, 2010, the Task Force released an Interim Progress Report which outlines the Task Force's progress to date and recommends key components to include in a national strategy on climate change adaptation. These six components include:

1. Integration of Science into Adaptation Decisions and Policy
2. Communications and Capacity-building
3. Coordination and Collaboration
4. Prioritization
5. A Flexible Framework for Agencies
6. Evaluation

The Interim Progress Report is available for 60 days of public comment. Submit your comment here.

Workgroups

The Interagency Climate Change Adaptation Task Force formed workgroups to consider the capabilities of the Federal Government to respond to the impacts of climate change on various critical sectors, institutions, and agency mission responsibilities. Five initial workgroups began by reviewing existing policies, operations, procedures, and other tools that affect the Federal Government's response, and will suggest options for improving the government's capacity for adaptation to climate change. The five initial workgroups are focused on the following topics:

- **Agency Adaptation**: Develop recommendations on how agencies should plan and implement adaptation
- **Science Inputs to Policy**: Develop recommendations to couple the production of scientific and technical support to adaptation planning, prioritization, and resilience building within the USG, in the US, and internationally
- **Insurance**: Develop recommendations on opportunities for the United States Government to support insurance and adaptation issues
- **Water Resources Adaptation**: Develop recommendations on how Federal water management agencies should plan and implement adaptation actions related to climate impacts on water resources
- **International Resilience**: Develop recommendations on opportunities for the United States Government to support and lead international adaptation efforts

These workgroups have defined their scope and end products, and have begun initial analysis. Most workgroups have used stakeholder listening sessions to solicit feedback from various government and regional actors on adaptation issues within their respective issue area.

Listening Sessions

The five initial Interagency Climate Change Adaptation Task Force workgroups hosted twenty listening sessions with key stakeholders and experts. The listening sessions were designed to engage the expertise and recommendations of external organizations into the workgroup deliberations early in this review process.

Final Product

October 2010, the Task Force will report to the President on the development of domestic and international dimensions of a U.S. approach to climate change adaptation and what Federal Agencies are doing to support this effort. The Task Force also will recommend additional aspects to consider in the development of a comprehensive national strategy.

Progress Report of the Interagency Climate Change Adaptation Task Force

March 16, 2010

Introduction

The impacts of climate change already are being felt across the United States and the entire world. The U.S. Global Change Research Program 2009 report, *Global Climate Change Impacts in the United States*, summarizes the science of climate change and the impacts of climate change on the United States, now, and some of those expected in the future.[1] These impacts will influence how and where we live and work as well as our cultures, health, and environment. In the years and decades to come, they will grow and affect future generations. It is therefore imperative to take action now to adapt to a changing climate. Given the uncertainty of many specific impacts, we also need to build resilience to help minimize the risks associated with climate change and maximize any opportunities that climate change may create.

Continuing to reduce greenhouse gas emissions is critical to limiting the extent of climate change impacts, and resulting damage. The Obama Administration is committed to creating a clean energy economy and mitigating climate change by reducing emissions. While increased mitigation efforts will reduce the effects of climate change, impacts will continue to occur, reinforcing the need for adaptation and a focus on resilience.

> ***Adaptation*** is defined by the Intergovernmental Panel on Climate Change as "adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities."
>
> ***Resilience*** is defined as "the capacity of a system to absorb disturbance and still retain its basic function and structure."

Adaptation and resilience will require a set of thoughtful, preventative actions, measures and investments to reduce the vulnerability of our natural and human systems to climate change impacts. This will require new approaches and preparation, especially at the local level as regional impacts differ greatly. Adaptation and resilience will require action from all segments of society—the public sector, local to Federal government, the private sector, the nonprofit sector and individuals. This challenge provides Federal, Tribal, State, and local governments with significant opportunities for innovation.

Process

The U.S. Global Change Research Act of 1990 established the U.S. Global Change Research Program (USGCRP) "to understand, assess, predict, and respond to human-induced and natural processes of global change." For more than 20 years, the USGCRP has been effectively delivering on understanding and predicting climate change. To further advance and coordinate Federal agency efforts to assess and respond, the USGCRP is currently conducting a national climate assessment and developing the research and science necessary to support a Federal adaptation strategy.

In parallel and in coordination with USGCRP, the White House Council on Environmental Quality (CEQ), the White House Office of Science and Technology Policy (OSTP), and the National Oceanic and Atmospheric Administration (NOAA) convened the Interagency Climate Change Adaptation Task Force to begin to develop Federal recommendations for adapting to climate change impacts both domestically and internationally. More than twenty Federal Agencies, Departments and Offices are participating in this Task Force and contributing their operational capabilities and expertise through a series of workgroups, coordinated with USGCRP, on specific topics related to climate change adaptation.[ii] President Obama placed special emphasis on adaptation when he ordered, on October 5, 2009, the establishment of an integrated strategy towards sustainability in the Federal Government. Part of this order referenced the work of the Task Force and called on it to report to him within a year on Agency actions in support of developing the domestic and international dimensions of a U.S. strategy for adaptation to climate change.

Goals of the interagency adaptation work include:

- Forming recommendations toward a national adaptation strategy that uses a set of best practices derived from the best available science and the experience and knowledge of governments and stakeholder groups across the United States and abroad.
- Integrating climate change resilience and adaptive capacity into Federal government operations, and coordinating interagency preparations for climate change impacts with domestic and international activities.
- Broadening the understanding of vulnerability to climate impacts, equipping communities with information to use in local adaptation policies, and learning from communities who have taken steps to adapt.

As required by Executive Order 13514, the Interagency Climate Change Adaptation Task Force will deliver a report to the President in the Fall of 2010. The report will detail the development of domestic and international dimensions of a U.S. strategy for adaptation to climate change, agency actions in support of that strategy development process, and recommendations for any further measures to advance towards a national strategy. The Task Force will not, however, deliver a complete U.S. adaptation strategy to the President.

Five workgroups (on science inputs to adaptation, agency process, water resource management, insurance, and international assistance) are currently reviewing existing policies, operations,

procedures, and other tools that affect the Federal government's ability to respond to and prepare for climate impacts. These workgroups will suggest options for improving the government's adaptive capacity as climate change continues. To date, the workgroups have reviewed relevant literature, analyzed existing agency adaptation activities, and conducted listening sessions with external groups and experts on managing climate impacts and adaptation efforts. Case studies, legislative proposals, and comparisons of other governments' approaches are also being reviewed and considered.

Progress to Date

The Task Force has found that climate change is affecting, and will continue to affect, nearly every aspect of our society and the environment. Some of the impacts are increased severity of floods, droughts, and heat waves, increased wildfires, and sea level rise. Climate change impacts are pervasive, wide-ranging and affect the core systems of our society: transportation, ecosystems, agriculture, business, infrastructure, water, and energy, among others. Climate change already is affecting the ability of Federal agencies to fulfill their missions. As a result of these changes, U.S. government interests, missions and operations must adapt to climate change and build resilience. It is imperative that adaptation to climate change and building resilience both help to manage climate change risks to human well-being and ecosystems and take advantage of the opportunities created by climate change. Both domestically and internationally, the U.S. government must better understand how to build resilience to climate change risks and adapt to its effects in order to make wise investments and effective policies. The U.S. government also will need to help support local, regional and international adaptation and resilience efforts.

The Task Force has found that there already is substantial U.S. government and non-government activity towards adapting and building resilience to climate change risks. Current activities include landscape conservation cooperatives supported by the Department of the Interior, to a comprehensive risk assessment of Gulf Coast transportation infrastructure by the Department of Transportation, to the Environmental Protection Agency's efforts to support local decision-makers through Climate Ready Estuaries and the Climate Ready Water Utilities Working Group, and the Department of Energy's research and development to reduce water intensity of energy technologies. However, there still are significant gaps in the U.S. government's approach to climate change adaptation and building resilience. These include:

- Coherent research programs to identify and describe regional impacts associated with near-term, long-term, and abrupt global climate change
- Relevant climate change and impact information that is accessible and usable by decision-makers and practitioners
- A unified strategic vision and approach
- Understanding of the challenges at all levels of government
- Comprehensive and localized risk and vulnerability assessments
- Organized and coordinated efforts across local, State and Federal agencies

- Strong links between, and support and participation of, Tribal, regional, State, and local partners
- A strategy to link resources, both financial and intellectual, to critical needs
- A robust approach to evaluating and applying lessons learned

A national strategy for climate change adaptation and resilience would help address these gaps. The strategy should emphasize two major changes in the way the U.S. government operates. First, agency climate change adaptation and resilience requires a flexible, forward thinking approach. This represents a shift away from using past conditions as indicators of the future, and a requirement for on-going investigation, revision and adaptive management. Second, responses to climate change challenges and opportunities should be integrated into current plans, processes and approaches of the U.S. government. This integration will allow adaptation and building resilience to become part of existing activities, and to be considered within the context of the broader system of stresses, risks and opportunities.

The approach to developing a national strategy should be guided by a set of principles informed by the Task Force's work to date. The national strategy should emphasize planning and preparation, ensuring the engagement of stakeholders, including States, Tribes, local governments, the private sector and non-government institutions, and understanding and accommodating differing vulnerabilities across people and places. It should include a systemic approach to the problem, considering how a range of risks and opportunities interact, as well as how existing and potential stresses reduce or amplify these risks and opportunities. Environmental sustainability and coordination with greenhouse gas mitigation efforts also are critical to national adaptation efforts.

At a minimum, a national strategy should include the following six elements:

1. **Science Inputs to Adaptation Decisions and Policy.** In making recommendations toward a national strategy, the Task Force may recommend approaches for coordinating, developing, distributing and integrating science, from physical to socioeconomics, into all aspects of adaptation. Managers and planners need to understand how to best access and take advantage of science as improvements are made to guidance, standards, and best practices. Integrating science into the decision-making process will allow us to confront uncertainty about future outcomes with improved information about risks and opportunities.

   Adaptation capacity also can be enhanced through participatory processes, improved communication, and better access to improved science translated for users. Finally, institutional changes are needed to enable the use of science that informs adaptation, including the translation of this science into decision-support tools and policy. The Task Force may develop recommendations on advancing and integrating science for users and increasing coordination with research communities.

2. **Communications and Capacity-building.** A key communications goal is to build awareness and engage relevant stakeholders in developing adaptation approaches and ensuring the success of adaptation efforts. Additional capacity also will be required at multiple levels, within and outside of local, State and Federal governments, which will be essential for sustained adaptation and resilience. The Task Force may develop recommendations on communicating climate change impacts, adaptation, and resilience and on building capacity within the U.S. government, including prioritizing opportunities for additional training and resources.

3. **Coordination and Collaboration.** Adaptation to climate change and building resilience will require collaboration and coordination between U.S. government entities. It is also critical to engage local stakeholders, including States, Tribes, local governments, the private sector and non-government institutions. A formal approach, with clear processes and facilitation, is required to ensure that this coordination and collaboration occurs. The Task Force may develop recommendations for structuring the national adaptation strategy within the Federal government and for increasing and improving coordination and collaboration across the government and with partners. Where appropriate, the Task Force may recommend approaches to address existing policies or public sector programs that work at cross-purposes with efforts to build resilience or adapt to climate change, including those that subsidize behavior or investments that increase vulnerability to climate risks.

4. **Prioritization:** Since climate change has multiple impacts and resources are limited, it will be critical to identify priority areas for a coordinated government response. The Task Force may consider and make recommendations on how to identify priorities; this discussion of how to identify priorities could include such criteria as the presence of co-benefits and resource needs for the areas. Combined with the structural elements of a national adaptation strategy, these priorities will require coordinated planning, and in some cases, collaborative actions. The Task Force has begun work on several areas that may require a coordinated government response, and is developing recommendations for water resource management and for international adaptation and resilience.

    - Recommendations for water resource management may include those addressing: coordinated planning and evaluation for water resources adaptation and resilience; water resources and climate change data; assessing vulnerability of water resources to climate change; water use efficiency; integrated water resources management; and education of water resource managers.

    - Recommendations for international adaptation may include those addressing: increasing the integration of adaptation into existing inter-agency international efforts; increasing coordination among U.S. government agencies on international adaptation and increasing collaboration with international partners to build knowledge, increasing

the harmonization of efforts, more effectively supporting multilateral organizations, and further developing the role of the private sector.

Additional areas will be added as the Task Force continues its work.

5. **A Flexible Framework for Agencies.** U.S. government agencies and entities need a consistent but flexible framework to understand, analyze, and respond to climate change challenges and opportunities. Adapting to climate change and building resilience requires planning within and across agencies. There is no single planning approach appropriate for all agencies, but each should use a consistent framework to facilitate coordination across agencies and allow agencies to leverage common tools and methods. This flexible framework will help agencies identify and address climate vulnerabilities and opportunities and build resilience to climate change.

   The framework includes a set of principles to guide agency adaptation and resilience activities, an approach to climate change adaptation and resilience agency planning, and a proposed set of government-wide priorities to support the effective implementation of the planning framework. Critical components of the planning approach are: building agency skills and capacity; developing an adaptation mandate with success measures; assessing the substantial risks, vulnerabilities, and opportunities posed by climate change; developing adaptation and resilience-building actions; and assessing the results and learning from the process to improve future adaptation and resilience.

   Implementing the framework will require a focus on common tools and information. These tools could include common scenario-based analyses, integrated climate change database management, or new modeling tools that match downscaled climate information with other data collected by individual agencies such as demographics, land use, or energy production. The Task Force may implement agency pilots to further develop and test the framework, and will continue to develop recommendations on the common tools required to support implementation.

6. **Evaluation.** Adaptation to climate change and building resilience must come with a commitment to dynamic engagement, iterative understanding of results, and rigorous evaluation. Though the evidence base for many stressors influenced by climate change is established, assumptions and models for implementation and evaluation have to change as scientific knowledge increases and the climate continues to change. Also, lessons learned and information collected in one effort may contain useful lessons for others.

   Adaptation plans must allow for a "feedback" mechanism, whereby new information, lessons learned, and modified priorities can be incorporated into ongoing adaptation processes. Evaluation and lessons learned will help provide clear guidance for decision-making that enhances adaptation and resiliency. The Task Force may develop recommendations on how to evaluate the success of adaptation and resilience building efforts.

Next Steps

Over the next seven months, the Interagency Climate Change Adaptation Task Force may refine recommendations around structural issues such as improving and integrating science results in developing policy and a framework for Federal agency adaptation, as well as cross-cutting topics, including water resources management and international adaptation. The Task Force also may establish additional workgroups, in cooperation with USGCRP, including those to inform the development of a national strategy in the areas of communications and capacity-building, coordination and collaboration across government and with partners, evaluation and learning, and other priority issues. Through a series of regional outreach meetings and pilot activities, the Task Force will continue moving towards recommendations on the development of a national strategy on climate change adaptation.

This report is available and public comment is being accepted on our website at www.whitehouse.gov/ceq/initiatives/adaptation.

Information on the Arctic Marine Shipping Assessment

AMSA Executive Summary with Recommendations

The Arctic is undergoing extraordinary transformations early in the 21st century. Natural resource development, governance challenges, climate change and marine infrastructure issues are influencing current and future marine uses of the Arctic. The Arctic Council, recognizing these critical changes and issues, at the November 2004 Ministerial meeting in Reykjavik, Iceland, called for the Council's Protection of the Arctic Marine Environment (PAME) working group to "conduct a comprehensive Arctic marine shipping assessment as outlined under the Arctic Marine Strategic Plan (AMSP) under the guidance of Canada, Finland and the United States as lead countries and in collaboration with the Emergency Prevention, Preparedness and Response (EPPR) working group and the Permanent Participants as relevant." *The Arctic Marine Shipping Assessment*, or *The AMSA 2009 Report*, is the product of that Arctic Ministerial decision in Reykjavik and was approved at the 2009 Ministerial meeting in Tromsø.

The decision to conduct the AMSA followed the release in 2004 of two relevant Arctic Council reports. First, the Arctic Climate Impact Assessment (ACIA) was a major study that received global attention and reported on the rapid and severe climate change ongoing in the Arctic. One of the key findings of the ACIA was that "reduced sea ice is very likely to increase marine transport and access to resources." The second report, the Arctic Marine Strategic Plan (AMSP), presented the council's strategic goals for protecting the Arctic marine environment. The AMSP called for future application of an ecosystems approach to the Arctic Ocean and for a comprehensive assessment of Arctic marine shipping.

The AMSA is designed to be circumpolar in breadth and also to consider regional and local perspectives. The assessment's central focus is on ships: their uses of the Arctic Ocean, their potential impacts on humans and the Arctic marine environment and their marine infrastructure requirements. The AMSA does not place a

primary focus on determining the operational and economic viabilities of specific marine routes within and across the Arctic Ocean.

The AMSA, led by Canada, Finland and the United States, reached out to a broad community, including the global maritime community consisting of shipping companies, ship designers, shipbuilders, ship classification societies, marine insurers, non-commercial partnerships and shipping associations. With the support of the Permanent Participants (indigenous organizations) of the Arctic Council, town hall meetings were held in selected Arctic communities in Canada, Iceland, Norway and the United States to listen to issues and concerns about future Arctic marine activity. The AMSA linked directly with experts of PAME for marine environmental protection issues and overall guidance and leadership of the AMSA. Two additional Arctic Council working groups were also consulted: the Emergency Prevention, Preparedness and Response (EPPR) working group on spill response and marine infrastructure requirements; and the Sustainable Development Working Group (SDWG) on issues related to the human dimension.

All ship types are considered in the AMSA under the general topic of Arctic shipping: tankers, bulk carriers, offshore supply vessels, passenger ships, tug/barge combinations, fishing vessels, ferries, research vessels and government and commercial icebreakers. The result of the AMSA data survey effort produced a comprehensive estimate of how many ships (less naval vessels) operated in the Arctic for a given year. This survey represents an historic capture of information from the Arctic states that can be used as a long-term database against which to measure future Arctic marine traffic levels. In addition, more than 185 experts participated directly in the work of the AMSA. Thirteen major AMSA workshops were held from July 2006 through October 2008 on a broad range of relevant topics, including scenarios of future Arctic navigation, indigenous marine use, Arctic marine incidents, environmental impacts, marine infrastructure, Arctic marine technology and the future of the Northern Sea Route and adjacent seas. The AMSA workshops provided extensive information for developing the report sections.

Synopsis of the Assessment Findings

The AMSA 2009 Report is focused on current and future Arctic marine activity. The results of this comprehensive assessment are a range of key findings linked to the main topics identified. These findings are listed in full throughout *The AMSA 2009 Report* at the end of each section. Presented here is a synopsis, or review, of the AMSA findings for each section.

Arctic Marine Geography, Climate and Sea Ice: Arctic sea ice has been observed to be decreasing in extent and thickness during the second half of the 20th century and early 21st century. Global Climate Model simulations indicate a continuing retreat of sea ice, but also show that the winter sea ice cover will remain. There is a possibility of an ice-free Arctic Ocean for a short period in summer perhaps as early as 2015. This would mean the disappearance of multi-year ice, as no sea ice would survive the summer melt season. It is highly plausible there will be greater marine access and longer seasons of navigation, except perhaps during winter, but not necessarily less difficult ice conditions for marine operations.

History of Arctic Marine Transport: There is a long history of Arctic marine transport conducted primarily around the ice-free periphery of the Arctic Ocean. Year-round navigation has been maintained since 1978-79 in the ice-covered western regions of the Northern Sea Route (between the port of Dudinka on the Yenisei River and Murmansk). Previous Arctic marine transport studies for the Northern Sea Route, Canadian Arctic, Alaska's coastal seas and other regions have significant relevance to developing any future regulatory framework for the Arctic Ocean. Most of these past studies involved public-private partnerships and close international cooperation.

Governance of Arctic Shipping: The Law of the Sea as reflected in the *United Nations Convention on the Law of the Sea* (UNCLOS) provides a fundamental framework for the governance of Arctic marine navigation and allows coastal states the right to adopt and enforce non-discriminatory laws and regulations for the prevention, reduction and control of marine pollution from vessels in ice-covered waters (Article 234). The International Maritime Organization (IMO) is the competent UN agency with responsibility for issues related to the global maritime industry. IMO has been proactive in developing voluntary *Guidelines for Ships Operating in Arctic Ice-covered Waters*, which continue to evolve. The International Association of Classification Societies (IACS) has also developed non-mandatory Unified Requirements for their members that address ship construction standards of the *Polar Classes*, which are defined in the IMO Guidelines. There are no uniform, international standards for ice navigators and for Arctic safety and survival for seafarers in polar conditions. And, there are no specifically tailored, mandatory environmental standards developed by IMO for vessels operating in Arctic waters. Mandatory measures, drawn up in accordance with the provisions of customary international law as reflected in UNCLOS, would be an effective way to enhance marine safety and environmental protection in Arctic waters. Expanded Arctic marine traffic increases the possibility of, for example, introducing alien species and pathogens from ballast water discharge and hull fouling.

Current Marine Use and the AMSA Shipping Database: There were approximately 6,000 individual vessels, many making multiple voyages, in the Arctic region during the AMSA survey year; half of these were operating on the Great Circle Route in the North Pacific that crosses the Aleutian Islands. Of the 6,000 vessels reported, approximately 1,600 were fishing vessels. Nearly all shipping in the

Arctic today is destinational, conducted for community re-supply, marine tourism and moving natural resources out of the Arctic. Regions of high concentrations of Arctic marine activity occur along the coasts of northwest Russia, and in the ice-free waters off Norway, Greenland, Iceland and in the U.S. Arctic. Significant increases in cruise ships, a majority not purpose-built for Arctic waters, have been observed in the summer season around Greenland within the past decade. There have been recent marine operations in the ice-covered central Arctic Ocean for scientific exploration and marine tourism.

Scenarios, Futures and Regional Futures to 2020: Arctic natural resource development (hydrocarbons, hard minerals and fisheries) and regional trade are the key drivers of future Arctic marine activity. However, there are many other factors and uncertainties of importance including governance, Arctic state cooperation, oil prices, changes in global trade, climate change variability, new resource discoveries, marine insurance industry roles, multiple use conflicts and Arctic marine technologies. Future Arctic marine activity will include many non-Arctic stakeholders, multiple users in Arctic waterways and potential overlap of new operations with indigenous uses. Arctic voyages through 2020 will be overwhelmingly destinational, not trans-Arctic. A lack of major ports, except for those in northern Norway and northwest Russia, and other critical infrastructure will be significant limitations for future Arctic marine operations. The Bering Strait region, ringed with indigenous communities and a highly productive ecosystem with many species of marine mammals, fish and seabirds, may require formally established vessel routing measures. Offshore hydrocarbon developments may lead to increased marine traffic in the Bering Strait region. For the Canadian Arctic, the Northwest Passage is not expected to become a viable trans-Arctic route through 2020, but destinational shipping is anticipated to increase. Marine transportation of oil from the Pechora Sea to Europe is considered technically and economically feasible; the volume of oil and gas may be as high as 40 million tons per year by 2020 on the western Northern Sea Route.

Human Dimensions: Marine shipping is one of many factors impacting Arctic communities. There may be some positive economic impacts to increased shipping. However, Arctic residents express concern for the social, cultural and environmental effects of such expansion. The possibility of oil spills is a major concern and hunters are especially concerned about the disruption of marine species and their hunting practices. The costs and benefit of Arctic shipping will likely be unevenly distributed among and within communities and regions. Constructive and early engagement of local residents in planned Arctic marine development projects can help to reduce negative impacts and to increase positive benefits. Importantly, many local Arctic residents today depend heavily on marine resources for subsistence and the local economy; over-the-ice travel and boat transport allow the use of large marine areas during much of the year. Such life in the Arctic is dependent on movement over the ice and ocean and sea ice is integral to this movement.

Environmental Considerations and Impacts: The most significant threat from ships to the Arctic marine environment is the release of oil through accidental or illegal discharge. Additional potential impacts of Arctic ships include ship strikes on marine mammals, the introduction of alien species, disruption of migratory patterns of marine mammals and anthropogenic noise produced from marine shipping activity. Changes in Arctic sea ice will not only provide for possible longer seasons of navigation, but may also result in increased interaction between migrating species and ships. Black carbon emissions from ships operating in the Arctic may have regional impacts by accelerating ice melt. Other ship emissions during Arctic voyages, such as SOx and NOx, may have unintended consequences for the Arctic environment and these emissions may require the implementation of additional IMO environmental regulations.

Arctic Marine Infrastructure: There is a general lack of marine infrastructure in the Arctic, except for areas along the Norwegian coast and northwest Russia, compared with other marine regions of the world with high concentrations of ship traffic. Gaps in hydrographic data exist for significant portions of primary shipping routes important to support safe navigation. In addition, for safe operations in the Arctic there is a need for the same suite of meteorological and oceanographic data, products and services as in other oceans, plus comprehensive information on sea ice and icebergs. Except in limited areas of the Arctic, there is a lack of emergency response capacity for saving lives and for pollution mitigation. There are serious limitations to radio and satellite communications and few systems to monitor and control the movement of ships in ice-covered waters. The current lack of marine infrastructure in all but a limited number of areas, coupled with the vastness and harshness of the environment, makes conduct of emergency response significantly more difficult in the Arctic.

The Arctic Marine Shipping Assessment Recommendations

The focus of the AMSA is marine safety and marine environmental protection, which is consistent with the Arctic Council's mandates of environmental protection and sustainable development. Based on the findings of the AMSA, recommendations were developed to provide a guide for future action by the Arctic Council, Arctic states and many others. The AMSA recommendations are presented under three broad, inter-related themes that are fundamental to understanding the AMSA: Enhancing Arctic Marine Safety, Protecting Arctic People and the Environment, and Building Arctic Marine Infrastructure. It is recognized that implementation of these recommendations could come from the Arctic states, industry and/or public-private partnerships.

I. Enhancing Arctic Marine Safety

A. Linking with International Organizations: That the Arctic states decide to, on a case by case basis, identify areas of common interest and develop unified positions and approaches with respect to international organizations such as: the International Maritime Organization (IMO), the International Hydrographic Organization (IHO), the World Meteorological Organization (WMO) and the International Maritime Satellite Organization (IMSO) to advance the safety of Arctic marine shipping; and encourage meetings, as appropriate, of member state national maritime safety organizations to coordinate, harmonize and enhance the implementation of the Arctic maritime regulatory framework.

B. IMO Measures for Arctic Shipping: That the Arctic states, in recognition of the unique environmental and navigational conditions in the Arctic, decide to cooperatively support efforts at the International Maritime Organization to strengthen, harmonize and regularly update international standards for vessels operating in the Arctic. These efforts include:

---Support the updating and the mandatory application of relevant parts of the *Guidelines for Ships Operating in Arctic Ice-covered Waters* (Arctic Guidelines); and,

---Drawing from IMO instruments, in particular the Arctic Guidelines, augment global IMO ship safety and pollution prevention conventions with specific mandatory requirements or other provisions for ship construction, design, equipment, crewing, training and operations, aimed at safety and protection of the Arctic environment.

C. Uniformity of Arctic Shipping Governance: That the Arctic states should explore the possible harmonization of Arctic marine shipping regulatory regimes within their own jurisdiction and uniform Arctic safety and environmental protection regulatory regimes, consistent with UNCLOS, that could provide a basis for protection measures in regions of the central Arctic Ocean beyond coastal state jurisdiction for consideration by the IMO.

D. Strengthening Passenger Ship Safety in Arctic Waters: That the Arctic states should support the application of the IMO's *Enhanced Contingency Planning Guidance for Passenger Ships Operating in Areas Remote from SAR Facilities*, given the extreme challenges associated with rescue operations in the remote and cold Arctic region and strongly encourage cruise ship operators to develop, implement and share their own best practices for operating in such conditions, including consideration of measures such as timing voyages so that other ships are within rescue distance in case of emergency.

E. Arctic Search and Rescue (SAR) Instrument: That the Arctic states decide to support developing and implementing a comprehensive, multi-[illegible] Arctic Search and Rescue (SAR) instrument, including aeronautical and maritime SAR, among the eight Arctic nations and, if appropriate, with other interested parties in recognition of the remoteness and limited resources in the region.

II. Protecting Arctic People and the Environment

A. Survey of Arctic Indigenous Marine Use: That the Arctic states should consider conducting surveys on Arctic marine use by indigenous communities where gaps are identified to collect information for establishing up-to-date baseline data to assess the impacts from Arctic shipping activities.

B. Engagement with Arctic Communities: That the Arctic states decide to determine if effective communication mechanisms exist to ensure engagement of their Arctic coastal communities and, where there are none, to develop their own mechanisms to engage and coordinate with the shipping industry, relevant economic activities and Arctic communities (in particular during the planning phase of a new marine activity) to increase benefits and help reduce the impacts from shipping.

C. Areas of Heightened Ecological and Cultural Significance: That the Arctic states should identify areas of heightened ecological and cultural significance in light of changing climate conditions and increasing multiple marine use and, where appropriate, should encourage implementation of measures to protect these areas from the impacts of Arctic marine shipping, in coordination with all stakeholders and consistent with international law.

D. Specially Designated Arctic Marine Areas: That the Arctic states should, taking into account the special characteristics of the Arctic marine environment, explore the need for internationally designated areas for the purpose of environmental protection in regions of the Arctic Ocean. This could be done through the use of appropriate tools, such as "Special Areas" or Particularly Sensitive Sea Areas (PSSA) designation through the IMO and consistent with the existing international legal framework in the Arctic.

E. Protection from Invasive Species: That the Arctic states should consider ratification of the IMO *International Convention for the Control and Management of Ships Ballast Water and Sediments*, as soon as practical. Arctic states should also assess the risk of introducing invasive species through ballast water and other means so that adequate prevention measures can be implemented in waters under their jurisdiction.

F. Oil Spill Prevention: That the Arctic states decide to enhance the mutual cooperation in the field of oil spill prevention and, in collaboration with industry, support research and technology transfer to prevent release of oil into Arctic waters, since prevention of oil spills is the highest priority in the Arctic for environmental protection.

G. Addressing Impacts on Marine Mammals: That the Arctic states decide to engage with relevant international organizations to further assess the effects on marine mammals due to ship noise, disturbance and strikes in Arctic waters; and consider, where needed, to work with the IMO in developing and implementing mitigation strategies.

H. Reducing Air Emissions: That the Arctic states decide to support the development of improved practices and innovative technologies for ships in port and at sea to help reduce current and future emissions of greenhouse gases (GHGs), Nitrogen Oxides (NOx), Sulfur Oxides (SOx) and Particulate Matter (PM), taking into account the relevant IMO regulations.

III. Building the Arctic Marine Infrastructure

A. Addressing the Infrastructure Deficit: That the Arctic states should recognize that improvements in Arctic marine infrastructure are needed to enhance safety and environmental protection in support of sustainable development. Examples of infrastructure where critical improvements are needed include: ice navigation training; navigational charts; communications systems; port services, including reception facilities for ship-generated waste; accurate and timely ice information (ice centers); places of refuge; and icebreakers to assist in response.

B. Arctic Marine Traffic System: That the Arctic states should support continued development of a comprehensive Arctic marine traffic awareness system to improve monitoring and tracking of marine activity, to enhance data sharing in near real-time, and to augment vessel management service in order to reduce the risk of incidents, facilitate response and provide awareness of potential user conflict. The Arctic states should encourage shipping companies to cooperate in the improvement and development of national monitoring systems.

C. Circumpolar Environmental Response Capacity: That the Arctic states decide to continue to develop circumpolar environmental pollution response capabilities that are critical to protecting the unique Arctic ecosystem. This can be accomplished, for example, through circumpolar cooperation and agreement(s), as well as regional bilateral capacity agreements.

D. Investing in Hydrographic, Meteorological and Oceanographic Data: That the Arctic states should significantly improve, where appropriate, the level of and access to data and information in support of safe navigation and voyage planning in Arctic waters. This would entail increased efforts for: hydrographic surveys to bring Arctic navigation charts up to a level acceptable to support current and future safe navigation; and systems to support real-time acquisition, analysis and transfer of meteorological, oceanographic, sea ice and iceberg information.

Guide to Acronyms and Abbreviations

ACRONYM	DEFINITION
ACIA	Arctic Climate Impact Assessment
AIS	Automatic Identification System
AMAP	Arctic Monitoring and Assessment Programme (Arctic Council working group)
AMSA	Arctic Marine Shipping Assessment
AMVER	Automated Mutual-Assistance Vessel Rescue System
ARCOP	Arctic Operational Platform
ATON	Aid to Navigation
AWPPA	*Arctic Waters Pollution Prevention Act* (Canada)
CCG	Canadian Coast Guard
CFC	chlorofluorocarbon
CH4	methane
CNIIMF	Central Marine Research & Design Institute (Russian Federation)
CO	carbon monoxide
CO2	carbon dioxide
COLREG	*Convention on the International Regulations for Preventing Collisions at Sea, 1972*
DEW	Distant Early Warning Line
DWT	deadweight tonnage
ECDIS	Electronic Chart Display and Information System
EEZ	Exclusive Economic Zone
EPPR	Emergency Prevention, Preparedness and Response (Arctic Council working group)
EU	European Union
GCM	Global Climate Model
GHG	greenhouse gas
GIS	Geographic Information System
GPS	Global Positioning System
HF	high frequency
IAATO	International Association of Antarctic Tour Operators
IACS	International Association of Classification Societies
ICC	Inuit Circumpolar Council
IHO	International Hydrographic Organization
IMO	International Maritime Organization
INSROP	International Northern Sea Route Programme
IPCC	Intergovernmental Panel on Climate Change
kW	kilowatt (1,000 watts)
LME	Large Marine Ecosystem
LNG	liquefied natural gas
LPG	liquefied petroleum gas
M/V	Motor Vessel
MARPOL 73/78	*International Convention for the Prevention of Pollution from Ships, 1973 as Modified by the Protocol of 1978 Relating Thereto*
MF	medium frequency
MMT	million metric ton
MPA	marine protected area
NEP	Northeast Passage
NGO	non-governmental organization
nm	nautical mile
NOAA	National Oceanic and Atmospheric Administration (U.S.)
NOx	nitrogen oxide
NSR	Northern Sea Route
NWP	Northwest Passage
PAME	Protection of the Arctic Marine Environment (Arctic Council working group)
POP	persistent organic pollutant
ppm	parts per million
PSSA	Particularly Sensitive Sea Area
RACON	radar beacon
RORO	roll on, roll off (type of cargo ship)
SAR	search and rescue
shp	shaft horsepower
SOLAS	*International Convention on Safety of Life at Sea, 1974*
SOx	sulfur oxide
STCW	*International Convention on Standards of Training, Certification and Watchkeeping for Seafarers, 1978*
TDW	tonnage draft weight
TEU	twenty-foot equivalent (measure used in container shipping)
UNCLOS	*United Nations Convention on the Law of the Sea, 1982*
USCG	United States Coast Guard
VHF	very high frequency
VTS	Vessel Traffic Service
WMO	World Meteorological Organization

AMSA Executive Summary with Recommendations

The Arctic is undergoing extraordinary transformations early in the 21st century. Natural resource development, governance challenges, climate change and marine infrastructure issues are influencing current and future marine uses of the Arctic. The Arctic Council, recognizing these critical changes and issues, at the November 2004 Ministerial meeting in Reykjavik, Iceland, called for the Council's Protection of the Arctic Marine Environment (PAME) working group to "conduct a comprehensive Arctic marine shipping assessment as outlined under the Arctic Marine Strategic Plan (AMSP) under the guidance of Canada, Finland and the United States as lead countries and in collaboration with the Emergency Prevention, Preparedness and Response (EPPR) working group and the Permanent Participants as relevant." *The Arctic Marine Shipping Assessment*, or *The AMSA 2009 Report*, is the product of that Arctic Ministerial decision in Reykjavik and was approved at the 2009 Ministerial meeting in Tromsø.

The decision to conduct the AMSA followed the release in 2004 of two relevant Arctic Council reports. First, the Arctic Climate Impact Assessment (ACIA) was a major study that received global attention and reported on the rapid and severe climate change ongoing in the Arctic. One of the key findings of the ACIA was that "reduced sea ice is very likely to increase marine transport and access to resources." The second report, the Arctic Marine Strategic Plan (AMSP), presented the council's strategic goals for protecting the Arctic marine environment. The AMSP called for future application of an ecosystems approach to the Arctic Ocean and for a comprehensive assessment of Arctic marine shipping.

The AMSA is designed to be circumpolar in breadth and also to consider regional and local perspectives. The assessment's central focus is on ships: their uses of the Arctic Ocean, their potential impacts on humans and the Arctic marine environment and their marine infrastructure requirements. The AMSA does not place a

primary focus on determining the operational and economic viabilities of specific marine routes within and across the Arctic Ocean.

The AMSA, led by Canada, Finland and the United States, reached out to a broad community, including the global maritime community consisting of shipping companies, ship designers, shipbuilders, ship classification societies, marine insurers, non-commercial partnerships and shipping associations. With the support of the Permanent Participants (indigenous organizations) of the Arctic Council, town hall meetings were held in selected Arctic communities in Canada, Iceland, Norway and the United States to listen to issues and concerns about future Arctic marine activity. The AMSA linked directly with experts of PAME for marine environmental protection issues and overall guidance and leadership of the AMSA. Two additional Arctic Council working groups were also consulted: the Emergency Prevention, Preparedness and Response (EPPR) working group on spill response and marine infrastructure requirements; and the Sustainable Development Working Group (SDWG) on issues related to the human dimension.

All ship types are considered in the AMSA under the general topic of Arctic shipping: tankers, bulk carriers, offshore supply vessels, passenger ships, tug/barge combinations, fishing vessels, ferries, research vessels and government and commercial icebreakers. The result of the AMSA data survey effort produced a comprehensive estimate of how many ships (less naval vessels) operated in the Arctic for a given year. This survey represents an historic capture of information from the Arctic states that can be used as a long-term database against which to measure future Arctic marine traffic levels. In addition, more than 185 experts participated directly in the work of the AMSA. Thirteen major AMSA workshops were held from July 2006 through October 2008 on a broad range of relevant topics, including scenarios of future Arctic navigation, indigenous marine use, Arctic marine incidents, environmental impacts, marine infrastructure, Arctic marine technology and the future of the Northern Sea Route and adjacent seas. The AMSA workshops provided extensive information for developing the report sections.

Synopsis of the Assessment Findings

The AMSA 2009 Report is focused on current and future Arctic marine activity. The results of this comprehensive assessment are a range of key findings linked to the main topics identified. These findings are listed in full throughout *The AMSA 2009 Report* at the end of each section. Presented here is a synopsis, or review, of the AMSA findings for each section.

Arctic Marine Geography, Climate and Sea Ice: Arctic sea ice has been observed to be decreasing in extent and thickness during the second half of the 20th century and early 21st century. Global Climate Model simulations indicate a continuing retreat of sea ice, but also show that the winter sea ice cover will remain. There is a possibility of an ice-free Arctic Ocean for a short period in summer perhaps as early as 2015. This would mean the disappearance of multi-year ice, as no sea ice would survive the summer melt season. It is highly plausible there will be greater marine access and longer seasons of navigation, except perhaps during winter, but not necessarily less difficult ice conditions for marine operations.

History of Arctic Marine Transport: There is a long history of Arctic marine transport conducted primarily around the ice-free periphery of the Arctic Ocean. Year-round navigation has been maintained since 1978-79 in the ice-covered western regions of the Northern Sea Route (between the port of Dudinka on the Yenisei River and Murmansk). Previous Arctic marine transport studies for the Northern Sea Route, Canadian Arctic, Alaska's coastal seas and other regions have significant relevance to developing any future regulatory framework for the Arctic Ocean. Most of these past studies involved public-private partnerships and close international cooperation.

Governance of Arctic Shipping: The Law of the Sea, as reflected in the *United Nations Convention on the Law of the Sea* (UNCLOS), provides a fundamental framework for the governance of Arctic marine navigation and allows coastal states the right to adopt and enforce non-discriminatory laws and regulations for the prevention, reduction and control of marine pollution from vessels in ice-covered waters (Article 234). The International Maritime Organization (IMO) is the competent UN agency with responsibility for issues related to the global maritime industry. IMO has been proactive in developing voluntary *Guidelines for Ships Operating in Arctic Ice-covered Waters,* which continue to evolve. The International Association of Classification Societies (IACS) has also developed non-mandatory Unified Requirements for their members that address ship construction standards of the *Polar Classes*, which are defined in the IMO Guidelines. There are no uniform, international standards for ice navigators and for Arctic safety and survival for seafarers in polar conditions. And, there are no specifically tailored, mandatory environmental standards developed by IMO for vessels operating in Arctic waters. Mandatory measures, drawn up in accordance with the provisions of customary international law as reflected in UNCLOS, would be an effective way to enhance marine safety and environmental protection in Arctic waters. Expanded Arctic marine traffic increases the possibility of, for example, introducing alien species and pathogens from ballast water discharge and hull fouling.

Current Marine Use and the AMSA Shipping Database: There were approximately 6,000 individual vessels, many making multiple voyages, in the Arctic region during the AMSA survey year; half of these were operating on the Great Circle Route in the North Pacific that crosses the Aleutian Islands. Of the 6,000 vessels reported, approximately 1,600 were fishing vessels. Nearly all shipping in the

Arctic today is destinational, conducted for community re-supply, marine tourism and moving natural resources out of the Arctic. Regions of high concentrations of Arctic marine activity occur along the coasts of northwest Russia, and in the ice-free waters off Norway, Greenland, Iceland and in the U.S. Arctic. Significant increases in cruise ships, a majority not purpose-built for Arctic waters, have been observed in the summer season around Greenland within the past decade. There have been recent marine operations in the ice-covered central Arctic Ocean for scientific exploration and marine tourism.

Scenarios, Futures and Regional Futures to 2020: Arctic natural resource development (hydrocarbons, hard minerals and fisheries) and regional trade are the key drivers of future Arctic marine activity. However, there are many other factors and uncertainties of importance including governance, Arctic state cooperation, oil prices, changes in global trade, climate change variability, new resource discoveries, marine insurance industry roles, multiple use conflicts and Arctic marine technologies. Future Arctic marine activity will include many non-Arctic stakeholders, multiple users in Arctic waterways and potential overlap of new operations with indigenous uses. Arctic voyages through 2020 will be overwhelmingly destinational, not trans-Arctic. A lack of major ports, except for those in northern Norway and northwest Russia, and other critical infrastructure will be significant limitations for future Arctic marine operations. The Bering Strait region, ringed with indigenous communities and a highly productive ecosystem with many species of marine mammals, fish and seabirds, may require formally established vessel routing measures. Offshore hydrocarbon developments may lead to increased marine traffic in the Bering Strait region. For the Canadian Arctic, the Northwest Passage is not expected to become a viable trans-Arctic route through 2020, but destinational shipping is anticipated to increase. Marine transportation of oil from the Pechora Sea to Europe is considered technically and economically feasible; the volume of oil and gas may be as high as 40 million tons per year by 2020 on the western Northern Sea Route.

Human Dimensions: Marine shipping is one of many factors impacting Arctic communities. There may be some positive economic impacts to increased shipping. However, Arctic residents express concern for the social, cultural and environmental effects of such expansion. The possibility of oil spills is a major concern and hunters are especially concerned about the disruption of marine species and their hunting practices. The costs and benefit of Arctic shipping will likely be unevenly distributed among and within communities and regions. Constructive and early engagement of local residents in planned Arctic marine development projects can help to reduce negative impacts and to increase positive benefits. Importantly, many local Arctic residents today depend heavily on marine resources for subsistence and the local economy; over-the-ice travel and boat transport allow the use of large marine areas during much of the year. Such life in the Arctic is dependent on movement over the ice and ocean and sea ice is integral to this movement.

Environmental Considerations and Impacts: The most significant threat from ships to the Arctic marine environment is the release of oil through accidental or illegal discharge. Additional potential impacts of Arctic ships include ship strikes on marine mammals, the introduction of alien species, disruption of migratory patterns of marine mammals and anthropogenic noise produced from marine shipping activity. Changes in Arctic sea ice will not only provide for possible longer seasons of navigation, but may also result in increased interaction between migrating species and ships. Black carbon emissions from ships operating in the Arctic may have regional impacts by accelerating ice melt. Other ship emissions during Arctic voyages, such as SOx and NOx, may have unintended consequences for the Arctic environment and these emissions may require the implementation of additional IMO environmental regulations.

Arctic Marine Infrastructure: There is a general lack of marine infrastructure in the Arctic, except for areas along the Norwegian coast and northwest Russia, compared with other marine regions of the world with high concentrations of ship traffic. Gaps in hydrographic data exist for significant portions of primary shipping routes important to support safe navigation. In addition, for safe operations in the Arctic there is a need for the same suite of meteorological and oceanographic data, products and services as in other oceans, plus comprehensive information on sea ice and icebergs. Except in limited areas of the Arctic, there is a lack of emergency response capacity for saving lives and for pollution mitigation. There are serious limitations to radio and satellite communications and few systems to monitor and control the movement of ships in ice-covered waters. The current lack of marine infrastructure in all but a limited number of areas, coupled with the vastness and harshness of the environment, makes conduct of emergency response significantly more difficult in the Arctic.

The Arctic Marine Shipping Assessment Recommendations

The focus of the AMSA is marine safety and marine environmental protection, which is consistent with the Arctic Council's mandates of environmental protection and sustainable development. Based on the findings of the AMSA, recommendations were developed to provide a guide for future action by the Arctic Council, Arctic states and many others. The AMSA recommendations are presented under three broad, inter-related themes that are fundamental to understanding the AMSA: Enhancing Arctic Marine Safety, Protecting Arctic People and the Environment, and Building Arctic Marine Infrastructure. It is recognized that implementation of these recommendations could come from the Arctic states, industry and/or public-private partnerships.

I. Enhancing Arctic Marine Safety

A. Linking with International Organizations: That the Arctic states decide to, on a case by case basis, identify areas of common interest and develop unified positions and approaches with respect to international organizations such as: the International Maritime Organization (IMO), the International Hydrographic Organization (IHO), the World Meteorological Organization (WMO) and the International Maritime Satellite Organization (IMSO) to advance the safety of Arctic marine shipping; and encourage meetings, as appropriate, of member state national maritime safety organizations to coordinate, harmonize and enhance the implementation of the Arctic maritime regulatory framework.

B. IMO Measures for Arctic Shipping: That the Arctic states, in recognition of the unique environmental and navigational conditions in the Arctic, decide to cooperatively support efforts at the International Maritime Organization to strengthen, harmonize and regularly update international standards for vessels operating in the Arctic. These efforts include:

---Support the updating and the mandatory application of relevant parts of the *Guidelines for Ships Operating in Arctic Ice-covered Waters* (Arctic Guidelines); and,

---Drawing from IMO instruments, in particular the Arctic Guidelines, augment global IMO ship safety and pollution prevention conventions with specific mandatory requirements or other provisions for ship construction, design, equipment, crewing, training and operations, aimed at safety and protection of the Arctic environment.

C. Uniformity of Arctic Shipping Governance: That the Arctic states should explore the possible harmonization of Arctic marine shipping regulatory regimes within their own jurisdiction and uniform Arctic safety and environmental protection regulatory regimes, consistent with UNCLOS, that could provide a basis for protection measures in regions of the central Arctic Ocean beyond coastal state jurisdiction for consideration by the IMO.

D. Strengthening Passenger Ship Safety in Arctic Waters: That the Arctic states should support the application of the IMO's *Enhanced Contingency Planning Guidance for Passenger Ships Operating in Areas Remote from SAR Facilities*, given the extreme challenges associated with rescue operations in the remote and cold Arctic region; and strongly encourage cruise ship operators to develop, implement and share their own best practices for operating in such conditions, including consideration of measures such as timing voyages so that other ships are within rescue distance in case of emergency.

E. Arctic Search and Rescue (SAR) Instrument: That the Arctic states decide to support developing and implementing a comprehensive, multi-national Arctic Search and Rescue (SAR) instrument, including aeronautical and maritime SAR, among the eight Arctic nations and, if appropriate, with other interested parties in recognition of the remoteness and limited resources in the region.

II. Protecting Arctic People and the Environment

A. Survey of Arctic Indigenous Marine Use: That the Arctic states should consider conducting surveys on Arctic marine use by indigenous communities where gaps are identified to collect information for establishing up-to-date baseline data to assess the impacts from Arctic shipping activities.

B. Engagement with Arctic Communities: That the Arctic states decide to determine if effective communication mechanisms exist to ensure engagement of their Arctic coastal communities and, where there are none, to develop their own mechanisms to engage and coordinate with the shipping industry, relevant economic activities and Arctic communities (in particular during the planning phase of a new marine activity) to increase benefits and help reduce the impacts from shipping.

C. Areas of Heightened Ecological and Cultural Significance: That the Arctic states should identify areas of heightened ecological and cultural significance in light of changing climate conditions and increasing multiple marine use and, where appropriate, should encourage implementation of measures to protect these areas from the impacts of Arctic marine shipping, in coordination with all stakeholders and consistent with international law.

D. Specially Designated Arctic Marine Areas: That the Arctic states should, taking into account the special characteristics of the Arctic marine environment, explore the need for internationally designated areas for the purpose of environmental protection in regions of the Arctic Ocean. This could be done through the use of appropriate tools, such as "Special Areas" or Particularly Sensitive Sea Areas (PSSA) designation through the IMO and consistent with the existing international legal framework in the Arctic.

E. Protection from Invasive Species: That the Arctic states should consider ratification of the IMO *International Convention for the Control and Management of Ships Ballast Water and Sediments*, as soon as practical. Arctic states should also assess the risk of introducing invasive species through ballast water and other means so that adequate prevention measures can be implemented in waters under their jurisdiction.

F. Oil Spill Prevention: That the Arctic states decide to enhance the mutual cooperation in the field of oil spill prevention and, in collaboration with industry, support research and technology transfer to prevent release of oil into Arctic waters, since prevention of oil spills is the highest priority in the Arctic for environmental protection.

G. Addressing Impacts on Marine Mammals: That the Arctic states decide to engage with relevant international organizations to further assess the effects on marine mammals due to ship noise, disturbance and strikes in Arctic waters; and consider, where needed, to work with the IMO in developing and implementing mitigation strategies.

H. Reducing Air Emissions: That the Arctic states decide to support the development of improved practices and innovative technologies for ships in port and at sea to help reduce current and future emissions of greenhouse gases (GHGs), Nitrogen Oxides (NOx), Sulfur Oxides (SOx) and Particulate Matter (PM), taking into account the relevant IMO regulations.

III. Building the Arctic Marine Infrastructure

A. Addressing the Infrastructure Deficit: That the Arctic states should recognize that improvements in Arctic marine infrastructure are needed to enhance safety and environmental protection in support of sustainable development. Examples of infrastructure where critical improvements are needed include: ice navigation training; navigational charts; communications systems; port services, including reception facilities for ship-generated waste; accurate and timely ice information (ice centers); places of refuge; and icebreakers to assist in response.

B. Arctic Marine Traffic System: That the Arctic states should support continued development of a comprehensive Arctic marine traffic awareness system to improve monitoring and tracking of marine activity, to enhance data sharing in near real-time, and to augment vessel management service in order to reduce the risk of incidents, facilitate response and provide awareness of potential user conflict. The Arctic states should encourage shipping companies to cooperate in the improvement and development of national monitoring systems.

C. Circumpolar Environmental Response Capacity: That the Arctic states decide to continue to develop circumpolar environmental pollution response capabilities that are critical to protecting the unique Arctic ecosystem. This can be accomplished, for example, through circumpolar cooperation and agreement(s), as well as regional bilateral capacity agreements.

D. Investing in Hydrographic, Meteorological and Oceanographic Data: That the Arctic states should significantly improve, where appropriate, the level of and access to data and information in support of safe navigation and voyage planning in Arctic waters. This would entail increased efforts for: hydrographic surveys to bring Arctic navigation charts up to a level acceptable to support current and future safe navigation; and systems to support real-time acquisition, analysis and transfer of meteorological, oceanographic, sea ice and iceberg information.

INTRODUCTION

The Arctic is regarded as containing some of the last physically undisturbed marine spaces on earth. Early in the 21st century, the Arctic has also been undergoing extraordinary environmental and developmental changes. Long known as a storehouse of untapped natural resources, high commodity prices and a growing worldwide demand in recent years have the Arctic poised as a significant contributor to the global economy. Increasing regional and coastal marine transport to support the exploration and extraction of oil, gas and hard minerals, coupled with the increasing presence of the global marine tourism industry, have brought a complex set of users to the maritime Arctic. The potential impacts of these new marine uses - social, environmental, cultural and economic - are unknown, but will be significant for Arctic indigenous people and the marine environment already undergoing significant changes due to climate change.

Simultaneous with the globalization of the Arctic, marine access in the Arctic Ocean has been changing in unprecedented ways driven by global climate change. Arctic sea ice is undergoing an historic transformation - thinning, extent reduction in all seasons and substantial reductions in the area of multi-year ice in the central Arctic Ocean - which has significant implications for longer seasons of navigation and new access to previously difficult to reach coastal regions. The international scientific community has already taken advantage of these changes through pioneering voyages in the central Arctic Ocean. The same sea ice retreat also has important influences on the regional, Arctic marine ecosystems and future fisheries. Taken together, these changes present increased demands on the existing legal and regulatory structures challenged to meet the needs for enhanced marine safety and environmental protection in the face of increasing Arctic marine activity. Such challenges will

require unprecedented levels of cooperation among the eight Arctic states and broad engagement with many non-Arctic stakeholders within the global maritime industry.

Actions Leading to a Shipping Assessment

The Arctic Council anticipated the need to evaluate current and future increasing use of the Arctic Ocean. In 2002 at the Council's third Ministerial meeting in Inari, Finland, the ministers recognized "that existing and emerging activities in the Arctic warrant a more coordinated and integrated strategic approach to address the challenges of the Arctic coastal marine environment." The ministers agreed to "develop a strategic plan for the protection of the Arctic marine environment under leadership by the Protection of the Arctic Marine Environment (PAME) working group." The Arctic Marine Strategic Plan (AMSP) was developed by PAME and approved by the Arctic Council in 2004. Four strategic goals were outlined in the AMSP: reduce and prevent pollution in the Arctic marine environment; conserve Arctic marine diversity and ecosystem functions; promote the health and prosperity of all Arctic inhabitants; and advance sustainable Arctic marine resource use. The AMSP addressed the need for future application of an ecosystem approach to management of the Arctic marine environment and also called for a comprehensive assessment of Arctic marine shipping.

In November 2004, the Arctic Council released a major study, the Arctic Climate Impact Assessment (ACIA), which received global attention. The ACIA found that the Arctic: is extremely vulnerable to observed and projected climate change; is today experiencing some of the most rapid and severe climate change on Earth; and will experience accelerated climate change during the 21st century. Widespread physical, ecological, social and economic changes, many of which have already begun, were projected. Of particular relevance to marine use and Arctic transport, one of ACIA's 10 Key Findings (#6) stated: "Reduced sea ice is very likely to increase marine transport and access to resources."

Consistent with the work of the AMSP and the ACIA, the Arctic Council Ministers in November 2004 in Reykjavik asked PAME to "conduct a comprehensive Arctic marine shipping assessment as outlined in the Arctic Marine Strategic Plan (AMSP) under the guidance of Canada, Finland and the United States as lead countries and in collaboration with the Emergency Prevention, Preparedness and Response (EPPR) working group of the Arctic Council and Permanent Participants as relevant." AMSA data gathering and planning began in summer 2005.

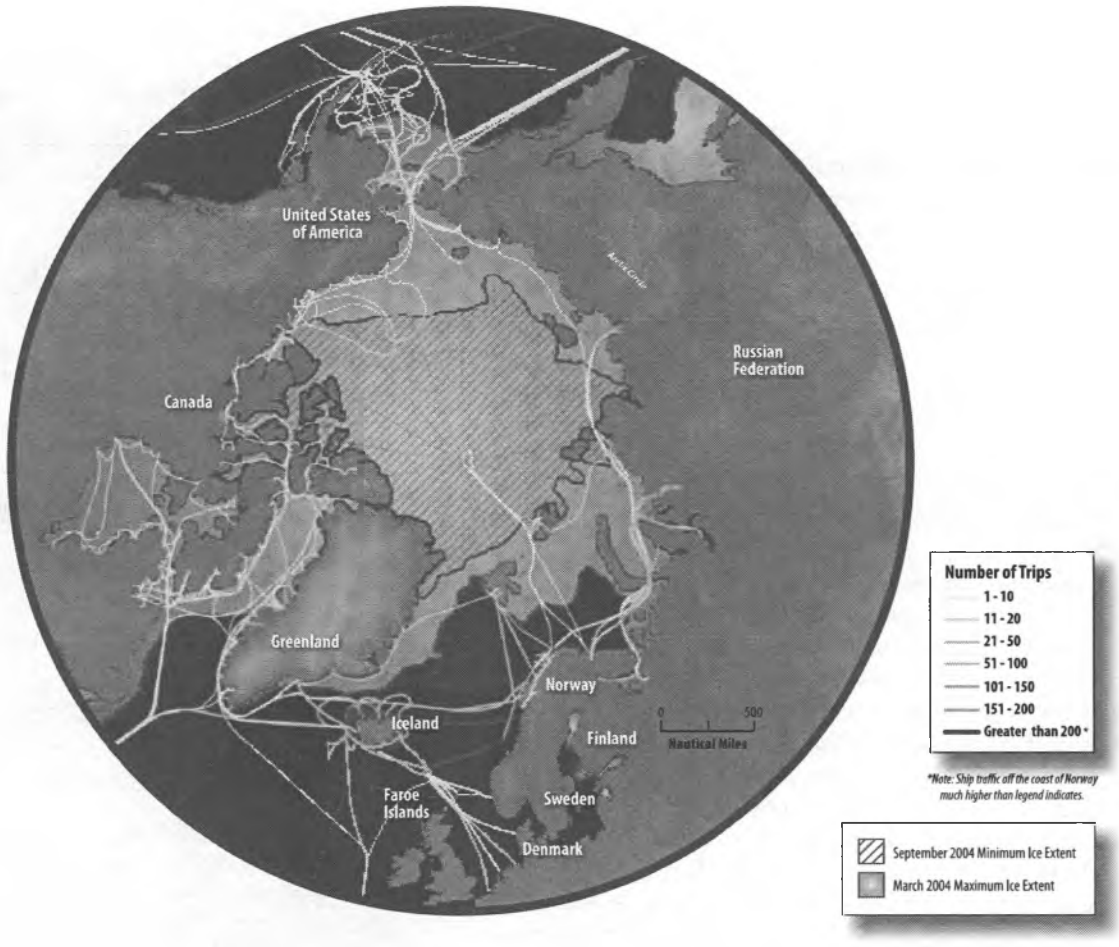
Arctic Council

The Ottawa Declaration of 1996 formally established the Arctic Council as a high level intergovernmental forum to provide a means for promoting cooperation, coordination and interaction among the Arctic states, with the express involvement of Arctic indigenous communities and other Arctic inhabitants on common Arctic issues, especially issues of sustainable development and environmental protection in the Arctic.

The Arctic Council is comprised of Canada, Denmark (including Greenland and the Faroe Islands), Finland, Iceland, Norway, the Russian Federation, Sweden and the United States of America.

In addition to the member states, the council created the category of Permanent Participants in order to provide for the active participation of, and full consultations with, Arctic indigenous representatives within the council. Open equally to Arctic organizations of indigenous people with a majority of Arctic indigenous constituency, the Permanent Participants represent a single indigenous people resident in more than one Arctic state, or more than one Arctic indigenous people resident in a single Arctic state. The following organizations are Permanent Participants of the Arctic Council: Aleut International Association, Arctic Athabaskan Council, Gwich'in Council International, Inuit Circumpolar Council, Saami Council and Russian Arctic Indigenous Peoples of the North.

Working groups of the Arctic Council execute the programs and projects mandated by the Arctic Council ministers. Each working group, with its supporting scientific and technical expert groups, holds meetings at regular intervals throughout the year, ahead of the meetings of Senior Arctic Officials and Arctic Council Ministers. The six working groups include: Arctic Contaminants Action Program; Arctic Monitoring and Assessment Programme; Conservation of Arctic Flora and Fauna; Emergency Prevention, Preparedness and Response; Protection of the Arctic Marine Environment; and Sustainable Development Working Group.



Map 1.1 Shipping traffic in the Arctic for survey year 2004. *Source: AMSA*

Focus and Conduct of the Assessment

The focus of the AMSA is marine safety and marine environmental protection, which is consistent with the Arctic Council's mandates of environmental protection and sustainable development. The AMSA was designed to be circumpolar in breadth, but also considers regional and local perspectives where impacts, particularly on Arctic communities, are considered to be greatest. However, the overall scope of the AMSA focuses on ships and their infrastructure needs and impacts in the Arctic Ocean.

The AMSA lead countries (Canada, Finland and the United States) recognized early in the planning the importance of contributions from the broader, global maritime community. Therefore, the AMSA reached out to such key stakeholders as non-Arctic states (examples include the United Kingdom and Germany), shipping companies, ship designers, shipbuilders, ship classification societies, non-commercial partnerships, marine insurers and non-governmental environmental organizations. With the assistance of the Permanent Participants of the Arctic Council, town hall meetings were organized in selected Arctic communities to listen to issues and concerns about future Arctic marine activity. AMSA also linked with the Arctic Council working group experts of the Emergency Prevention, Preparedness and Response (EPPR) working group on issues related to spills, and response infrastructure requirements, and with the Sustainable Development Working Group (SDWG) on issues related to the human dimension.

The AMSA covers all types of marine transport under the general topic of "shipping": tankers, bulk carriers, offshore supply vessels, passenger ships, tug/barge combinations, fishing vessels, ferries, research vessels and government and commercial icebreakers. Knowing the sum of the voyages completed by these different ships will help to understand the potential environmental impacts (especially from discharges and emissions) of Arctic marine shipping operations. An AMSA Database Survey, requesting these ship types, was sent to the Senior Arctic Officials of the Arctic states in February 2006 to obtain the official shipping statistics of each state for the survey year 2004. The objective was to create the first baseline database of all ships (less naval vessels) operating in the Arctic during a single year. Each Arctic state defined its own Arctic waters for the purpose of the AMSA data collection effort. The AMSA data effort yielded an historic survey that provides a comprehensive estimate for how many ships had operated in the Arctic for the survey year.

More than 185 experts participated directly in AMSA. Thirteen major AMSA workshops were held from July 2006 through October 2008; workshop topics included: scenarios of future Arctic navigation; indigenous marine use; Arctic marine incidents; environmental impacts; Arctic marine infrastructure; and the future of the Russian Federation's Northern Sea Route. AMSA town hall meetings were held in northern communities in Canada, Iceland, Norway and the United States. AMSA leads and team members conducted outreach and presented AMSA topics at 56 professional venues throughout the world during 2005-2008.

A large number of source documents were collected from the following activities: the results of the AMSA workshops, reports of the AMSA town hall meetings, the AMSA Data Survey, special reports created by maritime experts, and reviews of AMSA topics drafted by lead and contributing authors. These documents, referred to collectively as the AMSA Research Documents, will be found on the PAME and Arctic Council websites. The AMSA Research Documents represent a significant body of work and, while they have not been reviewed by the Arctic Council, the documents provided the background for drafting the AMSA 2009 Report, which was approved by the Arctic Council Ministers at the 2009 Ministerial meeting in Tromsø, Norway.

Modes of Arctic Marine Transport

In addition to the ship types to be addressed in the assessment, four modes, or types of voyages undertaken in the Arctic Ocean, were identified. They are:

Destinational transport, where a ship sails to the Arctic, performs some activity in the Arctic and sails south. Examples include: large cruise ships sailing from southern ports to the west coast of Greenland in summer; LNG and oil tankers sailing from ports in northern Norway and northwest Russia to world markets; and an icebreaker from Europe conducting scientific operations in the central Arctic Ocean in summer.

Intra-Arctic transport, a voyage or marine activity that stays within the general Arctic region and links two or more Arctic states. A key example is the marine route between the port of Churchill, Manitoba, Canada on Hudson Bay and Murmansk, Russia, touted as an "Arctic-bridge" between the two continents. Two other examples include an Icelandic fishing vessel working in Greenlandic waters, and tug-barge traffic operating between Canada's Northwest Territories and the U.S. Beaufort Sea off the Alaskan coast.

Trans-Arctic transport or navigation, voyages which are taken across the Arctic Ocean from Pacific to Atlantic oceans or vice versa. These are full voyages between the major oceans using the Arctic Ocean as a marine link. There are several options for trans-Arctic navigation.

Cabotage, to trade or marine transport in coastal waters between ports within an Arctic state. A prime example is the year-round traffic between the port of Dudinka on the Yenisei River and Murmansk - Russian-flag ships carrying nickel plates processed at the industrial complex in Norilsk to Murmansk for further distribution to Russian and international markets. Other examples are the summer sealift of cargoes to Canadian Arctic communities from southern Canadian ports and the delivery of consumer goods to Russian Arctic communities using the Northern Sea Route.

The Origin of the AMSA

The Arctic Council Ministers in November 2004 in Reykjavik asked PAME to "conduct a comprehensive Arctic marine shipping assessment as outlined in the Arctic Marine Strategic Plan (AMSP) under the guidance of Canada, Finland and the United States as lead countries and in collaboration with the Emergency Prevention, Preparedness and Response (EPPR) working group of the Arctic Council and Permanent Participants as relevant."

Protection of the Arctic Marine Environment: PAME

PAME is an example of the international cooperation that is a hallmark of the Arctic Council: while the PAME Secretariat is based in Akureyri, Iceland, its chairmanship in the spring of 2009 is held by Canada.

Increased economic activity and significant changes due to climatic processes are resulting in increased use, opportunities and threats to the Arctic marine and coastal environments. These predicted changes require more integrated approaches to address both existing and emerging challenges of the Arctic marine and coastal environments.

PAME's mandate is to address policy and non-emergency pollution prevention and control measures related to the protection of the Arctic marine environment from both land and sea-based activities, including coordinated action programs and guidelines complementing existing legal arrangements.

According to the Arctic Marine Strategic Plan, PAME aims to improve knowledge and respond to emerging knowledge of the Arctic Marine Environment. The AMSA is the primary action item for this objective. The plan also calls on PAME to determine the adequacy of applicable international/regional commitments and promote their implementation and compliance; and facilitate partnerships, program and technical cooperation and support communication, reporting and outreach both within and outside the Arctic Council.

At the 2004 Arctic Council ministers meeting in Iceland, the Reykjavik Declaration asked the PAME work group "to conduct a comprehensive Arctic marine shipping assessment as outlined in the Arctic Marine Strategic Plan (AMSP) under the guidance of Canada, Finland and the United States as lead countries and in collaboration with the Emergency Prevention, Preparedness and Response (EPPR) working group of the Arctic Council and Permanent Participants as relevant."

Emergency Prevention, Preparedness and Response: EPPR

The EPPR Secretariat rotates with the chairmanship of the Arctic Council and ... such is located in the spring of 2009 at the Norwegian Coastal Administration, Department for Emergency Response, Norway.

Harsh conditions and lack of infrastructure in much of the Arctic create a higher vulnerability to emergencies than in more temperate climates. Consequently, prevention, preparedness and response must be adapted to Arctic conditions. Accordingly, international cooperation in this area is of major importance.

The mandate of the EPPR working group is to deal with the prevention, preparedness and response to environmental emergencies in the Arctic. Members of the working group exchange information on best practices and conduct projects (for example, development of guidance and risk assessment methodologies, response exercises, training, etc.). EPPR is not a response agency. In 2004, EPPR was directed by the Arctic Ministers to expand its mandate to include natural disasters.

Ongoing EPPR projects address oil pollution spill response in the face of increased Arctic shipping and development; technological support of radiological and other hazard assessments; and natural disaster response, particularly catastrophic river flooding.

The Assessment Report Structure

The AMSA 2009 Report is designed to educate and inform the Arctic Council, the Arctic community, the global maritime industry and the world at large about the current state of Arctic marine use and future challenges. The topics presented in the report include:

- Arctic Marine Geography, Climate and Sea Ice
- History of Arctic Marine Transport
- Governance of Arctic Shipping
- Current Marine Use and AMSA 2004 Database
- Scenarios, Futures and Regional Futures to 2020
- Human Dimensions
- Environmental Considerations and Impacts
- Arctic Marine Infrastructure

The initial sections on Arctic marine geography and Arctic marine transport history provide background and context for the subsequent sections. The complex geography of the Arctic Ocean and its surrounding coastline influences all aspects of Arctic marine operations. The history section emphasizes that industrial and commercial uses of the Arctic Ocean date back to the 17th century. There is also a rich history of marine operations in the Russian and Canadian Arctic regions, around Svalbard and Greenland, and off Alaska. Governance is identified in the AMSA as one of the key uncertainties and drivers of future Arctic marine navigation, and this section provides a critical overview and current state of international and coastal state governance of Arctic marine activities. The section on current marine use provides a comprehensive and historic baseline of Arctic marine activity early in the 21st century, developed principally from the AMSA Data Survey.

AMSA scenario workshops in 2007 and 2008 identified natural resource development and trade as key drivers and uncertainties. Two regional AMSA studies - for the Bering Strait and Canadian Arctic, as well as outcomes of ARCOP and INSROP - all emphasize oil and gas and hard minerals development as important indicators for future Arctic marine transport requirements.

The human dimension section communicates the results of the AMSA town hall meetings and identifies important concerns and issues of the Arctic indigenous people. Impacts are also highlighted in the environmental considerations section where ship types and their specific impacts are characterized. The final section of the report on Arctic infrastructure identifies the Arctic Ocean as a region with limited infrastructure in most areas, lacking communications, response capability, salvage and other basic services that are readily available to the maritime community in lower latitudes.

The Arctic Marine Shipping Assessment is a comprehensive study and evaluation of Arctic marine activity today and the future. The AMSA 2009 Report highlights a single set of findings and recommendations important to the future protection of Arctic people and the marine environment. The AMSA team of experts has also provided for each section in the report a list of non-negotiated research opportunities that can be considered by the Arctic research community and organizations such as the International Arctic Science Committee. The AMSA Report is a strategic guide for understanding the complexity and multiple factors that will determine the future of Arctic shipping operations.

Long known as a storehouse of untapped natural resources, high commodity prices and a growing worldwide demand in recent years have the Arctic poised as a significant contributor to the global economy.

ARCTIC MARINE GEOGRAPHY, CLIMATE AND SEA ICE

Arctic Marine Geography

Our Earth has two polar regions, each with a large marine environment, that are vital to the well-being of the planet: Antarctica and the Arctic. Unlike Antarctica, though, which is a continent surrounded by an ocean, the Arctic is an ocean surrounded by continents. The Arctic Ocean, at 14.056 million km², is the smallest of the world's five oceans (Table 2.1). It is mostly an enclosed sea that has limited exchange of deep water with other oceans. Compared to the Mediterranean Sea, the Arctic has a much greater exchange of water, and it is more than 5.6 times larger. Consequently, the International Hydrographic Organization along with the International Maritime Organization recognizes the Arctic Ocean as one of the five major components of the world ocean that covers almost 71 percent of the Earth's surface. More importantly, the Arctic Ocean is the least sampled of the world's oceans and many areas remain where few, if any, soundings have been recorded. The implications of this lack of basic marine information are profound for charting hydrography and for basic Arctic navigation.

The Arctic is bordered by numerous coastal seas, all of which are seasonally covered with sea ice. Working from Greenland eastwards, the waters adjacent to the Arctic basin itself are Greenland Sea, Norwegian Sea, Barents Sea, White Sea, Kara Sea, Laptev Sea, East Siberian Sea and Chukchi Sea - all fronting on the Eurasia continental land mass. The Bering Sea, the Beaufort Sea, the waters within the Canadian Archipelago including those of the Northwest Passage, Hudson Bay and Hudson Strait, Lincoln Sea, Baffin Bay, Davis Strait and Labrador Sea are all bordering on the North American continent. Most Arctic marine activity, such as fishing, offshore hydrocarbon development and ship transits, takes place in these coastal seas.

Bathymetrically, the Arctic marine area is relatively shallow (Map 2.1) with broad continental shelves. The shelf extends 100 to 200 kilometers from the United States and Canada, and more than 1,000 kilometers in places extending north from the Russian Federation. Depths over the shelves average between 100 and 200 meters but are variable, especially as the continental landmasses and islands are approached. At the continental slopes, the break between the shelf and the deep ocean basin, depths are between 300 and 500 meters.

4,000 meters +
The depth of the Arctic Ocean at the North Pole.

	Size (million km²)	Percentage of Earth's Total Surface	Greatest Depth (m)	Average Depth (m)
Pacific	155.557	30.5	10,911	4,300
Atlantic	76.762	20.8	8,605	3,300
Indian	65.556	14.8	7,258	3,900
Southern	20.327	4.0	7,235	4,000-5,000
Arctic	14.056	2.8	5,160	1,050

Table 2.1 Arctic Ocean compared to other oceans. *Source: AMSA*

Country	Closest Point to the North Pole	Distance to Pole (km)
Greenland (Denmark)	Kaffeklubben Island, Perry Land	707
Iceland	Kolbeinsey, Eyjafjorour	2552
Norway	Rossoya Sjuoyane, Svalbard	1024
Russian Federation	Cape Fligely, Rudolf Island, Franz Josef Land	911
USA	Point Barrow, Alaska	2078
Canada	Cape Columbia, Ellesmere Island	769

Table 2.2 Distances from nearest land of Arctic states to the North Pole. *Source: AMSA*

There are two major deep basins - the Eurasia and Amerasia - separated by the Lomonosov Ridge stretching from the East Siberian Sea to the Lincoln Sea. The ridge is an underwater mountain chain rising, on average, 3,000 meters above the abyssal plain. On the Eurasian side of the Lomonosov Ridge, the basin is again split into two by the Nansen-Gakkel Arctic Mid-Ocean Ridge. Between the Lomonosov and Nansen-Gakkel Ridges lies the Pole Abyssal Plain in which is found the geographical North Pole at 90 degrees north. The depth of water at the pole is well over 4,000 meters. On the Amerasia side of the Lomonosov Ridge there are also two basins - the Makarov and Canada - separated by the Alpha and Mendeleev ridges. Of the two basins, the Canada Basin is the largest.

Major islands and island archipelagos fringe the Arctic marine area and they help frame the marine routes, legal regimes and navigational options in the Arctic Ocean. The largest island is Greenland at 2,166,086 km². The largest archipelago is the Canadian Archipelago with more than 36,000 islands including Baffin (507,451 km²), Victoria (217,291 km²) and Ellesmere (196,236 km²), which are among the world's largest 10 islands. The next largest single island fringing on the Arctic marine area is Iceland (103,000 km²). On the west, the Arctic Ocean is bounded by Svalbard (Norway) of which Spitsbergen is the largest island; Franz Josef Land (Russian Federation) with 191 islands; Novaya Zemlya (Russian Federation) with two major islands (Severny at 47,079 km² and Yuzhny at 33,246 km²); Severnaya Zemlya (Russian Federation) consisting of four major islands and 70 smaller ones; and New Siberian Islands (Russian Federation) with the Anzhu Islands and the Lyakhovskiye Islands. Between the New Siberian Islands group and the Bering Strait lies Wrangel Island (7,300 km²). Given these fringing islands, the distance from the nearest land to the North Pole is as little as 707 kilometers (382 nautical miles) (Table 2.2), but this distance is different for each Arctic nation. Of interest to the marine world is the approximate 2,100 nautical mile (1134 kilometer) distance (direct) from the Bering Strait to the North Pole to Fram Strait (between Greenland and Svalbard). All other distances along the coastal routes within the Arctic basin are longer.

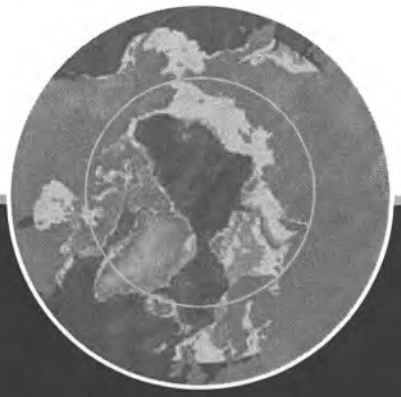
Although technically not on the edge of the Arctic Ocean, the Aleutian Islands in the Pacific Ocean provide the southern limit of the Bering Sea, which links through the Bering Strait into the Chukchi Sea and the Arctic Ocean. A global maritime trade route - the North Pacific's Great Circle Route - intersects with the Aleutian Islands and thousands of large ships pass north and south of these islands on voyages between the west coast of North America and Asian ports each year.

The water connections linking the Arctic and the Pacific and Atlantic oceans are limited. The narrow and shallow Bering Strait (85 kilometer width; 30-50 meter depth) is the only link between the Arctic and the Pacific. There are more and wider passages between the Arctic and the Atlantic. Davis Strait between Canada and Greenland links Baffin Bay with the Labrador Sea and the North Atlantic. At its narrowest point Davis Strait is about 300 kilometers wide; at its widest it is over 950 kilometers. Between Greenland and Iceland lies Denmark Strait (290 kilometers wide at its narrowest). The widest passage is the Norwegian Sea at about 1,100 kilometers separating Iceland from Norway.

These water passages between the Arctic Ocean and its northern coastal seas allow exchanges of water vital to the Arctic's climate and marine ecosystems. By far the greatest exchange of water takes place between the Arctic and the Atlantic. Relatively warm dense salty water, as part of the North Atlantic Current originating in the Gulf of Mexico and Caribbean Sea, enters the Norwegian Sea continuing into the Barents Sea. This warmer water means that the Southern Barents Sea is not generally ice-covered, a significant factor in the regulation and control of marine traffic in this northwest

corner of Europe that is by latitude located in the Arctic region. After much mixing and cyclonic (counter-clockwise) circulation, cold, less salty water exits between Svalbard and Greenland and Greenland and Iceland. This exiting water consists not only of the modified North Atlantic waters but, more importantly, continental river water from Eurasia, especially from the Ob', Yenisei and Lena rivers of the Russian Federation; freshwater from the Mackenzie River in Canada; and Pacific water which entered through the Bering Strait. The driving engine conveying the Pacific water and the river waters eastward is the Beaufort Gyre north of Alaska and western Canada. This gyre - a clockwise circulation of relatively fresh, less dense water - is driven by prevailing winds. When winds shift and the current lessens some water escapes and is caught up in the Trans Polar current, eventually linking with the outflow water into the Atlantic Ocean. Cold waters also exit from the Arctic to the Atlantic through Baffin Bay, Davis Strait and Hudson Strait.

An important geographical limit and a defining line is the Arctic Circle (66 degrees 33 minutes north). At this latitude places receive continuous light for 24 hours per day once a year and as one moves poleward the number of days of continuous light increases until at the North Pole continuous light is experienced for six months



Arctic Circle

The Arctic Circle is the circle of latitude at 66 degrees 33 minutes N (2606 kilometers/1619 miles from the North Pole) that encloses a northern area about 8 percent of Earth's surface. The Arctic Circle is the southern limit of the midnight sun, where north of the circle there is at least one day each year when the sun does not set.

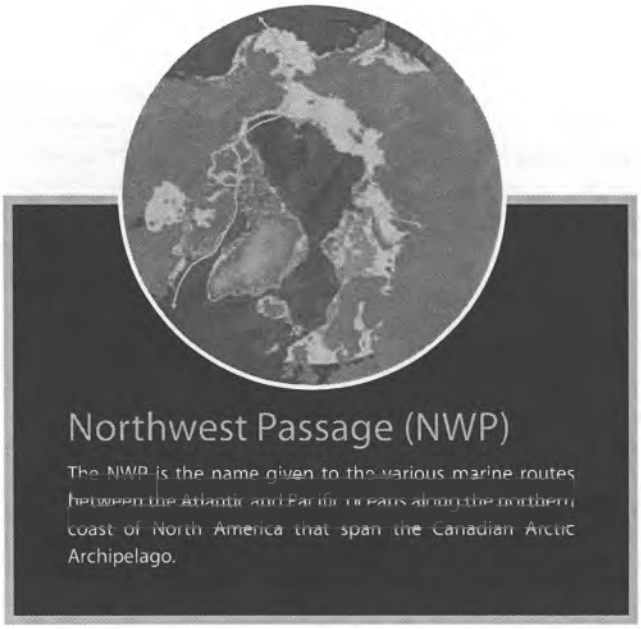
© Canadian Coast Guard

between the Vernal (March 21) and Autumnal equinoxes (September 21). Conversely, continuous dark is experienced at the pole for the other six months and decreasingly in time as one moves south. Significant for marine operations is that much of the central Arctic Ocean is shrouded in winter darkness with very low temperatures for half the year. This seasonal or diurnal cycle in the polar environment, while highly influential in the rhythmic behavior and adaptation of Arctic communities and animal populations, has broad implications for maritime use throughout the Arctic Ocean and its coastal seas.

The Canadian Maritime Arctic and Northwest Passage

The Canadian maritime Arctic is located across the north of Canada from the Beaufort Sea in the west to Baffin Bay in the east, and south to 60 degrees north latitude. The Canadian Arctic Archipelago stretches longitudinally about 1,900 kilometers from mainland Canada to the northern tip of Ellesmere Island. From west to east, it covers a distance of about 2,400 kilometers from Banks Island (west side) to Baffin Island (east side). The size of this roughly triangular area, including land and ocean, is approximately 2.1 million km², about the size of Greenland. As mentioned previously, it comprises approximately 36,000 islands, making it one of the most complex geographies on Earth. The area is sparsely populated along the coastline. The largest settlement is Iqaluit, Baffin Island, at 6,100 people; the entire Baffin region includes most of the eastern and northern portion of the Archipelago including all of Baffin Island. The most northern settlement is Grise Fjord on Ellesmere Island. Resolute on Cornwallis Island and the shores of Barrow Strait are an important staging area for air and marine traffic.

The Archipelago serves as a major impediment to shippers seeking a link between the Atlantic and Pacific oceans or for internal shipment of resources or community supplies. There are five recognized routes or passages, with variations, through the Archipelago (Table 2.3). They make up the much searched for Northwest Passage, which occupied European adventurers for more than 400 years. The NWP is the name given to the various marine routes between the Atlantic and Pacific oceans along the northern coast of North America that span the Canadian Arctic Archipelago. The



first complete ship transit of the NWP took place from 1903-06 by Norwegian explorer Roald Amundsen following Route 3b (Table 2.3). In 1940-42 the first eastward passage, using Route 4, was made by the *St. Roch* commanded by RCMP Sergeant Henry Larsen. This trip was followed in 1944 by a westward passage following Route 1, marking the first time the Northwest Passage had been navigated in a single season.

All passages have common eastern and western approaches. In the east, ships must proceed through the Labrador Sea, Davis Strait and Baffin Bay - the exception is for Route 5, which requires a transit through Hudson Strait. In the western approaches ships proceed through the Bering Sea, Bering Strait, the Chukchi Sea and the Beaufort Sea before deciding which route to follow. In general, the operating season is short - from late July to mid-October - depending on the route and year. Of the various passages, routes 1 and 2 are considered deep water ones, while the others have limiting shoals and rocks restricting the draft of vessels to less than 10 meters.

The Arctic Ocean is the least sampled of the world's oceans and many areas remain where few, if any, soundings have been recorded.

Water Routes of the Northwest Passage

Route	Routing (East to West)	Physical Description	Of Note
1	Lancaster Sound – Barrow Strait – Viscount Melville Sound – Prince of Wales Strait – Amundsen Gulf.	**Lancaster Sound:** 80 km wide, 250 km long, deep at over 500 m. **Barrow Strait:** 50 km wide, 180 km long, deep, string of islands west of Resolute disrupts clear navigation. **Viscount Melville Sound:** 100 km wide, 350 km long, experiences multi-year ice from M'Clure Strait. **Prince of Wales Strait:** minimum width of less than 10 km about half way through the Strait. 230 km long, limiting depth of 32 m. **Amundsen Gulf:** irregular shape, 90 km wide entrance, approximately 300 km long.	Suitable for deep draft navigation; the route followed by *St. Roch* in 1944 on westerly transit and the *SS Manhattan* in 1969.
2	Same as 1 but substitute M'Clure Strait for Prince of Wales Strait and Amundsen Gulf. Collectively Lancaster Sound – Barrow Strait – Viscount Melville Sound is known as Parry Channel.	**M'Clure Strait:** 120 km wide at east end, 275 km long to Beaufort Sea, deep at over 400 m, experiences multi-year ice from Arctic Ocean.	*SS Manhattan* attempted this route in 1969 but was turned back. Russian icebreaker *Kapitan Klebnikov* succeeded in a passage in 2001. In September 2007 was clear of Arctic pack ice for a limited time since satellite photos have been available; there was more ice in 2008.
3A	Lancaster Sound – Barrow Strait – Peel Sound – Franklin Strait – Larsen Sound – Victoria Strait – Queen Maud Gulf – Dease Strait – Coronation Gulf – Dolphin and Union Strait – Amundsen Gulf.	**Lancaster Sound and Barrow Strait:** see Route 1. **Peel Sound:** 25 km wide, deep at over 400 m at south end. **Franklin Strait:** 30 km wide. **Larsen Sound:** depths vary between 30 and 200 meters. **Victoria Strait:** 120 km wide, at southern end is blocked by Royal Geographical Society Islands, worst ice conditions along the mainland coast of Canada. **Queen Maud Gulf:** eastern entrance 14 km wide, but widens into an irregular area with width of up to 280 km before narrowing to 14 km at entrance to Dease Strait; numerous islands, reefs and shoals. **Dease Strait:** 14 – 60 km wide, 160 km long. **Coronation Gulf:** over 160 km long, many islands. **Dolphin and Union Strait:** 80 km wide at Amundsen Gulf, 150 km long, caution should be exercised in passage, several soundings of less than 10 m have been recorded. **Amundsen Gulf:** see Route 1.	Of the 3A, 3B and 4 routes, this is considered the best option but with a draft limit of 10 m.
3B	A variation of 3A. Rather than following Victoria Strait on the west side of King William Island, the route passes to the east of the island following James Ross Strait – Rae Strait – Simpson Strait.	**James Ross Strait:** 50 km wide, but restricted by islands, extensive shoaling. **Rae Strait:** 20 km wide, with limiting depths of between 5-18 m in mid channel. **Simpson Strait:** about 3 km wide at narrowest point, most hazardous navigation area in 3B route.	The route of Roald Amundsen. Also route of the *MS Explorer*, in 1984, the first cruise ship to navigate the Northwest Passage.
4	Similar to 3A. Rather than following Peel Sound on the west side of Somerset Island, the route passes to the east of the island through Prince Regent Inlet and Bellot Strait.	**Prince Regent Inlet:** 80 km wide, free of islands, deep. **Bellot Strait:** short and very narrow, strong currents, limiting depth of 22 m.	Route of *St. Roch* in 1940-42 on easterly transit.
5	Hudson Strait – Foxe Channel – Foxe Basin – Fury and Hecla Strait – Gulf of Boothia – Bellot Strait – remainder via routes 3A, 3B or 4.	**Hudson Strait:** 100 km wide, 650 km long, deep, also serves as entrance to Hudson Bay and Churchill port. **Foxe Channel:** 130 km wide, deep, with limiting shoal in the middle that can be avoided. **Foxe Basin:** very large, many islands in northern end. **Fury and Hecla Strait:** 160 km long, very narrow with fast current. **Gulf of Boothia:** very large waterway connecting to Prince Regent Inlet to the north (see route 4). No problems for navigation except at exit of Fury and Hecla Strait where Crown Prince Frederick Island is to be avoided.	Not generally considered a viable commercial passage for moderate to deep draft ships.

Table 2.3 Adopted from Pharand (1988) with additional material from Sailing Directions, Arctic Canada, Vol. 3, 5th edition, 1994 and Canadian Arctic Shipping Assessment, Transport Canada, 2007.

The Nature of Ice at Sea

Several forms of floating ice may be encountered at sea. The most extensive is that which results from the freezing of the sea surface, namely sea ice; but mariners must also be concerned with "ice of land origin" - icebergs, ice islands, bergy bits and growlers. Both icebergs and sea ice can be dangerous to shipping and always have an effect on navigation.

- Young ice: newly formed sea ice less than 30 centimeters thick. It forms extensively in the autumn as ocean surface temperatures fall below freezing and on leads that open in mid-winter due to shifts in the pack ice. It is not a significant safety hazard for most Arctic vessels although, when placed under pressure by winds or currents, it can impede progress.

- First-year ice: can easily attain a thickness of 1 meter but rarely grows beyond 2 meters by the end of the winter. It is relatively soft due to the inclusions of brine cells and air pockets and will not generally hole an ice-strengthened ship operated with due caution. Under pressure from winds or currents, first-year ice can impede progress to the point where even powerful vessels can become beset for hours or even days.

- Old ice: If first-year ice survives the summer melt season, it is then classified as old ice (subdivided into second-year and multi-year ice). It is typically 1 to 5 meters thick and is extremely hard. During the summer melt process, the brine cells and air pockets that characterize first-year ice drain out the bottom of the ice, leaving a clear, solid ice mass that is harder than concrete. Even ice-strengthened vessels are at risk of being holed by old ice. When under pressure, old ice can stop the most powerful icebreakers.

- Icebergs: are large masses of floating ice originating from glaciers. They are very hard and can cause considerable damage to a ship in a collision. Ice islands are vast tabular icebergs originating from floating ice shelves. Smaller pieces of icebergs are called bergy bits and growlers and are especially dangerous to ships because they are extremely difficult to detect.

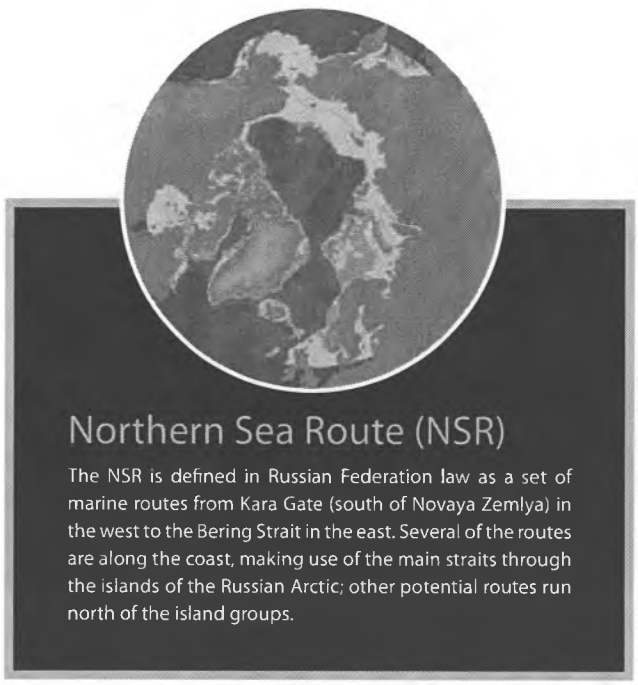
The Russian Maritime Arctic and Northern Sea Route

The physical environment of the northern coast of Eurasia - the Russian maritime Arctic - presents unique challenges to the mariner and to modern ship technology and systems. Shallow waters generally characterize the length of the coastline from the Norwegian-Russian border in the west (in the Barents Sea) to the Bering Strait. The average depths of the East Siberian and Chukchi seas are 58 meters and 88 meters respectively, making the entire coastal region in the east quite shallow for all marine operations. The average depth of the Laptev Sea is 578 meters (its northern limit extends into the Arctic Ocean basin); however, 66 percent of its area along the coast is in depths of 100 meters or less. The Kara Sea has an average depth of 90 meters and the Barents Sea is relatively shallow along the coast (10-100 meters) in the southeastern region and slopes to depths of 200-300 meters to the northwest. From the early years of exploration in the 17th century to today's offshore development and use of shipping routes, the consistently shallow bathymetry of this broad Arctic coast has been a key facet in all maritime affairs.

The Northern Sea Route is defined in Russian law as the set of Arctic marine routes between Kara Gate in the west and the Bering Strait. A number of narrow straits represent a significant constraint to navigation along the NSR. Yugorskiy Shar Strait is located along the south coast of Vaygach Island and is the southernmost entrance from the Barents to Kara seas (21 nautical miles long, 13-30 meters deep). Kara Gate is the main shipping strait between the Barents and Kara seas (18 nautical miles long, minimum depth of 21 meters) and shipping uses an established traffic separation scheme. Vilkitskiy Strait separates Severnaya Zemlya from the northernmost extremity of the Eurasian land mass, Cape Chelyuskin. This is a key NSR strait between the Kara and Laptev seas (60 nautical mile length, 100-200 meter depths), but it is ice-covered except for a short period in some summer seasons. Shokalskiy Strait is located in Severnaya Zemlya north of Vilkitskiy Strait and is a second possible shipping route between the Kara and Laptev seas (80 nautical miles long, minimum depth of 37 meters).

In the eastern reaches of the NSR, Dmitry Laptev Strait, oriented east-west, is the southernmost passage between the New Siberian Islands and the Russian mainland, linking the Laptev and East Siberian seas. This strait is 63 nautical miles long and has depths of 12-15 meters; however, the eastern approach has only depths of 10 meters or less, restricting traffic to ships with less than a 6.7 meter draft. Sannikov Strait is a second passage through the New Siberian Islands linking the Laptev and East Siberian seas (160 nautical miles long, minimum depths of 13 meters). From a navigation perspective, the low surrounding New Siberian Islands make visual and radar observations difficult to obtain, especially during long periods of reduced visibility. Long Strait separates Wrangel Island from the Russian mainland and links the East Siberian and Chukchi seas (a 120-nautical mile southern route along the coast with 20 meter minimum depths; a 160-nautical mile northern route with 33 meter minimum depths).



Northern Sea Route (NSR)

The NSR is defined in Russian Federation law as a set of marine routes from Kara Gate (south of Novaya Zemlya) in the west to the Bering Strait in the east. Several of the routes are along the coast, making use of the main straits through the islands of the Russian Arctic; other potential routes run north of the island groups.

Several marine route distances are notable: from Murmansk to the Bering Strait is 3,074 nautical miles; and the Northern Sea Route from Kara Gate to the Bering Strait is 2,551 nautical miles. The Dudinka to Murmansk marine route that is maintained year-round is 1,343 nautical miles, while it is approximately 500 nautical miles between the offshore region of the Pechora Sea (site of new oil terminals) in the southeast corner of the Barents Sea and Murmansk. Compared with the Canadian Arctic, the Russian maritime Arctic has many more viable ports located along the length of the NSR. Primary NSR ports from west to east include: Amderma, Dikson, Yamburg (Ob' Gulf), Dudinka (north Yenisei River), Igarka (south Yenisei River), Khatanga (Khatanga River on the Laptev Sea), Tiksi (Tiksi Gulf near the Lena River), Zeleny Mys (Kolyma River) and Pevek.

Geographic North Pole

The Geographic North Pole, the Earth's northernmost point, is located at the northern end of the Earth's axis of rotation. The latitude of the Geographic North Pole is 90 degrees N and it is the point where all the meridians of longitude and all 24 of the world's time zones converge.

Arctic Climatology

One defining threshold of the Arctic environment that is often used is set by the 10°C July isotherm. This isotherm marks the southern Arctic boundary where the monthly mean temperature in July is below 10°C. This limit also closely corresponds to the northern limit of the treeline. Because of the mix of landmasses, water and ice in the northern latitudes the isotherm pushes north above the Arctic Circle in all of Eurasia, but is south of the Arctic Circle in much of central and eastern Canada, southern Greenland and the Aleutian Islands. For example, the mean monthly July temperature at Honningsvåg, Norway (latitude 70° 58′ N) is 10.3°C; at Murmansk, Russia (latitude 68° 58′ N) it is 13.4°C. However, at Inukjuak, Quebec, Canada on the east side of Hudson Bay (58° 27′ N) the average July temperature is only 9.4°C; at Paamiut, Greenland on the south west coast (62° 00′ N) it is 5.5°C.

In January, mean temperatures everywhere within the Arctic Circle are all below 0°C, varying from about -5°C along the north coast of Norway to greater than -35°C in central Greenland, the northern part of the Canadian Archipelago and in northern Siberia. The average January temperature at the North Pole is estimated at between -30 and -35° C; however, this is difficult to know given that no permanent recording station exists at the pole. Over virtually all of the Arctic Ocean mean winter air temperatures are not as cold as they are in fringing continental land masses in Siberia, Alaska and Canada.

Precipitation, generally, is light within the Arctic at less than 250 millimeters per annum. Only along exposed coastal regions in southern Baffin Island, western Greenland and northern Scandinavia are amounts greater than this regularly experienced. The main component of the precipitation in the central and high Arctic is snow, but it too is light, at less than 25 centimeters per annum. Although light, snow tends to be blown in all regions and accumulates in drifts and around structures; in marine environments drifting snow accumulates along ice edges and other features on the sea ice creating considerable additional barriers to normal navigation. Almost all snow disappears nearly everywhere in the summer, except in glacier areas.

One of the factors explaining the climatic patterns and annual weather events in the Arctic is the distribution of high and low pressure systems through the year. In winter two semi-permanent low pressure areas set up in the region: one over Iceland and the

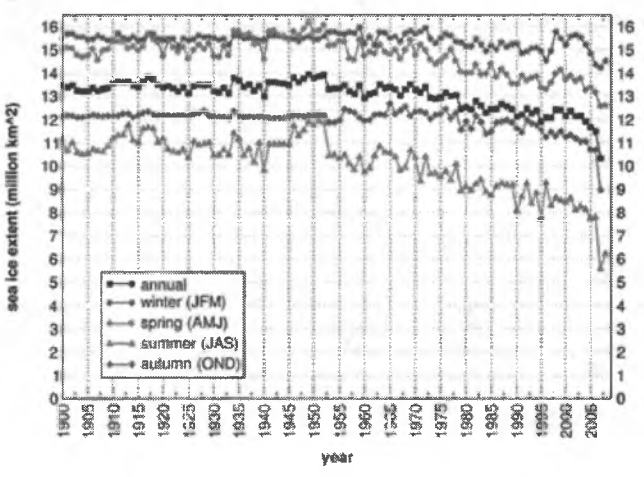
North Atlantic extending into the Barents Sea, the other over the Gulf of Alaska in the North Pacific. In contrast, high pressure areas are established over Siberia and the Yukon in Canada. The pressure differences bring about frequent and intense cyclonic storms moving generally from west to east. In summer, the lows weaken, the Siberian high disappears and the Canadian high shifts north over the Canadian Archipelago. As a result, pressure gradients are less and cyclonic activity declines, providing a fairly benign Arctic marine environment for voyages and regional operations. By October, the winter configuration begins to take effect and storminess increases with declining temperatures. Again, the seasonality of the polar environment, in this case the overall annual weather patterns over the Arctic Ocean, is a critical, strategic aspect for planning current and future marine transport systems throughout the Arctic basin.

Arctic Sea Ice: Changing Operating Conditions in the Arctic Ocean

Introduction

The Arctic sea ice cover is undergoing an extraordinary transformation that has significant implications for marine access and shipping throughout the Arctic basin. The Arctic Climate Impact Assessment, released by the Arctic Council at the Iceland Ministerial meeting in November 2004, documented that Arctic sea ice extent has been declining for the past five decades. Research has also

Graph 2.1 Northern Hemisphere sea ice extent. *Source: J. Walsh, W. Chapman*



Future Arctic navigation and all marine activity will depend on more frequent, reliable and near real-time sea ice thickness measurements.

indicated that sea ice thickness has been decreasing during the same period, and the area of multi-year ice has also been declining in the central Arctic Ocean.

Global Climate Models used in the ACIA and the Intergovernmental Panel on Climate Change Fourth Assessment Report (IPCC AR4 released in 2007) simulate a continuous decline in sea ice coverage through the 21st century. One ACIA model showed it is plausible that during mid-century, the entire Arctic Ocean could be ice-free for a short period in the summer, a finding that garnered significant media attention.

Recent research (2006-2008) has indicated this plausible ice-free state of the Arctic sea ice cover may occur as early as 2040, if not sooner. It is important to note that despite the remarkable, ongoing changes in Arctic sea ice and some uncertainty surrounding the output of the GCMs, no research and none of the GCM simulations have indicated that the winter sea ice cover of the Arctic Ocean will disappear during this century.

This fact alone - that there will always be an Arctic sea ice cover to contend with - has important implications for all future Arctic marine activity and for the development of ship standards and measures to enhance Arctic marine safety and environmental protection. The resulting sea ice conditions for future Arctic marine operations will be challenging and will require substantial monitoring and improved regional observations. This new Arctic Ocean of increasing marine access, potentially longer seasons of navigation and increasing ship traffic requires greater attention and stewardship by the Arctic states and all marine users.

In assessments of ongoing and projected climate change, Arctic sea ice is a critical and highly visible element. Observed sea ice extents derived from satellite passive microwave data for 1979-2006 indicate a decrease or annual loss of 45,000 km² of ice (3.7 percent decrease per decade). The same data analysis shows negative ice extent trends for each of the four seasons and each of the 12 months; the decline in summer extent (6.2 percent decrease per decade) is larger than in winter (2.6 percent decrease per decade).

Interestingly, the five smallest September ice-covered areas for the Arctic Ocean during the modern satellite record (1979-2008) have occurred in the five most recent seasons (2004-2008). Map 2.2 shows the sea ice coverage derived from satellite at the time of minimum extent of Arctic sea ice on September 16, 2007.

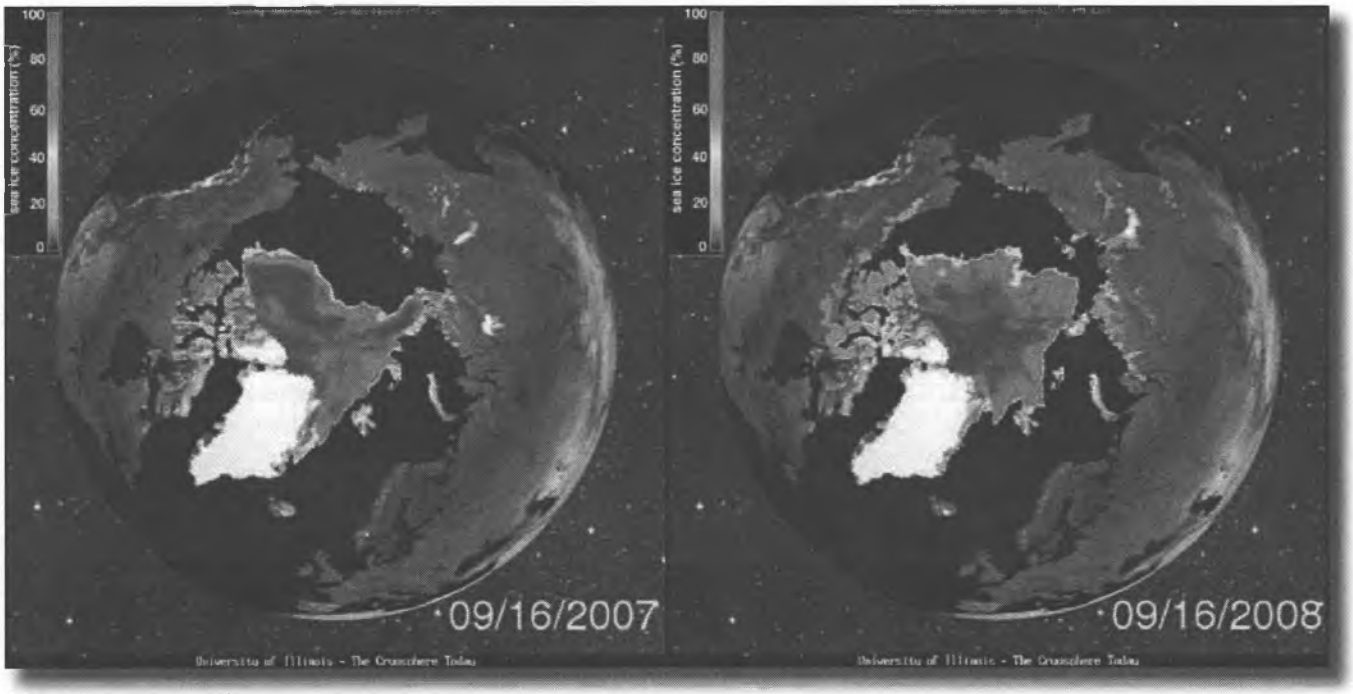
This snapshot represents the minimum coverage of Arctic sea ice in the satellite era of observations. Striking are several notable features: the largely ice-free areas across the Russian Arctic coastal seas (north of the Eurasian coast), except for a small region in the western Laptev Sea; an ice edge that has retreated north of Svalbard and well north in the Beaufort and Chukchi seas; several ice-free passages through the Canadian Archipelago; and a large area of the central Arctic Ocean that previously has not been observed open or without even a thin ice cover.

These extraordinary changes in the summer ice cover of the Arctic Ocean, represented by a single, iconic satellite image for September 16, 2007, are major factors in the potential lengthening of the navigation season in regional Arctic seas, particularly in the summer. It should be noted though that during the same timeframe, the Fram Strait contained more ice than normal, underscoring the regional variability of sea ice extent.

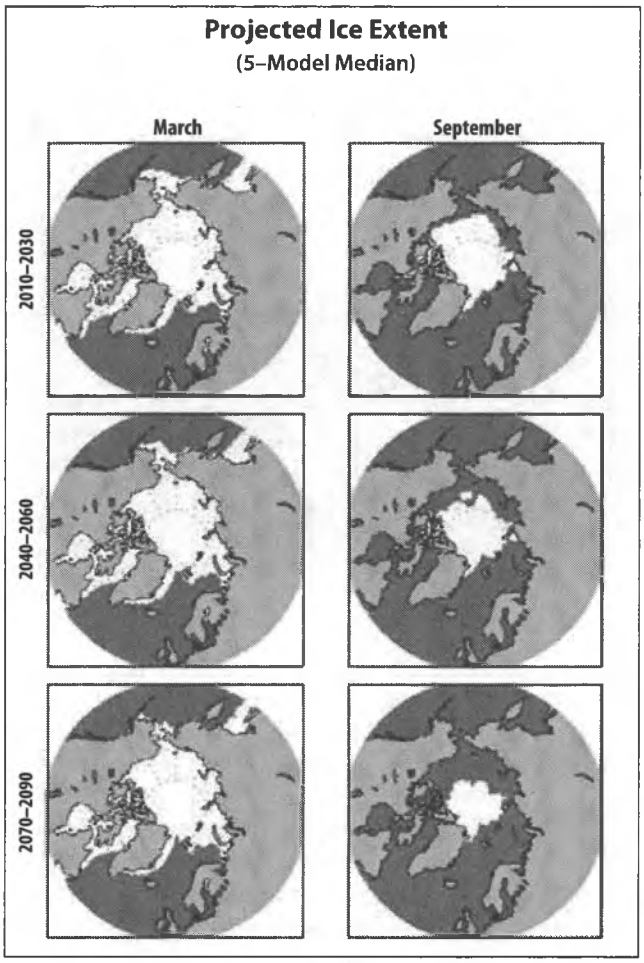
Arctic Climate Impact Assessment

The ACIA, approved by the eight Arctic countries, was called for by the Arctic Council and the International Arctic Science Committee. The assessment found that the Arctic is extremely vulnerable to observed and projected climate change and its impacts. The Arctic is now experiencing some of the most rapid and severe climate change on earth. During the 21st century, climate change is expected to accelerate, contributing to major physical, ecological, social and economic changes, many of which have already begun. Changes in Arctic climate will also affect the rest of the planet through increased global warming and rising sea levels. Of direct relevance to future Arctic marine activity, and to the AMSA, is that potentially accelerating Arctic sea ice retreat improves marine access throughout the Arctic Ocean.

The assessment confirmed, using a wealth of current Arctic research, that declining Arctic sea ice is a key climate change indicator. During the past five decades the observed extent of Arctic sea ice has declined in all seasons, with the most prominent retreat in summer. While the ACIA models have now been surpassed by more capable GCMs, each of the five GCMs used in the ACIA did project a continuous decline in Arctic sea ice coverage throughout the 21st



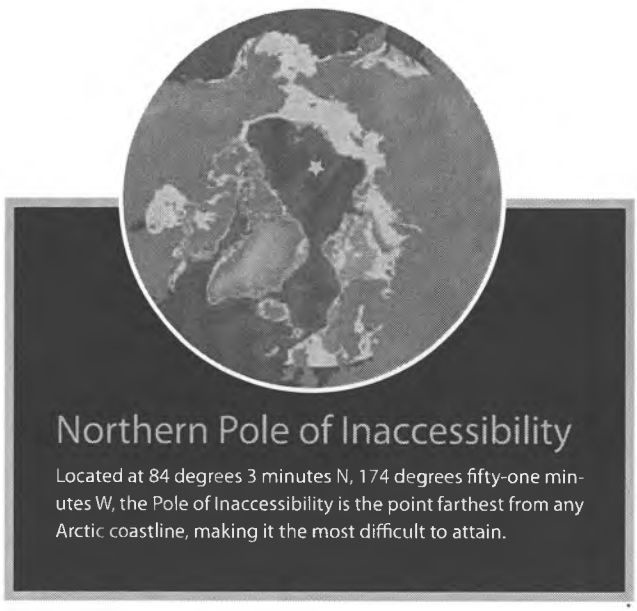
Map 2.2 Satellite images of summer sea ice cover. *Source: University of Illinois – The Cryosphere Today*



Map 2.3 Arctic sea ice simulations for the 21st century.
Source: Arctic Climate Impact Assesment

century (Map 2.3). From a strategic planning perspective, this is a key factor for evaluating future Arctic marine transport systems. As noted previously, one of the models simulates a summer ice-free Arctic Ocean by 2050, a future scenario of great significance for Arctic shipping and offshore development. Such a physical occurrence would mean that multi-year ice could possibly disappear in the Arctic Ocean. All of the next winter's ice would be first-year: no ice will have survived a winter season (and be able to gain strength and thickness).

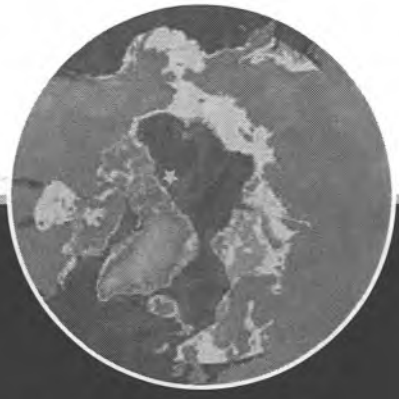
GCM projections to 2100 suggest that in the summer the Arctic sea ice will retreat further and further away from most Arctic coasts, potentially increasing marine access and extending the season of navigation in nearly all Arctic regional seas. One critical limitation of the GCMs is that they are not useful for determining the state of sea ice in the Northwest Passage region. Their spatial resolution is much too coarse to be applied to the complicated geography of the Canadian Arctic Archipelago.



In the ACIA, the only reliable observed data for the region comes from the Canadian Ice Service and this information, archived since the late 1960s, shows a mean negative trend of sea ice coverage in the Canadian Arctic, but very high year-to-year variability. The ACIA models, however, could be applied very crudely to the more open coastal seas of the Russian Arctic. The ACIA sea ice projections for Russia's Northern Sea Route indicated longer periods of ice-free conditions which could translate into a longer navigation season throughout the 21st century.

The ACIA confirms that the observed retreat of Arctic sea ice is a real phenomenon. The GCM projections to 2100 show extensive open water areas during the summer around the Arctic basin. Thus, it is highly plausible there will be increasing regional marine access in all the Arctic coastal seas. However, the projections show only a modest decrease in winter Arctic sea ice coverage; there will always be an ice-covered Arctic Ocean in winter although the ice may be thinner and may contain a smaller fraction of multi-year ice. The very high, inter-annual variability of observed sea ice in the Northwest Passage and non-applicability of the GCMs to the region prevent an adequate assessment of this complex region.

It is important to note that despite the remarkable, ongoing changes in Arctic sea ice and some uncertainty surrounding the output of the GCMs, no research and none of the GCM simulations have indicated that the winter sea ice cover of the Arctic Ocean will disappear during this century.



North Magnetic Pole

The North Magnetic Pole is a non-stationary pole in the Arctic to which compass needles point from any direction. The magnetic field at this point points straight down or is at right angles to the Earth's surface. The position of the Pole continues to wander and is currently northwest of the Canadian Arctic.

Although the ACIA projections indicate an increasing length of the navigation season for the Northern Sea Route (20-30 days per year in 2004, to 90-100 days by 2080), detailed quantification of this changing marine access also tested the limitations of the ACIA GCMs. Since the work of the ACIA, advances and refinements in the models may allow them to provide more robust strategic information on the length of time regions remain ice-free and year-to-year regional sea ice variabilities. There is a definite need for improved Arctic regional models to adequately assess future changes in sea ice extent and thickness, and their considerable implications for expanded marine use of the Arctic Ocean. And, there is a significant need for more sea ice observations to improve the calibration and validation of the GCMs.

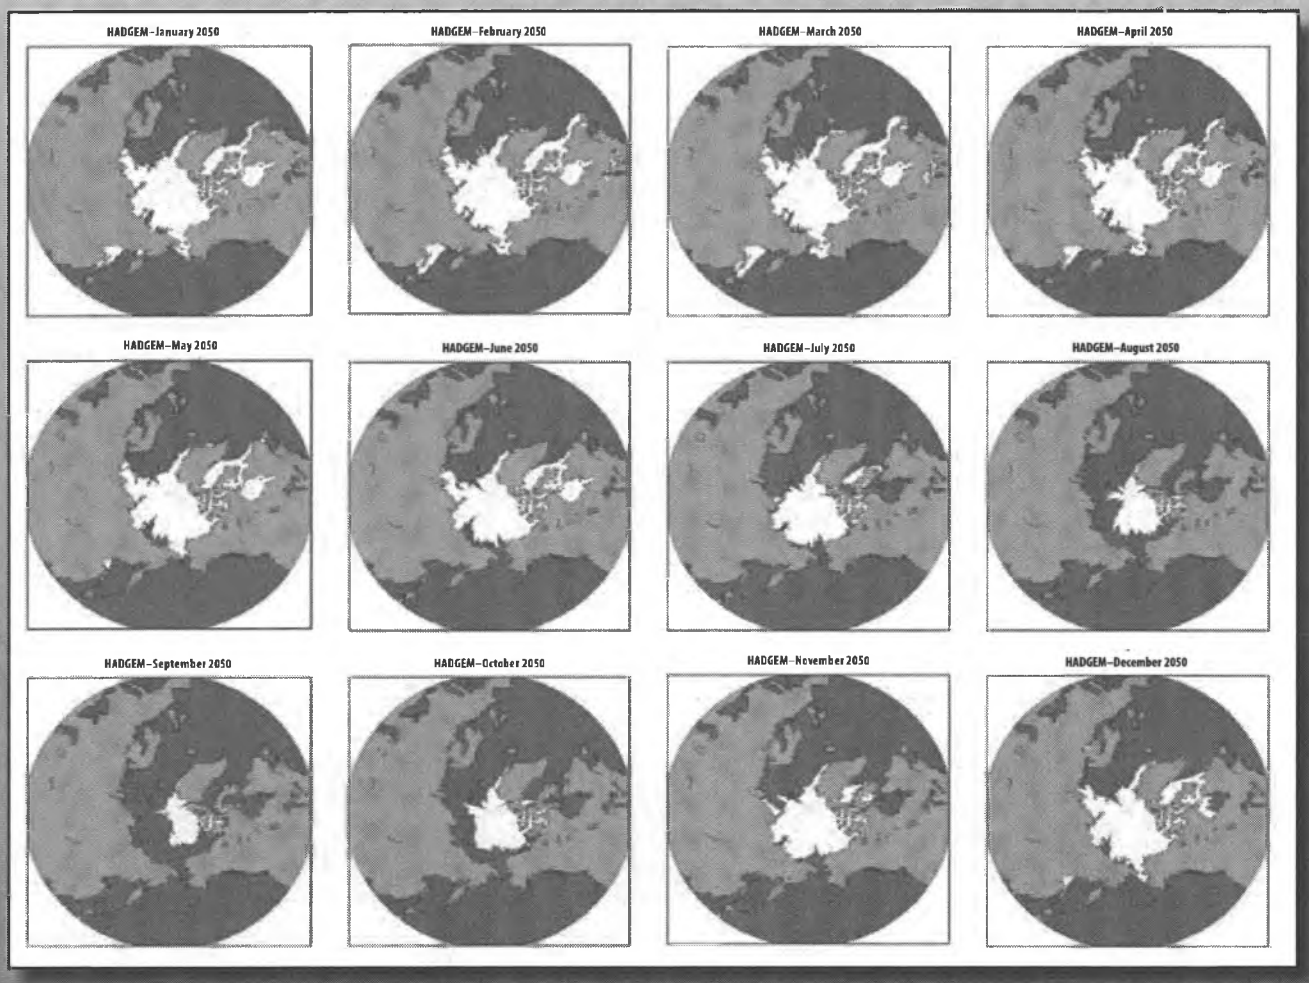
The final ACIA report lists 10 major findings that are essentially the key impacts of climate change on Arctic people and the environment. The ACIA key finding #6 states, "Reduced sea ice is very likely to increase marine transport and access to resources." One of the follow-on Arctic Council activities addressing this ACIA finding is the AMSA.

Intergovernmental Panel on Climate Change Fourth Assessment and Beyond

The Intergovernmental Panel on Climate Change (IPCC) was established in 1988 by the World Meteorological Organization of the United Nations Environment Programme. IPCC is an intergovernmental body that provides scientific and technical information to policy makers. The 2007 IPCC 4th Assessment report indicated the lack of comprehensive sea ice data prior to the satellite era. However, observed data analyses have been able to confirm a sustained decline in Arctic sea ice since the early 1970s, notably during the summer melt season. The report also comments that the accuracy of satellite-derived ice concentration is usually 5 percent or better; errors of up to 10-20 percent can occur during the melt season as the passive microwave sensors measure the thin surface layers of melt water on the sea ice surface. Of critical importance to future navigation, the assessment also summarizes the information on the remarkable decrease in multi-year ice throughout the Arctic Ocean.

The possibility of an ice-free Arctic Ocean, even for a brief period, was advanced as an intriguing outcome of the ACIA. Recent analyses of GCM sea ice simulations using models from the IPCC AR4 (applying global warming scenarios) show near-complete loss of Arctic sea ice in September for 2040 to beyond 2100. However, additional research also indicates abrupt reductions in sea ice coverage during the 21st century are a common feature in many of the GCM simulations. Whether these periods of accelerated summer sea ice retreat might provide windows of opportunity for improved marine navigation is unknown. However, these research results and recent model inter-comparisons show the many uncertainties that remain in simulating the future ice cover of the Arctic Ocean.

Map 2.4 Hadley Centre Arctic Sea Ice Simulations, 2050. *Source: IPCC4 - 2050*



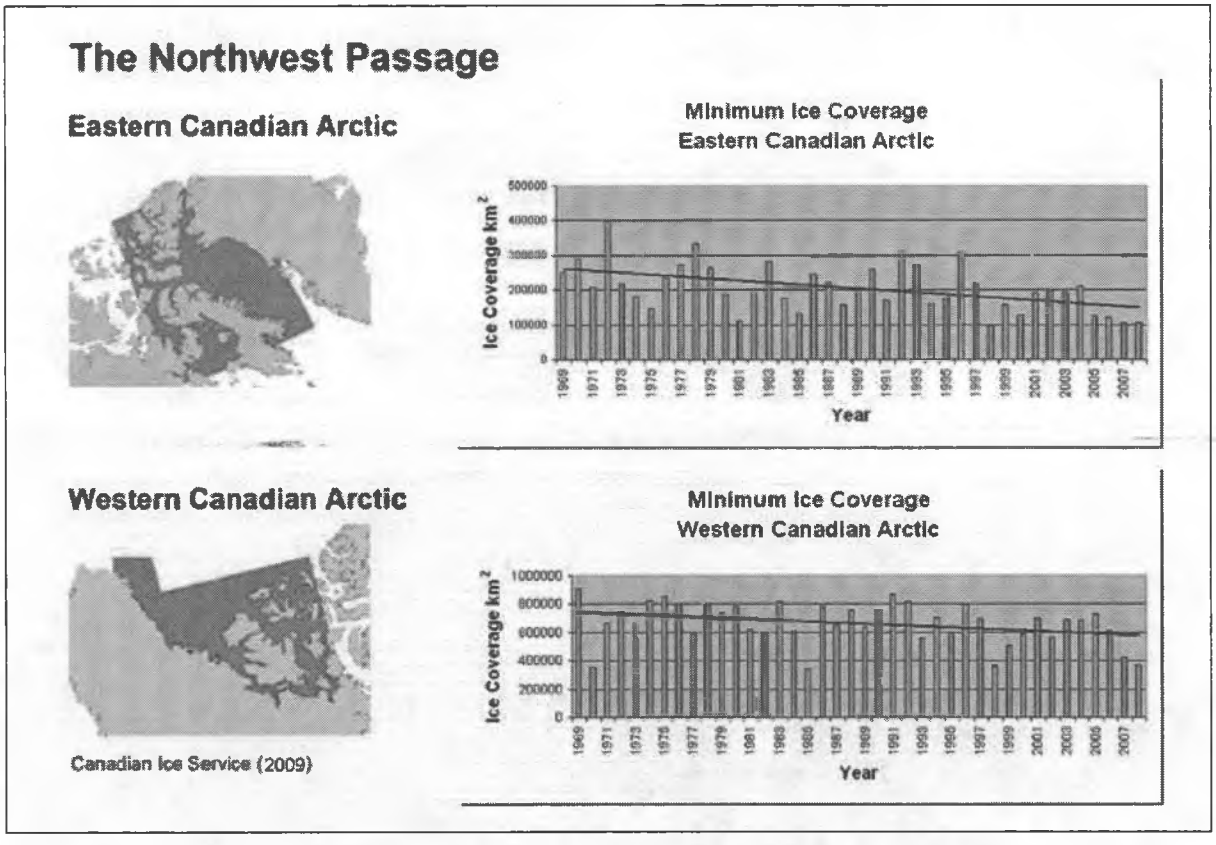
© Fednav, Ltd.

Further research on the performance of the IPCC AR4 models (Map 2.4) reveals that none of the GCMs have negative trends for sea ice as large as the observed sea ice coverage trend for the period 1953-2006 (7.8 percent per decade reduction). The observed trend is three times larger than the multi-model mean of a 2.5 percent per decade loss. This is an extraordinary development that also means the current summer sea ice minima are as much as 30 years ahead of the mean of the model simulations. With continued greenhouse gas emissions, it is highly plausible that the Arctic Ocean could become completely ice-free for a short summer period much earlier than 2040.

Just as important to ship navigation, these simulations indicate large areas of the coastal Arctic seas to be ice-free for longer periods in the spring and autumn months. Arctic marine access continues to increase in nearly all the scenarios posed by the ACIA and the more recent IPCC assessments.

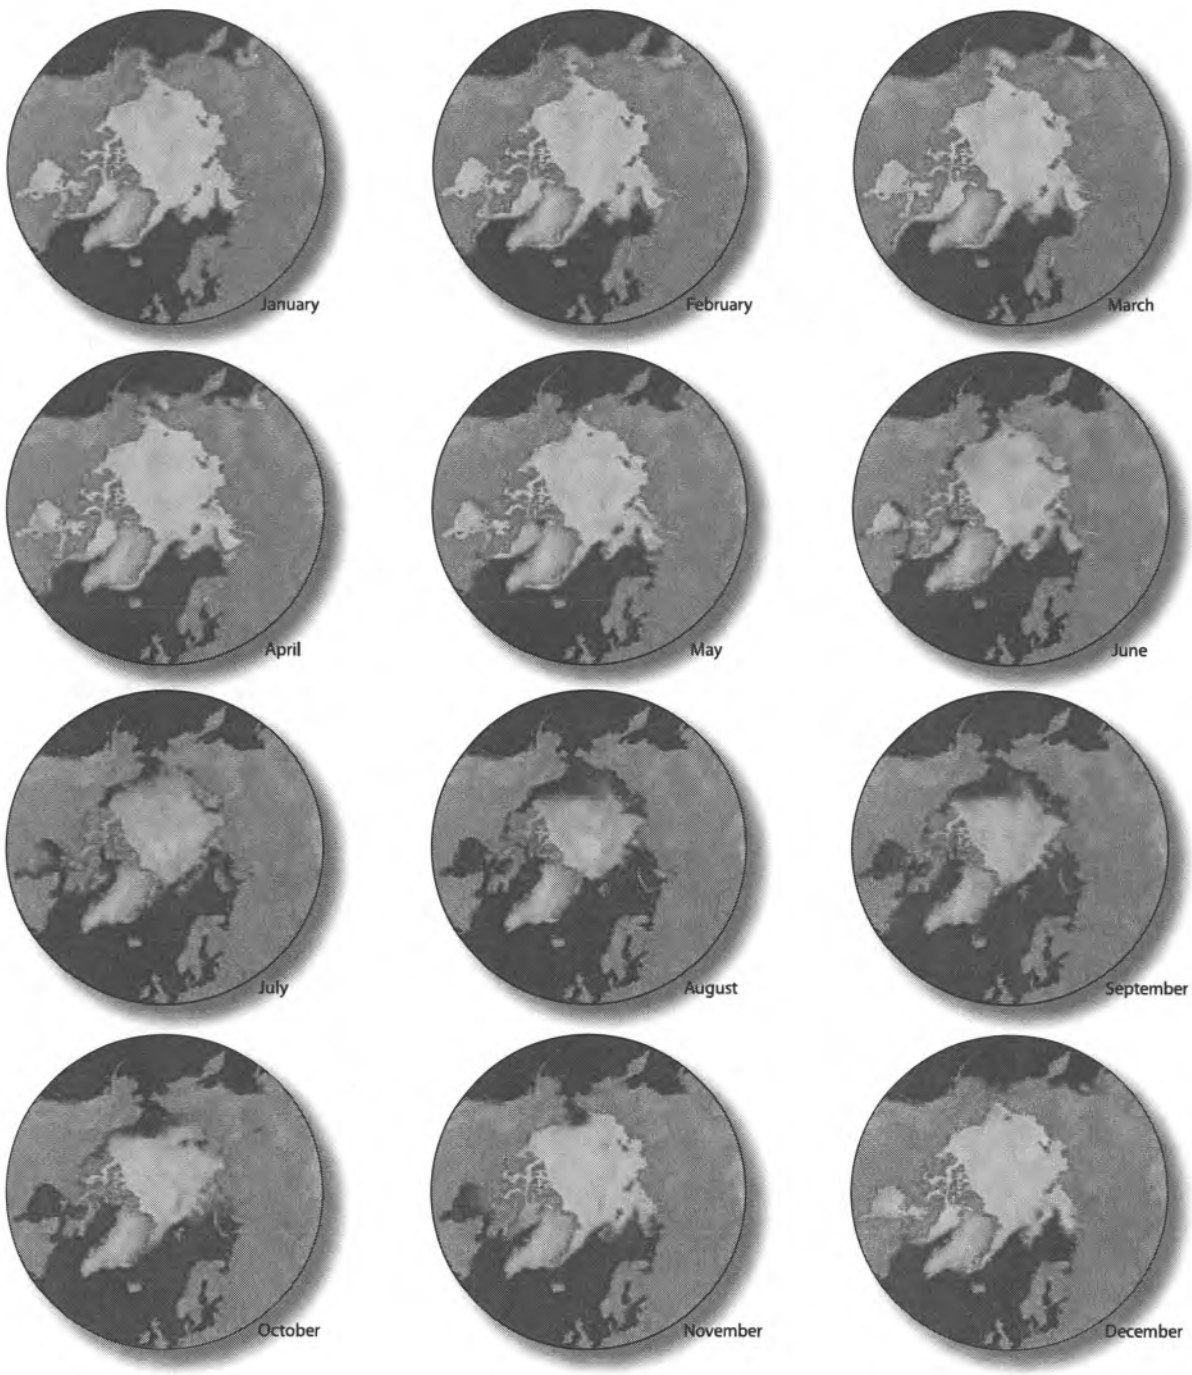
Additional Sea Ice Trends and Research

Earlier observations from aircraft and ships, and three decades of daily satellite observations, suggest that the September 2007 minimum sea ice extent (Map 2.2) was the lowest since the early 1950s; however, the September 2008 minimum extent indicated a slightly larger area of sea ice coverage. The Arctic sea ice cover is at a maximum extent in March and this maximum coverage has also been observed to decrease at approximately 2 percent per decade during the period 1979-2008. These extent reductions have been observed in all seasons of a year, but perhaps more significant have been observations of a rapid decline of thick, multi-year sea ice in the central Arctic Ocean. A study of satellite data for winter during 1978-1998 revealed that the multi-year sea ice cover had declined by 7 percent per decade. A second trend analysis for 25 years of summer ice minima (1978 to 2003) reports a decline of multi-year sea

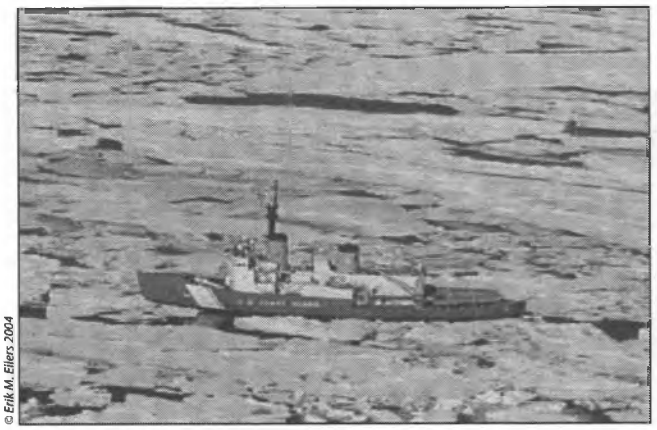


Graph 2.2 Sea ice variability in the Canadian Arctic and Northwest Passage. *Source: Canadian Ice Service*

Monthly Arctic Sea Ice Extent and Coverage, 2004



Map 2.5 Sea ice depictions for the AMSA shipping survey year of 2004. *Source: AMSA*



© Erik M. Ellers 2004

ice as high as 9.2 percent per decade. One important result of these trends should be a decrease in the presence of multi-year ice in the Arctic's coastal seas where seasonal navigation and marine activity are highest.

Arctic sea ice thicknesses have been much more difficult to monitor and evaluate during recent decades. Direct measurements of first-year sea ice in the Arctic coastal seas by the Arctic and Antarctic Research Institute in St. Petersburg, the Russian Federation, along the Russian Arctic, generally yield 1-2 meter thicknesses. For the central Arctic Ocean, thicknesses of multi-year sea ice can be as high as 4-5 meters. One pioneering study using sea ice draft data acquired on submarine cruises (data from 1958-1976 compared with cruise data for 1993-1996) indicated a decrease in thickness at the end of the melt season for the central Arctic Ocean from 3.1 to 1.8 meters. This represented a volume decrease of 40 percent and a widespread decrease in sea ice draft. This 40 percent reduction was adjusted to 32 percent in a subsequent study once additional submarine tracks were added.

One key issue is that future sampling of Arctic sea ice thickness requires enhanced monitoring systems for more effective spatial and temporal measurements. Modern measurement systems such as electromagnetics, upward looking sonars and satellites have been developed that are improving thickness observations. Future Arctic navigation and all marine activity will depend on more frequent, reliable and near real-time sea ice thickness measurements.

Sea Ice Regional Trends

Canadian Maritime Arctic and Northwest Passage

The observed record of minimum sea ice extent for the eastern and western regions of the Canadian Arctic is illustrated in Graph 2.2. Although the observations for both regions show negative trends for the period 1969-2008, the year-to-year variability in coverage is quite extreme. Both regions also exhibit large differences for a given year; for example, in 1991 the western Canadian Arctic showed one of the highest or largest ice coverage areas, while in the eastern region a more normal coverage area at the summer minimum was observed. These regional variabilities create a challenge for seasonal operations. While these observations indicate an overall decrease in the ice cover of the waterways that comprise the Northwest Passage, the two key variabilities - year-to-year and spatial - create challenges for planners judging risk and the reliability of an Arctic marine transportation system for the long-term.

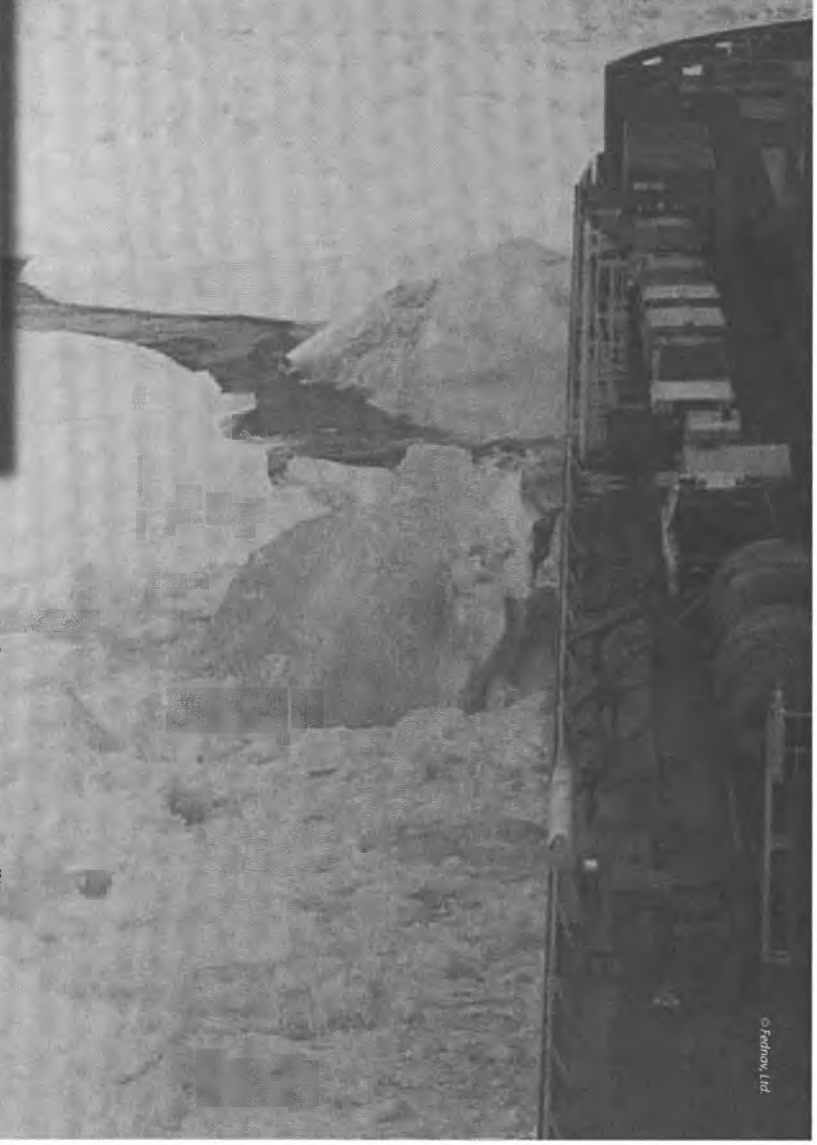
The five models used in the ACIA revealed that the last regions of the Arctic Ocean with sea ice coverage in summer would be in the northern waterways of the Canadian Archipelago and along the northern coast of Greenland. The flow of more mobile multi-year ice through these waterways presents another potential challenge to marine operations. Enhanced satellite monitoring (with high resolution imagery) of this complex region will be a necessity if expanded marine operations beyond summer are to be realized.

The five models used in the ACIA revealed that the last regions of the Arctic Ocean with sea ice coverage in summer would be in the northern waterways of the Canadian Archipelago and along the northern coast of Greenland.

Research Opportunities

- Research to improve regional models for increased understanding and enhanced forecasting of regional Arctic sea ice variability. New regional models should include ice thickness, snow cover and ice ridging, all key parameters of importance to Arctic navigation.
- Comprehensive analyses of current and future Global Climate Model simulations of Arctic sea ice extent to quantitatively assess the range of plausibly ice-free and partially ice-covered conditions.
- Considering the ongoing development of the Sustained Arctic Observing Network (SAON), develop and contribute a set of parameters to be observed and more observations that will be relevant to enhancing marine safety and marine environmental protection.
- Continued data analysis and updating of the International Bathymetric Chart of the Arctic Ocean (IBACO) with a long-term goal to create a comprehensive, integrated digital database of all bathymetric information for the Arctic Ocean.

The physical environment of the northern coast of Eurasia - the Russian maritime Arctic - presents unique challenges to the mariner and to modern ship technology and systems.



© Fednav Ltd

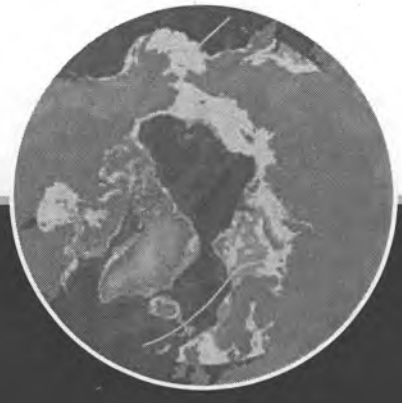
Russian Maritime Arctic and Northern Sea Route

Map 2.2 indicates that a nearly ice-free summer passage could have been made in 2007 and 2008 from Kara Gate through to the Bering Strait along the length of the Northern Sea Route except for sea ice in the western Laptev Sea. Passive microwave satellite observations of sea ice in the Russian Arctic seas from 1979 to the present show large reductions in sea ice extent in summer and reductions in winter extent in the Barents Sea. All of the ACIA model simulations and more recent IPCC AR4 model simulations confirm that large summer ice edge retreats should occur in the Laptev, East Siberian and western Chukchi seas. With a continued shrinkage of the fraction of multi-year sea ice in the central Arctic Ocean, it is plausible that fewer multi-year ice floes may be observed along the navigable eastern passages of the Northern Sea Route.

Long-term fast ice thickness measurements of the four Russian marginal seas (Kara, Laptev, East Siberian and Chukchi seas) have been analyzed for trends using 65-year observational records (1930s to 1990s). Long-term trends are small and inconclusive: the trends are small (approximately 1 centimeter per decade); the trends for the Kara and Chukchi seas are positive and the trends for the Laptev and East Siberian seas negative.

A review of recent assessments, observations and studies indicate that there remains much to understand about the present and future trends in Arctic sea ice. The operating conditions for Arctic ships will remain challenging, particularly in winter. It is also highly plausible that Arctic sea ice will be more mobile, particularly in spring, summer and autumn, as the cover continues to retreat from Arctic coastlines. Arctic coastal seas may experience increased ridging of seasonal sea ice, potentially creating more difficult operating conditions for marine navigation. The observed records of sea ice extent in the Canadian and Russian Arctic areas display high inter-annual variabilities. Such year-to-year variability poses a serious challenge to risk and the overall reliability of Arctic marine transport systems. Three key conclusions with direct relevance to Arctic shipping include:

- Arctic sea ice has been observed to be diminishing in extent and thinning for five decades. Also, model simulations indicate a continuing retreat of Arctic sea ice throughout the 21st century. However, no research indicates Arctic sea ice will disappear completely and a substantial winter sea ice cover will remain.
- Even a brief ice-free period in summer for the Arctic Ocean would mean the disappearance of multi-year sea ice in the central Arctic Ocean. Such an occurrence would have significant implications for design, construction and operational standards of all future Arctic marine activities.
- Observed sea ice trends and GCM simulations show coastal Arctic regions to be increasingly ice-free, or nearly ice-free, for longer summer and autumn seasons. Longer open water seasons increase the potential for greater coastal erosion, which can impact support infrastructure for Arctic development and marine transportation.



Northeast Passage (NEP)

The NEP is defined as the set of sea routes from northwest Europe around North Cape (Norway) and along the north coast of Eurasia and Siberia through the Bering Strait to the Pacific.

Regarding future needs, a key requirement is the development of high resolution, regional sea ice models that can provide more robust and realistic forecasting of marine operating conditions. There is also a critical requirement for more real-time sea ice observations, especially ice thickness measurements, to support all future Arctic marine uses. The national ice centers and ice services are critical providers of such sea ice information and greater international collaboration among the centers will enhance the development of more integrated products. New satellite sensors hold the promise of providing greater, near real-time ice thickness information for Arctic ships that are underway on future voyages.

A global maritime trade route - the North Pacific's Great Circle Route - intersects with the Aleutian Islands and thousands of large ships pass north and south of these islands on voyages between the west coast of North America and Asian ports each year.

Findings

1] Arctic sea ice coverage (extent) has been decreasing since the 1950s in all seasons. Observations of sea ice in the central Arctic Ocean have also indicated thinning during the past four decades. However, there remains a significant, year-to-year variability in regional sea ice coverage.

2] Global Climate Model simulations indicate a continuing "retreat" of Arctic sea ice through the 21st century. Observed sea ice trends and GCM simulations show coastal Arctic regions to be increasingly ice-free or nearly ice-free for longer summer and autumn seasons. Importantly, all simulations indicate that an Arctic sea ice cover remains in winter.

3] Recent sea-ice model simulations indicate the possibility of an ice-free Arctic Ocean for a short period of time in summer by earlier than mid-century. The key implication for this physical change will be the near (or complete) disappearance of multi-year sea ice.

4] Future sea ice conditions remain uncertain. It is highly plausible that Arctic sea ice will be more mobile in partially ice-covered coastal seas, particularly in spring, summer and autumn. Coastal seas may experience an increase and greater frequency of ice ridging and shorter periods of coastal fast ice.

5] The resolutions of GCM simulations are much too coarse for adequate coverage of the complex geographies of the Canadian and Russian Arctic. GCM Arctic sea ice simulations also lack robustness to provide detailed information on future marine operating conditions such as the length of the navigation season, "residence time" of ice-free conditions, frequency of leads and ridges and more.

6] Recent GCM Arctic sea ice simulations have not replicated the observed sea ice reductions from the 1950s to today. For example, the model simulations have not shown the drastic decrease of observed sea ice extent during recent years.

7] Climate change as indicated by Arctic sea ice retreat is a facilitator of marine access. It is highly plausible there will be greater marine access and longer seasons of navigation, except perhaps during winter, but not necessarily less difficult ice conditions for marine operations.

HISTORY OF ARCTIC MARINE TRANSPORT

The Arctic Ocean and adjacent seas have been used by mariners since the beginning of time. Historical Arctic marine transport activities reflect continuous indigenous marine use, expeditions and explorations, community supply/re-supply and expanding use by the global shipping community.

The first Arctic explorers were the indigenous people. Though most of their journeys remain undocumented, indigenous people have been traveling and exploring Arctic waters for thousands of years in search of food, supplies and settlement areas. They remain the original explorers and founders of the region.

Early Western marine transport in the Arctic was driven by searches for the Northwest Passage and Northeast Passage (Table 3.1). With the passages discovered, the focus shifted from searching to improving marine routes. Many notable Arctic voyages occurred and the scope of Arctic marine shipping advanced such that vessels even ventured to the then elusive North Pole. Advances in ship design, construction and operation, coupled with advancements in infrastructure, crew training and governance, have led to massive improvements in Arctic shipping.

This section will review briefly the rich history of the search and development of the Northwest Passage through the Canadian Archipelago, the Northeast Passage and later the Northern Sea Route along the northern coastline of Russia, as well as the history of Arctic tourism that can be found throughout the Arctic today.

Northwest Passage

The first European Arctic explorer was the Greek navigator Pytheas who sailed northward in 325 B.C. and is credited with having reached the vicinity of Iceland and perhaps even Greenland. In the late 9th century (aided by a period of worldwide climatic warming), the Norwegians found and colonized Iceland. Later Icelandic explorers found and colonized Greenland, and explored the northeast coast of North America.

It was not until the 1490s that Europeans began to investigate the possibility of a Northwest Passage (NWP) in order to find a more direct route to the Orient and the lucrative trade with India, Southeast Asia and China. In 1497, John Cabot sailed from Bristol in *Matthew* in an unsuccessful search for the passage.

Canadian place names reflect some of the many attempts that followed, with most via Hudson Bay, including Martin Frobisher, John Davis, Henry Hudson and Luke Foxe. In 1778, James Cook made the first attempt at locating the NWP from the west. In the 1800s, the Royal Navy explored the labyrinth of islands and channels that is now the Canadian Arctic Archipelago. In 1845, Sir John Franklin's ships, the *Erebus* and *Terror*, sailed north into Baffin Bay and disappeared. The Royal Navy mounted a massive search during the following decade for Franklin and his 129 men and as a result, the entire archipelago was explored.

It wasn't until 1906 that Norwegian explorer Roald Amundsen in his 47 ton sloop *Gjoa* emerged in the Pacific to become the first vessel to complete the NWP. Amundsen took three winters to complete the voyage and credit for his survival through the harsh Canadian winters goes to the Inuit. The first complete transit from west to east was completed in 1942 by the Canadian ship *St. Roch*. Captain Henry Larsen made the return trip from east to west in only 86 days and became the first vessel to transit the NWP in one season. Transits of the NWP after the *St. Roch* remained fairly sporadic until the 1970s.

In the period from 1945 to 1969, national security was the primary driver for navigation in the passage: the Canadian icebreaker *HMCS Labrador* became the first ship after the *St. Roch*, as well as the first armed Canadian ship to successfully complete transit of the NWP. Three years later, the *Labrador* escorted three U.S. Coast Guard icebreakers - *Storis, Spar and Bramble* - on part of the journey from west to east through the NWP.

From the 1969 voyage of the American oil tanker *Manhattan* (discussed later in this section) to the end of the 1980s, more than 30 complete transits of the passage were undertaken by a variety of vessels, as the focus shifted from national security to economic

Date	Event
Since time immemorial	Indigenous people are the original explorers, founders and settlers
325 B.C.	Greek astronomer / geographer / navigator Pytheas sails northward to Iceland
850 A.D.	The Vikings of Scandinavia sail northward and colonize Iceland
981	Viking, Erik "the Red" Thorwaldson, sails westward and discovers Greenland. Vikings colonize southeastern parts of Greenland
11th century	Russian settlers and traders on the coasts of the White Sea, the Pomors, had been exploring routes in the region
1490	John Cabot first proposes existence of a NWP
1500's	Whalers explore from Baffin Island to Novaya Zemlya
1576	Martin Frobisher lands in what becomes known as Frobisher Bay
1596	William Barents discovers Spitsbergen and seeks NEP
1610-11	Henry Hudson expedition survives Arctic winter
1615	Robert Bylot, with William Baffin as pilot, explores Hudson and Baffin bays
1648	Cossack Semen Dezhnev sailed east from the mouth of Kolyma to the Pacific, thus proving that there was no land connection between Asia and North America
1726	First Northern Expedition, with Vitus Bering in command, discovers Bering Strait while seeking NEP
1733-43	The Great Northern Expedition takes place with Vitus Bering in command
1778	James Cook makes the first serious attempt at locating the NWP from the west
1831	John Ross reaches magnetic North Pole
1845	John Franklin's lost expedition proves existence of NWP
1854	Robert McClure receives the Admiralty's prize for 'discovering' the NWP
1878-79	Nordenskjold in the *Vega* becomes the first known vessel to achieve a transit of the NEP
1893	Fridjof Nansen's ship *Fram* proves the existence of Arctic current
1903-06	Roald Amundsen in the *Gjoa* successfully completes the first transit of the NWP by ship
1932	Soviet expedition led by Otto Schmitt was the first to sail in one season transit the NSR
1940-42	Henry Larsen in the *St. Roch* was the second vessel to transit the NWP, the first to do so from west to east
1944	*St. Roch* is the first vessel to make a one-season transit (in only 86 days going east to west)
1977	*Arktika* is the first surface vessel to reach the North Pole

Table 3.1 Significant early history of Arctic marine transport. *Source AMSA*

The first European Arctic explorer was the Greek navigator Pytheas who sailed northward in 325 B.C.

development. The bulk of the transits were Canadian vessels involved in the search for hydrocarbon resources offshore in the Canadian shelf in the Beaufort Sea. Also included in the period were tankers carrying fuel for the various explorations and bulk carriers transporting ore from the Nanisivik mine on Strathcona Sound. The year 1993 saw the Government of Canada spearhead an initiative bringing together various international shipping companies and Arctic coastal states in an attempt to develop a shared set of international standards that could govern the operation and construction of vessels that would function in Arctic waters.

Growing population in the 21st century, together with increases in community re-supply and oil and gas development, has led to a greater demand for shipping in the region. The uncertainty of the NWP due to seasonality, ice conditions, complex archipelago, draft restrictions, choke points, lack of adequate charts, insurance and other costs prohibits the likelihood of regularly scheduled trans-Arctic voyages; yet destinational shipping is anticipated to increase incrementally in the Canadian Arctic. Although community growth will drive a steady increase in the demand for seasonal re-supply activity, the primary areas of increased activity will be resource-driven (See page 112).

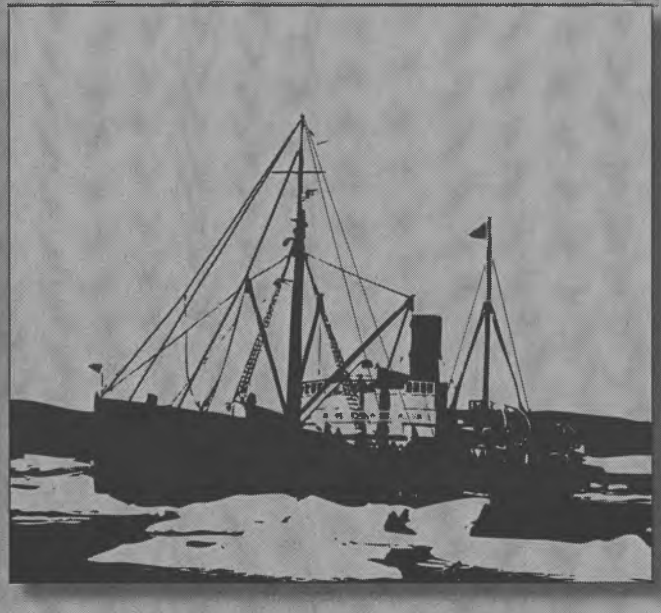
Cold War Marine Activity: Construction of the DEW Line

The Distant Early Warning (DEW) Line was a linked chain of 63 communication and radar systems, spanning 3,000 miles - from Alaska's northwest coast to Baffin Island's eastern shore opposite Greenland - set up to detect incoming Soviet bombers during the Cold War. It was located entirely within the Arctic Circle, with 42 of the 63 sites situated on Canadian territory.

Between 1954 and 1957, the DEW Line was constructed, and more than 300 ships plied Arctic waters during the two summer navigation seasons carrying more than 300,000 tonnes of cargo. This initiative allowed access into the Canadian Arctic through three major sealifts: the West Coast Sea Lift, the East Coast Sea Lift and the Inland Sea Lift.

Hudson Bay Company Voyages

In terms of commercial shipping, the most impressive record of voyages in ice-infested waters, both in terms of length and its successes, is that of the annual voyages by the ships of the Hudson's Bay Company. For 243 years, from 1670 to 1913, 600 voyages were made from London, England, to trading posts in Hudson Bay, Canada. Of the ships involved in the 600 voyages, 18 were wrecked (the majority of these was not sunk by ice; most either ran aground or foundered in open water). In 1912, the steel-hulled steamer *Nascopie*, which sailed out of Montreal, replaced the ships sailing annually from London. In her first year, the *Nascopie* ran aground in uncharted waters, underlining the achievements of the Hudson's Bay Company's earlier captains who safely made 582 voyages from London through the icy waters of Hudson Strait to its various posts in the Bay, and back.



39,251
Whaling voyages from 1610-1915.

Whaling

Undoubtedly the most massive, sustained activity in terms of Arctic marine shipping was that of whaling. Between 1610-1915, a little more than 39,000 voyages were undertaken in the Arctic in pursuit of the bowhead whale. This activity focused on four main areas: the Svalbard/Greenland Sea area, Davis Strait and Baffin Bay, Hudson Bay, and the Bering, Chukchi and Beaufort seas. The main participating nations were the Netherlands, Germany, Britain and the United States.

This activity was pursued mainly in ice-infested waters and the number of ships and men lost was extremely high. At the same time, the whaling industry resulted in the accumulation of a vast amount of specialized knowledge of patterns of ice distribution and of ship-handling in ice knowledge upon which the Royal Navy, for example, [illegible] by appointing usually two whaling captains as ice-pilots on board each of the vessels engaged in the search for the missing Franklin expedition in 1848-1855.

Many of the ships lacked ice-capability, a fact that often resulted in shorn propeller blades and hull punctures. Beyond retroactive measures, such as adding a nickel-aluminum-bronze alloy propeller or steel sheathing, the American Military Sea Transportation Service engaged in a construction program that saw the building of ships designed specifically for operation in an Arctic environment. A new class of tankers included construction features that were standard for Arctic vessels, such as cargo booms and a secondary wheelhouse.

Largely as a result of American interest in the North, Canada was driven to acquire icebreakers and cultivate a greater navigational ability in Arctic waters. Increases to Canada's Arctic vessel capacity, in the early-to-mid 1950s, took the form of the *CGS d'Iberville* (1952) and the *HMCS Labrador* (1954).

The U.S. fleet was split into two task forces. The first - with three icebreakers, a pair of tankers, 27 cargo ships and nearly two-dozen support craft - sailed east and around Point Barrow, bringing with it supplies that would be delivered to the Northern Transportation Company. The second and larger task force comprised seven icebreakers, a dozen tankers, 14 support vessels, four passenger ships and 31 cargo ships. In 1957, the U.S. Coast Guard sent three icebreakers on a complete transit through the passage with partial Canadian icebreaker support, in a successful attempt to gauge whether ships could escape to the east when iced-in on the west.

Cold War operations, especially the creation of the DEW Line, played a unique role in Arctic shipping. Knowledge gained - from design modifications, crew competency, vessel maneuverability in ice, infrastructure and governance concerns - continues to be expanded upon.

Manhattan

The *SS Manhattan* became the first commercial ship to break through the NWP. Even though the *Manhattan* carried no cargo on the initial NWP voyage (the tanks were filled with water to simulate loading), the ship picked up a symbolic barrel of oil in Alaska, returning to New York a merchant hero. The voyage prompted passionate discussions in Canada about sovereignty, followed by the passage of the *Arctic Waters Pollution Prevention Act* (AWPPA). Information gleaned from the two *Manhattan* Arctic voyages - test trials in ice - proved extremely valuable to future icebreaking designs (See page 40).

The discovery of a major new oil field on Alaska's North Slope at Prudhoe Bay in the spring of 1968 signaled the start of a new era of oil transportation technology. Two of the three

The Manhattan was successful as a large model test ship, as the vessel broke thicker ice than any ship in history.

companies involved, ARCO and BP, intended to build a pipeline over Alaska's Brooks Range to deliver the crude to an ice-free port in Valdez for tanker shipment south. But because of traditional tanker "flexibility credits" and the possibility of delivering crude direct to both U.S. west and east coasts, a small group in the third company, Humble Oil and Refining (now ExxonMobil) persuaded parent company Standard Oil of New Jersey, to make a study of icebreaking tankers.

In 1969, four shipyards, an international team of maritime experts and three major oil companies pitted their considerable technical, creative and financial resources together to attain the goal of taking a tanker through the infamous NWP. For this voyage the *Manhattan* had to undergo extensive refit to convert this merchant vessel into an icebreaking tanker. The conversion, lasting eight months (from December 1968 to August 1969) with work being split among four shipyards, cost $US28 million (the entire experiment, with two test voyages originally estimated at $US10-15 million, eventually ended up, 21 months later, costing $US58 million).

The *Manhattan* set sail in August of 1969 with 126 on board (45 crew members, journalists, U.S. politicians, Canadian parliamentarians, scientists, naval architects, marine engineers, etc.) for the 4,400-mile journey. Of key importance and significance were the escorting icebreakers accompanying the *Manhattan*, especially the Canadian icebreakers *John A. MacDonald* and later the *Louis S. St. Laurent*. In this voyage the *Manhattan* was successful as a large model test ship, as the vessel broke thicker ice than any ship in history.

In its second voyage the following April, the multi-year ice was so tough that the ship couldn't enter the passage but went instead to Pond Inlet where further icebreaking tests were carried out. Following the two voyages, a model of the *Manhattan* was built and tested in Wartsilla's new ice model basin in Finland. Built specifically to support the *Manhattan* voyage, the basin opened the door for ice technology exchange between Soviet and Finnish scientists, a lesser-known part of the *Manhattan* legacy.

Map 2.1 The route followed by the *SS Manhattan*. *Source: AMSA*

Lessons Learned from the *Manhattan* Voyage

What had clearly been learned in the 1969 voyage were several basic Arctic icebreaking truths:

- A large mass moving at decent speed (our "model") could break very tough multi-year ice and ridges, but it would need real backing power to prevent getting stuck, an absolute "must" if un-escorted tankers were to succeed.
- Maneuverability in ice is very difficult for a "parallel body" merchant ship shape even with bow bulges.
- Geared steam turbine machinery with new propellers and shafts could withstand the severe shocks that broken ice floes going through the propellers often caused.
- In near open water conditions, growlers and bergy bits were able to cause major structural damage in non-reinforced parts of the ship's hull.
- Success of icebreaking tankers would be very much in the hands of a ship's crew, even with reconnaissance by aircraft and side-looking radar, to find preferable routes though the ice.

Most important was the conclusion supported by all who participated in the *Manhattan* voyage was that it is technically and economically feasible to use non-escorted large icebreaking merchant ships for the routes explored, and most likely also for the Northern Sea Route.

M/V Arctic

Within the same time period as Beaufort Sea activity, another important Arctic marine story, that of *M/V Arctic*, was taking place. The *M/V Arctic* was built in 1978 at a shipyard on the Great Lakes, and subsequently has a relatively narrow maximum allowable beam of 22.9 meters as required for passage through the Great Lakes lock system. Coupled with a required deadweight and draft limitation, this resulted in a 38,500 ton vessel having a rather high length to beam ratio of 9.2. This is far from ideal for an Arctic vessel, since it limits maneuverability in close ice. However, the ship is still a workhorse in the Canadian Arctic, more than 30 years later. The *M/V Arctic's* operations have mostly been stand-alone, with no dedicated icebreaker support, as is the commercial Canadian Arctic marine tradition. The ship was upgraded extensively in 1986 with a new flat Melville bow and increased hull strength. The original geared diesel, deeply immersed, single ducted CPP propulsion system was unaltered. These modifications allowed *M/V Arctic* to extend its operating field and season. The ship serviced the Nanisivik and Polaris mines in the high Arctic for nearly 20 years until 2002, and then the Raglan mine in northern Quebec and Voisey's Bay mine in Labrador. The ship also transported the first Arctic oil to market from Bent Horn on Cameron Island in 1985 and continued that operation until 1996.

Research and development has been constant through many projects over the years, and for three decades the ship has provided valuable ship performance data on vessel design, hull strength and trafficability. Of particular importance to future Arctic transportation, *M/V Arctic* has always been a test platform for the development of advanced ice navigation systems that have integrated the latest remote sensing technologies with bridge navigation equipment.

The Great Northern Expedition

In Russian history, the Great Northern Expedition refers to a wide enterprise initially conceived by tsar Peter I the Great. The tsar had a vision for the 18th century Russian navy to map the Northern Sea Route to the East. This vast and far-reaching endeavor was sponsored by the Admiralty College in St. Petersburg. In 1725, Russian explorers under the leadership of Captain Vitus Bering, a Dane serving in the Russian navy, made the first expedition voyage on *Sviatoy Gavriil* starting in Kamchatka and going north to the strait that now bears his name.

The major sailing of the Great Northern Expedition was undertaken between 1733 and 1743 through a series of voyages led by Aleksei Chirikov. The goal of the expedition was to find and map the eastern reaches of Siberia, and to hopefully continue on to the western shores of North America to map them as well.

The important achievements of the expedition included the discovery of Alaska, the Aleutian Islands, the Commander Islands and Bering Island, as well as a detailed cartographic assessment of the northern and northeastern coast of Russia and the Kuril Islands. The expedition also refuted definitively the legend of a land mass in the north Pacific. It also included ethnographic, historic and scientific research into Siberia and Kamchatka. When the expedition failed to round the northeast tip of Asia, the dream of finding an economically viable Northeast Passage, alive since the 16th century, was at an end.

With more than 3,000 people directly and indirectly involved, the Second Kamchatka expedition was one of the largest expedition projects in history. The total cost of the undertaking, completely financed by the Russian state, reached the estimated sum of 1.5 million rubles, an enormous amount for the period. This corresponded to one-sixth of the income of the Russian state for the year 1724. Because of its complexity and scale, the voyages became known as the Great Northern Expedition.

Despite the extreme hardships and numerous deaths, mainly from scurvy, the Great Northern Expedition represented a remarkable accomplishment in terms of organization, perseverance and courage. More so, it resulted in an outstanding compilation of knowledge. In tangible terms, the expedition resulted in 62 maps and charts of the Arctic coast and Kamchatka. It is interesting to contrast the general chart of the Russian Arctic resulting from the Great Northern Expedition with what was known of the Arctic coast of North America at the same date (by then William Baffin's voyages and Baffin Bay had long been forgotten and the only part of the Arctic coast reliably known and charted was that of the Hudson Bay and Strait).

The quest for a new route to reach China and India from the Atlantic via north of the Russian coastline spanned more than five centuries, beginning in the 15th century with English, Dutch and Russian navigators.

Northeast Passage

The quest for a new route to reach China and India from the Atlantic via north of the Russian coastline spanned more than five centuries, beginning in the 15th century with English, Dutch and Russian navigators sailing along the northern coast of Russia and far into the Arctic seas.

Early explorers of the area included Willem Barents and Olivier Brunel. Under the auspices of the Russian tsar Peter I the Great, Semyon Dezhnyov is likely to have sailed the region in 1648 and Vitus Bering is known to have sailed northward through the Bering Strait in 1728.

In Russia, the idea of a possible seaway connecting the Atlantic and the Pacific was first put forward by the diplomat Gerasimov in 1525. However, Russian settlers and traders on the coasts of the White Sea, the Pomors, had been exploring parts of the route as early as the 11th century. By the 17th century they established a continuous sea route from Arkhangelsk as far east as the mouth of Yenisei.

In 1648, the most famous expedition, led by Fedor Alekseev and Semyon Dezhnev, sailed east from the mouth of Kolyma to the Pacific and doubled the Chukchi Peninsula, thus proving that there was no land connection between Asia and North America.

Eighty years after Dezhnev, in 1725, another Russian explorer, Danish-born Vitus Bering on *Sviatoy Gavriil* made a similar voyage in reverse, starting in Kamchatka and going north to the strait that now bears his name. It was Bering who gave their current names to the Diomede Islands, discovered and first described by Dezhnev. Bering's explorations in 1725–30 were part of a larger scheme initially devised by Peter the Great and known as the Great Northern (or Kamchatka) expedition. The Second Great Northern Expedition took place between 1735-42. The Northeast Passage (NEP) was not traversed by anyone until Baron Adolf Erik Nordenskjöld of Sweden accomplished the feat in 1878-79 aboard the *Vega*.

Coupled with the ongoing search for a NEP, voyages using the Kara Sea route to Western Siberia played a pivotal role in Arctic marine transport. Two expeditions achieved transits of a substantial part of the NEP, including Fridjof Nansen's *Fram* (1893-1896) and the Baron Eduard Toll expedition on board *Zarya* (1900-1903). *Maud,* commanded by Roald Amundsen (1918-1920), was the fourth ship to complete a transit of the NEP and, as a result, Amundsen achieved the distinction of being the first person to circumnavigate the Arctic Ocean, since he had now linked up with the track of his voyage in the *Gjoa*.

The first one-season transit route was not accomplished until 1934, when Glavsevmorput (Glavnoye Upravleniye Severnogo Morskogo Puti or GUSMP - Chief Administration of the NSR) mounted a successful attempt with the icebreaker *Fedor Litke*.

The crew of the *Fram*. *Source: The National Library of Norway, Picture Collection*

The Northern Sea Route

The Northern Sea Route, or NSR, stretching from the Kara Gate in the west to the Bering Strait in the east, was highly developed by the Soviet Union as an important national waterway, peaking in 1987 with 331 vessels on 1,306 voyages. The western end of the NSR (Kara Sea) has been maintained for year-round navigation since 1978-79 with ships sailing between Murmansk and Dudinka on a regular basis.

The history of commercial use of the NSR can be distinguished by four distinct stages: exploration and settlement (1917-1932); organization of regular navigation coupled with the development of fleet and ports (1932-early 1950s); transformation of the newly developed NSR into a regular operating transportation line during the summer-autumn periods (early 1950s-late 1970s); and finally, efforts to establish year-round shipping (late 1970s-present).

During the first stage, 1917-1932, the NSR was utilized for community re-supply, in addition to sporadic attempts at regional exploitation of resources such as furs, wood, fish, salt, coal, whaling and sealing. In 1932, a Soviet expedition led by Otto Yulievich Schmidt was the first to sail from Arkhangelsk to the Bering Strait in the same summer without wintering en route. The Northern Sea Route was officially open and exploitation began in 1935. Advanced Soviet navigational skills, technological capability and experience in ice navigation were unrivaled and traffic in the Arctic continued to grow. From 1917-1934 there were only two sinkings out of the 178 round-trip voyages across the Kara Sea to import finished goods to, and export timber from Igarka, along the Yenisei River in central Russia.

From 1932-1953, administration of the Russian Arctic marine activity rested with the Chief Administration of the Northern Sea Route (CANSR), a direct arm of the Council of Peoples Commissars of the Soviet Union, with its goal "to develop the NSR from the White Sea to the Bering Strait, to equip it, to keep it in good order, and to secure the safety of shipping along it." Major additions were made to the Arctic fleet, which carried 100,000 to 300,000 tons of cargo annually and employed 40-150 ships per year.

In 1940, the German vessel *Komet*, an armed raider disguised as a merchant ship, was the first foreign ship in more than 20 years to be granted passage, and it was the last foreign transit for another 50 years. When the Soviet Union entered the war in 1941, the route became important for bringing Allied supplies into the country. In the four seasons of 1942-1945, 120 ships transported approximately 450,000 tons of relief supplies, which amounted to half the freight turnover for the NSR during this period.

In 1953 CANSR became a department under the Ministry of Merchant Marine in Moscow and for 17 years the infrastructure was improved to provide the capability for both summer and autumn shipping. In 1959, the Soviets launched the world's first nuclear-powered surface ship, the icebreaker *Lenin*, extremely significant as it expanded the range of travel in isolated regions.

After CANSR became the Administration of the Northern Sea Route (ANSR) in 1970, the emphasis became year-round trafficability. By the 1978-79 season, the western end of the NSR achieved year-round navigation with ships sailing between Murmansk and Dudinka on a regular basis. Other landmark voyages during this era of Russian Arctic marine transport history include the 1977 voyage of the *Arktika* to the geographic North Pole and the first complete high latitude passage by the surface vessel *Sibir* in 1978. By the mid-80s, the total volume of traffic passages through the NSR amounted to 6.6 million tons annually.

The NSR was formally opened to non-Russian vessels in the summer of 1991, only a few months before the Soviet Union was dissolved. Several developments have occurred during this modern period of Arctic marine transport history: the creation of the NSR Administration, the commissioning of the International Northern Sea Route Programme, the formation of the Noncommercial Partnership for the Cooperation of the Northern Sea Route Usages, leasing cargo space aboard Soviet SA-15 icebreaker cargo carriers, great strides in developing fleet and port infrastructure, and the establishment of year-round navigation in the western part of the Arctic.

The NSR is a substantially shorter passage (35-60 percent savings in distance) for shipping between northern European ports and those of the Far East and Alaska than routes through the Suez or Panama Canals. The ANSR, responsible for the overall planning, coordination and execution of organizational and regulatory activities for marine operations, is working to strengthen the competitiveness of the NSR. The Russian fleet of the world's most powerful icebreaking ships and special ice-strengthened ships for moving most types of cargo, highly developed infrastructure along the NSR and specialized ice navigation skills demonstrate that navigation along the NSR is technically feasible and that there is a cargo base for import, export and conceivably transit.

1991
The year the Northern Sea Route was open to non-Russian ships.

Arctic Tourism

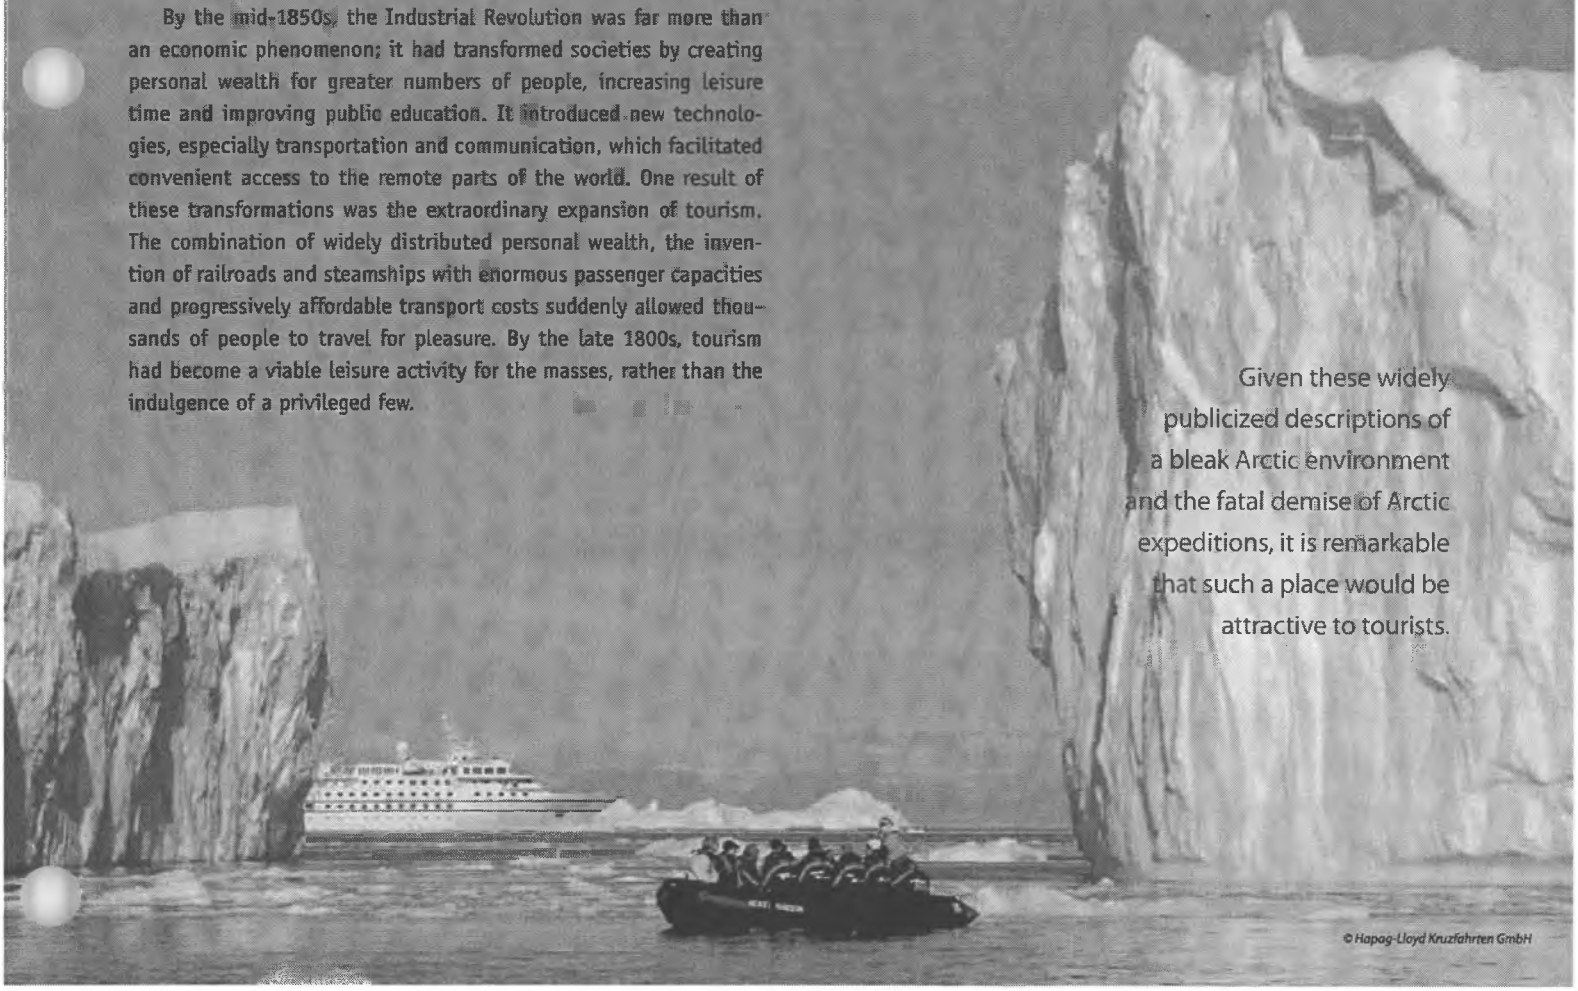
For most of European and American history, the many attempts to explore and occupy high latitudes were characterized by peril and tragedy. From 1576 onwards, numerous ventures into these cold, remote and icy places were conducted to obtain economic benefits and expand empires. All of the expeditions experienced hardships and many ships foundered and men perished in their attempts to penetrate these unknown seas and lands. By the 1800s, newspaper and book publications describing both the heroic and tragic aspects of polar exploits were immensely popular. Given these widely publicized descriptions of a bleak Arctic environment and the fatal demise of Arctic expeditions, it is remarkable that such a place would be attractive to tourists. But, in fact, tourists began visiting the Arctic in the early 1800s and their attraction to this unlikely destination has grown steadily for more than two centuries.

Arctic Tourism for the Masses

By the mid-1850s, the Industrial Revolution was far more than an economic phenomenon; it had transformed societies by creating personal wealth for greater numbers of people, increasing leisure time and improving public education. It introduced new technologies, especially transportation and communication, which facilitated convenient access to the remote parts of the world. One result of these transformations was the extraordinary expansion of tourism. The combination of widely distributed personal wealth, the invention of railroads and steamships with enormous passenger capacities and progressively affordable transport costs suddenly allowed thousands of people to travel for pleasure. By the late 1800s, tourism had become a viable leisure activity for the masses, rather than the indulgence of a privileged few.

By the late 1800s, steamship and railroad companies had achieved the capacity to transport large numbers of passengers. Given intense competition between those companies, travel costs were progressively lowered to attract customers and successfully compete. Simultaneously, companies aggressively expanded their transport networks to previously inaccessible regions, including the Arctic. All of those business decisions enabled more people to travel to more destinations.

In 1850, Arctic marine tourism by commercial steamship was initiated in Norway. By the 1880s, Arctic marine tourism was a booming business. Arctic destinations included Norway's fjords and North Cape, transits to Spitsbergen, Alaska's Glacier Bay and the gold rush sites as far north as Homer, riverboat cruises in the Canadian Yukon, and cruises to Greenland, Baffin Bay and Iceland. The tourist experience aboard the steamships was a mixture of exploration and luxury. Little known or recently discovered glaciers, bays, wildlife and indigenous communities attracted curious tourists led by Arctic explorers and naturalists. Shipboard life emphasized lavish meals, concerts



Given these widely publicized descriptions of a bleak Arctic environment and the fatal demise of Arctic expeditions, it is remarkable that such a place would be attractive to tourists.

Researchers and experts from more than 100 institutions in 14 countries – the numbers involved in the International Northern Sea Route Programme.

provided by orchestras, beauty parlors and barbershops, photography studios and lectures presented within library settings. All of the 19th century Arctic destinations were commercially successful and cruise ship companies have continued to operate and expand their itineraries throughout those and other Arctic regions for more than a century. In addition, the combined themes of expedition and luxury cruising have also persisted to the present time.

By 1900, Arctic tourism was a flourishing commercial activity. Its diversity included independent travelers pursuing a variety of adventurous recreation activities in marine and land environments, as well as groups touring natural, wildlife, historical and cultural attractions. All of these Arctic tourism activities were extensively promoted in guidebooks and the popular press. Companies specializing in guidebooks, such as John Murray and Baedeker, came into existence at this time. And travel literature encouraging mass travel regularly appeared in widely distributed periodicals such as Harper's Weekly, The Century Magazine and the National Geographic Society Magazine. From the mid-1800s onward numerous editions of Arctic guidebooks would regale the splendors of the Land of the Midnight Sun.

The economic benefits of the Arctic tourism industry were immediately evident to both private companies and Arctic governments. Tourism provided jobs, personal income, revenues and financial capital for infrastructure. It also represented a new way to use the Arctic's natural resources. It was a departure from the resource extraction and depletion industries such as hydraulic mining, rampant timber harvesting, and the exploitive commercial fishing and whaling practices of the 19th and early 20th centuries.

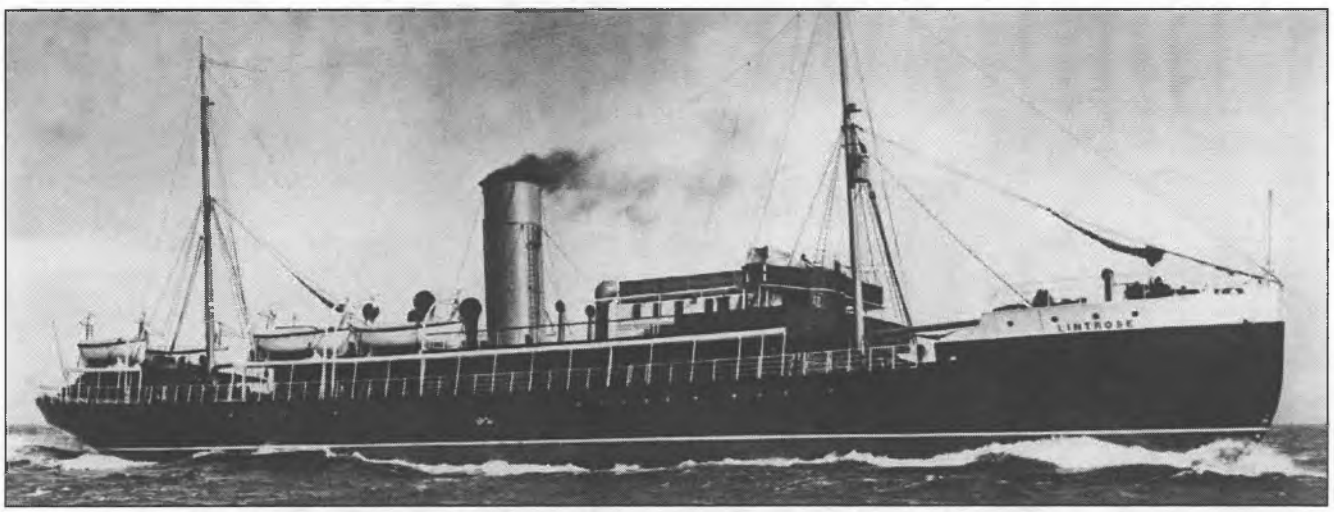
Major Arctic Marine Transport Programs, Studies and Workshops

Previous Arctic marine transport studies, workshops and reports contain a wealth of findings, recommendations and research agendas of significant importance to the AMSA and to any policy and regulatory framework for the future. Broad Arctic navigation studies, such as the 1993-1999 International Northern Sea Route Programme (INSROP), the 2001-2005 Arctic Operational Platform (ARCOP) and the 2002-2005 Japan Northern Sea Route-Geographic Information System (JANSROP-GIS) form a knowledge base on Arctic navigation in addition to localized findings such as the Alaskan trafficability studies. A summary of the 2004 Cambridge Workshop provides an intellectual synthesis of Arctic marine transport.

International Northern Sea Route Programme

The International Northern Sea Route Programme was the most comprehensive marine transport study ever undertaken prior to the AMSA, with the aim to create a research-based knowledge bank of commercial, international shipping on Russia's Northern Sea Route across the top of Eurasia in the Arctic Ocean.

The program was led and coordinated by three principal partners: the Ship and Ocean Foundation (SOF) of Tokyo, Japan; the Central Marine Research and Design Institute (CNIIMF) of St. Petersburg, Russia; and the Fridtjof Nansen Institute (FNI) in Oslo, Norway. The numbers involved are impressive: 468 researchers and experts from more than 100 institutions in 14 countries; 104 projects; an experimental voyage through the NSR; two large international conferences.



Historic photo

Growing population in the 21st century, together with increases in community re-supply and oil and gas development, has led to a greater demand for shipping in the region.

This work produced 167 peer reviewed working papers and a large number of articles and books governing almost every relevant aspect of shipping on the NSR. Funding was provided by the Nippon Foundation, Ship and Ocean Foundation, both from Japan, as well as various Norwegian sponsors and the Soviet Union.

It was acknowledged that the international shipping industry would need information and analysis before committing investments or vessels to the previously unknown route. On the initiative of the Soviet Ministry of Merchant Marine, contact was made with FNI to create an international research project, with St. Petersburg-based CNIIMF coordinating on the Soviet side. A pilot study was produced in 1990-1991. In 1992, SOF joined the partnership, and in May 1993 the three organizations signed an agreement establishing a secretariat at the Fridtjof Nansen Institute in Norway to coordinate the effort.

INSROP was designed as a multi-national, five-year effort, to be executed in two phases with a review conducted after three years. Four sub-programs were identified: 1) Natural conditions and ice navigation; 2) Environmental aspects; 3) Trade and commercial shipping factors; and 4) Political, legal and strategic aspects. In August 1995, a successful experimental transit voyage was conducted from Yokohama, Japan to Kirkenes, Norway onboard the Russian ice-strengthened carrier *Kandalaksha*, demonstrating the NSR's technical feasibility.

In 1999, final findings of INSROP were presented at an NSR user conference in Oslo, Norway, bringing to a close the massive research project. It took years of diplomatic networking, negotiations and lobbying to shape the program and to obtain funding. It was often difficult to bridge language and cultural gaps between the three principal partners - the Japanese, the Norwegians and the Russians - who often maintained different priorities and varying business practices.

INSROP demonstrated that navigation along the NSR was technically feasible, with a cargo base for export, import and conceivably transit. INSROP also noted challenges to overcome. INSROP did not include research on climate change and how ice conditions might eventually enable large scale shipping.

A wealth of new and unique knowledge on the Russian Arctic was produced and made available to the international community. INSROP also pioneered cooperation between Russian and foreign researchers in Arctic-related fields, and created a platform for further Arctic multidisciplinary studies.

Research Opportunities

- Extraction of sea ice data from historical journals and log books from Arctic exploring and whaling ships.
- Comprehensive study of the history, design evolution and use of icebreakers.
- Regional and local studies with mapping of the multiple uses (indigenous, commercial & government) in Arctic waterways.
- Develop a comprehensive database of damages to ships operating throughout the Arctic Ocean for use in risk assessments; develop, where possible in the historic record, detailed cause & effect reviews of each damage case.
- Comprehensive review of changes in Arctic marine technology during the past six decades, specifically for Arctic commercial ships, and how these changes may influence the future of Arctic marine transport systems.

U.S. Trafficability Studies of 1979-86

With the advent of offshore oil and gas leases in the 1970s, studies were required to assess the feasibility of year-round marine transportation in ice-covered waters of the Alaska Arctic, yet no amount of analytical modeling or studies without actual field data could provide the information and insight needed. Therefore, the U.S. Maritime Administration (MARAD) embarked on a multi-year program (1979-1986) to:

- Demonstrate the operational feasibility of commercial icebreaking ships along possible future Arctic routes;
- Define environmental conditions along routes in the Bering, Chukchi and Beaufort seas; and,
- Obtain data to improve design criteria for ice-capable ships and offshore structures.

To assess the feasibility of commercial icebreaking ships along possible future Arctic routes, two U.S. Coast Guard *Polar Class* icebreakers, the *Polar Star* and *Polar Sea*, the world's most powerful non-nuclear icebreakers and the only U.S. ships capable of mid-winter Arctic operations, were utilized as data collection platforms. During the eight-year research program, 15 icebreaker deployments occurred aboard the icebreakers and 14 of those were in the Alaska Arctic. General ship performance of trafficability data was continuously collected and summarized in 30-minute increments whenever the icebreakers changed locations.

Two dedicated transits (1981, 1983) from the south Bering Sea to the north Chukchi Sea were designed to simulate, as best as possible, a non-stop transit from the ice edge to northern Alaska. These voyages indicated that routing in the future could be around both ends of St. Lawrence Island and refuted the views of some experts that transit through the Bering Strait was not feasible in winter.

Thousands of ice thickness measurements were made, resulting in the formulation of a representative set of ice conditions for an Alaska route; supplemented with tables that offer suggestions on changes to reflect mild and severe ice conditions and possible voyage delays due to pressured ice conditions. In addition, zones of ice severity for the Bering, Chukchi and Beaufort seas were developed to provide designers and operators with a strategic perspective on year-round Arctic marine transportation systems.

Several major projects were performed onboard the icebreakers to aid in the development of advanced icebreaking hull forms and Arctic commercial vessels capable of year-round operations. The resulting analysis from eight years of data collection made a significant contribution to the knowledge of ice loads and the structural design of all icebreaking ships.

With 15 voyages of data, the U.S. Arctic Marine Transportation Program of 1979-86 was one of the most extensive field tests of icebreakers in history and has provided a valuable knowledge base for future considerations and a model for future cross-border research initiatives. Briefly, key findings from the operational, environmental and technical data can be summarized as follows:

- Field data can provide the at-sea ground truthing of ship modeling/studies, which may help to reduce the perceived risks of year-round marine transportation in the Arctic.
- The offshore Bering, Chukchi and Beaufort seas are extremely dynamic and ship icebreaking activities must be able to cope with the ever-changing ice environment. The most critical elements for successful ice navigation are crew skills and applied technology.

Arctic Marine Transport Workshop: Cambridge University

Amid growing interest and concern over the rapid climate changes occurring in the Arctic, experts in Arctic marine transport and international marine safety, as well as researchers of sea ice and climate change, met at the Scott Polar Research Institute at Cambridge University in October 2004 to create a research agenda and identify critical issues related to the future of Arctic shipping.

Co-sponsored by the Institute of the North, the United States Arctic Research Commission and the International Arctic Science Committee, the international gathering included 54 maritime experts and representatives from 11 countries (United States, Canada, Russian Federation, Sweden, Iceland, Denmark, Norway, the United Kingdom, Finland, Germany and Japan).

The three-day workshop provided the opportunity to study the extraordinary retreat of Arctic sea ice and what that means to the Arctic Ocean as a potential waterway for marine operations. While each area of discussion produced suggested topics for scientific research and questions on policy issues that were incorporated in the conference report, a few crosscutting conclusions emerged:

1. An inter-disciplinary research agenda needs to include economic analysis, assessments, Law of the Sea, indigenous Arctic communities, core issues of conflict, marine safety and environmental protection, and climate change impacts on future marine access.
2. The magnitude of sea ice variability creates difficult challenges for Arctic marine transport planning and adequate risk assessment.
3. Arctic marine charts and aids to navigation need to be updated and airborne ice information enhanced with satellite coverage.
4. Two key factors are needed to expand and develop the use of the Arctic Ocean as a shipping corridor: route reliability and security. Increased Arctic shipping will require an increase in the monitoring and enforcement of national and international laws governing ship security.
5. Multiple economic drivers could fuel expanded use of Arctic marine transportation. Incremental expansion would result in an incremental growth in regional traffic. However, a decision by world shippers to use the Arctic Ocean as an alternate route would require large scale global investments of escort vessels, aids to navigation and staging ports to transfer cargo between ice-strengthened and non ice-strengthened ships.

The workshop identified that the retreat of Arctic sea ice may lead to several plausible futures for the Northern Sea Route, Northwest Passage and central Arctic Ocean, requiring further research, planning and cooperation, as well as consideration of future development of transshipment and port infrastructure.

Findings

1] Despite attempts through history to make the Northwest Passage (NWP) a viable route between the east and west, the passage has not become the global trade route it was originally envisioned.

2] The Northern Sea Route (NSR) was highly developed during the Soviet Union era as an important national waterway facilitating Arctic marine transport. Notably, year-round navigation on the western NSR (i.e., from the port of Dudinka on the Yenisei River to Kara Gate) has been maintained since the 1978-79 winter season.

3] Field data can provide the at-sea ground truthing of ship modeling/studies, which may help to reduce the perceived risks of year-round marine transportation in the Arctic.

4] Icebreaking technology has been key to the development of Arctic marine transport in all regions of the Arctic Ocean.

5] Previous Arctic marine transport studies, workshops and reports contain a wealth of findings, recommendations and research agendas of significant relevance to AMSA and to any regulatory framework for the future.

6] Joint agency/ministerial research, public-private partnerships and international cooperation have been beneficial to tackling the many challenges of future Arctic marine transport systems.

GOVERNANCE OF ARCTIC SHIPPING

The governance of shipping activities in the Arctic might be described as a complicated mosaic. The Law of the Sea, as reflected in the 1982 *United Nations Convention on the Law of the Sea* (UNCLOS), sets out the legal framework for the regulation of shipping according to maritime zones of jurisdiction. Other international agreements address specific elements of shipping such as marine pollution prevention standards, ship safety, seafarer rights and qualifications and liability and compensation for spills. In addition, Canada and the Russian Federation have adopted special national legislation for ships operating in ice-covered waters within their EEZs. Descriptions of international law, including as reflected in the UNCLOS, are included for the benefit of the reader and are not intended to constitute interpretations.

A wide range of actors affect the law, policy and practice applicable to shipping in the Arctic. In addition to governments, shipowners, cargo owners, insurers, port authorities, trade and labor union associations, among others, may be involved in determining when and where shipping in the Arctic should occur and under what conditions.

Governance of shipping is characterized by efforts to promote safety, security, protection of the environment from damage by accident, as well as harmonization and uniformity in international maritime law and standards. The International Maritime Organization (IMO), a specialized agency in the United Nations system, addresses a broad range of issues pertaining to international shipping, including maritime safety, security and environmental protection. Other intergovernmental organizations work closely with the IMO in the governance of international shipping. For example, the International Labour Organization (ILO) has played a seminal role in the establishment of minimum basic standards for seafarers' rights.

The IMO acts as secretariat for most international maritime conventions and facilitates their implementation through the adoption of numerous codes and guidelines aimed at operationalizing and facilitating the implementation of international rules and standards. International conventions and related protocols become binding only on those states that choose to become parties. Upon ratification of a convention, states must formally implement it into their national maritime regulatory regime. States can, however, legislate

the provisions of a convention or protocol without necessarily becoming a party.

An explanation of the governance of shipping would not be complete without noting the critical role played by standard form contracting and related "good practices" developed by industry. For example, in contracts for carriage by sea the carrier must prepare against foreseeable risks and provide a seaworthy ship for the voyage, which must be pursued without deviation or delay and with due care for the cargo or passengers. These standard forms have been recognized and applied by courts around the world.

Law of the Sea, as reflected in UNCLOS: The Overarching Legal Framework

The Law of the Sea, as reflected in UNCLOS, has struck a balance among the powers of coastal states, flag states and port states to exercise jurisdiction and control over shipping. The jurisdictional status of some Arctic waters, in particular internal waters and straits used (or potentially to be used) for international navigation, remains controversial and could give rise to future disputes concerning the exercise of national jurisdiction over international navigation through those waters.

Coastal State Jurisdiction and Control

For coastal states to claim maritime zones in the Arctic in accordance with UNCLOS, they must have coastal frontage in the region. Of the eight Arctic states, Canada, Denmark (Greenland), Norway, the Russian Federation and the United States have coastal frontage in the Arctic Ocean. Iceland has coastal frontage on the Norwegian Sea and Finland and Sweden in the Baltic Sea.

The extent of legislative and enforcement control over foreign ships by the coastal states of the Arctic Ocean varies according to the different maritime zones set out in UNCLOS, namely: internal waters, the territorial sea, the contiguous zone, the exclusive economic zone and the continental shelf (Table 4.1).

The seaward limit of the maritime zones and jurisdictions is based primarily on distance from a combination of the low-water marks along the coast, straight baselines and closing lines for bays. With the exception of the United States, the Arctic Ocean states have proclaimed straight baselines along most or all of their Arctic coasts. Table 4.1 sets out the limits of jurisdictional claims by Arctic Ocean coastal states.

For internal waters, coastal states are entitled to exercise full sovereignty and maximum jurisdiction over ships and can, pursuant to that authority, set conditions for entry into its ports. For example,

Arctic States	Territorial Sea		200 nm Zones		
	3 nm	12 nm	EEZ	Extended Fisheries Protection	Fisheries Protection
Canada		√	√		
Denmark (Greenland)	√		√		
Iceland		√	√		
Norway		√	√		
- Jan Mayen		√		√	
- Svalbard		√			√
Russian Federation		√	√		
United States		√	√		

Table 4.1 Arctic coastal state maritime jurisdictional zone claims. *Source: AMSA*

coastal states might prohibit entry of certain "risky ships", such as substandard ships or those carrying radioactive wastes or other hazardous cargoes, or they might impose "zero discharge" limits on particular ship-source pollutants. The only likely constraint on the exercise of this power is the traditional and customary duty to grant refuge in sheltered waters to a ship in need of assistance.

Internal waters include marine areas on the landward side of closing lines for bays, ports and harbors and historically recognized internal waters. A coastal state may also choose to draw straight baselines around a deeply indented coastline or where there is a fringe of islands in the immediate vicinity of the coast. Waters enclosed would be internal. UNCLOS sets forth the rules on setting baselines.

Exactly which Arctic waters may be claimed validly as internal has been contentious. For example, Canada enclosed its Arctic archipelago with straight baselines, effective January 1, 1986, but the United States and other states protested against the internal waters status claim.

Within the limit of the 12 nautical miles that may be claimed for the territorial sea, Arctic coastal states have full sovereignty, but foreign ships retain the right to innocent passage; that is, passage which is continuous and expeditious, and is not prejudicial to the peace, good order or security of the coastal state. For example, undertaking research or surveys or fishing without the coastal state's

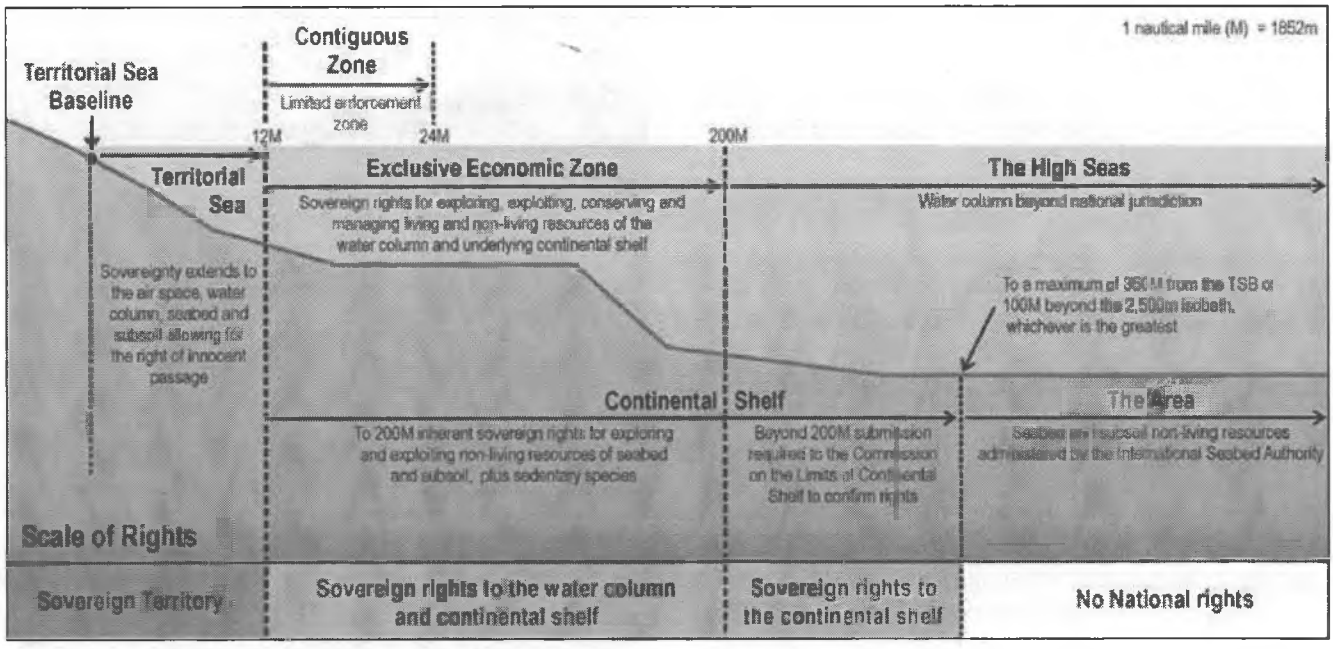

Illustration 4.1 Illustration of maritime zones (for illustrative purposes only). *Source: Geoscience Australia*

consent, or engaging in an act of serious and willful pollution in contravention of UNCLOS would be considered prejudicial to the interests of the coastal state.

UNCLOS allows coastal states the authority to adopt laws and regulations applicable to foreign ships transiting through the territorial sea. Domestic laws can be applied in relation to such things as safety of navigation, preservation of the marine environment and marine pollution control. There are two limits on this authority; namely, that coastal states cannot impose design, construction, crewing or equipment standards on foreign ships unless giving effect to generally accepted international rules or standards; and that such laws may not have the practical effect of denying or impairing the right of innocent passage. Coastal states may also, having regard to the safety of navigation, designate sea lanes and traffic separation schemes for foreign ships. However, the coastal state must take into account IMO recommendations and any channels customarily used for international navigation. They may not impose a charge on the passage itself; only specific fees for services rendered may be charged and without discrimination.

Coastal states may also claim a 12 nautical mile contiguous zone adjacent to the territorial sea (i.e., up to a seaward limit of 24 nautical miles). In this zone, coastal states may exercise necessary control over foreign ships to prevent infringement and to enforce violations of customs, fiscal, immigration or sanitary laws and regulations in their territory or territorial sea.

In a 200 nautical mile exclusive economic zone (EEZ), measured from the territorial sea baselines, coastal states have sovereign rights to explore, exploit, conserve and manage their natural resources, and jurisdiction over such things as protection of the marine environment. In part XII of UNCLOS, the issue of coastal states' ability to regulate shipping for the purposes of pollution prevention and control laws is addressed, which is that laws and regulations applicable to foreign ships must conform or give effect to international rules and standards established through the IMO.

A coastal state has limited enforcement powers in the EEZ against transiting foreign ships violating applicable international rules and standards for preventing and controlling pollution. A coastal state may only undertake physical inspection of a foreign ship where a violation has resulted in a substantial discharge causing or threatening significant pollution of the marine environment. Actual arrest and detention of a foreign ship is only allowed if a violation causes major damage or a threat of major damage to the coastline, interests or resources of the coastal state. In such a case, the coastal state may only impose monetary penalties.

UNCLOS defines the continental shelf of a coastal state as comprising the seabed and subsoil of the submarine areas beyond the

territorial sea to the outer edge of the continental margin, or to at least 200 nautical miles from coastal baselines where the outer edge of the continental margin does not extend to that distance. A coastal state with a continental shelf extending beyond 200 nautical miles has 10 years from the time the convention enters into force for that state to make a submission to the Commission on the Limits of the Continental Shelf. The limits of the continental shelf established by a coastal state on the basis of the recommendations of the commission shall be final and binding. While the coastal state's rights to the resources of the extended continental shelf are exclusive, the waters above the extended continental shelf are high seas. Therefore, the coastal state has no jurisdiction over foreign ships in those waters with very few exceptions (for example, where a foreign ship is undertaking exploration activities on the continental shelf without its consent.) The coastal state may locate artificial islands, installations or structures on an extended continental shelf and include safety zones that are consistent with international standards. However, it may not establish them where interference may be caused to the use of recognized sea lanes essential to international navigation.

Coastal states bordering a strait used for international navigation retain very limited powers over foreign ships because of their right to transit passage. States bordering straits cannot suspend passage and may only adopt ship-source pollution laws applicable to foreign ships if in accordance with international standards. Sea lanes and traffic separation schemes may be designated, but only with IMO approval. A ship exercising transit passage may do so in its "normal mode," a phrase taken to mean that a submarine may remain submerged, whereas in innocent passage it must navigate on the surface and show its flag.

UNCLOS does not specify the extent of international navigation required to transform navigable waters into a strait used for international navigation. National opinions have differed over the application of the straits used for an international navigation regime in the Arctic.

Article 234 of UNCLOS bolsters coastal state powers to regulate foreign shipping in order to prevent, reduce, and control marine pollution in the Arctic. It recognizes the coastal state's right to adopt and enforce special non-discriminatory pollution prevention, reduction and control laws in areas within the limits of the EEZ that are covered by ice for most of the year, when certain conditions are met. Additionally, the coastal state's laws and regulations must have due regard to navigation, protection and preservation of the marine environment and be based on the best available scientific evidence.

Article 234 raises various questions of interpretation. What is required to meet the litmus of "ice covering such areas for most of the year?" For example, will even partial ice cover suffice if there is an exceptional hazard to navigation? What is the significance of giving special coastal state powers only in the EEZ? One interpretation is that coastal states are given no greater powers than those applicable in the territorial sea. Another is that coastal states are granted broader powers, in particular the right to unilaterally adopt special ship construction, crewing and equipment requirements. Application of Article 234 to straits used for international navigation may also be questioned. Since UNCLOS does not exempt straits from the application of Article 234, questions of interpretation may again rise over the geographical scope of coverage and the breadth of coastal state regulatory powers.

© Neste Shipping Oy

Flag State Jurisdiction and Control

Flag states play a vital role in the governance of shipping. UNCLOS permits a state to fix conditions for granting its nationality (i.e., flying its flag) to ships so long as there exists a "genuine link." Ships can only sail under the flag of one state at a time. The flag state's domestic laws, for example, criminal law, apply to those aboard its ships. A flag state must also ensure that its ships conform to international rules and standards concerning matters such as safety at sea, pollution control and communication regulations. On the high seas, the flag state is granted exclusive jurisdiction with only limited exceptions.

It should be noted that the provisions of UNCLOS regarding the protection and preservation of the marine environment do not apply to any warship or other vessel owned or operated by a state and used, for the time being, only on government non-commercial service. However, each state must ensure, by the adoption of appropriate measures not impairing operations or operational capabilities of such vessels owned or operated by it, that such vessels act in a manner consistent, so far as is reasonable and practicable, with UNCLOS.

Port State Control

Under general international law, the port state has the authority to impose conditions for the entry of foreign ships into its ports. Under UNCLOS, when foreign ships are voluntarily in the port of another state, the host state has broad inspection and enforcement powers for pollution violations occurring not only in the port and internal waters, but also in the territorial seas and the EEZs of other coastal states when those states request the port state's assistance in enforcement. A flag state may also request the port state's assistance in relation to enforcement of pollution offenses on the high seas. A port state must comply with requests from other states for investigation of discharge violations. If a port state determines that a foreign ship is unseaworthy and threatens marine environmental damage, it may prevent the ship from sailing until the deficiencies are corrected.

Maritime Boundaries in the Arctic

To date, there are eight bilateral agreements delimiting maritime zone and continental shelf boundaries between the five countries that border the Arctic Ocean, in addition to unresolved boundary issues. Lack of clearly delimited maritime boundaries for territorial seas and EEZs is of potential concern for future shipping in the Arctic. Ship operators may face uncertainty over which national shipping laws are applicable in a disputed zone, particularly with reference to laws and regulations adopted pursuant to Article 234 of UNCLOS and with regard to penalties and compensation for damage caused by ship-source spills. Unresolved maritime boundaries may also reduce opportunities to develop marine resources and expand shipping in the Arctic. This situation is, however, no different than in other maritime areas where maritime boundaries are not agreed.

High Seas

Trans-Arctic shipping across the high seas of the Arctic (i.e., beyond EEZs) raises other governance issues. Because a coastal state's authority to regulate foreign shipping does not extend to the high seas, transiting ships would only be subject to global shipping safety, environmental and security rules and standards adopted through the IMO and as may be applied by the flag states. Thus the adequacy of international shipping standards for Arctic conditions and the need to provide special protective measures for the Arctic high seas must be considered.

© Fednav, Ltd.

International Public Maritime Law Framework

Ships and their crews operating in the Arctic environment face unique risks. A significant body of international public maritime law has established safety, environmental and security rules and standards for international shipping and seafarers. Generally, the contents of IMO safety conventions are not specific to Arctic shipping. Nonetheless, many of the requirements, for example, double hulls for tankers and increased safety and communications equipment systems for passenger ships and cargo ships, will affect ships trading into or transiting Arctic waters. Not all applicable standards are mandatory. Whereas the provisions of the *International Convention on Safety of Life at Sea, 1974* (SOLAS), for example, are mandatory, the *2002 IMO Guidelines for Ships Operating in Arctic Ice-covered Waters* (Arctic Guidelines) only provide internationally accepted recommendatory guidelines. These guidelines, however, are under review by the IMO.

Maritime Safety Rules and Standards

For the most part, international safety standards for merchant shipping are formulated in the rules, codes and procedures adopted within the framework of SOLAS (Table 4.2). The convention specifies minimum safety standards for the construction, machinery, equipment and operation of ships. Flag states are responsible for ensuring compliance of their ships with SOLAS requirements, and certificates are prescribed as proof that this has been done. Using port state control, contracting states can inspect ships of other states on a non-discriminatory basis. Chapter V of SOLAS sets forth provisions of an operational nature including the maintenance of meteorological services for ships, the ice patrol service, routing of ships and the maintenance of search and rescue services. Chapter VII of SOLAS regulates the carriage and care of dangerous goods through the *International Maritime Dangerous Goods* (IMDG) *Code* and the carriage of liquefied natural gas (LNG) through the *International Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk Code* (International Gas Carrier Code). The IMDG Code may need to be reviewed for the purpose of identifying any dangerous goods that may be affected by extremely low temperature during transportation in the Arctic.

The American Bureau of Shipping and the Russian Maritime Register of Shipping recently announced they are jointly developing classification rules for Arctic LNG carriers. Ice-strengthening for LNG carriers focuses on hull, containment system, propulsion and propeller requirements.

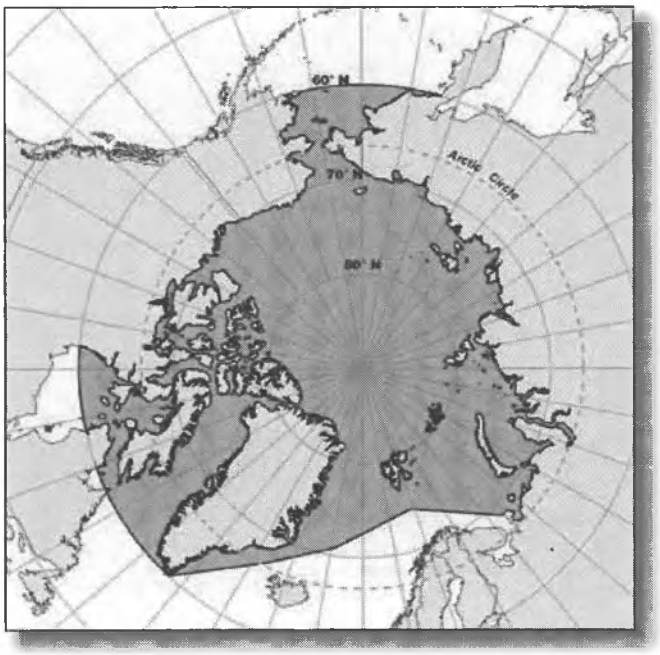
Table 4.2 Ratification of International Maritime Safety Agreements and Instruments. *Source: AMSA*

SOLAS also includes specifications for passenger ships. However, at this time there are no international construction requirements specific for cruise ships in polar operations. Cruise ships, which are not classed as ice-strengthened, may operate in the Arctic at certain times of the year and in areas of open water. The international cruise ship industry has initiated a Cruise Ship Safety Forum to develop design and construction criteria for new vessels and to consider other safety issues.

Additional non-mandatory industry standards for passenger ships have been adopted by the IMO. In January 2008, the IMO adopted *Guidelines on Voyage Planning for Passenger Ships Operating in Remote Areas,* also called the Arctic Guidelines. The Guidelines call for ships to develop detailed voyage and passage plans that include contingency plans for emergencies. Emergency contingency plans should be developed with reference to the IMO MSC/Circular 1184, *Enhanced Contingency Planning Guidance for Passenger Ships Operating in Areas Remote from SAR [Search and Rescue] Facilities.* This guidance document outlines extra steps that should be taken when passenger ships operate remote from SAR facilities, including keeping the appropriate authorities informed of the ship's position and intentions while the ship is operating in the remote area. Consideration should also be given to voyage "pairing" (i.e., coordinating travel with another vessel

Map 4.1 Geographical scope of the 2002 IMO *Guidelines for Ships Operating in Arctic Ice-covered Waters* (Arctic Guidelines) (shaded area). *Source: IMO Arctic Guidelines*



to ensure emergency assistance), the carriage of enhanced life-saving appliances and the provision of additional life-saving resources.

The 1994 *International Safety Management Code* (ISM Code), adopted under Chapter IX of SOLAS, provides an international standard for safe management and operation of ships and for pollution prevention. The code calls on shipping companies to establish a safety and environmental protection policy ("safety management system") that is both ship-based and shore-based. The safety management system should ensure compliance with mandatory rules and regulations, as well as industry standards, and is subject to certification by national maritime authorities and verification by both flag and port states. The ISM Code is applicable to ships operating in Arctic waters although its provisions do not deal with the special circumstances and operational hazards of Arctic navigation. As shipping activity increases in the region, express provision for safety management for ice navigation might need to be considered.

The voluntary Arctic Guidelines apply to ships covered by SOLAS, including passenger ships and cargo ships of 500 gross tonnage or more engaged in international voyages in ice-covered waters (Map 4.1). The Arctic Guidelines are additional provisions deemed necessary for consideration beyond existing SOLAS requirements. They provide the most comprehensive standards for ships in ice-covered waters, including construction, equipment and operational matters.

Polar Class	General Description
PC 1	Year-round operation in all Arctic ice-covered waters
PC 2	Year-round operation in moderate multi-year ice conditions
PC 3	Year-round operation in second-year ice which may include multi-year ice inclusions
PC 4	Year-round operation in thick first-year ice which may include old ice inclusions
PC 5	Year-round operation in medium first-year ice which may include old ice inclusions
PC 6	Summer/autumn operation in medium first-year ice which may include old ice inclusions
PC 7	Summer/autumn operation in thin first-year ice which may include old ice inclusions

Table 4.3 The Arctic Guidelines and the Unified Requirements, adopted by the International Association of Classification Societies, designate a system of *Polar Classes* for ships with different levels of capability and construction, structural and equipment requirements under various ice conditions. The Unified Requirements apply to ships of member associations constructed on or after March 1, 2008. *Source: IMO Arctic Guidelines*

The Arctic Guidelines are structured in four parts. Part A provides construction, subdivision and stability in damaged condition recommendations for new *Polar Class* ships. The guidelines suggest a harmonized classification of *Polar Class* ships into seven categories according to intended ship operations and the level of ice in the area (Table 4.3). Ships should be able to withstand flooding resulting from hull penetration due to ice damage. No pollutants should be carried directly against the hull in areas of significant risk of ice impact. Operational pollution of the environment should be minimized by equipment selection and operational practice. Navigational, communications, safety-related survival and pollution control equipment should be appropriate for Arctic conditions.

Part B applies to *Polar Class* and non-*Polar Class* ships and includes recommendations on fire safety, fire detection and extinguishing systems, life-saving appliances and arrangements and navigation equipment in conformance with SOLAS, Chapter V. All *Polar Class* ships should be provided with an Automatic Identification System. *Polar Class* ships are encouraged to carry fully enclosed lifeboats. Other ships are urged to carry lifeboats having tarpaulins of sufficient size to provide complete coverage from environmental conditions.

Part C concerns ship operations, crewing and emergencies. Ships should carry operating manuals, as well as training manuals with relevant information concerning operations in ice-covered waters, including emergency procedures. Qualifications and training for crew and ice navigators are suggested.

Part D provides for environmental protection and damage control equipment, recognizing the navigational and environmental hazards and limited response capabilities for assistance in Arctic ice-covered waters. All ships navigating in Arctic ice-covered waters should be adequately equipped and their crews properly trained to provide effective damage control and minor hull repair, as well as containment and cleanup of minor spills.

The Arctic Guidelines have been criticized for various deficiencies. Criticisms include the lack of details or uniform international standards on training, failure to require actual ice navigational experience for ice navigators and limited provisions on prevention and mitigation of sea-spray icing of ships. Guidance about towage in ice-covered waters is also limited. The IMO recently agreed to revise the Arctic Guidelines and to extend their application to the Antarctic.

The *Convention on the International Regulations for Preventing Collisions at Sea, 1972* (COLREGS) sets out technical and seamanship rules for ships on the high seas and in all other waters navigable by seagoing vessels connected thereto, including bays, straits, territorial seas and EEZs. COLREGS applies to navigation in the Arctic, but it does not contain specific rules for ships navigating in ice-covered waters. COLREGS covers a situation where a ship is constrained in its ability to maneuver due to size, draft or other reason such as ice. However, the application of some rules may need to be considered with reference to ice navigation. With an extended Arctic shipping season and increased ship traffic, COLREGS can be expected to assume greater importance.

The remoteness and harsh conditions present special search and rescue challenges in the Arctic. The *International Convention on Maritime Search and Rescue, 1979* (SAR Convention) provides for rescue coordination centers, ship position reporting systems and expedited entry of rescue units into the territorial waters of other states. Arctic state parties to the SAR convention shall coordinate SAR-incidents in their respective areas of responsibility and cooperate

The increased use of Arctic waters for tourism, shipping, research and resource development also increases the risk of accidents and, therefore, the need to further strengthen search and rescue capabilities and capacity around the Arctic Ocean to ensure an appropriate response from states to any accident. Cooperation, including on the sharing of information, is a prerequisite for addressing these challenges. We will work to promote safety of life at sea in the Arctic Ocean, including through bilateral and multilateral arrangements between or among relevant states.

~ Ilulissat Declaration, May 2008

© Fednav, Ltd.

with each other as required. The IMO has established 13 major search and rescue areas around the world, within which coastal states have designated search and rescue regions.

The Global Maritime Distress and Safety System (GMDSS) facilitates maritime safety communications for merchant and passenger ships. The Arctic is "Sea Area A4" and extends to 90°N for GMDSS purposes. Canada, Norway and the Russian Federation plan to coordinate navigational and related maritime safety information in one or more designated navigational areas (NAVAREAs) by 2011.

Representatives from the five Arctic coastal states meeting in Ilulissat, Greenland, recently adopted a declaration reaffirming their commitment to work together through the IMO to strengthen existing measures and to develop new measures to improve the safety of maritime navigation and prevent or reduce the risk of ship-based pollution in Arctic waters. The Ilulissat Declaration recognizes the need to further strengthen search and rescue capabilities and capacity around the Arctic Ocean.

As international shipping increases in the Arctic, it should be expected that ships will be more frequently in need of assistance. There are, however, practical difficulties in finding and supporting suitable places of refuge for ships in the Arctic, even during the summer navigation months. The 2003 IMO *Guidelines on Places of Refuge for Ships in Need of Assistance* provide a risk assessment and decision-making framework for coastal state decision-makers, masters of ships and salvors when a ship needs refuge in sheltered coastal waters such as a port or a bay. The guidelines are not mandatory. Many states have adopted places of refuge policies and/or designated such places, with the European Union requiring member states to designate places of refuge.

When a ship becomes a casualty and eventually sinks, it may continue to pose a hazard for navigation. Shipwrecks within and beyond the territorial sea will eventually be covered by the 2007 *Nairobi International Convention on the Removal of Wrecks*, which is not yet in force. Shipowners are responsible for locating, marking and removing ships, and must carry suitable insurance for this purpose.

Standards for Seafarers in the Arctic and Maritime Labor Law Issues

The Arctic presents a particularly hazardous work setting for those who must live and work under its extreme conditions. Both the IMO and the ILO set international standards for seafarers' competence and their working and living conditions (Table 4.4). In addition, the World Health Organization (WHO) sets standards for seafarers' health issues such as medical fitness for duties and requirements for on-board medical supplies. Most international standards are directed to flag states and apply to ships undertaking international voyages, although some requirements are directed to countries in their capacity as maritime labor supply states.

The IMO addresses seafarer competency and training and other safety matters for both ship and crew through the *International Convention on Standards of Training, Certification and Watchkeeping*

for Seafarers, 1978 (STCW) and SOLAS. The STCW is again being revised, including standards for medical fitness for duty and hours of work and rest.

Since 1920, the ILO has adopted more than 70 international conventions and recommendations addressing maritime labor conditions and standards for decent working and living conditions for seafarers, for example, hours of rest and work, accommodations, occupational safety and health, wages, food and medical care. More than 35 of these maritime labor conventions and related recommendations were consolidated in the 2006 *Maritime Labour Convention*, which is expected to enter into force by 2011.

IMO, ILO and WHO have not adopted specific mandatory instruments addressing Arctic or Antarctic shipping as distinct from the general requirements. Existing minimum standards apply to ships flying the flag of states party to these conventions, and flag states are responsible for enforcing them on their ships. However, they would also be enforced on non-party ships under the regime of port state control inspection. Outside STCW or the ILO standards, there do not appear to be any special requirements for minimum hours of rest or maximum hours of work and safe manning despite navigation under what could be regarded as especially hazardous conditions.

The Arctic Guidelines also make recommendations on labor issues not dealt with under SOLAS or STCW. The integrated approach adopted by the guidelines recognizes that safe operation in ice-covered conditions "requires specific attention to human factors including training and operational procedures." The guidelines recommend that crew have ice navigation and simulator training prior to entering Arctic waters, as well as exposure to ice-breaking operations and cold weather cargo handling; and that all ships operating in Arctic ice-covered waters should have at least one qualified ice navigator available to continuously monitor ice conditions when the ship is underway and making way in the presence of ice. The guidelines recommend that the ice navigator provide documentary evidence of having satisfactorily completed an approved training program in ice navigation. Currently, most ice navigation programs are ad hoc and there are no uniform international training standards. Although the Arctic Guidelines are not comprehensive with respect to seafarer training for the Arctic, they are the first international instrument to emphasize the need for specialized training in ice navigation.

Marine Environmental Rules and Standards

The *International Convention for the Prevention of Pollution from Ships, 1973 as Modified by the Protocol of 1978 Relating Thereto* (MARPOL 73/78) establishes international standards for pollutant discharges from ships. The standards are applicable in some Arctic waters (Table 4.5). Six annexes set out technical rules and procedures dealing with the prevention and control of pollution from ships by oil (I), noxious liquid substances (II), harmful substances in packaged form (III), sewage (IV), garbage (V) and air emissions (VI).

MARPOL does not totally prohibit the discharge of wastes in the marine environment. Establishing oily ballast and bilge water discharge limits, Annex I is an important annex for the protection of

© United States Coast Guard

the Arctic marine environment. Oily ballast water from tankers may be discharged at a rate of 30 liters per nautical mile while en route and over 50 nautical miles offshore. Annex I also establishes a 15 ppm discharge limitation on oily bilge water from oil tankers, as well as from other ships. Amendments to MARPOL in 1992 and 2003 introduced a mandatory requirement of double hulls for new oil tankers and an accelerated phase-out period for existing single-hull tankers, as well as prohibition of operation of single-hull oil tankers carrying heavy grade oil as cargo accordingly. A proposal is before IMO to prohibit the use and carriage of heavy grade oil in the Antarctic Special Area, which may be considered in the future whether it should also apply to the Arctic.

Annex IV sets out sewage regulations that apply to ships of 400 gross tonnage or more, or ships that are certified to carry more than 15 persons. Sewage may be discharged at a distance of more than three nautical miles from the nearest land when a ship has an approved treatment system and the sewage discharged is comminuted and disinfected. Sewage that is not treated may be discharged at a distance of more than 12 nautical miles from the nearest land if the ship is proceeding at not less than four knots and the discharge is not instantaneous but at a moderate rate.

Annex V, while prohibiting the disposal of plastics into sea, still allows ships to discharge some garbage generated by normal operations of a ship and depending on the distance from land. For example, ships are allowed to dispose of packing materials more than 25 nautical miles from the nearest land.

Annex VI allows special sulfur oxide (SOx) emission control areas to be declared, where sulfur content of ship fuels would be lowered for designated regions (1.5 percent m/m) from the global standard of 4.5 percent m/m. Amendments to MARPOL 2008 introduced increasingly stringent regulations, including gradually decreasing the global cap for SOx (from 4.5 percent m/m to 0.5 percent m/m) and decreasing SOx and particulate matter in Emission Control Areas from 1.5 percent m/m to 0.1 percent m/m. Stringent controls were also placed on nitrogen oxide (NOx) emissions and the ability to create Emission Control Areas for such emissions is now also available. These amendments enter into force on July 1, 2010. However, neither polar region has been proposed for special treatment.

Where the discharge standards under MARPOL Annexes I, II and V are not sufficient for protecting sensitive areas of the marine environment, IMO may designate special areas based on oceanographic and ecological as well as ship traffic conditions. For example, the Antarctic area (south of 60° latitude) is designated as a special area under all three annexes and a very high standard for discharges under Annex I has been established, namely a prohibition on any discharge of oil or oily mixtures from any ship. The Arctic may satisfy at least the oceanographic and ecological conditions for special area designation, if not also ship traffic conditions, as set out in the 2002 IMO *Guidelines for the Designation of Special Areas under MARPOL 73/78*. Before a special area becomes effective, regional coastal states must undertake to provide port reception facilities, an important consideration in the Arctic with its limited port infrastructure.

Marine areas can also receive special protection from the IMO because of their particular sensitivity to international shipping through designation as particularly sensitive sea areas (PSSAs). The IMO has developed *Guidelines for the Identification and Designation of Particularly Sensitive Sea Areas,* most recently revised in 2005. To be eligible for designation as a PSSA, there must be three elements: (1) the area must have certain attributes as set forth in the Revised PSSA Guidelines, (2) there must be an identified vulnerability from

international ship traffic and (3) there must be an IMO measure to address the identified vulnerability. These IMO measures are called associated protective measures and include such things as areas to be avoided, traffic re-routing and separation schemes, mandatory ship reporting, discharges, restrictions and designation as a special area. If the conditions and criteria set out above are satisfied in a given area of the Arctic, that area may be eligible for PSSA designation.

There is also the option of obtaining protective measures under SOLAS without necessarily involving the designation of a PSSA. Routing and reporting measures under SOLAS Chapter V (Regulations 10 and 11) normally associated with safe passage (such as recommended routes, precautionary area and area to be avoided) may be obtained through the IMO to protect the marine environment. Measures of this sort have already been obtained and applied in northern waters, such as Alaska's Prince William Sound, the Baltic Sea and waters off the coast of Norway, Iceland and Greenland.

The Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter, 1972 and its 1996 Protocol govern ocean dumping from ships (excluding wastes from normal ship operations) and the dumping (intentional sinking) of ships in the Arctic (Table 4.5). The convention permits dumping except for those wastes listed on a "black list" pursuant to a national ocean dumping permit. The 1996 Protocol adopts a precautionary approach, and only wastes listed on a global "safe list," for example, dredged material and organic wastes of natural origin, may be disposed of subject to a waste assessment audit and a national permit.

Seven Arctic states are parties to the 1990 *International Convention on Oil Pollution Preparedness, Response and Co-operation* (OPRC), which sets out a framework for cooperative measures in relation to pollution incidents involving oil (Table 4.5). The 2000 *OPRC-Hazardous and Noxious Substances (HNS) Protocol* provides a similar framework for cooperation in preparedness and response measures for dealing with HNS incidents, but not all Arctic states are parties. State parties are required to establish measures for dealing with oil and HNS pollution incidents, either nationally or in cooperation with other countries, and the conclusion of further bilateral or multilateral agreements is encouraged. The OPRC envisages an ongoing need to assess the adequacy of pre-positioned equipment for responding to pollution incidents in light of changing risks, such as an increase in shipping levels.

Under OPRC, trained crew and appropriate damage control materials must be on board ships and offshore installations to implement their ship oil pollution emergency plans to effect damage repair and mitigate pollution, including responding to ice damage. OPRC calls for the establishment of stockpiles of oil spill combating equipment, the holding of oil spill combating exercises and the development of detailed plans for dealing with pollution incidents. State parties have a duty to provide assistance to other states in pollution emergency situations.

Regional and bilateral arrangements are in place that provide a framework for cooperation among some Arctic states under OPRC in the Arctic. For example, the Arctic Council's Emergency Prevention, Preparedness and Response (EPPR) working group has noted the need to increase communication and to share information with the IMO in such areas as dispersant application, waste removal and treatment, in-situ burn up and spill response in ice and snow conditions. Several Arctic states have joint contingency planning arrangements. They include, among others, the *Canada/United States Joint Marine Pollution Contingency Plan* for the Beaufort Sea area, the *Russia/USA Joint Marine Pollution Contingency Plan*, the joint *Russian/Norwegian Plan for the Combating of Oil Pollution in the Barents Sea* and the *Canada/Denmark Agreement for Marine Environmental Cooperation,* which includes annexes for responding to shipping and offshore hydrocarbon spills.

© Hapag-Lloyd KreuzfahrtenGmbH

The *International Convention on the Control of Harmful Anti-Fouling Systems on Ships* addresses the use of anti-fouling systems, including paints containing toxic substances such as tributyltin (TBT). The convention, which entered into force on September 17, 2008, requires ships to either not use organotin compounds on their hulls by January 1, 2008 or to have a protective coating to prevent leaching of organotin compounds. Although several Arctic Council states regulate TBT use and the European Union has introduced a complete ban on TBT-based paints, only Denmark, Norway and Sweden are parties to the convention.

An additional vessel-source environmental concern is ballast water, whereby ships take up sea water in order to maintain ship stability and structural integrity. When ballast water is discharged, pathogens and alien living organisms may be released that can disrupt local marine species and ecosystems.

The 2004 IMO *International Convention for the Control and Management of Ships' Ballast Water and Sediments* is intended to prevent, minimize and ultimately eliminate the risks of introduction of harmful aquatic organisms and pathogens via ships' ballast water, but it is not yet in force. The convention details technical standards for the control and management of ships' ballast water and sediments with the goal of shifting ballast water management from exchange to treatment for all ships by 2016. Among the Arctic states, only Norway has consented to be bound by the convention.

The Ballast Water Convention encourages enhancement of regional cooperation, including the conclusion of regional agreements. The 2007 non-binding IMO *Guidelines for Ballast Water Exchange in the Antarctic Treaty Area* provide an example of a regional approach. Various measures are recommended, including the exchange of ballast water before arrival in Antarctic waters. The specific impact of ballast discharges in the Arctic marine environment remains largely unknown. These issues require further research.

The Role of Ports in International Maritime Law

Port state control could play an important role in promoting maritime safety and marine environmental protection in the Arctic. A global network of memoranda of understanding (MOUs) on port state control among national maritime authorities provides a systemic ship inspection approach to ensure compliance with international standards on ship safety, labor, training and pollution prevention such as SOLAS, COLREGS, MARPOL 73/78 and STCW. The inspection data is centralized in databases to which member authorities have access, and is used to track the compliance of a particular ship and the record of violations by flag. The Paris MOU among European maritime authorities is potentially relevant for ships navigating within the Arctic Circle. The maritime authorities of the Arctic Council states, except for the United States, are parties to the Paris MOU. The United States administers its own port state control system, but has cooperating observer status with the Paris MOU.

© Lawson Brigham

Regional maritime authorities in the Arctic may wish to consider whether existing MOUs are sufficient to enforce higher regulatory safety and environmental standards applicable to the Arctic or to coordinate port state control enforcement efforts through a new dedicated MOU. Arctic states would need to consider what uniform standards would be enforced through port state control. Currently, only Canada and the Russian Federation have designated national safety and environmental standards for navigation in their Arctic waters separately from international standards adopted under the auspices of the IMO, including the Arctic Guidelines. The Russian Federation employs a ship inspection system for passage through the Northern Sea Route. Canada requires that ships comply with the *Arctic Waters Pollution Prevention Act* and regulates construction and other standards before navigating in Arctic waters, and inspects for this purpose.

Ports and maritime authorities also play a role in the international maritime security regime. In 2002, the IMO introduced the mandatory *International Ship and Port Facilities Security Code* (ISPS Code), which is linked to chapter XI-2 of the SOLAS Convention, for all commercial vessels over 500 gross tonnage engaged in international trade, as well as mobile offshore drilling units. Public and private ports and terminals must be secure, and ships may be required to provide notice and information to the maritime authorities of the host state. For example, Canada and the United States have advance notice of arrival requirements for ships that vary with the duration of the voyage. Certificates are issued to ships, companies and ports and

security plans are subject to periodic audit. Arctic ports and terminals require a risk assessment followed by adoption of security plans to comply with the ISPS Code. Ships engaged in cargo operations, support services or cruises in the Arctic have to comply with the ISPS Code and cooperate with port and terminal security. In areas under their jurisdiction and in accordance with UNCLOS, Arctic coastal states should have ship control procedures in place, as well as a secure system of assessing threats and sharing intelligence among law enforcement agencies.

International Private Maritime Law Framework

The international customs and practices of the shipping, cruise and merchant communities are likely to govern the Arctic movement of goods and passengers in addition to international maritime law. Since ships move between different countries, their owners' contracts can be subjected to a variety of different national jurisdictions and laws. To reduce confusion, the international community has concluded international private law conventions that establish uniform contractual regimes for the carriage of passengers and the carriage of goods under bills of lading (Table 4.6).

Shipowners interact with commercial parties, such as cargo owners and cruise passengers, or the suppliers of essential shipping services, like insurers and salvors, through private contracts. The essence of a contract of sea carriage is an agreement for safe transport and delivery by ship in exchange for payment of freight, hire or passage and the allocation of risks and responsibilities of the transit between the parties. These contracts also take into account the relevant international maritime law, with the carrier ensuring that its ship meets international standards for human safety and environmental protection (e.g., SOLAS, the 1972 *International Convention for Safe Containers* (CSC), MARPOL 73/78 and STCW). International shipping organizations and traders' associations have also developed standardized clauses for particular trades, cargoes and routes and organized them into blank forms of contracts.

The international customs and practices of the shipping, cruise and merchant communities are likely to govern the Arctic movement of goods and passengers in addition to international maritime law.

Contracts of carriage for the movement of petroleum, liquefied natural gas (LNG) and minerals moved in bulk in tankers and ore carriers that tramp (sail) around the world from port to port are known as charter parties. Industry bodies like the Baltic and the International Maritime Council (BIMCO) and International Association of Independent Tanker Owners (INTERTANKO) have devised generally accepted standard terms of trade for inclusion in individual charter parties. For example, BIMCO's voluntary "ice clauses" allow a carrier to deviate from the contracted carriage to prevent a ship from becoming icebound.

Packaged, crated and containerized items, including hazardous goods, are carried under contracts represented by bills of lading and sea waybills that are regulated under competing international rules with similar modes of operation and regulatory function. These rules differ in the standards of conduct expected of the carrier, the scope of application of the rules and the limits of liability for their breach. The 1924 *International Convention for the Unification of Certain Rules of Law Relating to Bills of Lading* as amended by the Protocols of 1968 and 1979 (Hague-Visby Rules), or some variant of them, are the most widely applied international regulations. The other rules are the 1978 *United Nations Convention on the Carriage of Goods by Sea* (Hamburg Rules) and the *1980 United Nations Convention on International Multimodal Transport of Goods* (Multimodal Rules). The United Nations Commission on International Trade Law has prepared a wholly new uniform set of rules, the *Draft Convention on Contracts for the International Carriage of Goods Wholly or Partly by Sea,* presented to the General Assembly in October 2008. States that are not party to a particular convention may choose to legislate the rules into carriage contracts, for example, Canada implements the Hague-Visby Rules through the Marine Liability Act. Each set of rules applies to marine transportation in the Arctic just the same as in any other ocean area.

Intergovernmental and non-governmental organizations also influence the standard of care set out in a carriage contract. Since 2006, a number of classification societies have introduced winterization guidelines for navigation in cold climates that establish standards of ship preparedness for Arctic shipping, thereby indirectly establishing the expected minimum standard of reasonable care for cargo.

The commercial carriage of passengers by sea, whether on ferries or cruise ships, is internationally regulated by the 1974 *Athens Convention Relating to the Carriage of Passengers and their Luggage by Sea* and its protocols of 1976 and 1990 not yet in force. A further protocol concluded in 2002 is also not yet in force: the consolidated treaty will be known as the *Athens Convention*, 2002. The carrier is responsible for the safety of everyone on board, whether crew, cruise company employees or fare paying passengers. The Athens Convention establishes liability rules and limitations for personal injuries to passengers and loss or damage to their luggage. The safety criteria to be followed in order to negate a finding of negligence are established by the international shipping practices of operators, for example, *Association of Arctic Expedition Cruise Operators Guidelines,* as well as by SOLAS and other binding IMO shipping safety rules.

Marine Insurance

Arctic shipping will not be sustainable without the availability of marine insurance at reasonable commercial rates. Unlike most other areas of shipping, the practice of marine insurance is not regulated in an international convention. A business and private law matter, marine insurance is legislated at the national level, for example, Canada and the Russian Federation; and occasionally at a sub-national level, for example, the United States. Insurance practices are driven by international insurance markets. Of particular significance for Arctic shipping is protection and indemnity insurance, offered through P & I Clubs. Until recently, Russian Federation shipping in the Arctic tended to be insured under state schemes, and now P & I coverage is a requirement for trading on the Northern Sea Route.

Although most of the risks associated with shipping are well known and understood by insurers and assureds alike, the risks associated with polar navigation are still not fully known or understood. With the exception of the Northern Sea Route, the Arctic is perceived as an unknown quantity or a marine frontier. As a result, the

provision of insurance for Arctic shipping tends to be on a case-by-case basis and expensive, with seasonal additional premiums. The availability and cost of marine insurance is a major constraint on Arctic marine shipping.

Salvage

The availability of salvage services can be expected to be vital for the future of commercial shipping in the Arctic. The 1989 *International Convention on Salvage* establishes the general legal principles for salvors and salvage operations. All Arctic Council states are parties to the convention. Salvage refers to the actual service provided to a ship in need of assistance, the body of law that exists to govern this maritime institution, and the reward due to the salvors for their services. Essentially, salvors are entitled to a reward (a percentage of the value of the salved property) for successful salving of the vessel or cargo, such as, "no cure, no pay". Most commonly, private firms of professional salvors respond to shipping casualties, although the Russian Federation has a fleet of polar vessels that provide salvage services. In general, the rights and obligations of the parties to a salvage operation are legislated and subject to industry standard form agreements, the best known being the *Lloyd's Open Form of Salvage Agreement*. If there is no contract, the parties will turn to domestic courts to obtain a salvage award. The convention provides for an enhanced salvage award for salvors preventing or minimizing damage to the marine environment.

Generally, there is limited infrastructure for ship repair and/or salvage and pollution countermeasures capability in the Arctic basin or companies with significant Arctic salvage experience. This lack of salvage capability is a concern to marine insurers.

Liability and Compensation

Should there be incidents resulting in oil or other hazardous substance spills that cause damage to the Arctic marine environment, property or economic loss, national and international systems of financial compensation for cleanup and losses sustained will become important. The current international system for compensation for pollution damage caused by ship-source pollution is fragmented and limited. Separate conventions address oil pollution liability and compensation from tankers; damages from the spill of bunker fuel carried in ships other than tankers, such as cargo ships; and hazardous and noxious substance spills from ships (Table 4.7). Compensation is only available to state parties to the respective conventions and to private bodies or individuals who have suffered damage as a result of the pollution. None of the conventions address damage to the high seas beyond national jurisdiction. In general, under the conventions, the shipowner is strictly liable for the loss or damage up to a certain amount. A supplementary fund may provide additional compensation when the victims do not obtain full compensation from the shipowner or the insurer.

The compensation regime for damage caused by persistent cargo and fuel (bunker) oil pollution from oil tankers is the 1992 *Civil Liability Convention* (1992 CLC) and the 1992 *Fund Convention*, as well as the 2003 *Supplementary Fund Protocol*. These conventions do not apply to spills of bunker oil from ships other than tankers. In the Arctic context, it is unclear if the conventions apply to floating production, storage and offloading units and permanently and semi-permanently anchored ships engaged in ship-to-ship oil transfer operations.

While seven Arctic states have adopted the 1992 Civil Liability and Fund conventions, the United States has established a separate regime under the *Oil Pollution Act of 1990*. The international regime limits compensation for environmental damage to actual restoration costs; U.S. regulations provide compensation for both diminution in value of natural resources and the cost of assessing such damages.

The *International Convention on Liability and Compensation for Damage in Connection with the Carriage of Hazardous and Noxious Substances by Sea, 1996* (HNS Convention) also establishes a two-tier international compensation regime for bulk solids (excluding coal and iron ore and radioactive materials), liquids including non-persistent oils, liquid gases such as LNG and liquefied petroleum gases (LPG) and packaged substances. Individual receivers of HNS by sea in state parties to the convention would contribute to the International Hazardous and Noxious Substances Fund. The HNS Convention is not yet in force. Among the Arctic states, only the Russian Federation is a party.

The 2001 *International Convention on Civil Liability for Bunker Oil Pollution Damage*, which entered into force on November 21, 2008, applies to pollution damage caused by the spill of bunker oil from a ship other than a tanker and makes the shipowner strictly liable. The Bunkers Convention preserves the right of the shipowner and insurer to limit liability under any applicable national or international regime. The convention is accompanied by a Resolution (Annex 1) that urges all states to ratify or accede to the 1996 Protocol to the 1976 *Convention on Limitation of Liability for Maritime Claims* (LLMC 1976) thus increasing the funds available for bunker pollution claims. Among the Arctic states, the Russian Federation, Denmark, Finland and Norway are parties.

Selected National Legal Frameworks: Canada and the Russian Federation

Canada and the Russian Federation regulate shipping in the Arctic under UNCLOS Article 234, as well as under other authorities.

Canada has established special ship construction, equipment and crewing requirements and near zero oil pollution discharge standards through the *Arctic Waters Pollution Prevention Act* (AWPPA) and its regulations. The legislation applies to a 100 nautical mile pollution prevention area, but recent amendments will extend this to the 200 nautical mile EEZ.

Pollution standards for discharges are stricter in Canadian Arctic waters than MARPOL, with only untreated sewage or emergency discharges permitted. The *Canada Shipping Act, 2001* authorizes regulations to be passed establishing vessel traffic services (VTS) zones in an Arctic shipping safety control zone whereby vessel reporting and clearance would be mandatory. To date, only a voluntary non-regulatory VTS zone known as NORDREG has been adopted for the Canadian Arctic. Currently, Canada effectively has a routing requirement in that the Shipping Safety Control Zones (adopted under the

Research Opportunities

- Comparative investigation of national construction and equipment standards for ships and their consistency with IACS Unified Requirements for *Polar Class* ships.
- Comparative examination of the extent to which states have followed the IMO Arctic Guidelines.

AWPPA) stipulate when and where ships of certain ice strength can operate. Recently, the Canadian federal government announced plans to extend the application of the AWPPA to 200 nautical miles and to move NORDREG to a mandatory reporting system for ships entering Canadian Arctic waters.

The Russian Federation has opened the Northern Sea Route for foreign shipping under certain conditions and has increased the number of ports in the Arctic region.

Regulations adopted in 1990 and 1996 allow navigation in the Northern Sea Route on a non-discriminatory basis for ships of all states based on *Regulation for Navigation on the Seaways of the NSR*, 1991; *Guide for Navigation through the NSR*, 1995; and *Regulation for Design, Equipment and Supply of Vessels Navigation the NSR*, 1995. In these documents, priority is given to prevailing international legal standards and appropriate rights of the coastal states to ensure maritime safety and to take measures for preventing the pollution of the marine environment. Pollution standards are stricter than MARPOL. For example, no garbage deposits or oily ballast water discharges from tankers are permitted. The regulations impose various conditions for using the Northern Sea Route. An application to Russian maritime authorities has to be made and they would give careful consideration to navigational safety and environmental concerns. A ship inspection (at the shipowner's expense) is required and at least two pilots need to be taken on board. Crew size must be sufficient to allow for a three-shift watch and the master should at least have a 15-day experience of steering ships under ice conditions along the Northern Sea Route. The NSR fee system is continuously improving. The existing fee system is in place to necessitate financial support for icebreaker assistance and NSR infrastructure throughout the year. In the case of future growth in cargo volumes, the charge for each individual vessel passing by the NSR is expected to decrease as the overall volume increases. The estimated volumes of maritime traffic are about 40 million tons of oil and gas per year by 2020, which may improve the economic effectiveness of cargo transportation through the NSR.

In Summary

Governance in shipping is characterized by efforts to promote harmonization and uniformity in international maritime law. The reason for the global approach to shipping governance is that by definition and function, shipping is essentially an international tool in the service of global trade. The term governance highlights the complex range of actors that affect shipping law, policy and practice in the Arctic. Indeed, the largest flag states and suppliers of marine labor do not border the Arctic Ocean.

Natural resource, cruise and maritime trade related shipping in the Arctic is on the increase. As marine insurance at reasonable rates becomes available and an appropriate infrastructure is put in place to service Arctic navigation routes, a concomitant increase in international shipping can be expected. This will raise, among others, safety and marine environment protection concerns: There are complex global and national legal regimes that establish standards for navigation and protection of the marine environment that are applicable in the Arctic, however, for those to be effective, a common understanding of those regimes, along with enhanced regional cooperation in ocean management and greater participation by Arctic states in the global international maritime conventions will be needed. If the Arctic marine environment is to be protected, existing regimes will need to be strengthened by Arctic states and the international community.

Not all Arctic states are parties to important conventions, and indeed not all relevant conventions are in force. There is a dearth of mandatory international standards specifically designed for navigation in the Arctic, as well as voluntary guidelines. Arctic states will need to work closely with global and regional international organizations, the people of the North and the international maritime community in regime-building to facilitate governance of Arctic shipping.

Findings

1] Differing national viewpoints over what waters may legitimately be claimed as internal and what waters constitute straits used for international navigation have yet to be fully resolved and could give rise to future disputes concerning the exercise of jurisdiction over shipping activities.

2] Coastal state authority to regulate foreign shipping in the Arctic Ocean in order to prevent, reduce and control marine pollution was bolstered by Article 234 of UNCLOS. However, the precise geographic scope of coverage (waters covered by ice most of the year within the limits of the Exclusive Economic Zone) and the breadth of regulatory powers, in particular the extent to which a coastal state may unilaterally impose special construction, crewing and equipment standards, given the requirements that such standards must give due regard to navigation and the protection and preservation of the marine environment based on the best available scientific evidence could give rise to differing interpretations.

3] The IMO international voluntary *Guidelines for Ships Operating in Arctic Ice-covered Waters* for the safety of ships and seafarers in the Arctic are currently under review. This review provides an opportunity to assess and strengthen guidance in the area of ship construction, equipment and operations and to consider the need for a legally-binding code in the future.

4] Safe navigation in ice-covered waters depends much on the experience, knowledge and skill of the ice navigator. Currently, most ice navigator training programs are ad hoc and there are no uniform international training standards. For example, this could be addressed by developing training standards for navigation in polar conditions and in Arctic safety and survival for seafarers that could be incorporated into IMO's *Standards of Training, Certification and Watchkeeping* (STCW 78/95).

5] The International Association of Classification Societies (IACS) has developed Unified Requirements for member societies addressing essential aspects of construction for ships of *Polar Class*. The IACS Unified Requirements for member societies are incorporated by reference into the IMO *Guidelines for Ships Operating in Arctic Ice-covered Waters*. If the application of the harmonized *Polar Class* were to be made mandatory, then it could be an effective way to strengthen safety and environmental protection in Arctic waters.

6] Specific international construction requirements for cruise ships operating in polar waters have not been adopted. The cruise ship industry has formed a Cruise Ship Safety Forum to further develop specific design and construction criteria for new vessels, but it remains to be seen how navigation in polar waters will be addressed.

7] The *International Convention for the Prevention of Pollution from Ships, 1973 as modified by the Protocol of 1978* (MARPOL) sets out minimum international standards for operational discharges and emissions from ships which are also applicable to Arctic waters. Pursuant to Article 234 of UNCLOS, coastal states may unilaterally impose additional, non-discriminatory requirements within the limits of their Exclusive Economic Zone (EEZ) when certain conditions are met. At this time, some national standards for regulating ship-source pollution in the Arctic are not consistent among Arctic states.

8] Stricter environmental standards have neither been proposed nor established by Member States through the IMO for the Arctic. For example, under MARPOL the Arctic Ocean could be designated as a "special area" where more stringent than normal discharge standards would apply under MARPOL Annexes I and V. Such an area could also be considered for designation as an Emission Control Area under Annex VI.

9] Expanded international shipping in the Arctic Ocean increases the possibility of introduction of alien species and pathogens through the discharge of ballast water and through hull fouling. The Ballast Water Convention imposes management (i.e., exchange and treatment) requirements on party ships to protect marine areas from the hazards posed by ballast water from ships and encourages establishment of regional approaches such as the *Guidelines for Ballast Water Exchange in the Antarctic*.

10] In the Arctic Ocean there is very little commercial or government salvage and ship repair response capacity. Salvage and ship repair are important to support commercial shipping and the lack of this capacity is of concern to the marine insurance industry.

11] The availability and cost of marine insurance is a major restraint on shipping in many parts of the Arctic. The underwriting of present shipping activities takes place only on a case-by-case basis.

12] The international liability and compensation regime is fragmented and limited, with separate conventions addressing pollution from oil tankers, bunker fuel from non-tankers, and hazardous and noxious substances from all ships. No convention or protocol addresses damage to the high seas beyond national jurisdiction.

CURRENT MARINE USE AND THE AMSA SHIPPING DATABASE

In order to better understand Arctic shipping today, a database of Arctic marine activity for a given year was seen as essential. Since no comprehensive database existed, AMSA undertook the collection of shipping data from all Arctic states. The result is the first comprehensive Arctic vessel activity database for a given calendar year. It contains a range of information on where and when different vessels are operating in the Arctic, what types of vessels, what activity they undertake and what cargo they may be carrying, among other information. The AMSA database is a flexible tool that can be built upon as additional information is obtained and can be used to further assess environmental impacts from vessel activity, locate areas of potential conflicting multiple use and provide a baseline for an analysis of future growth in vessel activity in the region.

Methodology

Vessel activity data for the AMSA study was collected from all Arctic states with coastal waters through the use of a specially designed questionnaire distributed to the Arctic Council's Senior Arctic Officials and PAME working group representatives in February 2006. A number of state administrations responded directly and, in some cases, other organizations were engaged to develop responses on a state's behalf. For the purposes of the study, 2004 was chosen to be the baseline year; where data was found to be insufficient for 2004, data from later years was provided and used for those areas only.

The data requested included such information as the number of vessels operating in the states' waters, the type of vessels, cargo

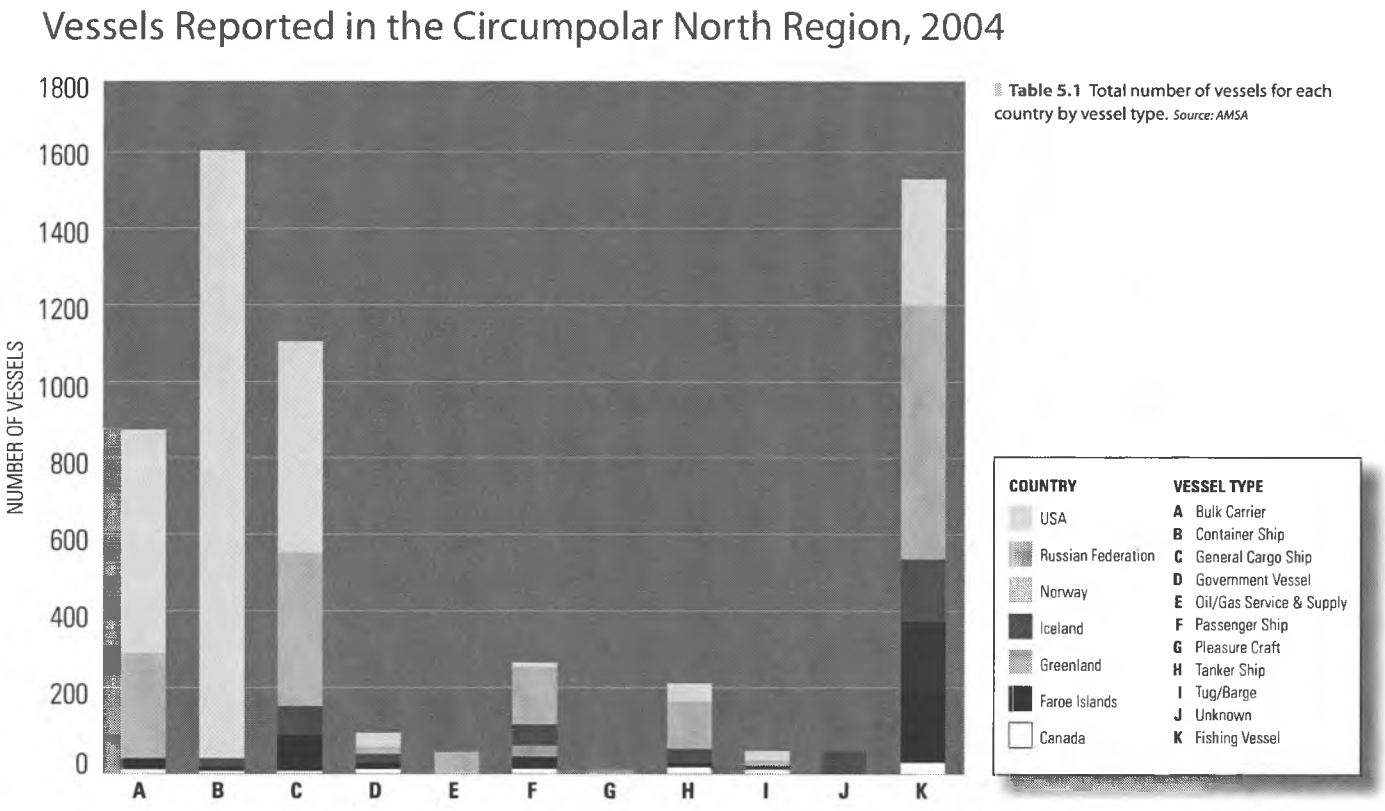

Table 5.1 Total number of vessels for each country by vessel type. *Source: AMSA*

carried, operational routes, fuel used, engine size of the vessels, date of operations, etc. Response to the questionnaire varied. Some responses were submitted with very detailed information, while some were submitted with very basic information or, at times, incomplete. In order to make the database more usable for most types of analysis, some assumptions have been made and post-processing of the data has been undertaken. For example, where route data was unavailable or contained obvious errors, such as passages across land, the information has been adjusted to follow known shipping routes. In terms of data reporting, there is some inconsistency in how states defined vessel types, as some states reported oil carriers as tankers, while others reported similar vessels as bulk carriers or tug and barge. There are also varying levels of certainty regarding the routes traveled, ranging from very complete records of course changes to records that provided only departure and arrival points.

Where limited vessel-specific information was provided, other data sources were integrated, including ferry and cargo vessel sailing schedules, to add additional parameters to the data set. To facilitate analysis of the raw data, vessels were grouped into standardized vessel categories by the country that reported it and by the season in which it operated (Table 5.2). A summary of total number of vessels per category per country is shown in Table 5.1. Seasons were defined as: Winter - December to February; Spring - March to May; Summer - June to August; Autumn - September to November. For the purposes of the AMSA, the Arctic has been defined according to the internal policies among Arctic Council member states. This has meant that some states reported vessel activity that is below 60 degrees north, the traditional definition of the Arctic.

To further enhance understanding and presentation of the data, the raw data was mapped into a Geographic Information System (GIS), which provided the tools required to manage and analyze the spatial as well as the attribute components. Incorporating the data into a GIS provided for the development of maps that create a visual presentation, allowing for further analysis of all Arctic vessel activities, such as modeling vessel CO_2 emissions and comparing current vessel traffic and mapped ecologically sensitive areas.

Table 5.2 AMSA vessel categories. *Source: AMSA*

Ship Category	General Description
Government Vessels and Icebreakers	An icebreaker is a special purpose ship or boat designed to move and navigate through ice-covered waters. For a ship to be considered an icebreaker it requires three components: a strengthened hull, an ice-clearing shape and the power to push through ice, none of which are possessed by most normal ships.
Container Ships	Container ships are cargo ships that carry all of their load in truck-size containers, in a technique called containerization.
General Cargo	Ships designed for the carriage of various types and forms of cargo and the combined carriages of general cargo and passengers with 12 or less fare paying passengers.
Bulk Carriers	Ships specifically designed for bulk carriage of ore with additional faculties for alternative, but not simultaneous, carriage of oil or loose or dry cargo. Bulk carriers are segregated into the following major categories: handysize (10,000 to 35,000 DWT), handymax (35,000 to 55,000 DWT), panamax (60,000 to 80,000 DWT), capesize (80,000 DWT and over).
Tanker Ships	Propelled ships designed and constructed for the bulk carriage of liquids or compressed gas, as in the case of natural gas.
Passenger Ships	Ships that carry passengers, whether for transport purposes only or where the voyage itself and the ship's amenities are part of the experience.
Tug / Barge	Tug: vessel designed for towing or pushing. Additional activities may include salvage, fire fighting and work duties of a general nature. Barge: non-propelled vessel for carriage of bulk or mixed cargoes on weather or protected decks. May carry liquid cargo in holds or tanks. Some barges are modified for specific purposes (for example, crane barge).
Fishing Vessels	Fishing boats can be categorized by several criteria: the type of fish they catch, the fishing method used, geographical origin and technical features such as rigging. Modern commercial fishing uses many methods: fishing by nets, such as purse seine, beach seine, lift nets, gillnets or entangling nets; trawling, including bottom trawl; hooks and lines, long-line fishing and hand-line fishing; fishing traps. Fishing boats are generally small, often little more than 30 meters (98 ft) but up to 100 meters (330 ft) for a large tuna or whaling ship and can feature holds large enough to keep a good-sized catch.
Oil and Gas Exploration Vessels	There are many specialized vessels that are designed specifically for the exploration and extraction of natural gas and oil.

Using the GIS, the fishing data was defined by fishing vessel days per year, taking the number of fishing days times the number of fishing vessels reported. This number was then assigned to the appropriate Large Marine Ecosystem (LME) based on where the fishing events took place. A bathymetry layer is also provided in GIS format and can be used to discern draft limits to navigation. Map 5.1 shows the map-based depiction of all of the vessel activity in the AMSA database, including fishing vessel activity by LME.

Results

In 2004, approximately 6,000 individual vessels were reported operating in the Arctic, including vessels traveling on the North Pacific's Great Circle Route between Asia and North America through the Aleutian Island chain, defined by the U.S. as within the Arctic. Great Circle Route vessels account for half of all the vessels reported. Excluding the vessels plying the Great Circle Route, the most vessels in one category were fishing boats, at slightly less than 50 percent of the total; with the next largest vessel category being bulk carriers at about 20 percent of all vessels. The AMSA database contains information on individual voyages into or through Arctic waters. This means that the number of individual vessels is not necessarily proportionate to the total number of voyages, as many vessels made multiple trips within the region. Results are also potentially an underestimation of total vessels and marine use for 2004, given probable underreporting bias and obvious data gaps in many areas and vessel types.

While 2004 provides a snapshot of current Arctic vessel traffic, clear trends emerged from the data to show what common types of vessels are operating in the Arctic, where and when most activity is typically taking place. The AMSA database identified four types of vessel activities as most significant in the Arctic in 2004: community re-supply, bulk cargo, tourism and fishing vessel activity operations.

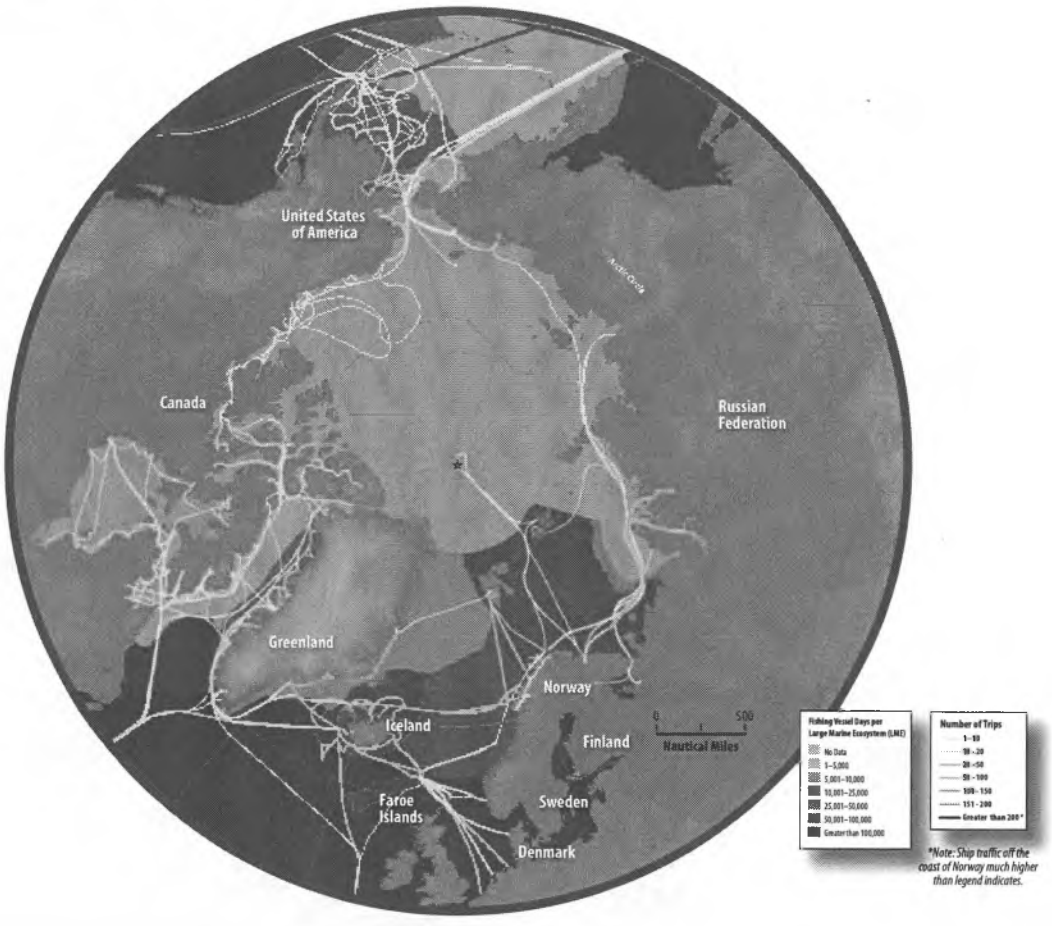


Map 5.1 Overview of all vessel activity for 2004, including fishing vessels. *Source: AMSA*

Regional Distribution of Vessel Activities

The overview map of vessel traffic shows that nearly all voyages took place on the periphery of the Arctic Ocean. Regions of high concentrations of traffic include: along the Norwegian coast and into the Barents Sea off northwest Russia; around Iceland; near the Faroe Islands and southwest Greenland; and in the Bering Sea. Different factors determine this distribution of marine activity. In the Bering Sea, in addition to the ships along the North Pacific Great Circle Route (through the Aleutian Islands), most of the ship traffic is bulk cargo ships serving the Red Dog mine in northwest Alaska, fishing and coastal community (summer) resupply. Traffic around Iceland, the Faroe Islands and southwestern Greenland is a

The AMSA database identified four types of vessel activities as most significant in the Arctic in 2004: community re-supply, bulk cargo, tourism and fishing vessel activity operations.

Icebreaker Navigation in the Central Arctic Ocean, 1977-2008

One of the historic polar achievements at the end of the 20th century and early in the 21st century has been the successful operation of icebreakers at the North Pole and across the central Arctic Ocean.

Between 1977 and 2008 access in summer has been attained by capable icebreaking ships to all regions of the Arctic basin. Seventy seven voyages have been made to the Geographic North Pole by the icebreakers of Russia (65), Sweden (five), USA (three), Germany (two), Canada (one) and Norway (one).

Nineteen of the 77 voyages have been in support of scientific exploration and the remaining 58 have been for marine tourism, all but one of the tourist voyages conducted aboard ice breakers.

Of the 76 icebreaker voyages that have been to the pole in summer, the earliest date of arrival has been July 2, 2007 and the latest September 12, 2005, a short 10-week navigation season for highly capable icebreaking ships.

The Soviet nuclear icebreaker *Arktika*, during a celebrated voyage, was the first surface ship to attain the North Pole on August 17, 1977. *Arktika* departed from Murmansk on August 9 and sailed eastbound initially north of Novaya Zemlya and through Vilkitski Strait to the ice edge in the Laptev Sea. The ship sailed northward to the pole along longitude 125 degrees east and reached the pole on August 17. *Arktika* arrived back in Murmansk on August 23 having sailed 3,852 nautical miles in 14 days at a speed of 11.5 knots.

The only voyage to the pole not to be conducted in summer was that of the Soviet nuclear icebreaker *Sibir*, which supported scientific operations during May 8 to June 19, 1987, reaching the North Pole on May 25. *Sibir* navigated in near-maximum thickness of Arctic sea ice while removing the personnel from Soviet North Pole Drift Station 27 and establishing a new scientific drift station (number 29) in the northern Laptev Sea. This successful voyage in the central Arctic Ocean could be considered the most demanding ice [illegible] ate.

No commercial ship has ever conducted a voyage across the central Arctic Ocean. However, seven trans-Arctic voyages, all in summer, have been accomplished by icebreakers in the central Arctic Oc[illegible]

A voyage across the central Arctic Ocean with tourists was conducted by the Soviet nuclear icebreaker *Sovetskiy Soyuz* in August 1991. The Arctic Ocean Section 1994 Expedition, conducted by Canada's icebreaker *Louis S. St-Laurent* and the *Polar Sea* of the United States, was the first scientific transect of the Arctic Ocean accomplished by surface ship. During July and August 1994 both ships sailed from the Bering Strait to the North Pole and to an exit between Greenland and Svalbard through Fram Strait. The expedition made

extensive use of real-time satellite imagery (received aboard *Polar Sea*) for strategic navigation and scientific planning.

Two trans-Arctic voyages with tourists through the North Pole were accomplished by the Russian nuclear icebreaker *Yamal* in summer 1996. In summer 2005, Sweden's icebreaker, the *Oden*, and the American icebreaker *Healy* also made trans-Arctic passages in a second and highly successful scientific expedition by surface ships across the central Arctic Ocean.

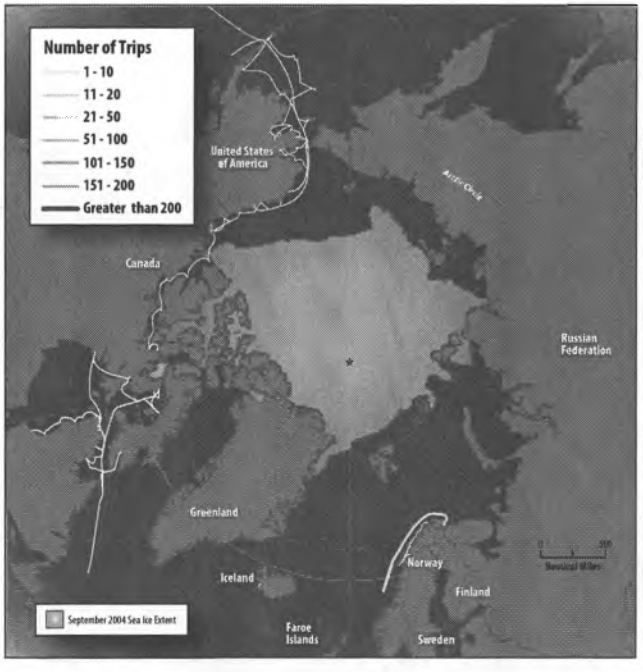
Although not a trans-Arctic voyage, the operation of a three-ship scientific expedition for Arctic seabed drilling during late summer 2004, mentioned earlier, is noteworthy included in the AMSA 2 004 database. The expedition was comprised of Russia's nuclear icebreaker *Sovetskiy Soyuz* and Sweden's *Oden*, both used extensively for ice management and the Norwegian-flag icebreaker *Vidar Viking* outfitted for drilling. One of the key accomplishments was the return of a 400-meter sediment core from the seabed that is being used for scientific studies of past Arctic climates.

A review of these historic polar voyages indicates that marine access in summer throughout the Arctic Ocean has been achieved by the 21st century by highly capable icebreakers. The nuclear icebreakers of the Soviet Union and later the Russian Federation have clearly pioneered independent ship operations in the central Arctic Ocean, especially on voyages to the North Pole in summer. Conventionally powered icebreakers have also operated successfully on trans-Arctic voyages in summer, as well as on scientific expeditions to high latitudes in all regions of the Arctic Ocean. Any planning for future navigation in the central Arctic Ocean would do well to understand the ship performance, environmental conditions and ice navigation capabilities of these successful operations in the ice-covered central Arctic Ocean.

mix of fishing, domestic cargo supply and cruise ships. The Barents Sea experiences the highest concentrations of marine activity in the Arctic region. Ships plying these waters include: bulk cargo carriers, oil tankers, LNG carriers, coastal ferries, fishing vessels, cruise ships and other smaller vessels. Many ships pass along the Norwegian coast and in Norwegian waters during bad weather en route to Murmansk and northwest Russia. There is tanker traffic in the region and ships servicing the Norilsk Nickel mining complex sail year-round from the port of Dudinka on the Yenisei River to Murmansk.

Marine Use: Arctic Community Re-supply

For 2004, community re-supply made up a significant portion of the ship traffic throughout the Arctic. In some areas of the region, this is also referred to as coastal Arctic shipping. In areas such as the Canadian Arctic, eastern Russia and Greenland, this activity was the basis for most ship traffic. Re-supply activities provide a lifeline to many communities that have no or very limited road access and no or limited capacity to handle heavy aircraft. Most communities serviced - mainly in Canada, the Russian Federation, Greenland, the United States, Svalbard and Bear Island - are ice-locked for parts of the year and rely heavily on marine transportation during the summer months for their dry foods, fuel, building materials and other commodities.



Map 5.2 Tug/barge traffic. *Source: AMSA*

Community re-supply and coastal Arctic shipping involve a range of ship types, including tankers, general cargo and container ships and, in some areas, tug/barge combinations. Tug/barge operations are particularly common in the western Canadian and Alaska Arctic and are used in these regions for mostly community re-supply, as well as for supplying mining and other construction projects. Tug/barge operations typically consist of a tug towing up to three barges. Depending on conditions, a tug/barge train can be a kilometer in length or more. Map 5.2 shows where the tug/barge activity took place, according to the data reported.

Summer resupply is handled by barge traffic along the Alaska Arctic, and in the Canadian Arctic a lack of deepwater ports requires lightering from larger supply ships at select Arctic communities. Lightering (shuttling goods from the anchored main ship to shore) is used to bring cargo ashore and tanker ships transfer petroleum products ashore by way of pumps and floating fuel lines, at many Arctic locations without deepwater access. There are select ports in Greenland, Svalbard and along the Northern Sea Route for normal cargo handling in small ports. Along the coasts of Norway and Iceland, and in Murmansk (northwest Russian Federation), all of which are ice-free year-round, there are deepwater port facilities to handle volumes of cargo from global shipping.

Community re-supply is expected to expand in the coming years due both to population increases in Arctic communities and increasing development in the region, stimulating demand for goods and construction materials. The 2004 AMSA data shows where this type of vessel traffic is occurring and can, therefore, serve as a good baseline tool when projecting future activity under various scenarios for population and economic growth.

Bulk transport of commodities such as oil, gas and various types of ore is a significant portion of total Arctic vessel traffic in 2004.

Marine Use: Bulk Transport of Ore, Oil and Gas

Bulk transport of commodities such as oil, gas and various types of ore is a significant portion of total Arctic vessel traffic in 2004 in volume of cargo transported. There are some very large mines in the Arctic producing commodities such as nickel, zinc and other ores, as well as oil and gas producing fields off the coast of Norway and in the Russian and U.S. Arctic. The Red Dog mine in Alaska is one of the world's largest zinc mines. The Norilsk Nickel mine near the port of Dudinka in the Russian Federation is also the world's largest producer of nickel and palladium. Nearly all bulk traffic in the Arctic is outbound, shipping extracted natural resources out of the region to the world's markets. In 2004, there were no Arctic transits of bulk goods east, west or through the central Arctic Ocean.

Most bulk transport takes place during the ice-free season or in ice-free parts of the Arctic including the Norwegian Arctic and parts of the Russian Arctic such as Murmansk. The exceptions are high-value perishable cargoes such as the concentrates from the Dudinka region and the nickel from Deception Bay in northern Quebec, Canada, which must be shipped year-round because they degrade if left too long without processing. In 2004, these two operations were the only all-season operations recorded in seasonally ice-covered parts of the Arctic, which demonstrates that given economic incentive, year-round operations may be possible in other areas where ice is a limiting factor. In other Arctic mining areas that are ice-locked throughout the winter, bulk cargoes are stored during winter and spring and are shipped out in the brief ice-free summer/autumn season. Because some of the mines, such as Red Dog, produce very large amounts of ore, the ice-free season means heavy traffic and carefully planned bulk shipments to ensure mines get all of the ore out before the fall ice forms. Large bulk carriers, Panamax and Handymax size up to 65,000 tons, visit Red Dog mine in Alaska during the short summer season. Many of the bulk carriers operating throughout the Arctic in the summer are not ice-strengthened or *Polar Class*.

Development of the rich natural resources in the Arctic is a rapidly growing industry. Since 2004, several significant new bulk shipments have begun operations, such as the year-round oil shipments out of Varandey in the Russian Arctic. In early 2008, an offshore lease sale conducted by the U.S. Minerals Management Service for the U.S. Arctic totaled nearly $US2.7 billion; offshore

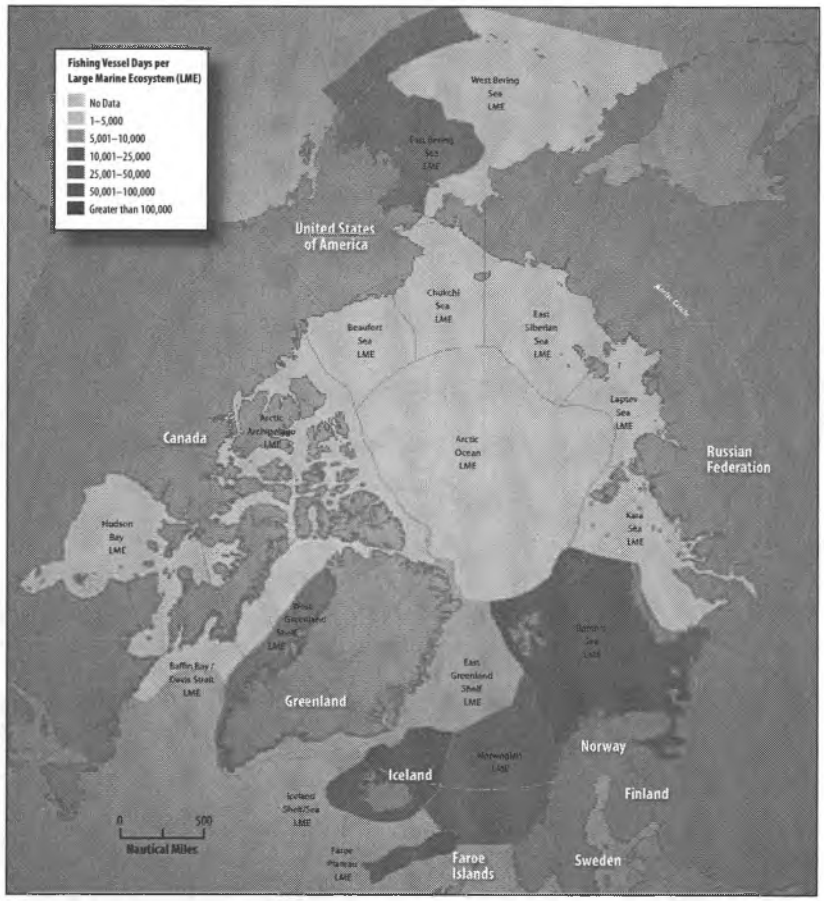
gas appears to be the resource under consideration for development in this Arctic region. In June 2008, the Government of Canada received record breaking bids for oil and gas exploration leases in the Beaufort Sea, including a $C1.2 billion bid for the rights to explore an offshore area of 611,000 hectares. In September 2008, a test shipment of some of the purest iron ore found on the planet was delivered to Europe from the Baffinland mine in Mary River on Baffin Island. Depending on the regulatory review, the mine could begin year-round operations in the next 3-5 years. As planned resource development projects such as these become operational, bulk carrier traffic in the Arctic will continue to increase. This type of ship activity is likely where the most growth will be witnessed in the near future.



Map 5.3 Fishing vessel activity. *Source: AMSA*

Marine Use: Fishing

Fishing vessel operations constitute a significant portion of all vessel activity in the Arctic in 2004, given that some of the world's most productive fisheries are in the Arctic region. The amount of fishing activity reported in the AMSA database almost certainly underestimates the amount of activity actually taking place, as there are regions of the Arctic for which no data was submitted, but there is known to be commercial fishing occurring. Also, much fishing activity is likely to take place on smaller vessels, which are, for the most part, not captured in the AMSA database. The reported fishing vessel activity takes place in a few key areas, including the Bering and Barents seas; on the west coast of Greenland; and around Iceland and the Faroe Islands. Very limited fishing activity occurs in the Arctic Ocean and the Canadian Arctic Archipelago, mostly small-scale food fisheries. Since fishing in the Arctic takes place up to the ice edge, not in close ice pack conditions, operations are in completely or seasonally ice-free or low ice concentration areas and opportunistic in nature. Fishing vessel activity in the database has been categorized according to the Large Marine Ecosystem in which the activity took place. LMEs are geographical entities defined as ecosystems based on a series of ecological criteria. Each comprises a fairly large sea area, typically 200,000 km² or larger, with distinct bathymetry, hydrography, productivity and trophically dependent populations.

Fishing vessel operations constitute a significant portion of all vessel activity in the Arctic in 2004, given that some of the world's most productive fisheries are in the Arctic region.

23
The number of commercial cruise ships transiting the Northwest Passage between 1984 and 2004.

Map 5.3 shows general levels of activity in each of the LMEs within the AMSA area of study and highlights those for which data was not available. Fishing vessel data is presented in terms of days in an area rather than as routes, because fishing vessels typically meander in search of catch rather than follow a specific itinerary. Although further analysis of the impacts of fishing or its potential growth fall outside the scope of this report, it is important to appreciate that fishing activity represents a significant proportion of all current vessel activity in the Arctic region in considering cumulative effects.

Marine Use: Passenger Vessels and Tourism

Passenger vessel activity represents a significant proportion of the vessel activity reported in the Arctic for 2004. The type of activity captured in the AMSA database includes ferry services, small and large cruise vessels and any other vessels where people are transported, whether for tourism purposes or otherwise. The type of activity taking place varies depending on its location. In Norway, Greenland and Iceland, some of the passenger vessel traffic consists of ferries, carrying people into and out of coastal communities. In other areas, such as Alaska and the Canadian Arctic, ferry services are non-existent and all passenger traffic would be vessels for marine tourism only. Some services, such as the Hurtigruten around Norway and ferry service to Iceland and Greenland from mainland Europe are hybrids, serving both as ferries and cruise ships. Map 5.4 presents the overall passenger vessel traffic in the Arctic for 2004.

Nearly all passenger vessel activity in the Arctic takes place in ice-free waters, in the summer season and the vast majority of it is for marine tourism purposes. In 2004, the only passenger vessels that traveled in ice-covered waters were the Russian nuclear icebreakers that took tourists to the North Pole, voyages they have been making for tourism purposes since 1990. The heaviest passenger vessel traffic in the AMSA 2004 ship activity database is seen along the Norwegian coast, off the coast of Greenland, Iceland and Svalbard. Though there was some passenger vessel traffic in the Canadian Arctic and Alaska, those numbers were small in comparison to the higher traffic areas.

Marine-based tourism is the largest segment of the Arctic tourism industry in terms of numbers of persons, geographic range and types of recreation activities. The size and type of vessels that service this industry range from relatively small expedition style vessels that hold less than 200 people, to large luxury cruise liners that can hold 1,000 or more. In the Arctic, marine tourism is highly diversified and is driven by five main types of tourists seeking out a range of activities. These include mass market tourists primarily attracted to sightseeing within the pleasurable surroundings of comfortable transport and accommodations; the sport fishing and hunting market driven by tourists who pursue unique fish and game species within wilderness settings; the nature market driven by tourists who seek to observe wildlife species in their natural habitats, and/or experience

the beauty and solitude of natural areas; the adventure tourism market driven by tourists who seek personal achievement and exhilaration from meeting challenges and potential perils of outdoor sport activities; and the culture and heritage tourism market driven by tourists who either want to experience personal interaction with the lives and traditions of indigenous people, or personally experience historic places and artifacts.

While Arctic ship-based tours are booked well in advance, many of the itineraries are somewhat opportunistic. The precise route and the ports and communities visited depend on the ice conditions and the difficulty and risk of access. Cruise ships often intentionally travel close to the ice edge and shorelines for wildlife viewing opportunities, increasing the risk of interaction with ice and other hazards. Many Arctic cruise ships visit destinations that were once totally inaccessible to the public, such as the North Pole, Northwest Passage and the Northern Sea Route. Between 1984 and 2004, 23 commercial cruise ships accomplished transits of the Northwest Passage; seven commercial tours were planned for 2008 alone.

According to the Cruise Lines International Organization, the number of passengers served worldwide has grown from about 500,000 in 1970 to more than 12 million in 2006. Additional growth is now occurring in the number and passenger capacity of new cruise ships entering the market. The Royal Caribbean's *Freedom of the Seas* entered the fleet in June 2007 with the largest passenger capacity yet – 3,634 – twice the size of ships built a decade ago. From 2000 to the end of 2008, 88 new cruise ships were introduced. The vast majority of these vessels were not constructed or designed to operate in Arctic conditions, yet as Arctic cruise tourism continues to grow, it is very likely that many of them may make trips to the region. The cruise ship industry considers Arctic voyages to be a vital and especially lucrative part of their international tourism product. This is apparent when considering the price that tourists pay to travel to this region. As of 2008, the prices for Arctic cruises range between $US2,900 and $US55,000 per person. The cruise ship industry has indicated that it not only intends to maintain an Arctic presence, but to expand in terms of ship passenger capacity, destinations and extended seasons of operations. This will be encouraged by circumpolar nations that consider tourism important for growing and strengthening their economies.

Cruise ship traffic in the Arctic region has increased significantly in the four years that have passed since the AMSA database was developed. An independent survey indicated more than 1.2 million passengers traveled in 2004 to Arctic destinations aboard cruise ships; however, by 2007 that number had more than doubled.

A specific example of where cruise ship traffic is increasing at a rapid rate is off the coast of Greenland. As Table 5.3 shows, cruise ship visits and the number of passengers visiting Greenland has increased significantly between 2003 and 2008. For example, between 2006 and 2007, port calls into Greenland increased from 157 to 222 cruise ships. The number of port calls in 2006 combined for a total of 22,051 passengers, a number that represents nearly half of Greenland's total 2006 population of 56,901.

In 2008, approximately 375 cruise ship port calls were scheduled for Greenland ports and harbors, more than double the number of port calls seen in 2006. The areas visited by the cruise vessels in Greenland are also changing. Likely driven by increased demand in adventure tourism, Tourism Greenland has reported that in the past few years there has been a marked increased interest in trips to the

Arctic Marine Tourism: A New Challenge

As passenger and cruise vessel traffic continues to increase in the Arctic, infrastructure and passenger safety needs will become of increasing concern. The large number of tourists already cruising Arctic waters now exceeds the emergency response capabilities of local communities (See page 172). The Arctic's cold air and water temperatures require the quick and efficient rescue of capsized vessels and tourists aboard lifeboats and rafts. Even limited exposure to cold weather and seas quickly reduces human endurance and chances of survival. These hazardous environmental conditions prevail in a region that has very scarce emergency response resources and where long distances result in lengthy response times. Emergency protocols become increasingly difficult as both small and large cruise ships seek remote wilderness settings and wildlife habitats. The primary polar attractions sought by tourists are rarely close to emergency response services. This combination of hostile environmental conditions and scarce emergency infrastructure is a serious threat to human life.

When performing search and rescue in the polar regions, there is an urgent need to respond quickly, as the prevention of injury and loss of life depends on timely response, prompt evacuation and the application of medical and other emergency response services. Effective responses can only be accomplished by the design and implementation of appropriate search and rescue management policies and programs, supported by appropriate physical infrastructure and well-trained personnel.

Ship evacuation produces a host of emergency response problems in the polar world. Passengers and crew must be sheltered from inclement weather, properly clothed, nourished and hydrated. The provision of these basic necessities in the polar environment, either sea or land, is formidable. The ability to successfully communicate a distress signal of any sort in the polar world can further exacerbate these threatening circumstances. Communications in the Arctic may be a challenge. However, ships equipped with adequate communication equipment (for example, digital selective calling-high frequency, or DSC-HF, and Electronic Position Indicating Radio Beacon, or EPRIB) are able to transmit distress messages.

© Harald Pinkler

It is not likely that communities located in the remote, high Arctic have sufficient medical resources to respond to illnesses involving hundreds, or perhaps thousands, of cruise ship passengers and crew. And given their histories, the indigenous people living in rural Arctic communities are understandably fearful of exposure to infectious diseases.

A dangerous consequence of the growing popularity and number of cruise ships operating in and transiting through polar waters is the significant increase of marine incidents. Serious marine incidents include sinkings, groundings, pollution and other environmental violations, disabling by collision, fire and loss of propulsion. Rapid increase in the number of cruise ship voyages has led to a similar increase in the number of incidents.

Given the large number of cruise ships and other recreational boaters currently operating throughout the polar seas and the probable growth of those markets, marine operators, Arctic governments and local communities are faced with significant management challenges.

far North of Greenland, an area that has traditionally not been visited by many tourists. In 2008, 28 vessels were scheduled to travel as far north as Uummannaq, some continuing on to Qaanaaq, both destinations far north of the Arctic Circle and far from good infrastructure or emergency response capabilities. Many of the cruise vessels traveling to these destinations are likely not ice-strengthened. Though this area is classified as ice-free in the summer, this does not mean that ice is not present and, even in small amounts, ice can pose a serious hazard. The Greenland government is very conscious of the rapid growth in cruise ship traffic in their waters and Island Command Greenland, the naval service covering Greenland waters that organizes both rescue and emergency operations, has recently put an increased focus on cruise activities in Greenland waters.

Passenger vessels, in particular cruise ships, is a sector that has experienced rapid growth in certain regions in the few years that have passed since the development of the AMSA database and is one which is expected to expand further in coming years. As this sector grows and more and larger ships begin to ply Arctic waters, it will become increasingly important to understand this type of activity so that Arctic states are prepared to meet the future needs of these vessels and their passengers.

Marine Use: Icebreaker, Government and Research Vessel Operations

Icebreakers, government and research vessels represent a relatively small proportion of the total vessel traffic in the Arctic. However, they are invaluable for surveying, oceanographic research, vessel escort in ice, salvage, pollution response and search and rescue. For the AMSA database, these vessel types were grouped since they conduct similar missions and also often carry out multiple tasks on a voyage. In the AMSA 2004 database, 83 of this type of ship were reported; however, several Arctic states did not include government vessels in their submission so the total for this category is likely larger. In keeping with the scope of the Arctic Council, naval or military vessels were not included in the AMSA database.

The icebreaker fleets of Canada and the Russian Federation conduct a range of tasks in their respective regions; summer sealift icebreaking duties are an important mission for these ships. Though several icebreakers might be capable of operating in the winter, nearly all icebreaker operations reported in the AMSA are conducted in the spring, summer and autumn. During summer 2004, the AMSA database indicates that there were eight voyages that reached the

Community re-supply is expected to expand in the coming years due both to population increases in Arctic communities and increasing development in the region, stimulating demand for goods and construction material.

Year-round Arctic Marine Transport to Dudinka in Support of Natural Resource Development and Production

Since the winter of 1978-79, one of the most advanced Arctic marine transport systems in the Arctic has been the year-round operation comprised of traffic between the mines of the Mining and Metallurgical Company Norilsk Nickel to the port in Dudinka, on the Yenisei River at the then 231 nautical mile sailing to Murmansk, on the Kola Peninsula.

MMC Norilsk Nickel is the world's largest producer of nickel and palladium, and is among the top four platinum producers in the world, as well as among the top 10 copper producers. MMC Norilsk Nickel is also a large global enterprise with production facilities in the Russian Federation, Australia, Botswana, Finland, the United States and the Republic of South Africa.

Mining in the Norilsk area began in the 1920s. The region quickly became a critical supplier of non-ferrous metals within the Soviet Union. During the 1950s, the Northern Sea Route Administration was tasked with building a year-round Arctic marine transport system on the western end of the NSR and into the Yenisei.

The development of large, nuclear icebreakers came first with the *Lenin* in 1959 (world's first nuclear surface ship) followed by a small fleet of larger icebreakers of the *Arktika* class. These icebreakers were designed to create tracks in the ice for lower-powered cargo ships to sail in convoy astern of a lead icebreaker.

With unlimited endurance, the nuclear icebreakers could provide year-round services in the deeper waters along the major routes of the NSR. Ice-strengthened cargo ships and shallow-draft icebreakers came next. By the 1978-79 winter season there was enough icebreaking capacity to maintain year-round navigation by convoying ships from the Yenisei west across the Kara Sea and into the Barents Sea to Murmansk. A continuous flow of non-ferrous metal concentrates could be maintained to smelters on the Kola Peninsula and to other industries in the Soviet Union.

During 1982-87, a new icebreaking cargo ship, the SA-15 or *Norilsk* class, was delivered by Finland's former Valmet and Wartsila shipyards to the Soviet Union. Nineteen of these Arctic freighters (174 m length and 19,950 dwt) were built and several today remain in service on the route between Dudinka and Murmansk.

In many respects, the *Norilsk* class multi-purpose carriers revolutionized Arctic shipping in the same manner as the commercial carrier *MV Arctic* developed for the Canadian Arctic during the same years. With high propulsion power (21,000 shp), the *Norilsk* class ships could operate under their own power as an icebreaker. These ships carried cargoes the length of the NSR in summer during the late 1980s; during the winter they were used effectively to support the Norilsk-Dudinka operation.

Their proven capability for independent navigation through ice fields without icebreaker support was a significant technological achievement, as well as a notable advance in efficient (and cost-effective) Arctic marine operations. The successful operation of these ships was a harbinger of the future for Arctic marine transport.

In April 1988, a new, shallow-draft polar icebreaker named *Taymyr* was delivered to the Soviet Union by Wartsila's Helsinki shipyard. A single nuclear reactor was installed at the Baltic shipyard in (then) Leningrad, and the ship was ready for service along the NSR and in the shallow Siberian rivers by 1989. A second ship of the class, *Yaygach*, was added to the Murmansk Shipping Company's icebreaker fleet in 1990.

The design of this class represents the apex in the development process for the Soviet nuclear icebreaker fleet. Combined in its design are Finnish advances in shallow-draft ship design with nuclear propulsion developed in the Soviet Union. A draft of only 8 meters was obtained with *Taymyr*, which compares favorably with the average 11-meters draft of the largest Soviet icebreakers of the period. A power plant producing 44,000 shp provided a capability of continuously breaking 1.8 meters of level ice at a 2-knot speed. These capabilities fit perfectly with the requirements for icebreaking (level river ice) on the shallow Yenisei River to the port of Dudinka; these extraordinary nuclear ships could maintain an ice track out to the Kara Sea through the winter in nearly all conditions.

Year-round shipping to Dudinka functioned throughout the 1990s and the early years of the new century despite the financial challenges facing the Russian Federation. MMC Norilsk Nickel was restructured several times and since 2001 the company has flourished, focusing on economic efficiencies, foreign marketing and potential investments. The marine transport component also received significant attention as the SA-15 *Norilsk* class ships supporting the Dudinka run began to age.

The company's marine operations department worked closely with the Finnish shipbuilder Aker Yards to develop a new freighter class that would be owned and operated by MMC Norilsk Nickel. The vision was for a fleet of five icebreaking containerships designed for year-round operations. The first of the ships, *Norilsk Nickel* (168 meter length, 14,500 dwt, 650 TEU capacity), was completed in Helsinki early in 2006. The new ship is designed as a "double-acting hull" and is fitted with an azimuthing pod for propulsion.

The Azipod concept, as it is called, allows the ship to move stern-first efficiently in the ice: the ship is designed to break 1.5 meter thick ice unassisted. In light ice or open water, *Norilsk Nickel* turns 180 degrees and moves bow first. Ice trials for the new ship were conducted in March 2006 in the Kara sea and Yenisei River, and the vessel achieved a 3-knot speed continuously moving through 1.5 meter thick ice.

Norilsk Nickel has performed well in operating unassisted (without icebreaker es[illegible] its initial two years of service. With four more of the class being built in Germany, MMC Norilsk Nickel will have an operational fleet of five icebreaking carriers, all highly capable of operating independently through the winter season to serve the port of Dudinka. Safe and efficient, the *Norilsk Nickel* class ships represent a new concept of Arctic marine operations. They will enhance a regional, Arctic marine transport system in western Siberia and better link a key Russian commercial enterprise to world markets.

North Pole, including a three-ship scientific expedition designed to drill into the Arctic seabed. The expedition was composed of the Russian Federation's nuclear icebreaker *Sovetskiy Soyuz*, Sweden's icebreaker *Oden* and the Norwegian-flag icebreaking drill ship *Viking Vidar*. During 2004-2008, there were 33 icebreaker transits to the North Pole for science and tourism. An increasing number of icebreakers and research vessels are conducting geological and geophysical research throughout the central Arctic Ocean related to establishing the limits of the extended continental shelf under UNCLOS.

Seasonality of Operations and Sea Ice Extent

The Arctic is defined by extreme seasonal variability, impacting the behavior of the animals that live in and migrate to and from the region, as well as human activity. Generally, most of the central Arctic is ice-covered, dark and very cold throughout the winter months. There are some areas, such as the Aleutian Island chain, the northern coast of Norway, southern Iceland and the Murmansk region in northern Russia where, due to ocean currents and other factors, ice does not form in the Arctic in the winter. However, these areas still experience darkness, extreme cold and variable conditions. The Arctic summer is the opposite extreme, with 24 hours of light and temperatures that can be uncomfortably warm. The pattern of vessel traffic in the AMSA database shows that vessel activity in the Arctic is highly affected by seasonal variability.

The AMSA GIS database includes Arctic sea ice maps for each month in 2004, with information collected and compiled by national ice administrations working cooperatively to create an Arctic sea ice picture. When layered with 2004 seasonal vessel traffic this data demonstrates how vessel traffic patterns interacted with the minimum sea ice extent at the time.

Maps 5.5 and 5.6 show the differences in sea ice extent between winter (January) and summer (July) traffic levels. Map 5.5 shows virtually no vessel activity in the central Arctic in the winter, although some takes place on the fringes in year-round ice-free zones. As mentioned earlier, the database indicates that only year-round commercial operations in the Arctic in seasonally ice-covered areas were into Dudinka in the Russian Federation and Deception Bay in Canada. These two operations were the only commercial icebreaking activities taking place in 2004; government icebreakers and research vessels conducted all other icebreaking that year. The data indicates that this was done only in the spring, summer and fall seasons.

Map 5.6 demonstrates the surge in vessel activity in the summer season, when all of the community re-supply takes place and most bulk commodities are shipped out and supplies brought in for commercial operations. Summer is also the season when all of the passenger and cruise vessels travel to the region. Wildlife in the Arctic also follows this pattern: although most species migrate

Source: AMSA

earlier in the spring before ice break-up, animals gather in large aggregations in the summer to feed and reproduce. This is important to consider when examining potential environmental and ecosystem impacts that may result from current or increased vessel activity in the region.

Summer and fall are the safest and most economical seasons for marine activity; therefore, activities such as resource development, tourism or community re-supply will most likely increase in the summer months. There may be a few exceptions, where high value commodities may drive year-round operations, but that will be driven by economics, not climate. If ice conditions continue to change and sea-ice extent reduces as predicted in the near term, the summer and fall shipping seasons will most likely lengthen. Even as perennial sea ice is reduced, winter in the central Arctic will remain inhospitable to marine navigation; therefore, future Arctic vessel activity will continue to be highly seasonal in the region.

Incidents and Accidents in the Arctic

The Arctic has always been and will continue to be a challenging environment for search and rescue and emergency response (See page 168). This is due to the very large geographic area involved and the relative low density of activity and response capabilities. In order to grasp potential threats to human safety and the marine environment as a result of potential incidents, it is important to understand what incidents may have occurred and where the areas are that have had the most incidents.

As part of the AMSA database, a summary of the incidents and accidents occurring in the Arctic region between 1995-2004 was developed. No one source of data was found to be sufficient to cover the circumpolar region; therefore a compilation of a number of sources was necessary to create the summary. The main sources

of information used were the Lloyds MIU Sea Searcher database, the Canadian Hydraulics Centre Arctic Ice Regime System database and the Canadian Transportation Safety Board (Marine.) Though this combined dataset is limited, it provides a basis for a very broad analysis of what type of incidents are occurring in the Arctic region and what areas may be more prone to incidents and therefore at a greater risk of further ones in the future.

The incidents and accidents were categorized by the type of incident that occurred, where and when it occurred, whether there were fatalities as a result, whether there was a significant oil spill involved and whether the vessel involved was considered a total loss for insurance purposes. Incident types were grouped into the following categories:

- **Grounding**: where a vessel came in contact with the bottom and, therefore, required assistance or significant effort to be re-floated. In some cases, vessels could not be re-floated and were either abandoned or broken up for salvage.
- **Collision**: where two vessels make contact resulting in minor to a serious damage to the vessel.
- **Damage to Vessel**: where damage to the vessel occurred, due to a variety of reasons ranging from contact with the pier, collision with ice, extreme weather or other factors.
- **Fire/Explosion**: where a fire or explosion occurred onboard a vessel, resulting in minor to very serious damage to the vessel and other consequences, such as fatalities.
- **Sunk/Submerged**: where a vessel was submerged in water for a period of time or sunk completely due to a range of causes.
- **Machinery Damage/Failure**: where a vessel sustained damage to machinery or complete machinery failure.

It is important to note that the incidents captured as part of AMSA excluded onboard incidents that may have involved injury to passengers and crew, but where there was no damage to the vessel. For a summary of the number and type of accidents and incidents involving vessels see Table 5.4.

Using the exact geographic locations for the different incidents and accidents, the data was entered into the GIS database, along with the different characteristics identified. The result was Map 5.7, which shows all of the reported incidents and accidents reported for the circumpolar region for the period of 1995-2004.

When looking at the geographic distribution of the incidents for the defined period shown in Map 5.7 there are certain gaps and trends that emerge. There is a complete absence of incidents reported in the Russian Arctic and there are some areas where there appears to be a concentration of incidents during the years collected. These areas are along the northern coast of Norway, around the Aleutian Island chain and in the Bering Sea, along the Labrador coast and in Hudson Strait in Canada and around Iceland and the Faroe Islands. These concentrations of incidents are consistent with the traffic patterns shown in the AMSA activity database – areas that show the concentrations of incidents are also those where the largest volume of vessel activity is occurring. This trend is even more apparent when the vessel routes for 2004 are shown on the same map as the incidents.

One of the most dramatic incidents in 2004 was the loss of life and sinking of the *Selendang Ayu* off the coast of Alaska. The incident is a graphic example of the key gaps in infrastructure, emergency response and salvage services that are readily available in other parts of the world's oceans.

The *Selendang Ayu* Disaster in the Alaska Arctic

On November 28, 2004, after loading 1,000 tonnes of fuel and 60,200 tonnes of soybeans, the *Selendang Ayu* departed Seattle, Washington, with a crew of 26 along the North Pacific Great Circle Route bound for Xiamen, China. Ten days later the 225-meter Malaysian-registered bulk carrier broke apart off the rugged coast of the Aleutian Islands of Alaska resulting in the deaths of six crew members, causing the crash of a U.S. Coast Guard helicopter and spilling an estimated 66 million metric tons of soybeans, 1.7 million liters of intermediate fuel oil, 55,564 liters of marine diesel and other contaminants into the environment further causing the deaths of seabirds and marine mammals (See page 151).

A U.S. National Transportation Safety Board marine accident brief is the basis for this report. Despite passing inspection by port authorities and U.S. Coast Guard officials prior to leaving Seattle, the seven-year old Panamax class vessel encountered engine problems approximately 100 nautical miles from Dutch Harbor, the closest place of refuge, and about 46 nautical miles from the nearest point of land. After leaving port in Seattle, the ship had encountered heavy seas and between gale and strong gale force winds.

On his second transit of the Bering Sea, the vessel's master, a citizen of India and a 32-year seagoing veteran, notified the harbormaster in Dutch Harbor via the vessel's satellite phone he was having difficulties and needed assistance. The Coast Guard immediately dispatched the cutter *Alex Haley* but because of the rough seas could only reach a top speed of 10 knots. Nearly six hours later, the cutter reached the *Selendang Ayu* and attempted to slow its drift toward the coastline by attaching a tow line to the vessel until the tugboat *Sidney Foss* arrived, which was then approximately 11 nautical miles away.

In the meantime, the wind and sea conditions continued to deteriorate. Arriving on scene, the tugboat master reported seeing the *Selendang Ayu* lying beam to the sea in 7.6-meter seas, hammered by 45- to 55-knot winds. Some crew members were desperately struggling to remain on the bow as the freighter rolled 25 to 35 degrees with waves crashing over the deck amid passing snow and ice squalls. The remainder of the crew, some who had been up for some 41 hours, worked frantically to restart the engines.

On the scene, the *Sidney Foss* was able to slow the drift but unable to turn the stricken ship's bow into the wind as the vessel drifted closer to the shore. A second tug, the *James Dunlap*, arrived from Dutch Harbor with sunrise 5 ½ hours away, noted the NTSB report. "Because of the sea state and the darkness, the masters of the *Sidney Foss* and the *James Dunlap* decided to wait until daylight before attempting to swing the bow of the *Selendang Ayu* around by putting a line on the stern."

Then, some three hours before sunrise, the towline parted and the stricken vessel continued its now unabated drift toward Unalaska Island. At sunrise, with the *Selendang Ayu* picking up speed toward the coastline, the ship's master dropped anchor in hopes to slow or even stop the drift. It almost worked.

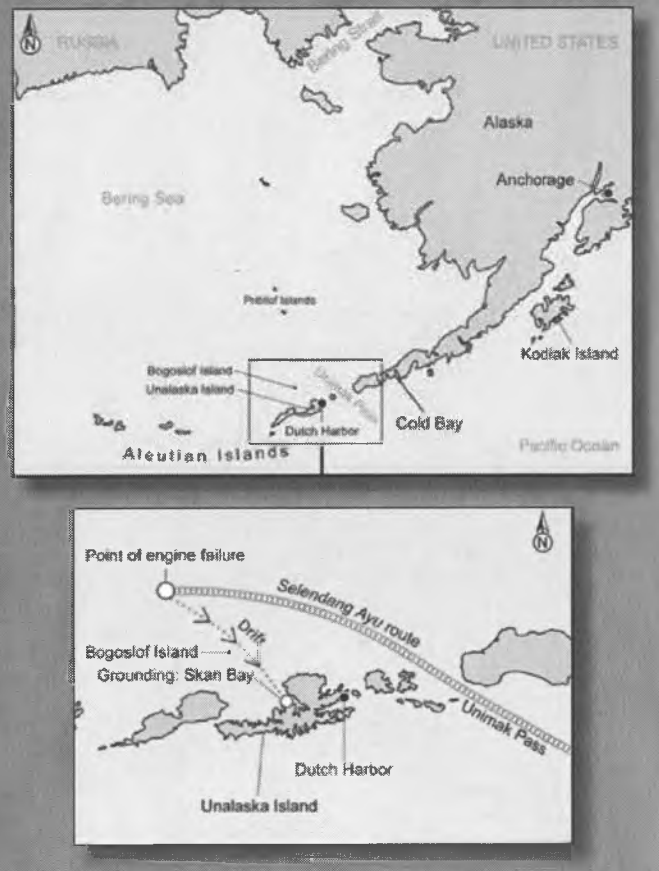
The port anchor immediately caught, slowing and almost stopping the vessel's drift. The feeling of relief was short-lived as some 15 minutes later the ship began slipping its anchor under the unrelenting pounding of the growing storm and started to drift at 2 knots toward shore. The weather continued to worsen with steep seas of 6 to 7.6 meters and periodic wind gusts of up to 65 knots, which occasionally pushed the waves to 9 to 10 meters. The Coast Guard suggested dropping the starboard anchor, "but the *Selendang Ayu* master said the starboard anchor might foul on the port anchor's chain," the report stated.

Several attempts to reestablish a towline failed and with now fading light and its proximity to shore, the Coast Guard recommended evacuating the crew. The master finally allowed a group of 18, those he considered the least essential for dealing with the emergency, to depart. Wearing lifejackets, but not the reddish-orange buoyant survival or immersion suit that protects against heat loss and ingress of water, they would be extracted in two groups. (At the time of the accident, the *International Convention for Safety of Life at Sea*, SOLAS, required a cargo vessel to carry at least three immersion suits for each lifeboat, unless the vessel had a totally enclosed lifeboat on each side. The *Selendang Ayu* carried two fully enclosed lifeboats, one port and one starboard and was equipped with three immersion suits. In an amendment effective July 1, 2006 the SOLAS regulation was changed to require one immersion suit for each person onboard a cargo ship. An exemption from this requirement for ships that voyage "constantly" in warm climates is not allowed for bulk carriers.)

Using a USCG HH-60 Jayhawk helicopter that had arrived from Cold Bay, Alaska, the first group of nine *Selendang Ayu* crew members were hoisted from the rolling deck. Then only a mile from shore, the ship's port anchor was dropped. It caught. Shortly thereafter, a second Jayhawk helicopter hoisted the second group of nine sailors from the ship. Eight crew members remained on board and continued to work frantically on the engines. As darkness began to close in, the Coast Guard radioed the master and said they wanted to remove the remainder of the crew before sunset. Then came the first of several shudders as the vessel ran aground on a small underwater shelf about 130 meters offshore. Knowing the ship's fate, the master radioed the *Alex Haley* and requested immediate extraction.

The eight remaining crew members gathered on the port bow, where the two previous evacuations had taken place. The vessel was rolling badly in the shallow water and increasing groundswell. Another HH-60 Jayhawk helicopter was dispatched from Dutch Harbor to the scene and a short time later the *Alex Haley* launched the smaller HH-65 Dolphin helicopter. Both aircraft reached the freighter around 6 pm with the larger Jayhawk helicopter performing the rescue. Fifteen minutes later all of the ship's crew, save the master and the USCG rescue swimmer, had been hoisted onboard when a huge rogue wave struck the bow of the freighter, sprayed up and engulfed the Jayhawk. The helicopter's engines stalled, spun around causing its tail and mail rotor blades to slam into the side of the crippled ship and crashed into the sea next to the *Selendang Ayu*'s forward port side. The Dolphin helicopter, which had been hovering close by, immediately went into rescue mode and quickly recovered the three-member flight crew and the one *Selendang Ayu* crew member who survived the

crash. With no other sign of survivors, the helicopter headed to Dutch Harbor. While the master and the Coast Guard swimmer were awaiting rescue, the ship broke in two on the rocks. After three hours of being bombarded by crashing waves, howling winds in total darkness, the ship's master and the USCG rescue swimmer were hoisted on board the Dolphin, which had returned from its trip to Dutch Harbor. It was 10:35 pm on December 8, nearly 60 hours since the *Selendang Ayu* engines failed.



Map 5.8 Accident location in Bering Sea. Inset shows route of *Selendang Ayu* through Unimak Pass, approximate point at which engine failed, path of vessel's drift without power, and site on Unalaska Island where it grounded.

Summary Discussion: Current Arctic Marine Use

As noted earlier, Arctic shipping has existed since the late 1400s, mostly on the periphery of the region. As in the past, most commercial activity today is generally linked to supplying communities or exporting raw goods out of the Arctic. The number of ships operating today in the Arctic is significant in the context of both the unique aspects of the Arctic environment and the insufficient infrastructure and emergency response in many parts of the region, relative to southern waters. However, from the outlook of the global maritime industry, the level of vessel activity found to occur in the 2004 baseline year is still relatively low. To put it into perspective, the total number of vessels reported as operating in the Arctic region (not including fishing vessels and the Great Circle Route traffic) represents less than 2 percent of the world's registered fleet of oceangoing vessels over 100 gross tonnage. Although the total vessels operating in the Arctic may represent a small proportion of the world's fleet, they can still have significant impacts on the environment in which they operate. At current shipping activity levels, it will not take many more ships operating in the Arctic in future years to double or triple the 2004 numbers.

Most shipping traffic in the Arctic is in waters that are either permanently or seasonally ice-free, an important distinction. Permanently ice-free waters include those in the Aleutian island chain, the northern coast of Norway, southern Iceland and the Murmansk region in northwest Russia. In other areas of the Arctic, which are seasonally ice-covered, nearly all the vessel activity occurring in 2004 took place in waters where the ice had melted or was melting and where icebreakers are not required for access. However, an area can be determined to be ice-free and still have ice-related dangers, such as bergy bits and pan ice, which are hard to detect and can damage a vessel.

In recent years, given the changing ice conditions in the Arctic, much attention has been paid to possible trans-Arctic shipping via the central Arctic Ocean, Northwest Passage or the Northern Sea Route. In the AMSA 2004 database, it was found that vessels operated on sections of both the NSR and NWP; however, there were no full transits by commercial vessels on any of three routes. The vessels reported as operating in the Northwest Passage were either community re-supply or Canadian Coast Guard. On the Northern

Sea Route, the only vessels reported were bulk carriers and tankers for community re-supply. None sailed the full route, and the only Russian traffic through the Bering Strait were bulk carriers servicing communities on the far northeast of Russia coming from the Bering Sea. In 2004, no ships transited the entire Arctic Ocean from the Pacific to the Atlantic or vice versa.

The only vessels that went into the central Arctic Ocean in 2004 were the eight trips made to the North Pole, three of which were research vessels carrying out a core drilling expedition and five Russian nuclear icebreakers for tourism purposes. Apart from those trips, all the vessel activity in 2004 took place around its periphery and largely in coastal waters.

In the four years that have passed since the AMSA 2004 baseline year for shipping activity, there has already been an increase in vessel activity in certain sectors. As discussed earlier, cruise vessels have been traveling to the Arctic in rapidly increasing numbers. There has also been new activity in other types of vessel traffic, particularly in the Barents, Kara and Norwegian seas. An Arctic tanker shuttle system has been established to support a route from a new Russian terminal in Varandey in the Pechora Sea to Murmansk and direct to global markets. The first 70,000 dwt tanker for this service, *Vasily Dinkov*, delivered its initial cargo to eastern Canada in June 2008; two additional icebreaking tankers for this operation have been built in South Korean shipyards. Two similar icebreaking tankers, under construction in St. Petersburg, will be used to ship oil from the Prirazlomnoye oil field in the northern Pechora Sea to a floating terminal in Murmansk. Again, year-round operations are envisioned in seasonally ice-covered waters, in this case to provide a continuous supply of oil to Murmansk for subsequent export by supertanker.

Off the coast of the Norwegian Arctic, the Snohvit ("Snow White") gas complex is now operational and its first shipment of gas arrived in Spain via an LNG carrier in October 2007; another shipment of Snohvit LNG was delivered to the U.S. East Coast in February 2008. LNG carrier operations out of northern Norway to world markets are poised to increase during the next decade and Norwegian Arctic offshore production is forecast through 2035.

In early 2008, an offshore lease sale conducted by the U.S. Minerals Management Service for the U.S. Arctic totaled nearly $US2.7 billion; offshore gas appears to be the resource under consideration for development in this Arctic region. Increasing Arctic marine operations off Alaska in the Chukchi and Beaufort seas to support oil and gas exploration are envisioned for the next decade.

While the AMSA database only looks at the year 2004, it is apparent, based on anecdotal information, that Arctic marine vessel activity is in a state of transition. The current types of vessel activities seen today are in support of community re-supply, bulk natural resource shipments, fishing and tourism. It appears there will be a growth in all Arctic shipping sectors, as well as the possible emergence of new opportunities.

Research Opportunities

- Develop a consistent and accurate circumpolar database of Arctic ship activity, as well as ship accidents and incidents to date.
- Trend analysis of shipping activity, using the 2004 AMSA database as the baseline.

Findings

1] There were approximately 6,000 vessels in the Arctic in 2004: nearly half the vessels were operating on the Pacific Great Circle Route, which crosses the Aleutian Islands and the southern Bering Sea. Of the remaining vessels, about 50 percent, or 1,600, were fishing vessels. The availability of data and reporting on Arctic marine activity varied greatly between Arctic states; several states could not provide comprehensive data for 2004. As a result, the AMSA database likely underestimates the levels of activity throughout the reporting year.

2] Marine activity took place throughout the Arctic in 2004 and in recent years icebreaking ships voyaged in the central Arctic Ocean in the summer. However, operations were primarily in areas that were ice-free, either seasonally or year-round.

3] The AMSA database indicates that no commercial vessels conducted trans-Arctic voyages on the Northwest Passage, Northern Sea Route or in the central Arctic Ocean in 2004.

4] Early in the 21st century there are only a few Arctic regions with year-round shipping in seasonal sea ice. These year-round operations are driven largely by natural resource development such as in the Canadian Arctic and northwest Russia.

5] Most shipping in the Arctic today is destinational, moving goods into the Arctic for community re-supply or moving natural resources out of the Arctic to world markets. Nearly all marine tourist voyages are destinational, as well.

6] Regions of high concentration of Arctic shipping activity occur along the coasts of northwest Russia, and in ice-free water offshore Norway, Greenland, Iceland and the Bering Sea.

7] Most of the Arctic fishing took place in the Bering and Barents seas, on the west coast of Greenland and around Iceland and the Faroe Islands.

8] The Arctic states do not generally collect and share Arctic marine activity data in any systematic manner.

9] Information about vessel incidents and accidents in the Arctic is not shared among Arctic states, other than through IMO processes. Knowing such information is an important step toward understanding and assessing future risks.

10] Cruise ship traffic into and around Greenland has increased exponentially in recent years. The majority of cruise ships observed recently in Arctic waters are not purpose-built for Arctic operations. Many are built for voyaging in open water in lower latitudes and warmer climates.

SCENARIOS, FUTURES AND REGIONAL FUTURES TO 2020

Plausible Futures for Arctic Marine Navigation

Marine use of the Arctic Ocean is expanding in unforeseen ways early in the 21st century. The continued depletion of natural resources in the world has led to an increase in interest in developing Arctic natural resources, and this interest has fostered a transformation of marine activity in the Arctic. In addition, regional climate change and the resulting Arctic sea ice retreat are providing for increased marine access in all seasons throughout the Arctic basin and its coastal seas. The AMSA takes a circumpolar view, but has also considered many regional and local issues where the impacts of expanded marine use may be greatest. The AMSA has also sought the views of the Arctic states, indigenous residents of the Arctic and many non-Arctic stakeholders and participants within the global maritime industry, so as to involve multiple perspectives.

The Arctic Climate Impact Assessment (ACIA) documented the recent changes in the Arctic sea ice cover: sea ice thinning, extent reduction and a reduction in the area of multi-year ice in the central Arctic Ocean. In addition, model simulations for the 21st century (using Global Climate Models) indicate increasing ice-free areas in all coastal Arctic seas, suggesting plausible increases in marine access and longer seasons of navigation. The AMSA has used the Arctic sea ice information from the ACIA and the 4th Assessment of the Intergovernmental Panel on Climate Change as guides to what marine access could be in future decades. The key task for the AMSA has been to understand more clearly the uncertainties that might shed light on the determinants of future Arctic marine operations. One way to do this is through the creation of a set of scenarios that are plausible, relevant and diverse.

© Aker Arctic Technology

AMSA Scenario Workshops

During 2007, scenario workshops were held in San Francisco (April) and Helsinki (July) to create a framework of plausible futures for Arctic marine navigation to 2050. The workshops were facilitated by Global Business Network, a pioneer in the application and evolution of scenario thinking, and drew some 60 maritime experts and stakeholders. The purpose of these strategic conversations was to identify the major uncertainties that would be critical to shaping the future of Arctic marine activity to 2020 and 2050. The use of different stories of future marine activity can indicate how critical uncertainties might play in ways that can challenge the Arctic states to make timely and effective decisions. The scenario narratives provide a rich source of material for strategic discussions about the future of marine safety and marine environmental protection among a diverse group of Arctic and non-Arctic stakeholders and decision makers.

Uncertainties from the Workshops

Participants in the AMSA scenario workshops identified nearly 120 factors and forces that could shape the future of Arctic marine activity by 2050. Among those factors deemed most important were: global trade dynamics and world trade patterns; climate change severity; global oil prices; the marine insurance industry; legal stability (governance) of marine use in the Arctic Ocean; the safety of other global trade routes (for example, the Suez and Panama canals); agreements on Arctic ship construction rules and global operational standards (International Maritime Organization); a major Arctic shipping disaster; limited windows of operation for Arctic shipping (the economics of seasonal versus year-round Arctic operations); the emergence of China, Japan and Korea as Arctic maritime nations; transit fees; conflicts between indigenous and commercial uses of Arctic waterways; new resource discoveries; an escalation of Arctic maritime disputes; a global shift to nuclear energy; and socio-economic impacts of global weather changes. This list of critical factors illustrates the great complexity and range of global connections surrounding future use of the Arctic Ocean (Table 6.1).

Key Uncertainties from the AMSA Scenarios Effort

Influences on the Future of Arctic Navigation

- Stable legal climate
- Radical change in global trade dynamics
- Climate change is more disruptive sooner
- Safety of other routes
- Socio-economic impact of global weather changes
- Oil prices ($US55-60 to $US100-150)
- Major Arctic shipping disaster
- Limited windows of operation (economics)
- Global agreements on construction rules and standards
- Rapid climate change
- China, Japan and Korea become Arctic maritime nations
- Transit fees
- Conflict between indigenous and commercial use
- Arctic maritime enforcement
- Escalation of Arctic maritime disputes
- Shift to nuclear energy
- New resource discoveries
- World trade patterns
- Catastrophic loss of Suez or Panama canals
- Maritime insurance industry engagement

Table 6.1 Key uncertainties from the AMSA scenarios effort. *Source: AMSA*

Illustration 6.1 Scenarios matrix. *Source: AMSA*

AMSA Scenarios Framework

The AMSA scenarios work created six potential matrices for framing a set of scenarios. Pairs of critical factors or uncertainties were chosen and crossed to produce candidate frameworks:

- Indigenous Welfare *crossed with* Resource Exploitation
- New Resource Development *crossed with* Maritime Disasters
- Climate Change *crossed with* Level of Trade
- Indigenous People *crossed with* Rise of Asia
- Legal Regime *crossed with* Value of Natural Resources
- New Resource Development *crossed with* Legal Regime

The strengths, weaknesses and applicability to the Arctic of each of these matrices were discussed. Through brainstorming and plenary discussions, two primary drivers and key uncertainties were selected as the axes of uncertainty for the final AMSA matrix:

Resource and Trade: the level of demand for Arctic natural resources and trade. This factor exposes the scenarios to a broad range of potential market developments, such as the rise of Asia or regional political instabilities. More demand implies higher demand from more players and markets around the world for Arctic resources, including increased access for trade in the Arctic Ocean. Less demand implies fewer players interested in fewer resources.

Governance: the degree of relative stability of rules for marine use both within the Arctic and internationally. Less stability implies shortfalls in transparency and a rules-based structure, and an atmosphere where actors and stakeholders tend to work on a unilateral basis. More stability implies a stable, efficiently operating system of legal and regulatory structures, and an atmosphere of international collaboration.

	Arctic Race	Polar Lows	Polar Preserve	Arctic Saga
Framing Uncertainties	▲ More Demand for Resources and Trade ◀ Less Stable Governance	▼ Less Demand for Resources and Trade ◀ Less Stable Governance	▼ Less Demand for Resources and Trade ▶ More Stable Governance	▲ More Demand for Resources and Trade ▶ More Stable Governance
High Concept	High demand and unstable governance set the stage for an economic rush for Arctic wealth and resources. This is a world in which many international players anxiously move to outwit competitors and secure tomorrow's resources today. Intense interest in Arctic natural resources.	Low demand and unstable governance bring a murky and underdeveloped future for the Arctic. This is a world in which domestic disturbances divert attention from global issues, and simmering frictions cause prolonged divisiveness. Global financial tensions are prevalent.	Low demand and stable governance slow Arctic development while introducing an extensive eco-preserve with stringent "no-shipping zones." This is a world where concern about the environment, coupled with geopolitical and economic interests elsewhere, drives a movement toward a systematic preservation of the Arctic Ocean.	High demand and stable governance lead to a healthy rate of development that includes concern for the preservation of Arctic ecosystems and cultures. This is a world largely driven by business pragmatism that balances global collaboration and compromise with successful development of the resources of the Arctic.
Primary Drivers of Change	• Global competition among many nations for future rights to resources intensified by rise of Asia; new oil & gas discoveries • Acute demand for water worldwide; continuing Middle East tensions • Climate warms faster than models predicted; tourism expands	• Global economic downturn and increasing national protectionism • Increased domestic troubles worldwide, including regional outbreaks of new-generation Avian flu • Recession of Arctic ice slower than models projected	• Arctic oil and gas reserves disappointing • Alternative energy emerges as viable source for global growth • Public concern about climate change and conservation, especially impacts to the Arctic	• Expanded global economic prosperity • Systematic development of oil, gas and hard mineral resources • Shared economic and political interests of Arctic states • Climate warms as expected
Implications for Arctic Marine Navigation	• Much activity dominated by destinational traffic supporting resource development • Unilateral governance regimes lead to inconsistent infrastructure with incompatible standards • Seasonal trans-Arctic passage possible, but not economical	• Minimal Arctic marine traffic, consisting of government re-supply and research, with periodic disruptions • Market for ice-class ships cools, reducing R&D and shipbuilding • Low attention to regulations, with unenforced and mismatched standards, and no new infrastructure	• Harmonized rules for Arctic ship design and mariner training • Seasonal trans-Arctic shipping possible but proves prohibitively expensive due to environmental restrictions, frequent patrols and aggressive enforcement • Growth of Arctic marine tourism allowed through limited number of "use permits"	• Wide range and variety of marine activity • Navigational infrastructure and aids expanded, making marine transport safer and more efficient • Comprehensive international Arctic ship rules • New technologies make seasonal trans-Arctic shipping a possibility

Scenarios

Scenarios are tools for ordering one's perceptions about alternative future environments in which today's decisions might be played out. In practice, scenarios resemble a set of stories, written or spoken, built around carefully constructed plots. Stories are an old way of organizing knowledge; when used as strategic tools, they confront denial by encouraging - in fact, requiring - the willing suspension of disbelief. Stories can express multiple perspectives on complex events; scenarios give meaning to these events.

Scenarios are powerful planning tools precisely because the future is unpredictable. Unlike traditional forecasting or market research, scenarios present alternative images instead of extrapolating current trends from the present. Scenarios also embrace qualitative perspectives and the potential for sharp discontinuities that econometric models exclude. Consequently, creating scenarios requires decision-makers to question their broadest assumptions about the way the world works so they can foresee decisions that might be missed or denied.

Within an organization, scenarios provide a common vocabulary and an effective basis for communicating complex - and sometimes paradoxical - conditions and options. Good scenarios are plausible and surprising; they have the power to break old stereotypes, and their creators assume ownership and put them to work. Using scenarios is rehearsing the future. By recognizing the warning signs and the drama that is unfolding, one can avoid surprises, adapt and act effectively. Decisions that have been pre-tested against a range of what fate may offer are more likely to stand the test of time, produce robust and resilient strategies and create distinct competitive advantage. Ultimately, the result of scenario planning is not a more accurate picture of tomorrow but better thinking and an ongoing strategic conversation about the future.

The chosen axes met three key criteria: degree of plausibility, relevance to the Arctic and maritime affairs and being at the right level or threshold of external factors. The roles of global climate change and continued Arctic sea ice retreat are fully considered in the AMSA scenarios. Retreating Arctic sea ice acts as a facilitator and is assumed to provide opportunities for improved marine access and potentially longer seasons of navigation. For the AMSA, globalization of the Arctic and development of natural resources are the primary drivers for increased marine use in the region. Greater access facilitates that use, but economic drivers are considered paramount.

Table 6.2 illustrates the crossed uncertainties (Resources & Trade and Governance) and outlines four resulting scenarios central to the message of the AMSA. The Arctic Race scenario, with high commodity prices and demand for Arctic natural resources, implies an "economic rush" for development, based in part on global markets, not a geopolitical "race" for sovereign rights or new territory. This is a region where the international maritime community has moved into the Arctic Ocean for resource extraction and marine tourism at a time when there is lack of an integrated set of maritime rules and regulations, and insufficient infrastructure to support such a high level of marine activity.

Polar Lows is a future of low demand for resources and unstable governance: a murky and undeveloped future for the Arctic. There is minimal marine traffic in the Arctic Ocean in this scenario and low attention is given to regulations and standards that remain weak and undeveloped.

Polar Preserve is a future of low demand, but with a stable and developed governance of marine use. This also is a world where environmental concerns, with geopolitical and economic interests focused elsewhere, drive a movement toward a systematic preservation of the Arctic. In this scenario, Arctic oil and gas reserves are disappointing, and there is strong public concern about climate change (environmental awareness is high) and conservation impacts on Arctic affairs.

Arctic Saga is a future of high demand for resources and trade coupled with a stable governance of marine use. This world leads to a healthy rate of Arctic development that includes concern for the preservation of Arctic ecosystems and cultures, and shared economic

and political interests of the Arctic states. There is improved marine infrastructure making marine transportation safer and more efficient, supporting systematic and safe development of oil, gas and hard minerals.

Arctic State Challenges from the Scenarios

A significant challenge facing the Arctic states is to recognize the international nature of shipping in the Arctic Ocean and to effectively engage with a very broad range of non-Arctic actors, stakeholders and decision-makers. Recognition of this global reach of the maritime industry also includes a responsibility to work toward balancing historic navigation rights under UNCLOS with regimes and mechanisms designed to enhance marine safety and to protect the Arctic marine environment. A major task will be for the Arctic states to convince the IMO membership to take into account the uniqueness of marine operations in the Arctic and work within the IMO and other global organizations for international standards. The Arctic states must also recognize there may be a host of new maritime players at the table with a stake in the future use of the Arctic Ocean.

If the retreat of Arctic sea ice continues, marine access should improve throughout the Arctic basin. Complementing this change will be new Arctic ship designs that will also allow greater access and independent operations (without icebreaker escort) during potentially longer seasons of navigation. Such extended marine operations will require greatly expanded search and rescue cooperation and expanded regional environmental response networks. Information and data sharing may also be a key to the future of the maritime Arctic.

Expanded surveillance and monitoring of marine operations, particularly in the central Arctic Ocean, will require agreements among the Arctic states (and other interested parties such as flag states) for the rapid transfer of ship transit information. Monitoring of the environment could be enhanced by the establishment of a Sustainable Arctic Observing Network (SAON), an activity that was promoted during the International Polar Year. Expanded traffic in the central Arctic Ocean will provide new and unique challenges to the Arctic states and the global maritime community, since there will be a lack of communications, salvage and other critical infrastructure.

The AMSA scenarios effort has identified three key issues, among many, for the Arctic states: the ongoing globalization of the Arctic through natural resource development and resulting destinational marine traffic; arrival of the global maritime industry in the Arctic Ocean with Arctic voyages of large tankers, cruise ships and bulk carriers on regional and destinational voyages; and the lack of international policies, until now, in the form of maritime governance to meet this arrival.

The Arctic states will continue to be challenged by a widespread lack of adequate maritime infrastructure to cope with current and future levels of Arctic marine operations. In order to better enhance marine safety and environmental protection, the Arctic states working within the IMO could develop an integrated, or complementary, system of rules and regulations governing Arctic marine activity. The Arctic states must continue to engage non-Arctic states and global institutions that will influence the future of Arctic marine operations. More cooperation in Arctic maritime affairs among the eight Arctic states will be an imperative to address complex marine use issues in an uncertain future.

Future Natural Resource Development

A U.S. Geological Survey report, issued in July 2008, indicates the Arctic may contain as much as one-fifth of the world's undiscovered oil and natural gas. More specifically, the assessment found the Arctic to potentially contain 90 billion barrels of undiscovered oil and 1,670 trillion cubic feet (47 trillion cubic meters) of undiscovered natural gas, representing 13 percent of the undiscovered oil and 30 percent undiscovered natural gas. Of the total for undiscovered oil reserves, more than half are estimated to occur in geologic provinces in the Alaska Arctic (offshore and onshore), the Amerasian Basin (offshore north of the Beaufort Sea) and in West and East Greenland (offshore). More than 70 percent of the undiscovered natural gas is estimated to be located in three areas: the West Siberian Basin (Yamal Peninsula and offshore in the Kara Sea), the East Barents Basin (location of the Russian Federation's giant offshore Shtokman field) and the Alaska Arctic (offshore and onshore). Each of these regions would require vastly expanded Arctic marine operations to

© Stena Drilling

support future exploration and development. Several regions, such as offshore Greenland, would require fully developed Arctic marine transport systems to carry hydrocarbons to global markets.

Despite the recent global recession, two Arctic nations, Norway and the Russian Federation, have already made significant investments during recent decades in developing Arctic hydrocarbons in offshore Arctic Norway and northwest Russia's offshore systems in the Pechora Sea. Arctic marine transport systems support each of these developments, and oil and LNG tanker traffic from the Barents Sea to world markets is expected to continue for several decades.

For the Russian Federation, future investments in developing the Shtokman gas field west of Novaya Zemlya in the east Barents Sea are evolving. This field, understood to be one of the world's largest gas fields, lies 600 kilometers offshore and in depths of water to 2,000 meters. Exploration and development of this large, offshore region will require extraordinary levels of Arctic marine operations, most conducted in waters that are not ice-covered, but under extreme cold temperatures. Natural gas from Shtokman would be transported by sub-sea pipeline or a marine tanker system, either of which would increase marine operations in this region of the Arctic. For the United States (Alaska) and Canada, where offshore Arctic lease sales were held for the Chukchi (U.S.) and Beaufort (Canada) seas in 2008, the future remains uncertain. The leases represent long-term, strategic investments. Marine exploration of the Arctic offshore should continue during the next decade.

One of the key factors in future Arctic offshore developments is that a majority of the seabed oil and gas resources are located within the Exclusive Economic Zones (EEZs) of the Arctic states (i.e., Arctic offshore regions of Alaska, Canada, Norway, Greenland and the Russian Federation). While there remain several, regional boundary disputes where potential resources may overlap, the general jurisdictional issues are clear and do not appear to be significant obstacles to future Arctic hydrocarbon development.

Hard minerals development in the Arctic will continue to be influenced by global commodities markets and prices. However, the largest zinc mine in the world (Red Dog in the Alaska Arctic) and the largest nickel mine (Norilsk in Siberia) will continue to be solely dependent on marine transport systems - seasonal in the case of Red Dog and year-round operations for Norilsk Nickel. It is plausible that the summer, ice-free season for support to the Red Dog mine could be extended as Arctic sea ice continues to retreat in the Chukchi Sea.

The Mary River iron ore deposits on Baffin Island, Nunavut in the Canadian Arctic represent a highly valuable mineral resource (high grade iron ore of 67 percent iron). Plans have been underway for some time to develop a mining operation and ship to European markets 18 million tons of ore each year, estimated to last for a minimum of 25 years. This is a large Arctic project that would involve a fleet of ice-capable cargo carriers operating on a year-round basis between Baffin Island and Europe. Ice navigation would be required for operations in the winter and early spring.

Greenland geology records more than four billion years of earth history, preserving significant mineral deposits. For example, the Kvanefjeld Project near the southwest tip of Greenland represents a multi-element deposit containing rare elements, uranium and sodium fluoride. Potentially world class and multi-commodity ore deposits exist in other regions of coastal Greenland. The exploration and development of these mines will require Arctic marine transport systems to carry these scarce commodities to global markets.

Future Arctic Marine Tourism

Tourists now represent the single largest human presence in the Arctic and the overwhelming majority of these visitors travel aboard ships. The Arctic's once forbidding marine environment now attracts growing numbers of tourists aboard more and larger ships to a greater diversity of Arctic destinations. The future of Arctic marine tourism represents serious challenges to public authorities and businesses seeking to address the issues of safe passage and resource management.

Managing Future Marine Tourism

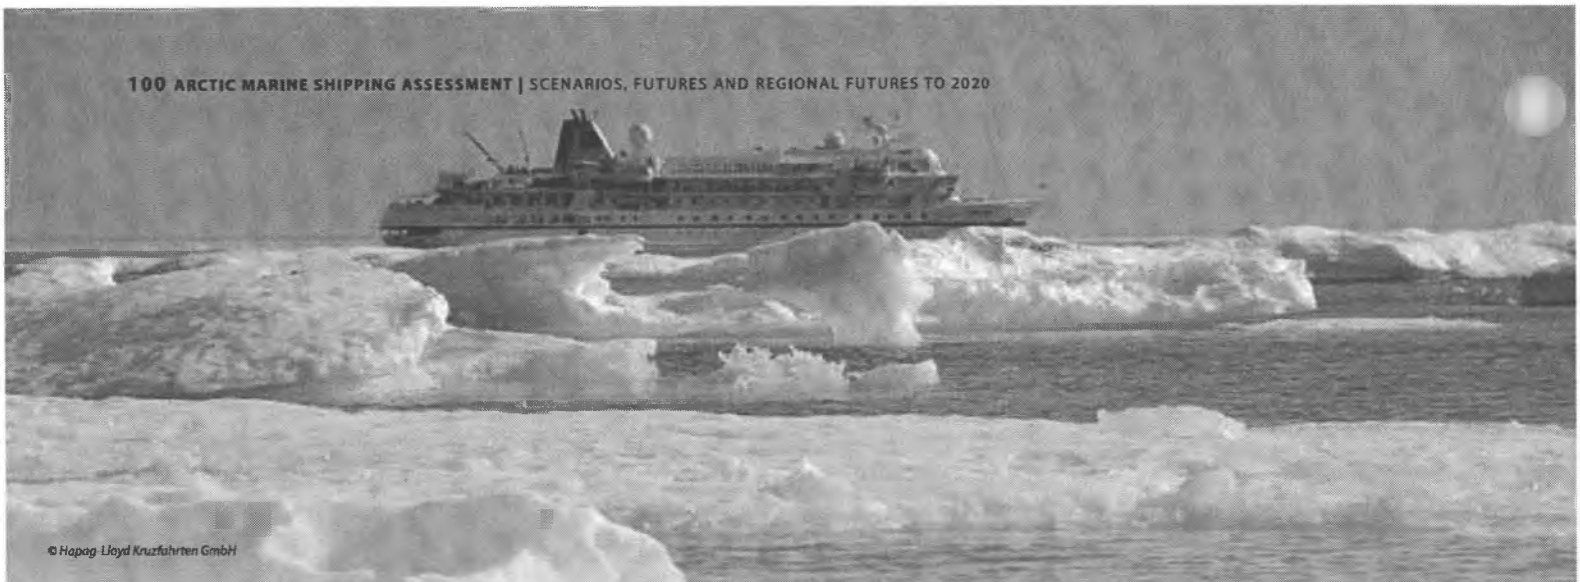
The growing popularity of polar marine tourism and the cruise industry's intentions to expand and diversify its polar market are creating significant management challenges. Foremost among those challenges are ice and weather conditions, lack of reliable hydrographic information, insufficient capacity of infrastructure to respond to emergencies, remoteness of tourist transits and destinations and the sheer size of vessels serving the polar cruise market. The legal and regulatory context defining appropriate ship and tourism operations consists of international treaty conventions, national laws, adopted regulations, industry guidelines and consensus-based guidelines brokered by non-governmental organizations. Governments, the tourism industry and non-governmental organizations are all determining the operational parameters for polar marine tourism through a variety of mechanisms.

National Laws and Regulations

The eight Arctic nations have enacted and enforce numerous laws and regulations governing marine operations and pollution. Based on international regulations, the national laws provide a framework to protect the Arctic environment, promote human safety and provide for a coordinated response to marine incidents, as well as enabling cooperation among the Arctic states. National attempts to regulate marine tourism extend from exceedingly stringent controls to considerably more flexible management techniques. Norway's government, for example, plans to significantly restrict cruise ship traffic around the Arctic archipelago of Svalbard and prohibit the use of heavy fuel oil. The new rules will limit to 200 the number of passengers allowed on board each ship that enters nature preserves on East Svalbard, and those tourists who are allowed entry are paying a special environmental tax. Another approach to the management of marine tourism, currently implemented by the U.S. government and the State of Alaska, is the use of onboard rangers who perform monitoring and pollution enforcement responsibilities. Some Arctic governments find themselves with the challenge of simultaneously trying to protect the environment while also promoting tourism.

Self-Imposed Industry Guidelines and NGO Codes of Conduct

Expedition cruise ship companies operating in both the Arctic and Antarctic are utilizing self-imposed guidelines to enhance marine operations, visitor safety and provide environmental and cultural resource protection. The creation and application of self-imposed industry guidelines for the conduct of environmentally responsible and safe polar tourism began with the formation of the International Association of Antarctic Tour Operators (IAATO) in 1990. The guidelines specifically address the management issues of ship operations, visitor behavior ashore, emergency response plans, the protection of Antarctica's marine and land resources and the preservation of



© Hapag-Lloyd Kreuzfahrten GmbH

the southern continent's heritage resources. IAATO's *Emergency Contingency Plan* has been successfully implemented on several occasions and is constantly updated to improve emergency response capabilities. Given the fact that these guidelines are directly relevant to polar conditions, marine tourism operations and the management of tourists when ashore, Arctic governments, communities and tour operators should benefit from their application to Arctic tourism.

The Association of Arctic Expedition Cruise Operators (AECO) was founded in 2003 for the purpose of "managing respectable, environmentally friendly and safe expeditions in the Arctic. The members agree that expedition cruises and tourism in the Arctic must be carried out with the utmost consideration for the vulnerable natural environment, local cultures and cultural remains, as well as the challenging safety hazards at sea and on land. AECO members are obligated to operate in accordance with national and international laws and regulations and agreed upon AECO by-laws and guidelines." AECO's offices are located in Longyearbyen, Svalbard, Norway and its geographical range in 2008 was Svalbard, Jan Mayen and Greenland. AECO developed its guidelines with considerable input from the Governor of Svalbard, Norwegian Polar Institute, World Wildlife Fund for Nature's Arctic Program, as well as Greenland Tourism, Greenland Home Rule, The Environmental and Nature Agency, and others. Participation by all Arctic coastal states would strengthen the association and its goals.

The WWF's program, in cooperation with tour operators, conservation organizations, managers, researchers and representatives from indigenous communities, has created the *Principles and Codes for Arctic Tourism*. The 10 principles encourage tourism development that protects the environment as much as possible, educates tourists about the Arctic's environment and peoples, respects the rights and cultures of Arctic residents and increases the share of tourism revenues that go to northern communities.

The Importance of Infrastructure

Infrastructure, defined for the purpose of marine tourism management, includes both the physical and human resources needed to prevent harm potentially arising from ship operations. Polar tourism currently operates in regions of the world that have either few or no infrastructure resources (See page 154). In many regions of the Arctic, the capacity to prevent loss of human life, protect property, contain environmental contamination, monitor sensitive resources and enforce laws is greatly diminished by remoteness, lack of capacity and severe environmental conditions.

Arctic nations, both individually and collectively, are legally responsible for providing infrastructure in order to prevent loss of life, property and environmental damage. These responsibilities are clearly within their sovereign domain of providing for the health, safety and welfare of their citizens, visitors and their environmental resources. The amount of information, facilities, equipment and human resources is not sufficient to meet the Arctic's current and anticipated volume of vessel traffic. For example, the number of passengers aboard polar cruise ships far exceeds the capacity of search and rescue assets, medical facilities and shelters needed to protect evacuees from the cold.

Factors Influencing the Future

A plausible future for Arctic marine tourism is that it will continue to grow, diversify and geographically expand as current obstacles are overcome. The most significant barriers influencing Arctic tourism include physical access, the ability of tourists to pay, the time and cost associated with traveling to remote destinations, the availability and capacity of infrastructure, environmental conditions and jurisdictional restraints that prohibit or restrict entry.

Arctic marine tourism's most likely future is that larger numbers of tourists, traveling aboard increased numbers of ships of all types, will be spending more time at more locations. The Arctic's environment, community infrastructure, social institutions and cultural values will be increasingly vulnerable to tourism-caused

Trans-Arctic Container Vessel Shuttle Option

Using the most modern container vessel design for the Arctic, it is technically feasible to establish a container traffic link between North America and Europe via the Northern Sea Route, a 2005 study concluded.

The evaluation, funded by the Institute of the North and executed by Finnish-based Aker Arctic Technology, used ice operational simulations and only evaluated the feasibility of vessel design, not the economic feasibility of the concept. Such economic analysis is still needed before a trans-Arctic shuttle operation can be considered as a serious alternative to today's route via the Panama Canal.

Assuming twin trans-shipment ports in Alaska and Iceland, the study evaluated vessels that were 750 TEU and 5,000 TEU. The simulations were based on two different kinds of years, average winter ice conditions and severe winter ice conditions, for both vessels. The evaluation used the double-acting operation design which allows the vessel to travel the traditional bow ahead in open water and, by using a propeller system that turns 180 degrees, to go stern ahead in ice-covered waters.

The 750 TEU Arctic container vessel for the study was a modified version of the Norlisk Nickel's *Arctic Express*, which moves nickel plate year-round and without icebreaker assistance between the ports of Dudinka and Murmansk in the Russian Federation (See page 82). The theoretical study vessel was modified from carrying nickel plate to container storage both below and above deck. The design also doubled the size of the fuel storage due to the longer sailing required. The ship could ply the shallow waters near the coastline of northern Russia, but simulation runs indicated it would need some traditional icebreaker assistance in severe winter conditions.

The 5,000 TEU vessel used the same icebreaking design, just on a larger scale. While the larger vessel will accommodate more containers, the size and especially the draft of 13.5 meters would prohibit it for use along the traditionally shallow-draft route of the NSR.

While the study does not look at the cost of fairway fees in this scenario, it does note that the current fee structure along the NSR is based on the paradigm of using icebreakers and "paying potential. Therefore, today the movement of natural resources along the NSR pays high fees whether using icebreaker assistance or not. This type of fee policy is not suitable for cargo vessels that are capable of independent operations, as the fee should be paid if the icebreaker assistance is needed, according to the study.

As noted, it is anticipated that the smaller study vessel would need icebreaker support some of the year, while the larger vessel would not. However, if the 5,000 TEU ship needed assistance it would require two icebreakers due to the width of the vessel. Another issue the larger study vessel poses is the ability to travel outside the traditional NSR routes.

Using only economic input related to the cost of the vessel, the operational costs, the amount of cargo that could be delivered and other related issues, the transport cost from the Aleutian Islands in Alaska to a port in Iceland via the NSR for the larger study vessel would be between $US354 TEU and $US526 TEU, and between $US1,244 TEU and $US1,887 TEU for the smaller container ship. It needs to be noted again that these figures do not include all of the economic considerations that are needed to make an accurate evaluation, such as fairway/icebreaker fees, port infrastructure costs, terminal and harbor costs and the cost to offload cargo onto the shuttle vessel, as well as transferring it back to an open-ocean vessel after reaching the twin port.

"All of these factors are unclear, uncertain and difficult to estimate," the study [illegible] "[illegible] of them might be the fairway fees, of which a current estimate of $US900 to $US1,000 TEU can be given for traffic" in 2005. "The second could be the cost for building and running the terminals which could be in the same category as the cost of the vessels. Of course, the terminals for the large and effective 5,000 TEU vessel are much more expensive than those for the 750 TEU vessel, but cost per container may be lower for the larger traffic volume. Of less importance and even more difficult to clarify and estimate may be the feeder link cost. Even the existing system using the southern route includes feeder links to the container hub ports and how this picture would be changed for the Arctic Shuttle Container Link remains to be clarified. However, it is expected that extra costs compared to the prevalent system could be created."

impacts. Simultaneously, Arctic governments, communities and businesses increasingly promote tourism and invest their resources to expand this type of economic development. The cruise ship industry, responding to the popularity of polar tourism and clear evidence of profitability, is committed to send more ships with larger passenger capacities to Arctic destinations. All of these significant investments and aggressive promotion by industry, governments and communities insures that Arctic marine tourism will continue to grow and that its management is essential.

Challenges of Trans-Arctic Navigation

For more than three centuries explorers and entrepreneurs have envisioned a direct route across the top of the world between the Pacific and Atlantic oceans. However, the Arctic sea ice cover - more than 2,100 nautical miles of sea ice present except in summer - has always been a significant physical barrier to developing such a global trade route. Although no commercial cargo ship has yet to cross the central Arctic Ocean, there have been trans-Arctic voyages during the summer season along the Russian Federation's Northern Sea Route and the Northwest Passage in the Canadian Arctic. Support was normally required by modern icebreakers leading ice-strengthened merchant ships in convoy. This system of transport was particularly the norm during the era of the Soviet Union when cargoes were carried during a short summer navigation season across the length of the NSR. In recent years, there were no cargo ships undertaking trans-Arctic voyages along either the NSR or NWP. Several ice-strengthened cruise ships and icebreakers have carried tourists on recent trans-Arctic voyages in summer. The fact remains that only six, high-powered polar icebreakers (nuclear and diesel-powered) have successfully navigated across the central Arctic Ocean and each of these voyages was conducted in summer.

The AMSA is focused on marine safety and environmental protection consistent with the Arctic Council's mandates of environmental protection and sustainable development. Neither the Arctic Council nor this assessment are the appropriate vehicles to determine the economic viability of any potential Arctic trade route, whether destinational or regional, intra-Arctic or trans-Arctic using the NSR, NWP or the central Arctic Ocean. For the purposes of the AMSA, the marine safety and environmental protection measures to be developed and implemented in accordance with international laws are essentially independent of the mode of Arctic marine transport. It is the global maritime industry that will decide if and when the potentially shorter Arctic routes can be safe, efficient, reliable and economically viable in comparison to other routes across the world's oceans. The marine insurance industry and ship classification societies will have significant influence in these route determinations, as will a host of other stakeholders and actors including investors and shipbuilders.

The AMSA has indicated, using a scenario-based strategic approach, that the primary mode of marine transport throughout the Arctic Ocean is destinational traffic related to natural resource development and regional trade. New economic linkages in the Arctic to global markets are influenced by commodities prices for scarce natural resources such as oil and gas; nickel, zinc, palladium, copper, platinum and high grade ore. Current and new Arctic marine transport systems and commercial ship traffic are primarily tied to the global demand for these resources.

The international media and proponents continue to provide broad visibility to the possibility of trans-Arctic navigation, postulating that commercial routes will be viable and fully functional in the near future. This premise is based in large measure on the recent and extraordinary retreat of Arctic sea ice that has garnered worldwide attention. Touted are the large distance savings on global trade routes by using the Arctic Ocean; one example is the nominal 11,200 nautical mile route between Rotterdam and Yokohama (using the Suez Canal), versus a 6,500 nautical route across the top of the world. Many maps are shown promoting these potential marine trade routes without indicating a key factor - that the Arctic's sea ice cover will be present for a majority of the year during the century. Just how plausible is trans-Arctic shipping given that the Arctic sea ice cover remains, but is a less imposing physical barrier?

Arctic nations, both individually and collectively, are legally responsible for providing infrastructure in order to prevent loss of life, property and environmental damage.

The Presence of Arctic Sea Ice

The observed record of Arctic sea ice noted in Section 2 indicates decreases in both extent and thickness during the past five decades. Global climate model simulations of Arctic sea ice indicate trends of increasing areas of the coastal Arctic Ocean that may be partially ice-covered or even open water. No credible scientific source, though, is arguing that there will be a complete disappearance of the Arctic sea ice cover. The models do indicate a strong possibility of an ice-free Arctic Ocean for a short period of time in September sometime in the future. Again, the significance of this physical change is that multi-year ice would disappear - no sea ice would survive the summer melt season and only new ice would grow through the autumn and winter months during the long polar night. It is uncertain how long the ice-free period will be during the late summer or exactly when it will occur in any given year. It could be a window of time as brief as a few days or several weeks, or nearly ice-free conditions could last longer in the central Arctic Ocean. However, most of the potentially navigable spring, summer and autumn months should remain ice-covered with ice that may be thinner, but more mobile, than in previous decades. The year-to-year variability of sea ice in coastal seas and straits, such as those along the NSR and NWP, will surely remain a challenge in evaluating risk for insurance purposes and determining the overall reliability of Arctic marine routes. The length of the navigation season in all Arctic regions remains uncertain from a sea ice perspective, before other factors such as ship performance and icebreaker support systems are applied.

Key Questions for Trans-Arctic Shipping

The complexity of the trans-Arctic navigation can be viewed through the lens of a range of key questions and issues:

* From the previous discussion, if all or some regions of the Arctic Ocean will remain ice-covered for much of the year, the need for polar ships designed for at least limited ice operations is obvious. The question of whether these ships will be icebreaking carriers in their own right and capable of independent ice operations is important. Will such ships require icebreaker convoy support and who will pay for the escorting icebreakers? Both are significant economic and safety issues. Relevant is the issue of whether polar icebreakers in support of navigation would be funded by commercial interests or Arctic state governments. Such commercial polar ships will also be more expensive to build and operate, and many questions remain as to their utilization beyond the Arctic Ocean on potentially long marine routes in the open ocean. Shorter routes in the Arctic imply that there is a potential for lower stack emissions into the lower Arctic atmosphere during transits. However, the presence of sea ice may require higher propulsion levels and ultimately similar or greater emissions during voyages compared with open ocean routes.

* Can the trans-Arctic routes be used year-round in a reliable and safe manner? This is a significant question as many global fleets would wish to integrate seamlessly the new route with established marine routes. If an Arctic route is only viable for part of the year,

will it be economically viable to use *Polar Class* ships on other routes? How viable and competitive would be a two to three month Arctic navigation season? How will shippers change and adapt their global shipping flows to a potentially seasonal operation along new and shorter Arctic routes? And what might be the response by the Suez and Panama canals to a seasonal route across the Arctic? Might they adjust their fee structures to accommodate this new competition?

* Are Arctic routes economically viable today or in the near future? For nearly two decades the NSR has been open for international business under a fee structure. However, a limited navigation season presents the most significant challenge to the global maritime industry. The economic viability of all trans-Arctic options will be based in part on what ship speeds can be maintained in both ice-free and ice-covered waters to take full advantage of the shorter transit distances involved.

* What are the risks assumed with using Arctic routes? For the marine insurers the risks could be higher if ships confront voyages of hundreds of nautical miles in ice. Higher risks for ice damage to ships and potential damage to cargoes in extreme cold temperatures, and the insufficient maritime infrastructure in the Arctic (such as salvage, ports and emergency response) will most likely be factors in determining future insurance rates. Navigation risks may also be compounded by operations in the polar night or during the spring/autumn seasons where night operations in ice will be required. Shippers may also face risks with the possibility of schedule disruption and other reliability issues due to the inherent uncertainty of Arctic ship navigation. Many of these risk factors can be mitigated with the use of highly capable polar ships with experienced Arctic mariners.

* Trans-shipment of cargoes may be a plausible option for using the Arctic Ocean for trans-Arctic shipments (See page 101). Which ports would be likely termination points at the ends of the Arctic voyages is a key question. The investment in terminals and in a fleet of Arctic ships that would operate year-round across the Arctic Ocean would be sizable. However, a key factor would be that the Arctic ships would be fully and solely employed on Arctic voyages. The addition of trans-shipment ports in the northern latitudes could add a new dimension to global trade routes and might add options for select cargoes to be carried from the Pacific to European ports, depending on the time delays associated with cargo transfers.

Potential Operators on Trans-Arctic Trades

The variability of Arctic sea ice and the uncertainties associated with sailing times make predictions for use by marine operators and certain vessel types (and trades) highly speculative. During the assessment's scenarios creation effort, it was identified that large LNG carriers and oil tankers would not likely use trans-Arctic routes for trading. Today, all such ships sail from western Siberian ports and northern Norwegian ports westbound for North America and European ports. Future pipelines across Eurasia and additional pipelines to central Europe appear to be strong competitors to oil and gas carriers potentially sailing eastbound along the NSR.

The challenges for container traffic and carriers using trans-Arctic routes are many, including schedule reliability and the need to satisfy very tight customer supply chains. The potential safety of the ships and cargoes, and the actual fuel costs and time savings (with ice navigation required on portions of the routes) are significant considerations that are not well understood. The investment in ice class ships would also be a major issue since their operation would be sub-optimal in non-Arctic trades if year-round Arctic operations could not be achieved.

It is plausible that several types of dry bulk and break-bulk carriers could conceivably use seasonal trans-Arctic routes. Bulk metal ores and concentrates (many can be stockpiled at the mine or the destination port) could be shipped along the NSR and even across the central Arctic Ocean if spot charters could be arranged on an opportunistic basis. However, suitable ice class ships would have to be built or be readily available for charter. Break-bulk carriers of forest products and pulp might use the Northern Sea Route to trade from northern Europe to Pacific and North American ports. It is reasonable to assume that experimental voyages of a commercial icebreaking carrier could take place within the decade to test the operational and technical challenges associated with trans-Arctic navigation.

The Need for Economic, Comparative and Technical Studies

There is a dearth of rigorous economic studies related to the evaluation of trans-Arctic shipping routes. Comprehensive economic studies using cost-benefit-risk analyses are needed for all three potential routes of trans-Arctic shipping (central Arctic Ocean, NWP and NSR). Such studies need to fully identify the global demands and key economic needs for use of these polar routes. Additional related studies are necessary to determine the economic benchmarks and indicators for viable seasonal and year-round trans-Arctic traffic. What might be the key commodities suitable and economically

viable for trading during even a partial or summer navigation season? Further economic research should be conducted on the potential for trans-shipment of cargoes across the Arctic Ocean in icebreaking carriers. An important component of such an analysis would be the economics of trans-shipment terminals/ports in Alaska, Iceland, northwest Russia and northern European sites.

Operational and technical studies are also lacking. A comparative analysis of icebreaker-assisted convoys versus independently-operated, icebreaking carriers for all trans-Arctic options is required as new Arctic ship technologies emerge. Risk assessments related to Arctic ship operational challenges, the general lack of marine infrastructure throughout the Arctic Ocean and the potential for ice damages would be useful to the marine insurance industry and all ship owners contemplating trans-Arctic navigation. Cost effectiveness studies for different icebreaking propulsion systems, including nuclear propulsion, should also include analyses of future emissions controls that are socio-economic responses to global climate change. The increasing size of ships (on global trade routes) may also have significant implications for all modes of Arctic marine transport including the trans-Arctic option. Studies should identify any maximum limitations, technical challenges and operational constraints for these very large ships on Arctic trade routes.

The uncertainties and complex interactions of many driving forces of trans-Arctic navigation require significant research. While it may be technically feasible to cross the Arctic Ocean today by modern icebreaker or even using an advanced icebreaking carrier, the operational, environmental and economic implications and challenges for routine trans-Arctic voyages are not yet fully understood.

Research Opportunities

- Comprehensive economic research including cost-benefit-risk analyses for all potential routes of trans-Arctic shipping.
- Comparative analysis of using Arctic marine transport in *Polar Class* ships versus pipelines for the carriage of Arctic oil and gas to world markets. Summarize the existing regional studies conducted for these comparisons.
- Comprehensive, comparative analysis of ice-assisted convoys versus independently-operated, icebreaking carriers for all modes of Arctic marine transport.
- Continued marine research on the changing nature of Arctic marine ecosystems related to climate change and the retreat of Arctic sea ice to determine the future level and operational impacts of fishing vessels in higher latitudes.
- Research on the socio-economic responses to global climate change (for example, ship emissions controls) and their potential impacts on Arctic natural resource development and Arctic marine transport.

REGIONAL FUTURES TO 2020: BERING STRAIT REGION

The Bering Strait is a narrow international strait that connects the North Pacific Ocean to the Arctic Ocean and forms the only corridor between northern and east-west transportation routes (Map 6.1). At the strait's narrowest point, the continents of North America and Asia are just 90 km apart. With diminishing summer sea ice in the Arctic Ocean, the Bering Strait region may experience increased destinational traffic to the oil and gas exploration areas in the Beaufort and Chukchi seas, and to the Red Dog Mine in northwest Alaska.

Sea Ice

Seasonally dynamic sea ice conditions are found in this natural bottleneck. Typically, sea ice develops along the coasts in October and November. During May-July the ice edge retreats northward through the region. First-year sea ice can develop to more than 1.2 meters thick during the winter. Except for shorefast ice, sea ice movement in the Bering Strait region is dynamic and forced by winds and currents. Ice has been observed to move through the region at speeds as high as 27 nautical miles per day. The seasonal ice field does not contain icebergs from land-based glaciers; however, multi-year ice from the Arctic ice pack has been observed to flow southward through the strait and into the Bering Sea. The future sea ice extent in the vicinity of the Bering Strait is projected to change only slightly in spring (April and May); however, a significant reduction (later freeze-up) is projected for the future in November and December.

Ecosystem and Bio-resource Considerations

The Bering Strait region is a highly productive area extensively used by many species, including several species listed under the U.S. Endangered Species Act. The prolific continental shelf seasonally supports a rich array of benthic feeders, such as gray whales, Pacific walruses and seabirds. Ice-dependent marine mammals seasonally move through the region as sea ice retreats in the summer and advances in the fall.

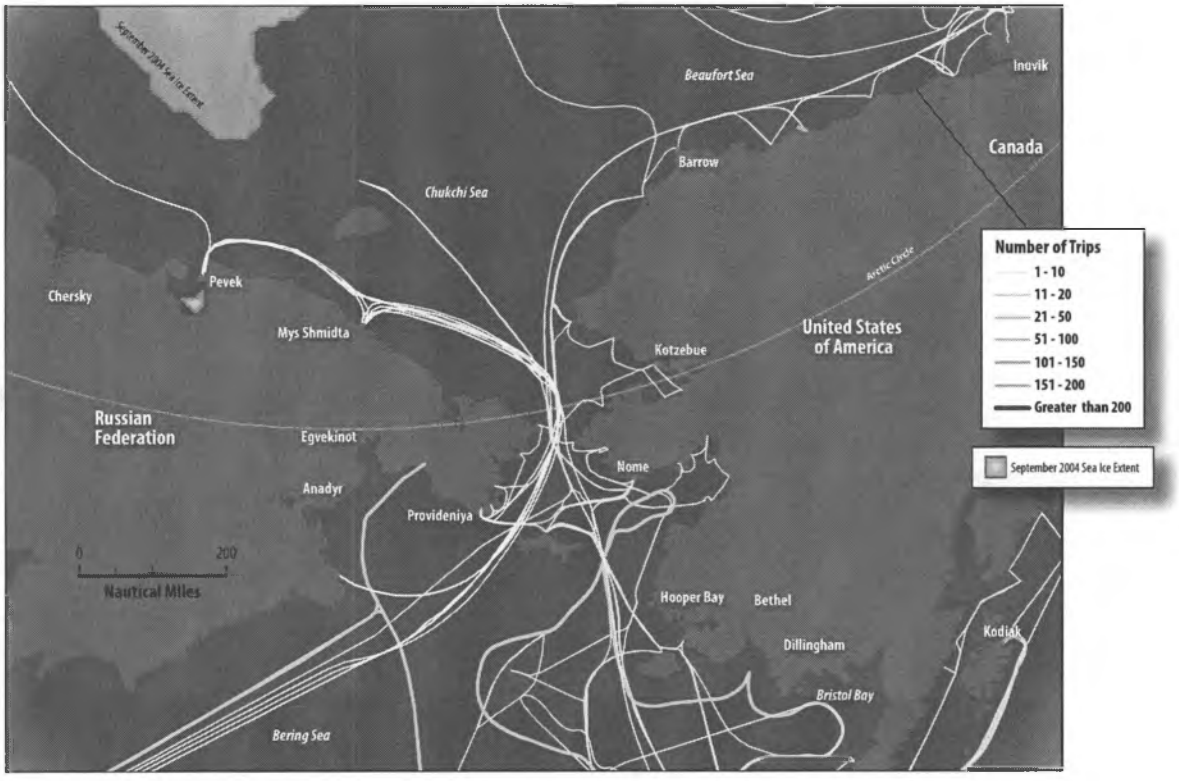
Many species depend upon primary productivity associated with sea ice, and the juxtaposition of the seasonal ice, shallow depth and productive benthos serves to support a unique diversity and high density of marine life. It is a dynamic region, and the physical constraints of the Bering Strait serve to seasonally concentrate species associated with the ice edge. The region is the only migration corridor for many species of fish, birds and marine mammals. Potential conflicts between increased ship traffic and large marine pinnipeds and cetaceans in the region are associated with increases in ambient and underwater ship noise, ship strikes, entanglement in marine debris and pollution (including oil spills).

Indigenous Marine Use

The Bering Strait region is home to three distinct linguistic and cultural groups of Eskimo people in Alaska: the Inupiaq, Central Yupik and Siberian Yupik on Saint Lawrence Island. The coastline of the Bering Strait region has been continually occupied by indigenous people for several thousand years. Human populations in this region have been dependent on marine resources, including mammals, fish, birds, macro algae, shellfish and other invertebrates. The hunting of large marine mammals has been the primary adaptive subsistence strategy of Bering Strait human populations for more than 1,000 years.

Currently, the population of the Bering Strait region is greater than 10,000 people, with Alaska Natives comprising more than three-fourths of the population. There are 15 year-round villages along the U.S. coast that range in population from approximately 150 to more than 750 residents.

The use of different marine resources occurs throughout the year. However, use strategies change seasonally with the animal migrations and life history stages. Regions where marine resources are gathered include beaches, coastal waters and/or nearshore waters, and may include offshore waters. For example, to adapt to the rapidly changing accessibility and availability of sea ice, hunting of large marine mammals (i.e., walruses) can take place up to 50 to 80 nautical miles offshore. Travel to these offshore locations is typically conducted in small open boats and a hunt can span several days before a vessel returns to its port of origin.

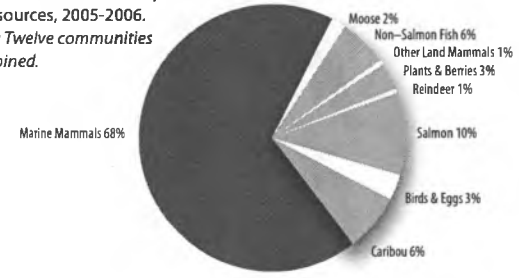


Map 6.1 Vessel traffic in the Bering Strait during the summer of 2004. *Source: AMSA*

Marine resources are of vital importance to peoples of this region. Not surprisingly, today's U.S. communities in this region, except White Mountain, are situated on the shores of the Bering or Chukchi seas and are strongly tied to subsistence lifestyles. This maritime reliance for subsistence in the Bering Strait region is very significant and, for marine mammal species such as walruses, whales and seals, comprises a significant portion of the total U.S. harvest. Additional marine-based resources are obtained through beachcombing, clamming, gathering seabird eggs, fishing, birding, gathering greens and other activities.

While Bering Strait region communities exhibit unique socio-economic, cultural and political differences, they all use the marine resources for nutritional reliance, cultural customs and economic dependence (for example, clothing, equipment, handicrafts, commercial fishing and hunting and limited ecotourism). The general patterns of large marine mammal hunting and reliance on other marine resources (i.e., fish, crabs, birds, beachcast invertebrates, macro algae) persist to the present time, despite technological changes.

Table 6.3 Harvest composition of resources, 2005-2006. *Note: Twelve communities combined.*

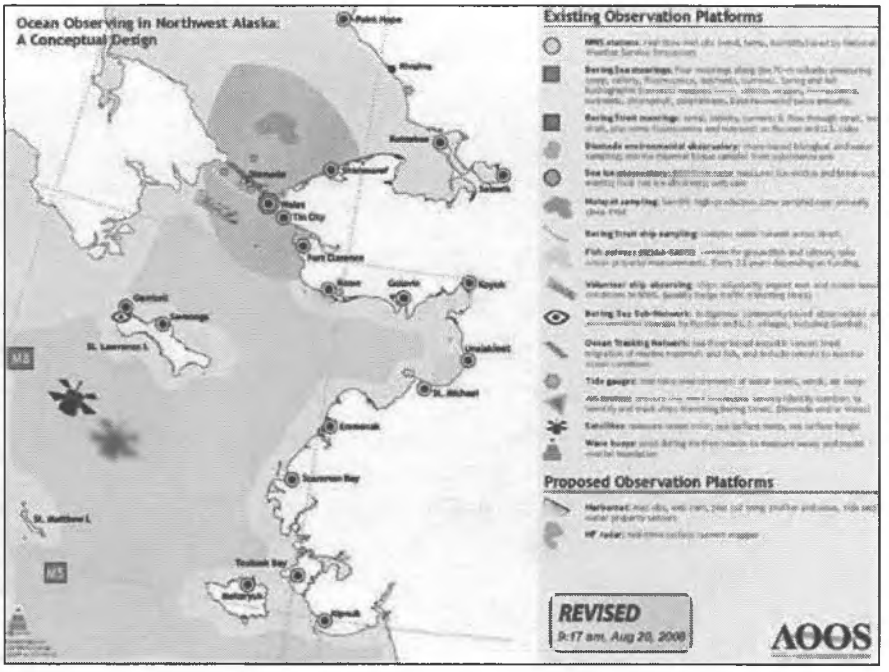


Source: Kawerak, Inc., North Pacific Research Board, Alaska Department of Fish and Game, 2005-2006 Comprehensive Subsistence Harvest Survey, Bering Strait/Norton Sound Region

Table 6.3 graphically demonstrates the maritime reliance for subsistence in the Bering Strait region with more than 85 percent of the harvested resources being marine-derived. The regional reliance on marine mammals is very significant.

The communities closest to proposed vessel traffic in the Bering Strait region (Gambell, Savoonga, Shishmaref and Wales) have a high

reliance on ocean-based resources. The St. Lawrence Island communities of Gambell and Savoonga are most dependent on marine resources, with the marine mammal harvest totaling over one million kilograms. More than 95 percent of their total subsistence harvests are marine-based resources (i.e., seabirds, eggs, fish and marine mammals). Shishmaref, on Sarichef Island, and Wales, on the mainland, demonstrate a high reliance on marine resources with more than 75 percent of their total harvest derived from the sea. In contrast, the coastal communities of southern Norton Sound, especially Stebbins and Unalakleet, demonstrate a higher reliance on fish, especially salmon, which is indicative of the highly productive river influences.



Map 6.2 A potential observing system for the Bering Strait region. *Source: Alaska Ocean Observing System (AOOS)*

Though current environmental patterns and predictions indicate a profound and long-term ecosystem change to the Bering Strait region, human reliance on marine resources for subsistence remains essential. The importance of the cooperative hunting of large marine mammals and the use of all available marine resources for nutritional, cultural and economic needs will persist in the region.

In 2001, Russia and the U.S. signed the *Agreement between Government of the Russian Federation and United States of America on Cooperation in Combating Pollution in the Bering and Chukchi Seas in Emergency Situations*. This agreement establishes cooperation in oil spill preparedness and response in the Bering Strait region.

Potential conflicts between increased ship traffic and indigenous marine resource use in the Bering Strait region include but are not limited to an increased amount of:

- Ambient and underwater ship noise - recognized as one of the primary concerns to marine mammal populations, especially within the narrow and shallow migration corridor;
- Ship strikes on large marine mammals;
- Entanglement of large marine mammals in commercial fishing gear;
- Potential for collision between coastal and offshore large ship traffic and small open boats using marine resources;
- Pollution affecting the availability and quality of offshore, coastal and beachcast marine resources, due in part, but not limited to:
  - lack of navigational and rescue infrastructure in an extremely challenging physical and marine environment;
  - concern for infrastructure to secure a large vessel in distress;
  - concern for infrastructure to assess and respond to an oil and/or chemical spill; and
  - language (for example, English, Russian, Siberian Yupik) and cultural communication barriers.

In spite of the intensive subsistence use of resources, dynamic ice conditions and biological richness, there are currently no operational ocean-observing platforms in this region. Map 6.2 describes a potential observing system for the Bering Strait region, building upon existing (mostly research) assets.

Commercial Marine Uses: Fishing, Oil and Gas, Minerals, Tourism and Shipping

In the Bering Strait region, there are three primary U.S. ports: Nome, Kotzebue and the DeLong Mountain Transportation System (DMTS) port serving the Red Dog mine. The main ports on the Russian side are just south of the Bering Strait, as they are on the U.S. side. The three largest ports are Provideniya, Anadyr and Egvekinot. The water depth in most U.S. and Russian ports in this region is about 10 meters or less.

Overall, approximately 150 large commercial vessels pass through the Bering Strait during the July-October open water period, with transits of these vessels most frequent at the beginning (spring) and end of the period (autumn). This estimate excludes fishing vessels, which are generally smaller, as well as fuel barges serving coastal mining activities and coastal communities.

Potential offshore development north of the Bering Strait region in the Chukchi and Beaufort lease sale areas could plausibly increase the numbers of support and supply ships transiting the region. There is no indication or information in support of ships transiting the Bering Strait on trans-Arctic voyages by 2020.

Infrastructure, Navigation and Communication

There are currently no established vessel routing measures in the Bering Strait region. A Traffic Separation Scheme (TSS) may need to be established in the region as vessel traffic increases. There is currently no active Vessel Traffic Service (VTS) or other traffic management system in place in the waters of the Bering Strait. Shipboard Automated Identification System (AIS) capability is currently limited. Presently the Marine Exchange of Alaska has established and is expanding AIS reception capability throughout portions of the Bering Sea.

There are no shore-based very high frequency (VHF) FM communication services available in the Bering Strait region. The U.S. Coast Guard does maintain VHF-FM sites in the Bering Sea, and maintains a HF radio guard for emergency and distress calling, but HF coverage of the Arctic region is poor. There are only three U.S. Coast Guard maintained navigational aids at the Bering Strait along the north side of the Seward Peninsula into Kotzebue Sound. There are no navigational aids north of Kotzebue Sound.

There is 100 percent coverage of the Bering Strait region from the Global Positioning System-Standard Positioning Service (GPS-SPS). However, the GPS constellation is not configured for optimal positioning in high latitudes, resulting in a potential degradation of position accuracy. There is currently no Differential GPS (DGPS) coverage of the area.

In the Bering Strait region, limited capabilities exist to respond to an incident, whether it is for lifesaving or oil recovery. Weather and oceanographic observations necessary to support search and rescue and oil recovery operations are also minimal. Even if a U.S. Coast Guard operating team were seasonally deployed to an Arctic coastal community, weather and distance to an incident site would remain huge challenges. Under present circumstances, vessels in distress must depend on other vessels or local communities in the area for assistance or wait until aid arrives. Few viable salvage vessels are available north of the Aleutian Islands.

Findings
Regional Futures to 2020
Bering Strait Region

1] The Bering Strait region is an international strait for navigation and a natural chokepoint for marine traffic in and out of the Arctic Ocean from the Pacific Ocean.

2] The region, seasonally ice-covered, is a highly productive area extensively used by many species of seabirds, marine mammals and fish. The highly productive continental shelf supports a rich array of benthic feeders; ice-dependent species also move through the region as sea ice retreats and advances. The Bering Strait serves to concentrate species associated with the ice edge and is the only migration corridor for many species.

3] The Bering Strait region is a prolific location for nesting seabird colonies, making it a vulnerable location for ecological disruptions.

4] Indigenous people have continually inhabited the coastline of the Bering Strait region for several thousand years. Marine resources today are of vital importance to coastal American and Russian populations throughout the Bering Strait region. They are dependent on marine resources including marine mammals, fish, birds, macro algae, shellfish and other invertebrates. Hunting of large marine mammals can take place 50-80 nautical miles offshore.

5] Ships related to a spectrum of uses are found in the Bering Strait region: fishing, hard minerals/mining, science and exploration, tourism and offshore oil and gas development. Approximately 25 large commercial ships (bulk carriers) annually sail north through the Bering Strait region (in the ice-free season) to the DeLong Mountain Terminal off Kivalina in northwest Alaska.

6] There are no formally established vessel routing measures in the Bering Strait region and there are very few visual aids to navigation in the region. Any future voluntary set of traffic routes, or a vessel traffic system, could be proposed by the United States and the Russian Federation to the International Maritime Organization.

7] Offshore oil and gas development may lead to increased marine traffic in the Bering Strait region during the next several decades. Multiple use management practices and measures to mitigate potential impacts (noise, emissions, ship strikes, discharges, etc.) from these new uses would be useful.

Breaking the Ice: Arctic Development and Maritime Transportation

Organized by the Icelandic Government, March 2007

Hosted by Iceland's Ministry of Foreign Affairs in March 2007, the "Breaking the Ice: Arctic Development and Maritime Transportation" conference provided the first opportunity under the International Polar Year banner for marine specialists and stakeholders to exchange information on Arctic shipping and the prospects of a trans-Arctic route between the North Atlantic and the Pacific oceans.

Designed as a contribution to the Arctic Marine Shipping Assessment, 90 delegates from all the Arctic countries, the United Kingdom, China and the European Commission discussed and debated issues on three key policy issues: the future of research and monitoring in the Arctic, the status of emergency prevention and response and the viability of trans-Arctic shipping.

The following are some of the observations made at the seminar:

- The extraordinary retreat of Arctic sea ice and the rapid decrease in multi-year ice has increased marine access throughout the Arctic basin and coastal seas.
- The development of "double acting Arctic ships," equally fit for open ocean and navigation through ice without icebreaker assistance, opens the possibility of year-round trans-Arctic container traffic between the North Atlantic and the North Pacific oceans. A number of double acting tankers and containerships are already operating in the Arctic. The economics and icebreaking capacity of such ships improve with larger size.
- Improved remote sensing technologies will make it possible to provide information on ice thickness and ice ridges. The emergence of ice forecast services can be used for plotting sailing routes through the ice.
- The globalization of world economy and rapid growth in international trade has led to capacity constraints of the Panama and Suez canals, hampering the integration of North Atlantic economies with fast growing economies in East and Southeast Asia. Trans-Arctic shipping would supplement present transportation routes and spur economic development.
- The opening of a trans-Arctic route would enhance economic security of the world. Present transportation links between the North Atlantic and emerging economies in the Far East are precarious. They are subject to delays because of accidents, mechanical breakdowns and maintenance, and they are vulnerable to disruption because of terrorist activities, regional conflicts and piracy.
- The high cost of technical development and infrastructure make it unlikely for private stakeholders to commence regular trans-Arctic transportation without governmental support.
- International cooperation for the development of trans-Arctic shipping should include stakeholders outside of the Arctic. Chinese delegates at the conference expressed a willingness to cooperate with the Arctic states in the research and development of Arctic shipping.
- Changing ice conditions may make it challenging to maintain tight transportation schedules and ensure the punctuality of certain cargoes. Enhanced monitoring, improved sea ice information and more efficient icebreaking carriers would significantly improve the situation.
- A comprehensive feasibility study is needed to estimate the commercial viability of trans-Arctic shipping, taking into account a wide range of economic and natural variables, including vessel cost, ice conditions, sailing speed on different routes, etc. New shipping routes and technologies should be pioneered with experimental voyages in order to gather better information on the shipping conditions and viability of new shipping routes.
- Care must be taken to minimize environmental effects of increased shipping activity in the Arctic. The capacity of the Arctic states for emergency response must be increased with appropriate equipment, materials and sufficient towing capacity, made available for various situations close to development sites and shipping routes. The Arctic Council can play a role in coordinating response to emergencies related to the shipping through the EPPR working group.
- While voluntary or recommended guidelines for Arctic shipping have been adopted by IMO, the movement toward mandatory rules for Arctic shipping must be accelerated.

- One presenter proposed the use of nuclear ships for trans-Arctic shipping to decrease the release of greenhouse gases and prevent the "graying" of the ice. Furthermore, nuclear ships would be relatively cheaper to operate in view of high and rising fuel costs.
- The participants agreed in general that Iceland could play a role in the opening of a trans-Arctic sea route because of its location in the middle of the Northern Atlantic. The new shipping routes that pass near Iceland (routes of commercial ships from Northwest Russia and northern Norway sailing to North America) could be linked by Iceland serving as a hub for container traffic in the northern Atlantic region.

The participants in the seminar concluded that experimental and limited trans-Arctic commercial voyages through the central Arctic Ocean could start during the summer navigation season within a decade; and that a year-round trans-Arctic marine transportation route between the North Atlantic and the North Pacific oceans could plausibly open in one or two decades, considering security, economic and environmental factors.

REGIONAL FUTURES TO 2020: CANADIAN ARCTIC AND NORTHWEST PASSAGE

General Description of the Region

The Canadian maritime Arctic is located across the north of Canada from the Beaufort Sea in the west to Hudson Strait in the east, covering approximately 2.1 million km². The Arctic Archipelago comprises approximately 36,000 islands, including three of the world's 10 largest islands. The coastal area is sparsely populated with fewer than 30,000 people. The Canadian Arctic also provides important habitat for a range of permanent and migratory species of marine mammals, seabirds and terrestrial animals such as caribou. Throughout this region there are many ecologically sensitive areas where animals gather in large numbers at certain times and may be vulnerable to impacts from shipping.

The Canadian Arctic has a long and rich history of marine use, beginning with its indigenous residents many thousands of years ago. Shipping in the Canadian Arctic has always been the safest and most economically effective means of moving goods to, from and within the region. It is a vast area with virtually no roads, no rail lines and where air services are both infrequent and very costly. There are also unique geographic and climatic conditions that make the region challenging for maritime navigation, including the presence of ice for most of the year, as well as the many narrow and shallow, often uncharted, areas through the archipelago. Canada has for many years strived to achieve a balance between development and environmental protection in its Arctic areas and for this purpose has a unique and extensive regulatory scheme in place to enhance marine safety and environmental protection in its Arctic waters. This regulatory scheme was ahead of its time when it was first established in the 1970s and is now in need of updating in order to bring it in line with recently developed international standards.

Sea Ice Conditions

Sea ice observations for the past three decades from the Canadian Ice Service show negative trends in coverage for the eastern and western regions of the Canadian maritime Arctic. The observations also show a very high, year-to-year variability of sea ice coverage in all regions, an important factor of uncertainty when considering marine insurance, investment, ship construction standards and other aspects of Arctic marine transport. Due to the unique geographic characteristics of the Canadian Arctic Archipelago (with many channels oriented north-south), the region is also expected to be one of the last areas of the Arctic Ocean to have a significant summer ice cover. It is plausible that if sea ice melt in the central Arctic Ocean continues, as many climate models indicate, there is a potential for more mobile multi-year sea ice to be swept southward through many of the northern passages of the archipelago. For the whole of the Arctic Ocean, including the Canadian maritime Arctic and Northwest

Canadian Arctic Shipping Activity

Expectations to 2020 may be summarized as follows:

- ***Dry bulk carriage*** **stimulated by resource development: definitive forecasts of substantive marine transportation projects are, for now, Mary River and High Lake developments.**
- ***Liquid bulk carriage*** **stimulated by resource development: minimal forecasts due to expectations that any substantive products in the Beaufort Sea will move out by pipeline.**
- ***Supply/resupply:*** **some important but manageable expansion in shipping activity is forecast, related to growing populations and for movement of supplies and equipment in support of exploration projects.**
- ***Cruise shipping:*** **projections of modest but largely unpredictable growth.**
- ***Container, bulk transit traffic:*** **no substantive activity seen in this sector in the timeframe under examination.**
- ***Other:*** **unknown activity for fishing, seismic, etc.**

Table 6.4 Canadian Arctic shipping activity expectations to 2020. *Source: AMSA*

Passage, global climate models indicate that sea ice will be present throughout the winter and for approximately nine months during each year. The Canadian maritime Arctic will have a generally more favorable sea ice situation in a short, summer period, but will be ice-covered for a majority of the year, a significant factor for Arctic transport regulation and protection of the marine environment.

Indigenous Use

The sea is very important to the way of life and culture. Inuit do not distinguish the water from the land in terms of their hunting and culture. All of the communities in the Canadian Arctic are coastal or situated on major waterways. Whether traveling in a boat or over the ice, the water provides a means of transportation, a connection between communities and a source of food. Though their technologies and style of living may have changed dramatically in the past hundred years, the Inuit are still by and large hunters who rely on country foods for a large portion of their diet. Some of the most important country foods are seal, walrus and whale, all of which are harvested on the ice edge or by boat. Any disruption of the ecosystem, such as an oil spill, dumping of waste or noise from machinery or ships could have effects on the animals and, therefore, the health and well-being of the Inuit. Despite the benefits of increased community re-supply, general shipping is a cause for concern to the Inuit. Vessels may scare away mammals needed for subsistence; they break ice tracks, disrupting travel on the ice via snowmobile and ships may affect wildlife in harbors and elsewhere.

Current Commercial Use

The types of commercial shipping activity currently taking place in the Canadian Arctic consist of community re-supply; bulk shipments of raw materials, supplies and exploration activity for resource development operations; and tourism. Commercial re-supply activities are serviced by southern points of origin, one in the west and several in the east. In the western Arctic, most cargo is moved by tugs and barges from Hay River down the Mackenzie River to Tuktoyaktuk for transfer and consolidation. Conventional ocean-going

general cargo vessels typically handle cargo in the eastern Arctic. Cargo is lightered ashore using small tugs and barges that are carried with the ships. Currently, there are no commercial vessels that regularly transit the Northwest Passage, aside from a few small specialty cruise operators. Other commercial shipping activities in the Canadian Arctic include a single-base metal operation in Deception Bay that ships nickel concentrates to Quebec, and grain shipments from Churchill to international markets. Exploration and resource development is ongoing. Recently, there has been heavy demand for logistics and supplies in both the eastern and western Arctic, particularly in the Beaufort Sea and at the Mary River iron ore mine, which shipped 120,000 tonnes of bulk cargo to European mills during the 2008 season.

Future Use

Destinational shipping is anticipated to increase in the Canadian Arctic. This will be driven largely by the demand for goods by growing communities, expanding resource development projects, as well as increasing tourism. The changing climate will result in increased accessibility and a longer shipping season, which will in turn also affect future activity levels. By 2020, it is projected that annual re-supply demand will increase enough that the current fleet will not be sufficient to meet the needs, despite the likelihood of a longer shipping season. In addition, the current fleet is aging and most ships would likely need to be replaced within that timeframe.

It is anticipated that the primary areas of increased marine activity will be resource driven. The lack of infrastructure and high operational costs have, until recently, made this region uneconomical for large-scale resource development. However, during the next 20 years, new bulk exports are expected to include: Mary River iron ore from a port at Steensby Inlet in the Foxe Basin, with possible commencement in 2010; Roche Bay magnetite from a port near Igloolik in the Foxe Basin, possibly beginning in 2015; and High/Izok Lake lead/zinc/copper concentrate shipping from either Gray's Bay or Bathurst Inlet, possibly starting in the same year. Imports will likely include logistics and fuel for the primary resource operations noted above; logistics and fuel, as well as barge-mounted production modules for the proposed Mackenzie pipeline; and delivery of production modules to the Alberta Oil Sands, among others. High operational costs in the Canadian Arctic are a limiting factor in this region. As a result, it may be many years before the Canadian Arctic matches the volume of resources extracted from Alaska or the Russian Arctic regions.

While the summer climate in the Canadian Arctic region is changing, ice will be present during most of the year and especially during the long, cold polar nights each winter. As a result, access to the Northwest Passage will continue to be controlled by ice conditions. Despite widespread speculation, the uncertainty of conditions in the Northwest Passage due to seasonal variability, changing ice conditions, complexity of routes, depth restrictions, lack of adequate charts and other infrastructure, high insurance and other costs, will diminish the likelihood of regular scheduled services. With the exception of nuclear icebreakers, very few ships have been built that could safely carry out year-round commercial navigation in the Canadian Arctic. The continued presence of ice even in open water will mean that operational costs will continue to be high.

Findings
Regional Futures to 2020
Canadian Arctic & Northwest Passage

1] The Northwest Passage is not expected to become a viable trans-Arctic route through 2020 due to seasonality, ice conditions, a complex archipelago, draft restrictions, chokepoints, lack of adequate charts, insurance limitations and other costs, which diminish the likelihood of regularly scheduled services from the Pacific to the Atlantic.

2] Destinational shipping is anticipated to increase in the Canadian Arctic, driven by increasing demand for seasonal re-supply activity, expanding resource development and tourism.

3] In the Canadian Arctic, ice conditions and high operational costs will continue to be a factor into the future. Irrespective of the warming climate, ice will remain throughout the winter, making viable year-round operations expensive.

4] Canada has a specific regulatory system for shipping in Arctic waters that is in need of an update in line with recently developed international standards.

Regional Futures to 2020: Northern Sea Route and Adjacent Areas

In 2003, participants representing the shipping industry, research community from five EU countries, Russia and Norway began a three-year research project: the Arctic Operational Platform (ARCOP). ARCOP was not to be re-negotiated by PAME, did not have a direct linkage to the AMSA objectives and did not express the views of the Russian Federation.

During the same period "JANSROP Phase II" in 2002 began a three-year program. In conjunction with INSROP (1993-1999), JANSROP II, funded by Japan's Nippon Foundation, emphasized the eastern part of the Northern Sea Route (Siberia, Far East Russia and the Sea of Okhotsk). INSROP (See page 46) was supported by the Russian Federation and funded by a consortium of Norwegian, Japanese and Russian sources. Four hundred and sixty experts participated in INSROP in economics, navigation, meteorology, hydrography, military operations and environmental protection from: Russian Federation, Norway, Japan, United States, United Kingdom, Denmark, Sweden, Germany and Finland. INSROP results included an experimental Arctic voyage from Yokohama to Rotterdam, international conference, three books and 167 peer-reviewed papers.

ARCOP, funded by the EU Commission and European shipping interests, examined the different elements of oil and gas transportation between northwest Russia and Europe. ARCOP included six separate work packages, each concentrating on a specific topic but also using one selected transportation task as a focus of the research. Fifty-seven research reports were produced by ARCOP and all reports can be found on the ARCOP website, www.ARCOP.fi. The contents of this section represent the views of the experts who worked within ARCOP and is presented as one of the assessments in the field.

Work Package 1, *The Ice Information System*, was started in early 2005. The research part of this work package was performed jointly with the Ice Ridging Information for Decision Making in Shipping Operations (IRIS) project, which is a separate EU-funded project coordinated by the Helsinki University of Technology (HUT). It developed methods to acquire online ice information and create accurate ice condition forecasts in a short time span. Kaeverner Masa Yards participated in this project and the results from IRIS were applied to ARCOP. Within ARCOP, the information from IRIS was compared to the experience within the Russian Arctic. The potential of the enhanced ice information system was demonstrated by economic analyses in the NSR conditions.

Work Package 2, *Administrative Measures for Marine Transport*, covered a large number of topics, varying from international law to rules and fees applicable in the Russian Arctic. Within international law, the regime in force in the Russian Arctic is in line with UNCLOS Article 234 and thus the situation regarding commercial shipping is more or less clear. It was also considered that UNCLOS Article 76, dealing with the extended continental shelves, does not really affect commercial shipping, since sailing in the central Arctic Ocean means passing through areas covered by Article 234.

Within the World Trade Organization and the *General Agreement on Trade in Services* (GATS), there are a number of issues that are not yet clear. But since the whole GATS regime covering shipping is still open, this is not a specific Arctic problem. Of interest to the Arctic shipping community is the question of icebreaker services. In some countries, this is considered a service that should be open for competition within the WTO. In the Russian Federation, as well as in Sweden, this is considered to be part of the infrastructure that the coastal state provides. A potential solution to this question will be realized only when large-scale transportation is in place.

The question of ice rules caused much discussion during the ARCOP workshops, and it appears the current system of rules is not consistent. When dealing with hull strength, the IMO recommendations refer to *Polar Classes*. But these *Polar Classes* in fact do not exist, since IACS has not published their Unified Requirements. Additionally, the Unified Requirements do not say anything about propulsion power. Among the national authorities like in Finland and the Russian Federation, there are, and obviously will be, requirements for minimum power. This puts the shipowners and ship designers in a

Non-commercial Partnership of the Coordination of the Northern Sea Route Usages: Facilitated Discussion

Formed in 2001, the Non-commercial Partnership of the Coordination of the Northern Sea Route Usages is a Moscow-based organization comprising federal and regional government officials, Russian shipping companies and international research and/or educational institutions.

Arthur Chilingarov, deputy chairman of the State Duma, is president of the Partnership with Mikhail Nikolaev, deputy chairman of the Council of Federation, as the vice-president. Captain Vladimir Mikhailichenko, former head of the Northern Sea Route Administration, is the managing director.

The organization has 32 members whose aim is to expand the use of the NSR, assist in safe navigation of Russian and international commercial use along the route, ensure adequate environmental protection in the region, stimulate research and development activities associated with the route; as well as addressing issues such as tariffs, taxation, insurance and other economic factors in the Arctic zone and the NSR.

In order to incorporate the thoughts of the partnership members into the AMSA, partnership member Institute of the North, in conjunction with the U.S. Arctic Research Commission, held a facilitated discussion during the organization's quarterly meeting in St. Petersburg, Russia in February 2008.

The participants were asked what opportunities and challenges they anticipated for the Northern Sea Route in the next 20 years, or longer. The following ideas were captured during the 2 ½ hour discussion and placed into seven topic areas: Emerging Routes, Infrastructure, Technological Considerations, Development and Shipping Economics, International Cooperation and Marine Environmental Safety, Training and Education and Arctic Ocean Observing Network/Monitoring.

Concerning emerging routes, participants generally agreed that the intermodal transportation system (rail and shipping) within Russia is poised to make "colossal" changes and that all Arctic shipping will be influenced by the developing intermodal transportation systems. There was agreement that there will be a greater increase in the shipment of oil and gas of western Russia through the Barents and Norwegian seas, and that regional development in the Russian Far East could reasonably tie rail and shipping in the Lena River with Chinese products going into the Russian Far East and possibly natural resources going out. All of the participants agreed that economics, not Arctic climate change, will drive increased shipping in the NSR.

When talking about infrastructure, the group agreed there is a need for better ice forecasting because ice is very difficult to predict. They envisage the icebreaker fleet in the future will be a mixture of a few large federal icebreakers and smaller commercial multi-purpose icebreakers to support offshore oil and gas development. They noted that shallow draft along the NSR coast and inland rivers made access difficult and challenging; however, the European Union ARCOP project indicated winter marine access along the Ob' River. The lack of major ports along NSR is one limiting factor in increased shipping and is compounded by the need for port improvements throughout the North. The members were adamant there is a need for better search and rescue resources deployed, as well as places of refuge identified. In addition, the capability of ships to provide assistance should be considered of prime importance, having due regard to the lack of repair facilities, the limited number of dedicated towing ships available and the response time.

As to technology, the group said the likely future for shipping in the NSR will occur with independent icebreaking cargo ships and a small number of federal icebreakers used to facilitate traffic, if necessary. Some members of the partnership believe there continues to be a need to maintain a federal icebreaker fleet, with the lead icebreakers of 100,000 shaft horsepower; while others see a different role for a smaller icebreaker fleet that are used to assist, when needed, independent icebreaking cargo ships.

Concerning development and shipping economics, some members suggested the NSR tariff structure needs to be evaluated with the goal of making it more competitive within the global maritime industry and economically sustainable. All operations, whether they are from within the Russian Federation or outside the country, should be subject to the same tariff structure. The group said redundancy of critical systems should be incorporated into ships operating in the NSR. Government should work closely with and be supportive of regional commercial icebreaking systems and regional relationships in the Barents Sea region (between nations and regional organizations) are important linkages for the future of the NSR.

When discussing international cooperation and marine environmental safety, the partnership members agreed there is a need to address the key challenges in combating oil spills in ice-covered waters. They called for the International Maritime Organization to create mandatory, not voluntary, regulations for all ships plying the waters of the Arctic and Antarctica. The partnership plans to work

© Ben Ellis

with the noncommercial organization Association Northwest, which includes 11 independent regions. They believe it is important that all ships in the NSR meet or exceed the voluntary *Guidelines for Ships Operating in Arctic Ice-covered Waters*. They also said that the Arctic environment imposes additional demands on ship systems, including navigation, communications, life-saving, main and auxiliary machinery, etc. They emphasize the need to ensure that all ships systems are capable of functioning effectively under anticipated operating conditions and providing adequate levels of safety in accident and emergency situations.

In the training and educational area, they suggested ice navigation simulators are needed to improve ice navigation and enhance marine safety. They emphasized the human factor is very important in all of these issues, but especially true when recruiting and training crew. Such training should include knowledge of cold water survival gear and other unique issues crew may be exposed to while navigating in ice-covered waters.

As to the Arctic monitoring, the partnership urged support for a future Arctic Ocean Observing System, recognizing that a robust and effective Arctic Ocean Observing System is essential to enhancing marine safety and environmental protection in the NSR and throughout the Arctic Ocean. They also supported obtaining reliable and detailed hydrometeorological and sea ice information in the near-real time as necessary for supporting safe ship navigation.

difficult situation since there is no generally approved basis for the requirements. A great deal of work is still required to unify and make the requirements consistent.

The issue of fees seems also to be a difficult one. Generally, it is considered that the current level of fees in the Russian Federation - for example, $US16 per ton of oil cargo - is far too high. The problem is that the fees are set based on the current cargo flow, which is less than two million tons per year. If the cargo flow should increase to 40 million tons or more per year, the fees could decrease to a level of $US1 per ton. This fee would be consistent with fees collected in Finland on the Baltic Sea.

The other issue is that the system defining the fee level in the Russian Arctic is not as transparent as it is in Finland. It is impossible to track how the funds collected as fees are used. Also criticized was that the fee system does not encourage the use of improved ship technology. A simple calculation shows that using a more expensive vessel, which requires less icebreaker assistance, is not beneficial to the shipowner since he is forced to pay for the icebreaker service that is not needed. Hopefully, this issue will be reconsidered in the future.

Work Package 3, *Integrated Transportation System*, was the actual core of the ARCOP project. This work package looked at the different elements that are needed, from tankers and icebreakers to loading systems, traffic management and crew training; and the economics of transportation were analyzed. The scenario for which the development work was done was selected to be realistic, but not yet commercially in operation.

The task was to transport 330,000 barrels per day of oil production from Varandey in northwest Russia to Rotterdam in Europe. Two different operational tanker modes were used, independent and assisted. There were three alternative designs of icebreakers, each capable to assist the tankers up to 120,000 DWT. The route alternatives used were either direct transportation to Rotterdam, or shuttle service to Murmansk and trans-shipment from there to open water tankers to Rotterdam. The result was that assuming a fee level of 1.2 Euros per ton, a cost level can be achieved of 12 Euros per ton. This is considered feasible when compared with the pipeline costs for similar routes that are approximately 20 Euros per ton. What is important to notice is that the difference between the best and worst alternative is nearly 100 percent. This means that with optimization, a savings of more than 100 million Euros per year can be achieved. Over the lifetime of the project, this would amount to more than 2.5 billion Euros.

The work with the Vessel and Traffic Monitoring and Information System (VTMIS) showed that there are a number of information services that could be combined in a system for the Arctic. In the future, ice information must be part of any VTMIS system.

The lack of crew training was an issue that was strongly identified in ARCOP. Although many international codes including IMO recognize the issue, there is no international standard or even training service available. The need for trained crews for ice operations is increasing: an estimated 3,000 positions require Arctic training in future years. The subject of adequate Arctic crew training is also strongly related to the issue of Arctic marine safety.

Work Package 4, *Environmental Issues*, primarily looked at the risk levels of Arctic marine transportation. With the scenarios that were created, it seems that the risk levels were quite low when compared to experience from other sea areas. It must be noted, however, that there is no existing experience with large-scale transportation in the Arctic conditions. The experience on ice damages is mainly based on Baltic conditions. This is an issue that needs to be thoroughly studied in the future. The second issue studied was oil drift after an accident. The several scenarios produced showed that depending on the accident location, either high capacity or quick response time is important. This means that the response strategy must take both of these into account. What was satisfactory was that the different simulation methods gave consistent results and thus at least the experts are confident that the methods are reliable. The third issue was the actual oil spill countermeasures. Knowing that the use of in-situ burning and dispersants is efficient, but their use limited due to other reasons, the project concentrated on bioremediation and mechanical oil recovery. In bioremediation, the problem still exists that the type of bacteria available today is not efficient in temperatures below freezing. This means that the development of more specific PAH-degrading cold-adapted bacteria needs to be continued. Within mechanical oil spill recovery several options were studied. It seems that none of them is proven in a large-scale oil spill. There are efficient methods like the LAMOR Arctic Skimmer, but they have been designed for a limited size of oil spills and need further development.

The original idea within ARCOP was to arrange a large-scale validation voyage with a large-size tanker to the Russian Arctic. Unfortunately, no commercial cargo was available for a large tanker by the time the voyage was planned. What was done instead was that the Russian participants in the project analyzed some of the ongoing

© ConocoPhillips

activities in areas that can be considered relevant. The current cargo operations at the Varandey terminal show that the downtime estimates used in the ARCOP economic analyses were quite close to those that are experienced today. Also, the time that is needed to perform the customs and other administrative formalities were realistic.

The analyses related to the operation of icebreakers with large tankers were done from experience in the Baltic. These analyses show that, at least in Baltic conditions, one icebreaker is often enough to assist one large tanker through the ice. Thus, the assumption that was used in ARCOP calculations may be slightly pessimistic.

During the project, eight workshops were arranged within the Work Package 6. The workshops gathered 401 specialists, representing 89 different organizations from 12 different countries during the whole project.

The workshops were an efficient tool to bring together different interest groups from industry, science and authorities. And although ARCOP was an EU-project, the workshops brought a circumpolar dimension into the work.

In general ARCOP managed to achieve most of its strategic objectives:

- The workshops formed a forum for continuous discussion between the EU and Russia with some circumpolar dimension toward the end.
- The review of the legal aspects resulted in a common understanding of the legal status of the Arctic sea routes, while raising a number of issues that need to be taken into consideration as the GATS regime for shipping is developed.
- The research of the rules, regulations and requirements brought some clarity to the consistency of the regulatory basis of Arctic shipping in the Russian Federation, while noting current IMO and IACS regulations were not fully satisfactory.
- The economic analysis of transportation showed how different factors, such as technology, fees, efficiency of the border formalities and the way of operating the icebreakers, were critical influences in decision-making.
- The studies on environmental issues gave a clear warning that readiness for accidents must be further developed and that all the safety-related factors have to be taken seriously.
- The work between the EU and Russian researchers improved the understanding between the cultures and led to the development of common recommendations on a number of topics.

ARCOP was considered a part of the EU-Russia energy dialogue. The results of the project will be of help when developing energy transportation policies from Arctic Russia to global markets.

Findings

Regional Futures to 2020 Northern Sea Route and Adjacent Areas

1] The marine transportation of oil from the Pechora Sea to Europe is considered to be both technically and economically feasible. Today cargo flow is more than 1.5 million tons per year. With future increases in cargo, the charge for every passing ship along the NSR will be decreased accordingly.

2] Russian rules and requirements are mostly consistent with international law and requirements (for example, UNCLOS and IMO Conventions). However, taking into account Russia's experience with navigation in the Arctic, it has adopted rules pertaining to vessels operating in the NSR that contain certain provisions that go beyond international rules and standards (for example, inspections, requirements for ice pilots and transit fees).

3] The estimated volumes of maritime traffic on the NSR are expected to be about 40 million tons of oil and gas per year by 2020, which may contribute to improved economic effectiveness of cargo transportation via the NSR.

4] New Arctic marine technologies can help solve some of the problems related to transportation economics. With proper technologies, marine transportation costs in the region will be lower than those of pipeline transportation of oil and gas.

5] The probability for major accidents is considered to be low even with the increased traffic volumes; however, the consequences of a major accident would be serious due to the sensitivity of the fragile Arctic environment, remoteness of the area, harsh environmental conditions and difficulties in conducting oil spill cleanup operations.

6] There are several, key infrastructure challenges for the region: the ice information services require support; adequate hydrographic services may become an issue and lack of adequate search and rescue capabilities along the NSR. Regional SAR agreements between Norway and Russia, and the U.S. and Russia, have improved response and coordination in the Barents Sea and Bering Sea accordingly.

Findings

1] Natural resource development and regional trade are the key drivers of increased Arctic marine activity. Global commodities prices for oil, gas, hard minerals, coal, etc., are driving the search for Arctic natural wealth. New Arctic resource discoveries are highly probable and most new developments will require marine transport and operational support.

2] Exploration and development of new Arctic natural resources take place in continually changing and hugely complex physical, economic, social and political environments. Few (if any) predictive/forecast capabilities of this broad scope and magnitude are available to provide quantitative information on these global sectors interacting together (and their relationships to Arctic marine transport requirements).

3] A large number of uncertainties define the future of Arctic marine activity. These uncertainties include: the legal and governance situation, degree of Arctic state cooperation, climate change variability, radical changes in global trade, insurance industry roles, an Arctic maritime disaster, new resource discoveries, oil prices and other resource commodity pricing, multiple use conflict (indigenous and commercial) and future marine technologies.

4] It is anticipated there will be a slow movement of Arctic marine ecosystems northward with retreating seasonal sea ice, which may open new fishing grounds in higher latitudes in the future.

5] Plausible longer seasons of navigation will have significant implications for multiple uses in regional Arctic waterways. The overlap and/or competing indigenous and new marine uses will provide many challenges for the Arctic coastal states.

6] There is anticipation that new Arctic ship technologies will set a norm for more independently operated, icebreaking commercial ships; however, icebreaker assistance will remain the principle element of Arctic infrastructure.

7] Increased marine traffic in the central Arctic Ocean is a reality - for scientific exploration and tourism. The future holds increasing exploration voyages, plausible increases in tourism and fishing and plausible trans-Arctic voyages in summer on an experimental basis.

8] Arctic voyages through 2020 will be overwhelmingly destinational (regional trade), not trans-Arctic. These destinational voyages are driven by natural resource development, marine tourism and supply/import of materials/goods.

9] Most ships built today for Arctic operations are purpose-built, such as bulk ore carriers, tankers and LNG carriers. There is an economic penalty to use these same ships in long, open ocean voyages since their higher construction standards and thicker steel plating for sailing in the Arctic adds considerable weight.

10] Arctic offshore leases in the Beaufort and Chukchi seas and large investments already made in offshore Arctic Norway and northwest Russia (Barents Sea) may stimulate decadal increases in coastal Arctic marine activity.

11] A lack of major ports and other maritime infrastructure, except for those along the Norwegian coast and Northwest Russia, is a significant factor (limitation) in evolving and future Arctic marine operations. There are significant linkages between infrastructure and to most environmental protection and marine safety measures and strategies.

12] Many non-Arctic stakeholders, such as non-Arctic states, marine shippers, insurers, shipbuilders, tour ship operators and more, will become actively involved in the future use of the Arctic Ocean.

13] It is highly probable that socio-economic responses to global climate change (for example, emission controls) will impact all elements of future Arctic marine activity.

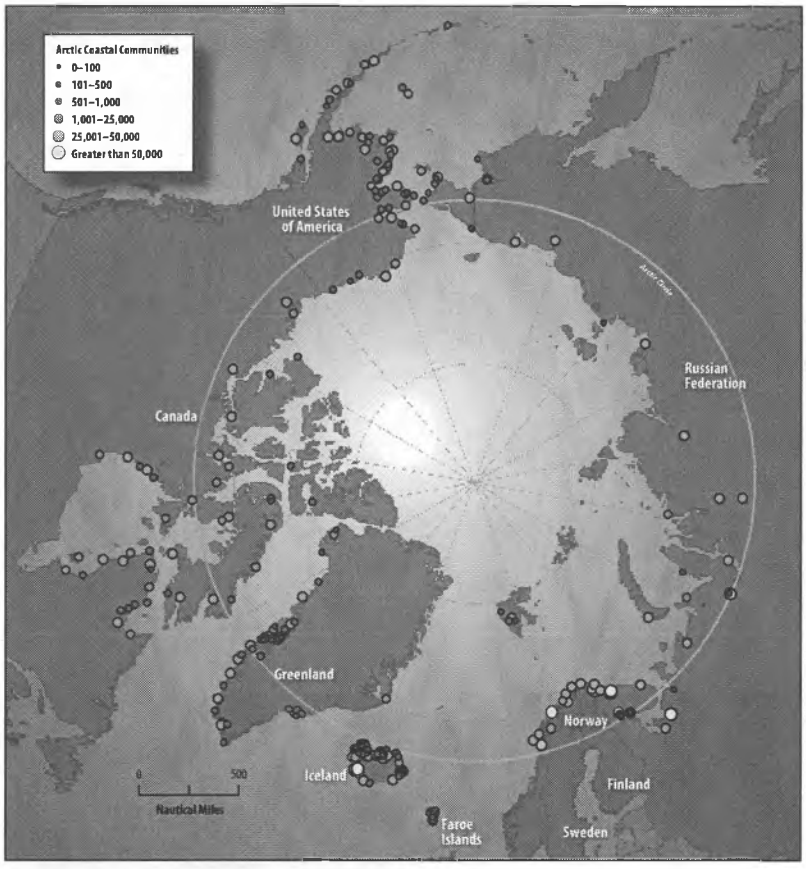
HUMAN DIMENSIONS

Human dimensions refer to the interrelationships of people and the environment, particularly with respect to environmental change. Often, human dimensions concern broad issues such as government policies or institutional responses to change. In the Arctic, human dimensions research has typically looked at local or regional cases. For marine shipping in the Arctic, both the broad and the local approaches are important to consider. Shipping will occur across the entire region, requiring national and international policies to provide effective management and regulation. Because trans-Arctic shipping will be driven largely by global economic factors, as will more local shipping for resource development, the role of institutions such as shipping companies, regulatory agencies and local or regional organizations who may be affected will all be pertinent.

This chapter addresses primarily the local aspects of human dimensions of Arctic marine shipping, with a particular focus on indigenous communities and traditional activities in the marine environment. Arctic marine shipping will occur in the context of many other changes affecting Arctic residents. Climate change, which will make the Arctic more accessible to marine shipping, will affect most aspects of the lives of Arctic residents, from traditional livelihoods to infrastructure to the spread of disease. Social and economic change will come from national and global trends in trade and communication. Impacts to the environment and society are most likely to stem from the interactions of human and environmental change, particularly as human choices influence the trajectories of change. In this context, shipping may play a significant role not only on its own, but also, and perhaps even more likely, through combining with other drivers of change.

Arctic marine shipping involves several distinct activities, each with different interactions with local residents and thus different implications and likely impacts. Trans-Arctic shipping of cargo, using the Arctic merely as a corridor between distant ports, has some potential for environmental impact, depending on cargo carried and volume, and thus for affecting local societies that depend on a healthy marine environment. The infrastructure required to support such shipping may include port facilities, search and rescue or emergency response capability, and mechanisms of governance



Map 7.1 Circumpolar coastal human population distribution. *Source: AMSA*

Economically, more shipping may increase trade or lower costs for Arctic communities, while increased resource development can provide employment and income for Arctic residents and regions.

or enforcement, which may include military presence to preserve sovereign claims over certain waters. Such facilities may provide employment and other economic opportunity for local communities, but could also lead to social disruption if many people move to small communities to take new jobs. Local shipping, to and from Arctic ports, is likely to have more direct influence on communities. Indeed, local shipping today provides for substantial shipments of cargo and fuel to remote communities, allowing for a higher standard of living and lower prices than would be possible by air or land shipment alone. Longer shipping seasons could reduce prices further, or allow greater access by visitors.

Another form of local shipping is that in support of resource development in the Arctic. Supplying mines, oil and gas installations, and other development sites, and transporting the materials that are produced there, is the dominant form of marine shipping in the region today. While it is not clear whether reduced sea ice will have a major influence on development trends, increased shipping is unlikely to constrain development. If indeed development increases, it will have far-reaching economic consequences for the regions in which it occurs, and will likely have environmental impacts as well.

In addition to mineral and petroleum extraction, fishing in Arctic waters is likely to increase as a result of greater access to ice-free waters. In Greenland in particular, the development of a shrimp fishery has had major impacts on coastal communities and indeed on the national economy, as shrimp constitute a major export from Greenland. In Alaska, participation in commercial fisheries has substantial social and economic impacts on communities, implying that increased involvement in fisheries by more northern communities could have major impacts both positive and negative.

One non-extractive industry likely to benefit from increased shipping access is tourism. For local communities, tourism can be a source of revenue but also a disruption, both from direct (though

A Container of Hazardous Materials Washes Ashore in the Commander Islands, Russian Federation

Bering Island, one of the Commander Islands, lies east of the coast of Kamchatka and west of the U.S. territories in the Aleutians. The only Aleut community on Russian soil and the only inhabited village on the Commander Islands is the village of Nikolskoye with about 750 residents, 300 of them Aleuts. The following is an account of an accident that should serve as a warning sign and an opportunity to examine the Achilles heel in shipping regulation and disaster preparedness, pointing the way toward policy changes to prevent worse disasters.

In July 2003, a 20-ton container filled with a hazardous chemical used in cement (tetraeth[illegible] glycol diheptanoate) washed up off the western coast of Bering Island, near the northwestern fur seal rookery and 15 kilometers from the local fishing grounds. The container, owned by the DuPont Corporation, was being shipped from South Africa to Korea and was lost at sea in March 2003.

When the container was discovered on the beach, there was no disaster response plan in place. Individuals who got close to the container to examine it did not have any training in the handling of hazardous materials or the necessary equipment and clothes. They were poisoned and needed medical assistance.

The first attempt to move the container away from the area where tidal waves could throw it on the rocks and break it was unsuccessful. The container cracked and approximately 15 tonnes of the chemical leaked, creating a 400 square-meter oily spill. A later survey counted 40 dead birds and one dead seal.

The Anchorage office of the Aleut International Association, after receiving first news of the accident, made a round of calls to maritime attorneys in an attempt to find legal counsel for the village of Nikolskoye. Finally a firm with appropriate expertise was located in Juneau, Alaska. A telephone conversation, however, was abruptly interrupted by the news that the firm had been hired to represent DuPont.

DuPont provided funds for clean up, environmental assessment and some emergency response equipment. The nature and size of this work was mostly determined by DuPont itself.

This particular accident was small, but it exposed potential problems. Governments may want to identify measures that can help prevent accidents and address response, especially in light of expected increases in shipping.

Reflections from the Kola Coast

Shipping is but one of the many aspects of the history of northwestern Russia, one of the many factors shaping today and tomorrow. Murmansk was a bustling seaport during the Soviet era, when at the height of the Cold War it was the fishing capital of Northern Russia. The Murmansk Region is home to about 2,000 Saami, who continue their traditional culture in the inland parts of the Peninsula.

© Arctic Council

In the Murmansk Region, history has been witnessed, lived, forgotten, suppressed, remembered and altered. Kola Bay, with its nuclear fleets, is poised to be the jumping off point for Arctic opportunities of shipping and mineral development. The Kola coast is a smaller version of the multi-faceted, complex and layered coastal landscape and seascape that is the Russian Arctic coast today.

As a part of the time of transformation, the Kola Saami are witnessing a painful rebirth of their culture and nation. Since the formation of the Russian Federation, they can collaborate with the Saami in neighboring countries. They can participate in the Arctic Council and influence, for example, the development of marine and ocean policies. Even though the seasonal salmon harvest along the fjords of Kola is over and seals are no longer harvested by the Kola Saami, many elders still remember the sites, places and songs of the Kola coast. They remember the yearly cycle of the ocean, birds, fish and other beings.

The Kola Saami are afraid that the increased shipping and construction of new pipelines will ruin the remaining wilderness areas of the Kola. Atlantic salmon spawning rivers, such as the Ponoi, are vital traditional fishing areas for the Saami and their productivity is directly related to the ecological status of the Russian sector of the Arctic Ocean. The Kola Saami are engaging in planning and decision-making to make sure that the people of the Sun Deer will be here now and forever.

likely inadvertent) interference with traditional and other activities, and also from greater attention to some local practices that may not conform with the values or expectations of non-Arctic societies. The presence of large cruise ships and their visits to communities that may have a fraction of the population of the ship itself cannot be ignored. An emergency involving such a ship could easily overwhelm local response capacity. Tourism, like fishing but unlike other forms of shipping, is likely to be focused on some of the same living resources (seabird colonies, marine mammals) that sustain local communities, thus increasing the potential for disruption and conflict.

The local human dimensions of Arctic marine shipping appear to be extensive, but there have been relatively few studies that have considered the implications either of current shipping activities or projections of what is likely to occur in the next few decades. The AMSA's description of human dimensions of Arctic marine shipping is neither comprehensive nor exhaustive, but is intended to demonstrate how and why marine shipping matters to Arctic communities and to consider what additional work is needed to be able to prevent, mitigate, or otherwise manage shipping to reduce negative impacts and maximize potential positive benefits.

In recent decades and today, Arctic coastal people travel far on sea ice and water, both along coastlines and also out to sea. A comprehensive, up-to-date catalog of indigenous use of the Arctic marine environment does not exist. Compilations of data from Canada and Alaska are two to three decades old. Some more recent studies have examined use patterns near individual communities, but even these are few and dispersed. It is thus impossible to present an overall map or description for the entire Arctic. This section provides instead a few examples of various uses of the Arctic marine environment and

"The Sea Ice Is Our Highway"

Canadian Inuit Perspective on Transportation in the Arctic

Within Canada, Inuit view the Arctic as the places where Inuit have traditionally lived: Nunatsiavut along the coast of Labrador, Nunavik in Northern Quebec, the entire territory of Nunavut, and the Inuvialuit settlement region along the northern coast and around the northern islands of the Northwest Territories.

Life in the Arctic is dependent on movement, and sea ice is integral to this movement. The Inuit have been a nomadic people living in the Arctic since ancient times. As such, our entire culture and identity is based on free movement on the land and sea. Much of the traditional knowledge passed down from generation to generation is meant to hone the skills necessary for hunting and fishing. In order to hunt and fish safely and effectively in the Arctic, we train our young people to recognize different types of ice and to know the dangers associated with different seasons. Inuit hunters spend much of their time out on the ice, mostly in small groups or even alone; therefore, reliable knowledge of the ice can be a matter of life and death.

Interviews conducted by ICC Canada in March 2008 indicate that despite the increased difficulty in finding and harvesting big game and sea mammals due to thinning and less predictable sea ice, Inuit communities are persistent in maintaining their traditional diets. When asked whether changes in ice conditions were affecting their traditional diets, respondents spoke of having to travel further or in a different month than usual; they spoke of dietary substitutions such as hunting more musk-oxen when the caribou migration shifted away from their area; or they explained how melting permafrost has made the natural ice cellars used to age and store meat less effective. Not one of them said anything to suggest they were giving up on hunting despite the considerable challenges some were facing in getting out on the ice and land.

When asked how his life might change because of poorer ice conditions in the future, Tommy Qaqqasiq from Pangnirtung, Nunavut said: "Then we'll use other equipment. People will still hunt. It's part of our life. When things change, you just have to go with it."

After describing in detail how climate change is forcing his community to deal with new challenges, John Keogak of Sachs Harbour shared this idea on how he can continue his harvesting practices:

"A buddy of mine is into making little sleds out of aluminum, which you can use as a little kayak or boat. If you're out on the ice and you have to cross an open lead or something you can use that. It's one of the things that can help. I'm going to get one of those. It's combined as a little sleigh and, if you have to, you can use it as a boat. That's one way I can adapt."

With few exceptions, Inuit settlements are located on sea coasts or on major waterways with easy access to the sea. This clearly reflects the importance of the sea to our Inuit way of life. Whether thickly frozen or open for the summer, the sea is our primary means of transportation. The usually ice-covered sea is our highway, the only physical connection between many of our communities and the only way we can access many of the animals we depend on for food (Table 7.1).

As climate change and reductions in sea ice affect the migration routes of the land and sea animals we rely upon, it may be necessary for us to travel even further than before in order to reach them. Inuit hunters are reporting many changes in the locations and times that our traditional animals can be found. In some communities this is reducing the territory that hunters need to cover, while in others they have to travel much further than before in order to harvest enough food for the communities. This is why we are very concerned that sea ice routes remain passable for hunters, as well as the migratory game they follow, and that the entire Arctic environment be kept free from contamination – both in the areas we are now using regularly and in those areas where we may need to hunt in the future.

The primary resource for Inuit is the animals. Our people have always known how to care for this resource. We live in harmony with the land. When we hunt, we only take what we need and make sure to leave enough of the herd so that it can replenish itself. When we talk about the future, we are not talking about a five-year plan or even a 10-year plan. We are talking about our children and our children's children. We are talking about living in the same communities where we can see the evidence of our ancestors. We are talking about preserving our way of life and the natural environment it depends upon for hundreds and thousands of years.

Ships coming through our seas are a cause for concern. On the one hand, they can be used to supply our communities with building materials and goods for our stores, which might bring a welcome reduction in the high cost of living in the Arctic. However, ships have also caused a lot of damage, as hunter Tommy Qaqqasiq of Pangnirtung explains:

"In recent years, all kinds of cruise ships are coming in to our area. Last year alone, there were maybe five or six cruise ships that came into town. More are coming every year. There's a national park here in Pangnirtung, further inside the fjord, that's what they are coming to see. The tourists come into town and buy all kinds of

art, like carvings, craft work, soapstone, whatever they can afford to buy. They help the artists. [All hunters have been complaining about those ships because they go all over Cumberland Sound even to the campsites. People are saying they are scaring away the animals, the mammals and whales. We are really noticing this because in the past couple of summers we hardly saw any narwhals around. Usually we catch our quota, but not in these past years."

Another example of the difficulties related to shipping comes from the community of Tuktoyaktuk on the Beaufort Sea coast. Tuktoyaktuk has long been a key hub for supply ships servicing many of the Inuit communities in Canada. Because the harbor is also teeming with various species of fish, Tuktoyaktuk is an instructive example of colliding interests between economic activities and Inuit use of the sea. Inuit hunter, trapper and fisherman Chucky Gruben describes the issues:

"We have a hunters and trappers committee here, we take care of the wildlife. We deal with the people, we deal with the shipping companies. We have done some things where, after freeze-up, the ships are not allowed to come into the harbor. But this past year, because of late shipping to other communities, we had to keep our harbor open longer than usual because the supplies hadn't gone out to the other communities.

"The community of Tuktoyaktuk is right in a harbor where a lot of fishing takes place. The east entrance is a place where a lot of people here that do their fishing set their nets right in the channel. Because the ships had made a ship track through the east entrance, they kept it open up right until November sometime, and the people couldn't set their nets there because of the ships going back and forth. That is one of the impacts of shipping on our harvest.

"Usually with that kind of thing, we do have a say on whether the ships can use the area, but times are changing and every year we get applications to come into the harbor later and later. They wanted to do that the year before last, too, but we had to say no. Last fall we didn't really have a choice because there was still fuel and a lot of supplies that needed to go out to the other communities, so we had no choice."

The point [illegible] accounts from various Inuit communities is that the environment is vital to our entire way of life as Inuit. If something were to happen to our fragile Arctic ecosystem, our way of life would be lost and we as a people would be lost. Therefore, any activity in the Arctic, whether it is resource extraction, tourism or military-related, must be undertaken according to the Inuit definition of sustainability – it must support the continuation of the Inuit way of life for thousands of years to come.

Table 7.1 Socio-economic projections for the Canadian North from the 2007 Canadian Arctic Shipping Assessment *Source: Transport Canada*

Region	Demographics	Transportation	Economy
Nunavut	• 2006 population: 29,500 • Growth rate 1.8% in 2005 to 2020	• No all-weather roads or rail links between communities • Most communities receive 2 re-supply calls per year	• Dominance of public sector for economic output and jobs • Significant non-wage and subsistence activity • >100 active resource exploration sites • Limited tourism • Growth at 4.7% to 2010, slowing thereafter
Northwest Territories (NWT)	• 2006 population: 41,861 • Most communities not expected to grow by 2020	• Mackenzie River communities served by all-weather or winter roads	• High unemployment in coastal communities • Presently no resource projects for river communities • Any shipping impact centred on Mackenzie Gas Project • High Arctic oil and gas potential, but not before 2020 • Some diamond mine development opportunities
Nunavik	• 2006 population: 10,783 • Population younger than Canadian average • Growth rate of 2.4% to 2018, to slow thereafter	• Community port programme receives fed/prov support • No all-weather road links to the 14 communities	• Significant non-wage and subsistence activity • Like Nunavut, wage economy is growing through govt., fishing and sealing, tourism, construction and resources • Resource development slow due to lack of road infrastructure
Coastal Cree Communities (in Quebec, Ontario, and Manitoba)	• 2006 population: 18,654 • Young population • Declining or levelling growth rates expected post-2010	• Port of Churchill • Limited all-year road access	• Largely subsistence economies • Some benefiting from hydro-electric developments • Resources on the horizon (diamond, gold, uranium) • Churchill – a viable link to Russia?

resulting interactions with marine shipping activities in different forms. These examples are intended to illustrate some of the range of potential interactions and effects.

Arctic marine shipping is one of many factors affecting, or with the potential to affect, the lives of Arctic residents. Predicting exactly how various developments in shipping will affect Arctic communities is difficult at best. For example, there is insufficient information to describe current local human uses of the Arctic marine environment adequately enough to assess the range of likely effects of marine shipping, and researchers cannot anticipate all potential information needs when conducting studies in advance. Rather, findings of the kind presented in this section can be used to identify areas of potential conflict or interaction between local uses and marine shipping, but further studies should be done of specific areas where shipping activities are planned, in which the details of shipping and current local uses can be compared and evaluated for potential impacts and mitigation strategies.

In the face of uncertainty about what activities will take place, what effects those activities will have and what other factors will be involved, a collaborative management approach and careful planning are required to identify and respond to negative impacts and to identify and harness positive benefits. One hallmark of the collaborative

Extent of Use of the Marine Environment by Aleut Communities

The marine environment is vital for coastal Arctic communities. This is especially true in the Aleut region, where communities are on islands or along the Alaska Peninsula, providing excellent access to the sea but relatively few options on land. As with other regions, the extent of marine use by Arctic indigenous communities, the information from the Aleut region is not consistent, comprehensive, and up to date for all communities. Instead, some reports are over a quarter century old, and more recent information does not cover all communities or all species. Nonetheless, tribal representatives confirm that the general pattern of marine use continues today.

Table 7.2 shows the results of surveys concerning traditional harvests in three predominantly Aleut communities in Alaska. Other studies have found that the overwhelming majority of households in Aleut communities use birds and eggs. In Nelson Lagoon, 92.3 percent of households used at least one bird or egg during the study period. In Akutan, the figure was 97.9 percent, compared with 88.9 percent in Nikolski and 74 percent in False Pass. Sharing of harvested birds and eggs was considered to have great cultural importance in all four communities.

Zenia Borenin, president of the Tribal Council for the Native Village of Akutan, described local use of the marine environment:

"The northeast near coastal waters of Akutan Island are important for black bass, chitons, halibut, salmon, razor clams, and sea lions. The southeastern-most near coastal waters is a viral cod and salmon fishing area. There is a sea lion haul out area on the eastern coast of Cape Morgan. A cod and halibut fishing area is located in the near coastal waters northeast of Talus Point.

"Akutan utilizes the coastal waters around Akun Island as well. Seagull eggs are harvested on the northwest shore of the island (Akun Head), and on the small islands southeast of Akun. Salmon and halibut are taken in the area of Lost Harbor. Halibut is harvested in the near coastal waters southwest of the island, and in several areas east of the island. Salmon are taken in Surf Bay, Trident Bay, and in Akun Bay in the area of Heliantinus Cove. Akun Bay is an important area for halibut, crab, cod, octopus, and sea bass."

Community	Per capita harvest (kg)	% from salmon	% from other fishes	% from marine invertebrates	% from birds and eggs	% from marine mammals
Sand Point	115.9	54	21	7	2	2
King Cove	116.0	53	17	8	4	1
False Pass	186.9	47	15	6	4	6

Table 7.2 Per capita harvests of wild resources from three Aleut communities, with percent contribution from various classes of marine resources.
Source: Fall et al. 1993a, b, 1996

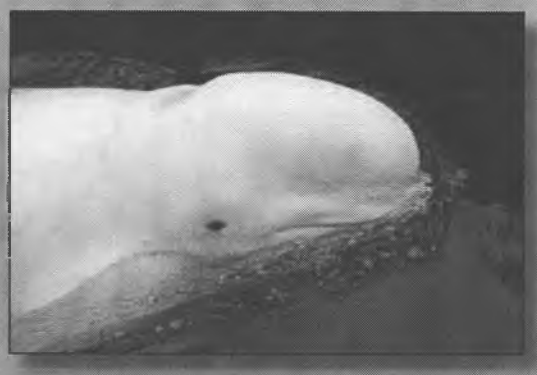
approach is that it is adaptive in the sense that it allows for adjustments and alterations based on experience and evaluation as changes take place, rather than creating a fixed system for addressing anticipated issues that may turn out to be ineffective when unanticipated events occur.

An advantage of substantive local involvement is that local residents are often best positioned to weigh the many factors affecting them. The example of the container that washed ashore in the Commander Islands describes the consequences when local capacity for addressing a problem is lacking, a situation exacerbated in that case by the lack of any larger precedent or system for response or accountability. In cases where local involvement in planning or carrying out shipping-related activities was higher, communities generally experienced better results.

One component of local involvement is communication. Many of the participants in the AMSA town hall meetings asked for better information about cruise visits and trans-Arctic shipping plans. Effective communication and continued interaction has been found to be important in oil and gas activities and in tourism in the Arctic. Communication can help reduce the number of surprises for all involved, and early identification of problems can allow more time for resolution.

As noted earlier, projection of shipping activities and their impacts is difficult due to the interactions of numerous factors in the environment and in human society. To some extent, researchers need to develop better methods for studying combined effects of these kinds, just as regulators need to develop better methods for balancing multiple management objectives. Just as importantly, those involved in marine shipping in any capacity need to recognize that flexibility and adaptiveness will be required to recognize and address challenges, problems and opportunities that arise.

Marine shipping encompasses a wide range of activities, taking place in different locations and seasons and with differing degrees of local involvement and effects. The quantity of shipping, likewise, may determine whether effects are largely beneficial or otherwise, and also who is most affected. For example, limited tourist traffic may provide a modest economic opportunity for local artists and handicraft makers, whereas higher levels of traffic may have environmental or other impacts that offset any benefits. As noted earlier, the details of effects will depend greatly on the details of shipping and the characteristics of specific times and places. Nonetheless, the case studies in this section and studies of other types of activities, such as mineral and petroleum development, suggest some observations about what can be expected from increases in Arctic marine shipping.



Beaufort Sea Beluga Whales

Local and Distant Effects of Shipping

The Beaufort Sea population of beluga whales, numbering in the tens of thousands, migrates from the Bering Sea through the Bering Strait into the Chukchi Sea and then eastwards into the Beaufort Sea. The animals pass through the Mackenzie Delta region and into the waters among the western islands of the Canadian Arctic Archipelago. This migratory path takes them through the waters of Russia, Alaska and Canada. The belugas are hunted in all three regions.

During their migration, Beaufort Sea belugas traverse several areas where shipping may be a major presence. The Bering Strait is a crucial chokepoint for any trans-Arctic shipping. The Mackenzie Delta area already sees extensive tug and barge traffic. Shipping through the Northwest Passage will pass through narrow waterways where belugas gather in summer. Offshore oil and gas activities, including shipping, may affect belugas throughout much of their range.

Shipping may also interfere with hunting activities and opportunity, compounding any effects at the level of the beluga population. Further work is needed to examine exactly where and when shipping will overlap with hunting and with key stages of the beluga migration. This information can be used to develop specific management and mitigation plans, perhaps including limitations on shipping to protect belugas and those who hunt them.

In addition to local initiatives, a broader management plan is required to address impacts in one region that may affect other regions. For example, a disaster in the Bering Strait could affect hunters in the Mackenzie Delta region, 2,000 kilometers away, undermining any conservation efforts they have made in their area.

Town Hall Meetings

Town hall meetings were held in various locations in the Arctic as part of the outreach effort of the Arctic Marine Shipping Assessment. The intent of these meetings was two-fold. First, the organizers presented the plans for the assessment and the expectation of increased marine shipping that was driving the study. Second, the organizers sought input from participants regarding their observations, concerns and questions related to marine shipping. This section presents a summary of the main themes that emerged from these meetings.

Arctic residents think about shipping, not by itself, but in a broader context of economic, environmental, political and social change. In the town hall meetings, shipping did not appear to be a cause of great hope or fear, but rather as an additional factor that would influence the future of Arctic communities in various ways. In addition, discussing the future of Arctic marine shipping raised concerns about the ability of small indigenous communities to influence large-scale economic activities.

Environmentally, shipping is seen as a potential source of disruption to marine species. Marine mammals, in particular, are seen as vulnerable to disturbance. In Resolute, Nunavut, a period of increased shipping in the 1990s pushed walrus away from the community, too far for hunters to reach them. Saami fishermen in northern Norway are concerned about impacts to fisheries and fish stocks, particularly from pollution or oil spills. Oil spills are, in fact, one of the largest concerns, especially with the lack of response capability in nearly all areas of the Arctic. Ship traffic also raises the possibility of introductions of invasive species.

Hunters are concerned about impacts to the animals and to their practices. Too much ship traffic could be dangerous for hunters in small boats. In many cases, hunters traveling over sea ice have been cut off by icebreakers, an impact that remains a big concern, especially when travelers' lives could be at risk from unexpected open water. In some areas of the Canadian Arctic Archipelago, caribou migrate over sea ice and could be affected by icebreaker traffic. On the other hand, hunters in Resolute and Iqaluit noted that some marine mammals follow ships. In Iqaluit, the arrival of a ship was often a signal to beluga hunters to look for whales that may have come into the bay. As one hunter in Cambridge Bay, Nunavut, said, hunters are going to adapt, but they cannot survive without healthy animals to hunt.

Economically, shipping offers many benefits. Participants in many communities spoke of the prospect of lower shipping costs if cargo ships can come more frequently or if larger ships can be used. Increased shipping and port activity can also provide jobs. In Canada, ports for mines have often been located away from communities at the communities' request, to avoid social impacts from the influx of workers. Communities may reconsider that approach or seek other ways to gain economic benefits from port activities. On a smaller scale, cruise ships provide an opportunity for carvers to sell their artwork, making their visits welcome to at least some Arctic residents.

The relative costs and benefits of shipping depend greatly on volume. Modest amounts of traffic, or a few visits by cruise ships, may be seen as largely positive. Increasing numbers of ships and visits, however, pose the threat of greater disruption and little time in between to recover. Culturally and socially, shipping can be a catalyst for disturbance if many newcomers arrive in the Arctic, as has been seen with other forms of development. The Arctic is already experiencing rapid social and cultural change, and additional pressures will only make adjustment harder.

In this context, many participants expressed concern over having little voice in shipping, development and other activities that have so much effect on their lives. In Norway, development of onshore mineral resources and offshore oil and gas are seen as major threats to the Saami way of life. With the extent of global environment, economic and social change, many Arctic people feel they have little ability to influence major developments like Arctic marine shipping. When shipping companies ignore local residents, the feeling of powerlessness is compounded. By contrast, when shipping companies or cruise lines communicate with local residents, the effort is well received and makes people better informed and thus better able to make any adjustments they need to in order to minimize the impacts of ship traffic.

An additional insight from the town hall meetings is that few Arctic residents are aware of the scope of activities that may be coming to their region soon. The meetings were able to provide some information, but many additional questions were raised about the scale of environmental change, the prospects of mineral development and other changes that can be expected in the near future. For Arctic residents, these influences are not separate things that can be treated one by one. Instead, each new factor merely joins the others in shaping people's lives. The degree to which Arctic people retain the ability to determine their own futures remains to be seen. Communication and the ability to exercise at least local influence are seen as key components of sustaining traditional ways and practices.

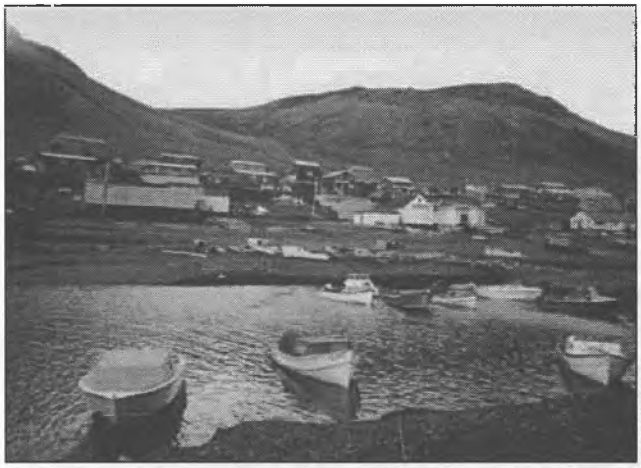
First, the impacts of shipping depend greatly on the type of shipping, the season(s) in which it occurs and the locations. Trans-Arctic shipping done in ice-free conditions and largely offshore may have few or no local effects, barring an accident. Nonetheless, as the Aleutian region has experienced, accidents can and should be expected, prepared for and responded to promptly and effectively. This is especially true in narrow waterways of the Arctic. In these places, ships must travel close to land and may well encounter local hunters or travelers out in boats. In addition, proximity to communities means proximity to hunting areas and the animals that people depend upon, so the potential for environmental impacts is correspondingly higher in these areas. Tourism, too, is likely to take place largely or exclusively in the ice-free season (with the exception of icebreaker voyages to the North Pole), though cruise ships are likely to visit communities or areas of high biological activity such as bird colonies or marine mammal haul-outs.

Shipping to and from destinations within the Arctic is also largely done during the ice-free season, with important exceptions in the Russian Arctic as well as occasional icebreaker transits throughout the region. Ice-breaking can interfere with over-ice travel by hunters and others and so is potentially a more significant impact than are open-water transits. Icebreaker activity may increase as mineral and petroleum resources are developed in the region, which might make interactions with local travelers more common. Here, too, the potential for environmental impacts is high, both from accidents and from destruction to key habitats such as areas where seals or polar bears make ice dens for bearing young. As with trans-Arctic shipping, the potential for local impacts is greatest near shore, particularly in narrow passages and straits.

Effects, too, come in several forms. Economically, more shipping may increase trade or lower costs for Arctic communities, while increased resource development can provide employment and income for Arctic residents and regions. As has been noted with regard to oil and gas activities in the Arctic, economic benefits may be considerable and can have a number of secondary effects, such as increased local capacity to provide social, cultural and health services as well as construct and maintain infrastructure.

Socially, increased economic activity and resource development can, but does not necessarily, lead to population growth through immigration, which can create social tension between newcomers and indigenous or other long-time residents. Often, those moving to the Arctic for employment are young men, creating a gender imbalance in the local population, which can exacerbate tensions and social problems. Changes in income, too, are often associated with increases in drug and alcohol abuse, as well as domestic violence and other crime. Many of these negative impacts can be addressed largely or in part, by establishing rotational work schedules, with workers traveling to the region for work shifts of one to several weeks and returning to their home communities during the periods they are off or by physical separation between a community and a development site.

Environmental effects are often the greatest concern from increased industrial activity of any kind, whether resource development or shipping. The environmental effects of Arctic marine



© Ross MacDonald

shipping are addressed in other sections of this assessment, but it is important to note that loss of hunting opportunities and degradation of the environment can have substantial impacts on local communities. Concern about these types of impacts can by itself cause stress, especially when hunting and other traditional activities are seen as pillars of cultural continuity but also under threat from other social and environmental changes.

The cultural effects of shipping and development may, therefore, be generally anticipated to be negative, but this is not necessarily the case. Environmental impacts and greater assimilation from exposure to outside influences can cause cultural loss, but tourism can boost local cultural awareness and pride and greater economic well-being can allow investments in cultural programs.

As noted earlier, the difference between negative impacts and positive or neutral ones is often a question of planning and preparation. A large influx of cash into a community can create a boom-and-bust atmosphere, with minimal investment for the long-term and a host of social problems in the short-term. The same economic boom can also be harnessed to produce lasting benefits. Doing so successfully requires extensive local involvement in the planning process, so that local concerns and ideas can be fully incorporated. Not all marine shipping activities will be beneficial for Arctic residents, and some are likely to have negative impacts. Nonetheless, careful attention to good communication and collaborative approaches to management can help keep increases in shipping activity from causing undue stress and harm to Arctic people and may result in benefits to many areas.

Research Opportunities

- Regional analyses of traditional marine use patterns (spatial and seasonal) for application in the development of strategies and measures to reduce potential conflicts and impacts of multiple users of Arctic waterways.
- Research on the impacts of noise/sound on marine mammals in regions where current and future marine operations overlap with indigenous hunting (examples: bowhead whale hunting off Alaska's northern coast and beluga hunting in the Canadian Arctic).
- Detailed, interdisciplinary analyses of the interactions and impacts of marine shipping with Arctic communities. Further assessment of the social, cultural, economic and environmental impacts from shipping to provide insights for planning future Arctic marine systems and operations.
- Mapping and study of changing indigenous use of Arctic sea ice as a transport medium in the face of climate change and sea ice retreat.
- Comprehensive review of changes in Arctic marine technology during the past six decades, specifically for Arctic commercial ships, and how these changes may influence the future of Arctic marine transport systems.

While it is not clear whether reduced sea ice will have a major influence on development trends, increased shipping is unlikely to constrain development.

Findings

1] Marine shipping is one of many factors affecting Arctic communities, directly and indirectly. The variety of shipping activities and the range of social, cultural and economic conditions in Arctic communities mean that shipping can have many effects, both positive and negative.

2] While economic effects of marine shipping may be positive, there are many concerns expressed by Arctic coastal communities about social, cultural and environmental effects.

3] There is insufficient information to identify with any precision the likely effects of marine shipping for most Arctic coastal communities. No current database exists for indigenous use in local Arctic waterways that could be used to develop multiple use management measures and potential mitigation strategies.

4] The costs and benefits from marine shipping will be unevenly distributed among and within communities and regions.

5] Constructive engagement of local residents at the earliest time in a planned Arctic marine development project can help reduce negative impacts, assist in a smooth interaction and increase positive benefits from marine shipping.

6] The marine environment and marine resources have long sustained Arctic communities. Thus, Arctic settlement patterns demonstrate a strong marine influence. Local Arctic residents today depend heavily on marine resources for subsistence and the local economy. A combination of over-the-ice travel (i.e., using ice as a platform and means of travel for hunting and fishing) and boat transport (i.e., for fishing, hunting and travel) allows the use of large Arctic marine areas during much of the year. Life in the Arctic is dependent on movement and sea ice is integral to this movement in the high Arctic. Remote indigenous coastal communities are especially vulnerable to marine accidents as they risk losing not only their vital marine resources, but the natural foundation of their cultures and way of life.

7] AMSA town hall meetings revealed that Arctic residents think about shipping, not by itself, but in a broader context of economic, environmental, political and social change. Shipping did not appear to be a cause of great hope or fear; rather, as an additional factor that would influence the future of Arctic communities in various ways.

8] AMSA town hall meetings indicated that from an environmental perspective, shipping is viewed as a potential disruption to marine species. Oil spills are one of the largest concerns. Hunters are also concerned about the impacts of ships on the animals and on their hunting practices.

Environmental Considerations and Impacts

Marine shipping, if not properly managed, poses a threat to natural ecosystems. This is especially true for the Arctic. Whether it is the release of substances through emissions to air or discharges to water, accidental releases of oil or hazardous cargo, disturbances of wildlife through sound, sight, collisions or the introduction of invasive alien species, the Arctic marine environment is especially vulnerable to potential impacts from marine activity.

Vulnerability of Arctic Species and Ecosystems

Extreme cold temperatures, ice and strong seasonal variability characterize the Arctic. These extremes have resulted in a range of adaptations among Arctic animals including the ability to store energy when food is plentiful and fast when it is not; highly insulating outer layers such as feather, fur or blubber to keep warm; and a high degree of seasonal migration to and from the region, especially among marine mammals and birds.

The extensive seasonal migrations of marine mammals and birds into and out of the Arctic are key features that determine the vulnerability of Arctic ecosystems. Seabirds, shorebirds and waterfowl move north to breed and feed during the short Arctic summer, exploiting the burst of productivity in the northern ecosystems. Whales and seals have similar migrations to northern feeding areas. Many species aggregate throughout the circumpolar north in very large numbers to feed, mate, give birth, nurture their young and molt. During the periods when Arctic species gather and in the areas where they do so, they are particularly vulnerable to potential environmental stresses, such as accidental discharges from ships and various types of disturbances that ships can cause.

Disturbance during critical stages could disrupt the short feeding season for Arctic species, causing some animals to not get enough food to provide the energy needed for the long migrations they face and for breeding and raising their young. Arctic species, which are reliant on feathers and fur to insulate against the cold, are especially

vulnerable to contamination from oil that will compromise their insulating layers, leaving them exposed and at risk of hypothermia and death. It is the unique adaptations of the various species which live in and migrate to the Arctic that make them vulnerable to potential adverse impacts as a result of shipping and other vessel activities.

The degree of oil pollution in the Arctic marine environment is low, according to the recent Arctic Council Assessment of Oil and Gas Activities, with natural seeps being the largest source of input of oil hydrocarbons. Accidental oil spills were seen as the largest threat. While the Arctic environment is still relatively clean for many types of contaminants, recent assessments by the Arctic Monitoring and Assessment Programme (AMAP) have shown that persistent organic pollutants (POPs) occur at high levels and pose a threat to top predators in marine food chains, including humans. Heavy metals such as mercury, cadmium and lead are also seen as issues of concern in some parts of the Arctic.

Arctic Species: Interactions with Shipping

Arctic marine mammals such as bowhead, beluga, narwhal, walrus and several species of seals migrate south in fall to spend the winter in the southern areas of seasonal ice. In spring, they move north again, using systems of polynyas and leads, often before the break-up of the ice. At this time, these mammals reproduce and give birth to their young. Important wintering areas for marine mammals are in the broken pack ice in the northern Bering Sea, Hudson Strait, Davis Strait and southeastern Barents Sea. From these areas, the mammals follow leads and openings north through the Bering Strait and the Chukchi Sea; north through Baffin Bay into Lancaster Sound, into Hudson Bay and Foxe Basin; and north and east into the Kara and Laptev seas. The leads and openings in the ice are also used by seabirds, eiders and other marine birds on their spring migration to the northern breeding areas.

As climate and sea ice conditions continue to change, the timing and movements of the animals' activity will also be modified, making predictions of the potential interactions between shipping and animals increasingly complex.

© United States Coast Guard

The migration corridors used by marine mammals and birds correspond broadly with the main shipping routes into and out of the Arctic. Currently, there is limited overlap during the spring migrations as all shipping activity will typically occur later in the spring than the animal migrations. In the fall, there is likely more opportunity for interaction between ships and migrating species, as both are leaving the Arctic ahead of the formation of the pack ice. As the Arctic climate continues to change, it is very likely that the shipping season could extend earlier in the spring and later into the fall. The spring migration corridors are particularly sensitive and vulnerable areas to oil spills, ship strikes and disturbances, and could be a time of vulnerability for marine mammals and birds. In the future there will be a need to consider the potential risk and interaction between ships and animals during this vulnerable period.

The geographic area covered by this assessment spans a wide range of environmental conditions, from pack ice in the Arctic Ocean to open subarctic waters in the Bering Sea and the Nordic seas in the northeastern Atlantic. The volume of current shipping traffic also varies considerably across the Arctic. Currently, there is significant year-round traffic along the subarctic coast of Norway, around Iceland, on the southeast coast of Greenland and out of the Yenisei River and Pechora Sea to the port of Murmansk in northwest Russia. There is a moderate amount of seasonal shipping to and from destinations in the North American Arctic, and no established trans-Arctic traffic. Risk of negative interaction between vessels and wildlife varies across the region. The North Pacific Great Circle Route between western North America and eastern Asia is a high volume shipping lane that swings through the Unimak Pass in the Aleutian chain, passing in close proximity to important marine mammal haul-outs, rookeries and nesting sites of marine mammals and seabirds, close to active commercial fishing grounds and one of the largest protected essential fish habitats in the world.

The Arctic is Changing

The Arctic climate is warming. The effects of this are now being seen in the retreating sea ice, melting permafrost and the changing timing of the onset of fall and spring, as well as the increasing variability within each season. These changes are affecting Arctic species and ecosystems. Where caribou used to migrate across frozen rivers, they now have to wade. Polar bears swim farther to find food and wait longer in the fall for the pack ice to reform, extending their fasting. Pacific walrus are now hauling out on land in the Chukchi Sea, where they used to haul out mainly on sea ice.

Arctic species and ecosystems are, by nature, highly evolved in function and finely tuned with the timing of seasonal events. Although some species will benefit from the changes, there are many that are now under stress as a result and, for some, at risk of steep decline. For many species, any potential impacts as a result of current or future shipping activity will be in addition to the stress they are already under due to the changes occurring in their environment. It is beyond the scope of the current assessment to examine the interaction between effects from climate change and effects from future shipping activities. This is in part because of the intrinsic difficulties and the many uncertainties about the future.

Climate experts are projecting that the main change in sea ice will be decreasing ice coverage in the summer along the coastal Arctic seas with the formation of first-year ice occurring later in the fall. Even with a warmer climate, the Arctic Ocean will still remain ice-covered for most of the year. As climate and sea ice conditions continue to change, the timing and movements of the animals' activity will also be modified, making predictions of the potential interactions between shipping and animals increasingly complex.

Ship Based Impacts

Accidental Discharge

The accidental release of oil or toxic chemicals can be considered one of the most serious threats to Arctic ecosystems as a result of shipping. The release of oil into the Arctic environment could have immediate and long-term consequences. Some Arctic animals are particularly sensitive to oil because it reduces the insulating properties of feathers and fur and they can quickly die from hypothermia if affected. This is the case for seabirds, including eiders and other sea ducks, and also polar bear and seal pups. Concentrated aggregations of birds and mammals, often in confined spaces such as leads and polynyas, increase the risk to the animals in the case of an oil spill in the Arctic. Crude and refined oils, including fuel oils used by ships, vary much in their physical and chemical properties. This, in addition to other factors such as temperature, light, waves and ice, plays a major role in the behavior of oil in the environment and the extent of biological effects.

Other potential problems from released oil include the transfer of oil to nests by sea birds landing on oil slicks and the ingestion of oil by animals while preening. This can lead to death or other biological effects both in the short and long term. Even small spills can have large consequences if they occur where marine birds are concentrated.

Chronic seepage of residual oil after a spill can affect the entire food chain in an area because hydrocarbons are taken up by bottom feeding invertebrates, which then end up as prey for sea birds and

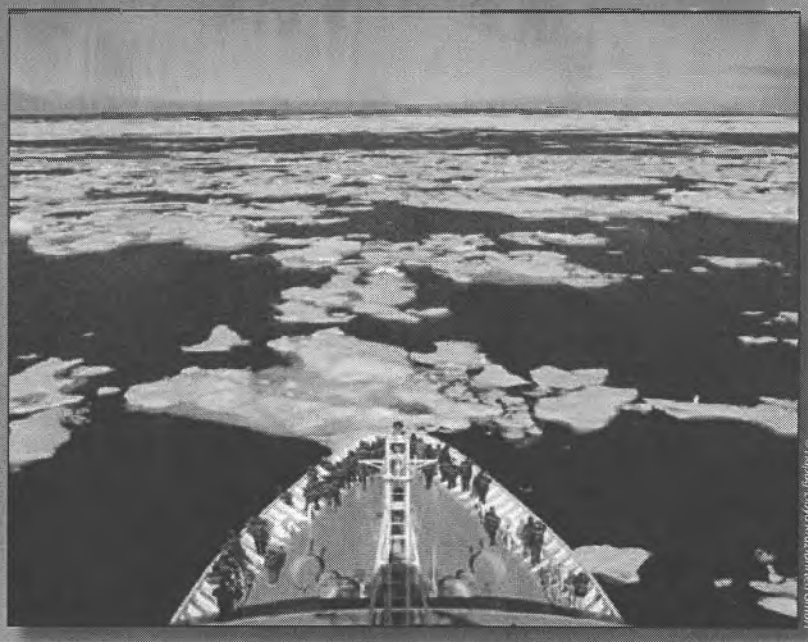
Environmental Impacts and Disturbances from Cruise Ships

The number of cruise ships operating in the Arctic is rapidly increasing. These ships are traveling to the region for the scenery and to actively seek out areas of special interest, including exceptional wildlife viewing opportunities. Wildlife is a primary attraction for polar tourists. Polar ecosystems, particularly in coastal environments, and wildlife migratory events provide tourists with opportunities to view many species of land and marine mammals as well as a remarkable diversity of birds. However, because cruise ships are specifically seeking out such events and opportunities, the potential is created for significant impacts on concentrations of wildlife due to disturbance from the ship.

There are numerous ways passenger ships can cause environmental harm. Emission of substances to the local air and ocean, possible incidents including sinkings and groundings, ship operations unsuitable for polar conditions and the inappropriate behavior of passengers ashore are the most prominent impacts. The 2004 U.S. Commission on Ocean Policy reported that, while at sea, the average cruise-ship passenger generates about eight gallons of sewage per day and an average cruise ship can generate a total of 532,000 to 798,000 liters of sewage and 3.8 million liters of wastewater from sinks, showers and laundries each week, as well as large amounts of solid waste (garbage). The average cruise ship will also produce more than 95,000 liters of oily bilge water from engines and machinery a week.

Sewage, solid waste and oily bilge water release are regulated through MARPOL. There are no restrictions on the release of treated wastewater. MARPOL restrictions typically prescribe the allowed distance from shore and rate at which wastes can be released or requires ships to deposit them in shore-side reception facilities. However, the Arctic region lacks infrastructure to adequately dispose of bilge water, sewage and solid waste. Many Arctic communities do not even have sufficient facilities to deal with the waste of their own communities, let alone that of tourist vessels. When ships are forced to stockpile wastes onboard where reception facilities are lacking, the risk of illegal or accidental release into sensitive areas is heightened. The alternative to depositing waste into onshore facilities is onboard incineration, a practice that also brings with it concerns about localized air pollution.

The extent of the impacts on different Arctic species from cruise ships is difficult to assess due to the lack of Arctic-specific baseline information on wildlife and the relatively recent increase in cruise ship activity. The cruise ship industry has a vested interest in maintaining healthy wildlife populations; however, there are currently no common best practices for the circumpolar Arctic as there is in the Antarctic through the International Association of Antarctica Tour Operators. The Arctic's one cruise organization, the Association of Arctic Expedition Cruise Operators, is limited in scope with its geographic range in the Svalbard, Jan Mayen and Greenland area. Cooperation among cruise ship operators, in partnership with academic and regulatory bodies, is necessary to ensure more sustainable eco-tourism in the Arctic.



© Hapag-Lloyd Kreuzfahrten GmbH

other animals, causing effects higher up the food web. Arctic animals are also particularly vulnerable to spills in certain areas and at certain times of the year when animals aggregate in large numbers to breed, nest, bear young and molt.

The Arctic is an extreme environment with a range of weather, light, hazards and with little human infrastructure. Responding to oil spills in these conditions is a major challenge, especially where ice is present. There are currently limited methods for recovering spilled oil in an ice-covered environment. The options currently available for oil spill recovery in the Arctic include mechanical methods, bio-remediation, dispersants and/or in-situ burning. Consequently, strong prevention measures must be of primary concern, while response measures, being both unreliable and untested, should be secondary. The risk of accidental release of oil and other contaminants increases with any increase in shipping activity that involves the use or transportation of oil or other chemicals.

Regular Discharges to Water

As a part of normal operations, ships produce a range of substances that must eventually be eliminated from the ship through discharge into the ocean, incineration or transfer to port-based reception facilities. Referred to as regular discharges these include oil, ballast water, bilge water, tank washings (oily water), oily sludge, sewage (black water), garbage and grey water. Regular ship discharges are regulated through the IMO's *International Convention for the Prevention of Pollution from Ships, 1973, as Modified by the Protocol of 1978 Relating Thereto* (MARPOL 73/78) and other IMO conventions, as well as through domestic regulation by coastal states (See page 59). MARPOL has effectively reduced pollution in the marine environment by regulating the release of regular discharges. However, it has not eliminated discharges into the world's oceans altogether.

Ship Category	Ship Sub-category/ Use	Ship Type-Specific Pollution Sources
Government Vessels and Icebreakers	Coast guard vessels, research icebreakers, private icebreakers, government icebreakers, other research vessels	Accident/incident recovery-produced contaminants, emergency dumping oil/fuel, nuclear icebreaker radiation contamination, explosives/munitions, impacts due to icebreaking activity (disruption of ice formation, marine mammals, etc).
Container Ships	Cargo transport	Hazardous goods in transit, convoy collision hazard, grounding hazard (uncharted waters, lack of experienced ice navigation).
General Cargo	Community re-supply vessels, roll on/roll off cargo	Hazardous goods in transit, accidental cargo release, contaminated cargo.
Bulk Carriers	Timber, merchant, oil, ore, automobile carriers	Release of metal contaminants, radiation contamination from cargo, hazardous goods in transit.
Tanker Ships	Oil tankers, natural gas tankers, chemical tankers	Liquid Nitrogen Gas contamination, chemicals and hazardous goods in transit, spills from oil transfer.
Passenger Ships	Cruise ships, ocean liners, ferries	Large volumes of black and grey water release, garbage disposal, cleaning contaminants, disturbance of wildlife through viewing activities, automotive contaminants w/ vehicles ferries .
Tug / Barge	Re-supply vessels Bulk cargo transport	Increased accident hazard (non-propelled), hazardous goods in transit, spills during oil transfer, heavy emitters of air contaminants (black carbon).
Fishing Vessels	Small fishing boats, trawlers, whaling boats, fish processing boats	Increased fire hazard, introduction of pathogens and other contaminants from released fish offal, accidental release of invasive species/related biological contaminants, release of plastics, ghost nets and other fishing debris, seafloor damage from bottom trawlers, depletion of marine species (if not managed), accidental release of refrigerant contaminants.
Oil and Gas Exploration/Exploitation Vessels	Seismic exploratory vessels, oceanic and hydrographic survey vessels, oil drilling vessels, oil and gas storage vessels, offshore re-supply, portable oil platform vessels, other oil and gas support vessels	Hazardous cargo, explosives, acoustic impacts from seismic activities, oil/hydrocarbon contamination, contamination from extraction chemicals, accidental loading/offloading spillage, fire hazards.

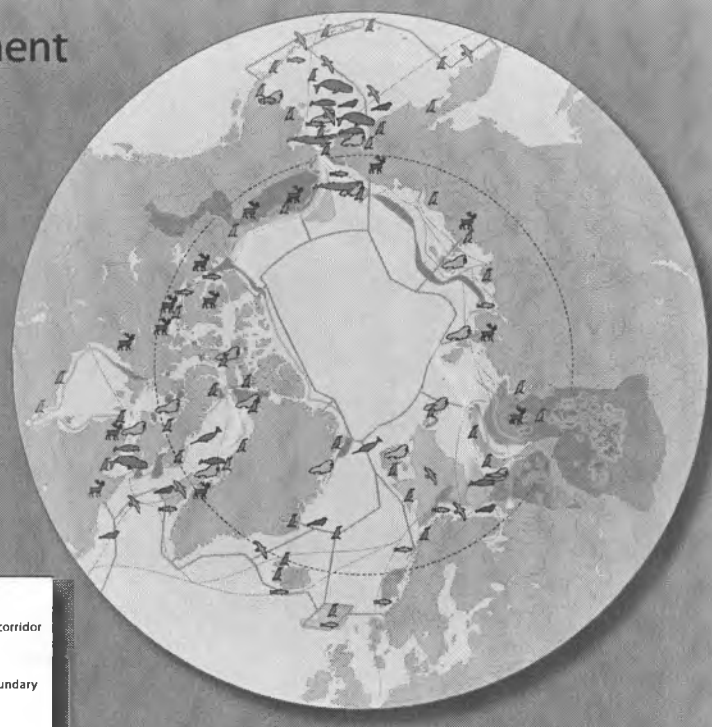
Table 8.1 A range of potential environmental impacts linked to ship types operating in the Arctic. *Note: All ships will have certain impacts linked to the release of grey water, sewage, ballast and bilge water; air emissions; regular and accidental discharge of fuel/oil; introduction of noise and other acoustics such as sonar; and possible strikes on animals. Those listed above are in addition to these and specific to the vessel type.* Source: AMSA

Oil is released with bilge water with a maximum allowed concentration of 15 parts per million (15 mg per m^3) after treatment with an oil separator. Oil is also released with water used for tank washings after required treatment and with restrictions on amount and rate of release to avoid formation of oil film at the surface (i.e., blue shine). Oily sludge, consisting of high molecular hydrocarbon substances, accumulates in fuel tanks in fairly large amounts, constituting typically 1-5 percent of the amount of fuel consumed. Oily sludge must not be released but stored on board and brought to reception facilities in ports.

A recent study of regular discharges from ships in the Norwegian and Barents seas provides an example of the level of discharge expected to be released in an area that has some of the heaviest ship traffic in the Arctic or subarctic region. In this study it was estimated that the amount of oil released via bilge water and tank washings that the MARPOL allowed 15 ppm totaled about two tons of oil per year, a relatively small amount. However, the study found ship operations generate about 13,000 metric tons of oily sludge annually.

Arctic Oil and Gas Assessment

A comprehensive assessment of the oil and gas activities in the Arctic was carried out in 2007 by the Arctic Council under the leadership of the Arctic Monitoring and Assessment Programme working group. This assessment summarized information on the history, current and projected oil and gas activities in the Arctic, and examined socio-economic and environmental effects associated with these activities. The assessment included a detailed description of the main features and species of the Arctic ecosystems and their vulnerability to oil spills and disturbances from oil and gas activities. An illustrative circumpolar map of vulnerable areas based on aggregations of mammals, birds, and fish was produced as an outcome.



An illustrative map from the Arctic Oil and Gas 2007 assessment of areas in the Arctic indicating where selected birds, mammals and fish form major aggregations to breed, stage, migrate or overwinter. When oil and gas activities including transportation occur in such areas, such aggregations are vulnerable to disturbances and oil spills. *Source: AMAP*

1.0%

The 2004 Arctic shipping contribution of CO_2 emissions to the total from the global shipping fleet.

Wild Card – Ship Stack Emissions – NOx, SOx, Black Carbon and Ozone

Ships are powered by engines and fuels that, like other transportation modes, emit CO_2 and water vapor, nitrogen oxides (NOx), sulfur dioxide (SO_2), carbon monoxide (CO) and particulate matter (including black carbon [BC]). Most oceangoing ships burn low-quality residual fuels that tend to contain high amounts of particulates from soot (black carbon), sulfur aerosols, ash and heavy metals.

These are pollutants specifically quantified in the inventory of emissions from Arctic shipping in this assessment. These pollutants are linked with specific environmental effects, and complex interactions occur among these substances in the regional and global atmosphere. For example, NOx is a gaseous contributor to tropospheric ozone formation; SOx gases form particles that contribute to acid rain and cloud effects on regional climate; and other fine particles like black carbon impact air quality, visibility and climate change.

Shipping's contribution to regional and global impacts from emissions such as CO_2, NOx and SO_2 have been evaluated by scientists and shown to be significant enough to motivate policy action. However, environmental and climate effects of NOx and ozone, sulfur aerosols and black carbon particles in the Arctic are only beginning to be understood. Black carbon has been proven to have significant climate forcing effects, in addition to its effects on snow and ice albedo, accelerating the retreat of Arctic sea ice.

Background levels of NOx, the precursor to ozone, are very low in the Arctic and recent studies have found that seasonal increases in ozone are closely linked to seasonal increases in shipping activity. Surface ozone is known to have harmful effects on plant growth and human health and is the basis for photochemical smog.

Ship stack emissions in and near the Arctic will increase along with growth in shipping activity, except where regulations like MARPOL Annex VI require steep reductions in sulfur emissions through fuel sulfur limits or pollution reductions in specially designated regions. The specific benefits of reducing impacts in the Arctic through control of ship emissions need to be further studied, and the AMSA inventory for 2004 provides a good baseline inventory to evaluate scenarios that may achieve these benefits.

Based on AMSA findings, the report recommends continued study of ship-based emissions and trends. Climate change policy is currently focused on CO_2 from ships and the potential climate response to lower ship sulfur emissions is becoming recognized. NOx emission controls may mitigate some of the Arctic regional ozone impacts suggested by one international study and the AMSA inventory provides an opportunity to update previous research findings.

More recently, scientists are recognizing that black carbon particles have potentially significant impacts on the vulnerable Arctic environment and climate that need to be quantified. The AMSA contribution to further research may be very important, given that recent studies suggest that reduction of the positive climate forcing due to BC would decrease both global warming and retreat of the sea ice and glaciers and would therefore provide an opportunity for effective short term mitigation of global warming.

The release and deposition of black carbon in the Arctic region is of particular concern because of the effect it has on reducing the albedo (reflectivity) of sea ice and snow.

1. A review and comparison of the AMSA estimated fuel use by General Cargo vessels with recent activity-based inventories completed by Norwegian researchers at DNV suggest that this category may be overestimated, due to the world fleet characteristics for general cargo ships reflecting larger vessels with more installed power than typical for Arctic operations.
2. A review and comparison of the AMSA Fishing vessel data with more direct activity-based estimates completed by DNV for Norwegian fishing vessels suggests that this first estimate may be in the range of three to four times higher than what was found by DNV. This is likely because the AMSA fishing vessel estimates are based primarily on days at sea, which assumes the vessel engine runs at varying capacity for the entire period at sea and may overestimate fishing vessel emissions and fuel use.

The amount of legally discharged oil under MARPOL in the Norwegian study indicates that current amounts of legally discharged oil should not pose a significant threat to the local ecosystem so long as the laws are strictly followed. MARPOL requires oily sludge to be disposed of in port-based reception facilities. Norway is unusual in the Arctic region in that it has good port reception facilities in all of its Arctic ports, but that is not the case in many other areas of the Arctic. In some areas, limited port side infrastructure as well as the cost of disposing of waste using port reception facilities provide incentive for illegal dumping of wastes produced on board.

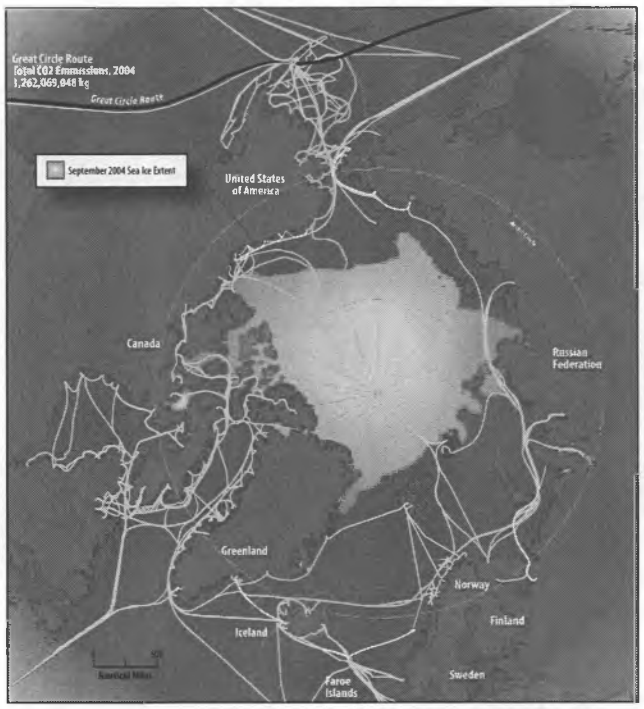
Considering the sheer volume of oily sludge produced in Norwegian waters alone, it would take only a small percentage of the oily sludge produced to be illegally discharged for it to cause environmental damage. Illegal release of oil and oily sludge can cause oiling of animals and birds, can be toxic to marine and terrestrial ecosystems and extremely difficult to clean up. Contamination can last for years in ocean sediment and other compartments of the marine environment, sometimes presenting contaminated prey upward within marine and coastal food chains. Oily sludge is not the only regular discharge that can end up in the ocean. Under MARPOL it is legal to discharge garbage and raw sewage into the water once a ship is a certain distance from shore. The presence of significant amounts of garbage and other debris in the ocean can result in a number of environmental impacts. These range from damage to marine habitat, entanglement of wildlife, introduction of bacteria and disease (from untreated human sewage) and the ingestion of plastics and other unsuitable items by marine mammals and birds. As vessel activity increases in the Arctic, the management of regular discharges from all vessels will need to be seriously considered so that environmental impacts are minimized.

Ship Emissions to Air

Studies assessing the potential impacts of international shipping on climate and air pollution demonstrate that ships contribute significantly to global climate change and health impacts through emission of GHGs (for example, carbon dioxide [CO_2], methane [CH_4], chlorofluorocarbons [CFC]), aerosols, nitrogen oxides (NOx), sulfur oxides (SOx), carbon monoxide (CO) and particulate matter (PM). Air quality impacts may result from the chemical processing and atmospheric transport of ship emissions. For example, NOx emissions from ships can combine with hydrocarbons in the presence of sunlight to produce ozone pollution, which can potentially affect visibility through haze, human and environmental health and has been associated with climate change effects.

The AMSA has developed the world's first activity-based estimate of Arctic marine shipping emissions using empirical data for shipping reported by Arctic Council member states. Emissions were calculated for each vessel-trip for which data was available for the base year 2004. The 515,000 trips analyzed represent about 14.2 million km of distance traveled (or 7.7 million nautical miles) by transport vessels; fishing vessels represent over 15,000 fishing vessel days at sea for 2004. Some results could be an underestimation of current emissions, given potential underreporting bias and anecdotal reports of recent growth in international shipping and

Map 8.1 Arctic shipping emissions map. *Source: AMSA*



Emission amounts were calculated using the AMSA marine activity database (See page 70), which is based on information reported by Arctic Council member states. Baseline information was provided in different formats and to different degrees of detail between states.

trade through the Arctic. Researchers at DNV recently completed a similar activity based emissions inventory for Norwegian waters (*Operational emissions to air and sea from shipping activities in Norwegian sea areas. DNV Report No. 2007-2030*). A review and comparison of the DNV results with the Norwegian portion of the AMSA results showed good agreement for all vessel types, except for general cargo and fishing vessel estimates. The AMSA results for Norway were sometimes greater than, and sometime less than, the DNV results, generally falling within 10 percent to 30 percent confidence. The AMSA evaluates ship emissions of greenhouse gases and air quality pollutants that may have regional or local impacts; however it does not directly conduct the detailed studies needed to determine the level of impact (Table 8.2).

Results show CO_2 emissions from international shipping in the Arctic region to be approximately 10,800 kilo tons per year tons (kt) CO_2 per year. Given that total CO_2 emissions from international shipping globally are about 1,000 MMT CO_2 per year, Arctic contributions for 2004 amount to about 1 percent of total ship CO_2 emissions, not an amount that would cause significant effects in the global context. However, pollutants such as black carbon (BC), particulate matter, nitrogen oxide (NOx), carbon monoxide (CO) and sulfur oxide (SOx), which may be small contributors to global inventories on a mass basis, may have regional effects even in small amounts. Current IMO regulations under MARPOL Annex VI that place requirements on the sulfur content of marine fuels, once implemented, will dramatically reduce SOx emissions from global shipping. As a result, observable impacts from SOx should decline and there may be indirect effects on the climate forcing properties of other air pollutants such as NOx and BC.

Black carbon is a component of particulate matter produced by marine vessels through the incomplete oxidation of diesel fuel. The release and deposition of BC in the Arctic region is of particular concern because of the effect it has on reducing the albedo (reflectivity) of sea ice and snow. When solar radiation is applied, reduced albedo increases the rate of ice and snow melt significantly, resulting in more open water, and thereby reducing the regional albedo further. In the Arctic region in 2004, approximately 1,180 metric tons of black carbon was released, representing a small proportion of the estimated 71,000 to 160,000 metric tons released around the globe annually. However, the region-specific effects of black carbon indicate that even small amounts could have a potentially disproportionate impact on ice melt and warming in the region. More research is needed to determine the level of impact this could have on ice melt acceleration in the Arctic and the potential benefits from limiting ships' BC emissions when operating near to or in ice-covered regions. The potential impacts of black carbon should also be a point of consideration when weighing the costs and benefits of using in-situ burning of oil in spill response situations.

As part of the AMSA emissions inventory, the amounts of carbon dioxide and black carbon emitted were mapped using the GIS database of shipping routes and areas of fishing vessel activity reported by Arctic states (Map 8.1).

The CO_2 emitted by all vessels was mapped according to the location of activity; emissions from transport vessels (non-fishing vessels) were assigned to reported routes and fishing vessel emissions were assigned to the Large Marine Ecosystem in which the fishing fleet operated. The map shows that the heaviest CO_2

Regional Environment Case Study

Aleutian Islands/Great Circle Route

The North Pacific's Great Circle Route is the most economic pathway for commerce between northern ports of the west coast of North America to ports in eastern Asia. The segment of this route considered in this analysis is the portion that extends from the western Gulf of Alaska, westward offshore from the Alaska Peninsula and through the Aleutian Islands including the passes at Unimak Pass and the Rat Islands. This portion of the route traverses two Arctic Large Marine Ecosystems (LMEs), the East Bering Sea LME and the West Bering Sea LME.

The East and West Bering Sea LMEs are characterized by their subarctic climate and are strongly influenced by a persistent atmospheric low pressure system that produces intense storm activity and strong ocean currents, particularly through the Aleutian Island passes. The marine and coastal environment in the region where the Great Circle Route passes includes rocky shorelines, fjords and tidal wetlands. This region seasonally supports populations of shorebirds, nesting seabirds, herring and other marine resources as well as millions of salmon during their migrations to streams of origin.

The route also passes through the U.S. Alaska Coastal Maritime Wildlife Refuge, which provides nesting and foraging habitat seasonally for millions of seabirds and year-round habitat for thousands of marine mammals. The populations of several marine species in this region are depressed, declining or otherwise considered particularly sensitive and in danger of potential extinction. Commercial fisheries in the region where the Great Circle route passes provide a large proportion of the annual landings by the U.S. fishing industry. Salmon, halibut, herring, crab, groundfish and many other fisheries are pursued annually in the region. In 2004, Alaska fish landings were 2.43 million metric tons, valued at $US 1.17 billion.

The AMSA estimates that approximately 2,800 vessels passed along this route in 2004. Environmental impacts due to shipping, which are of the most concern in the region of the Arctic where this route passes, include the potential for vessel strikes on marine mammals, particularly the Pacific right whale; the discharge of oil and other pollutants both from routine ship discharge and accidents; and the introduction of invasive species into local ecosystems.

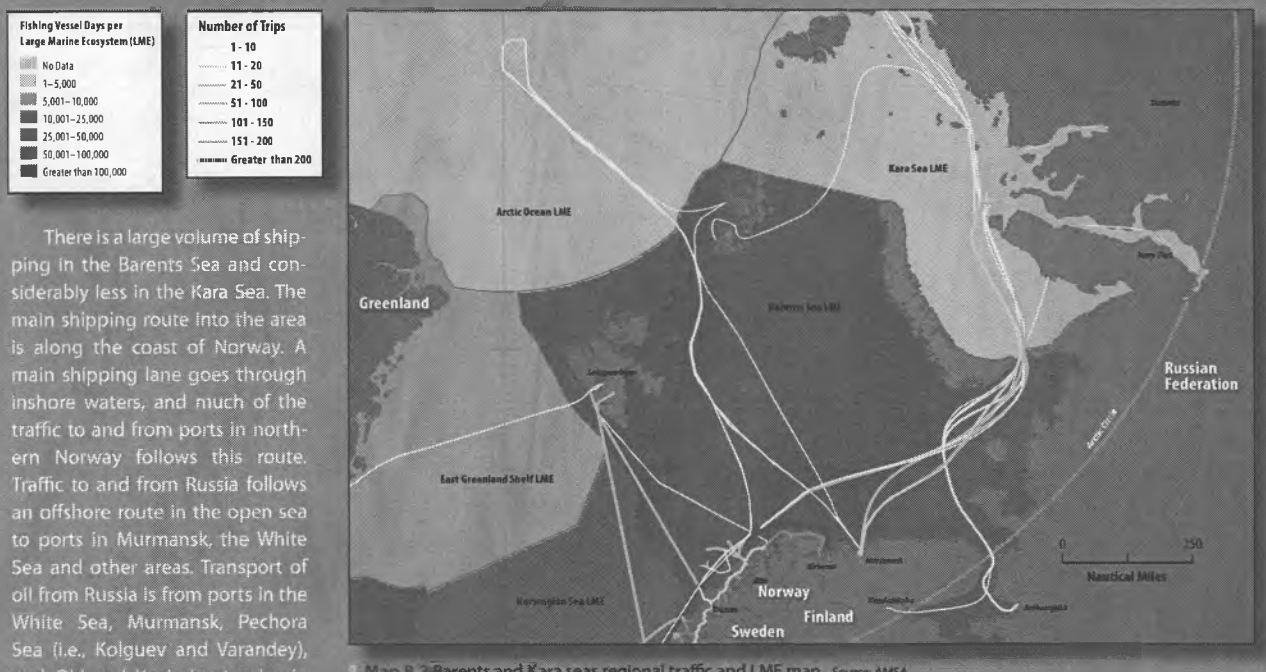
Metric tons – The approximate amount of oil sludge generated annually by ships operating in the Norwegian and Barents seas.

Regional Environment Case Study

Barents and Kara seas



Map 8.3 Barents and Kara seas regional traffic and LME map. Source: AMSA

There is a large volume of shipping in the Barents Sea and considerably less in the Kara Sea. The main shipping route into the area is along the coast of Norway. A main shipping lane goes through inshore waters, and much of the traffic to and from ports in northern Norway follows this route. Traffic to and from Russia follows an offshore route in the open sea to ports in Murmansk, the White Sea and other areas. Transport of oil from Russia is from ports in the White Sea, Murmansk, Pechora Sea (i.e., Kolguev and Varandey), and Ob' and Yenisei estuaries in the Kara Sea. There is also year-round shipping of nickel ore by Norilsk Nickel from a port in the Yenisei estuary. In the western Barents Sea, there is a shipping route to Svalbard with seasonal traffic of cargo ships supplying the communities, bulk carriers transporting coal and cruise ships. There is also a substantial number of fishing vessels that operate year round in the ice-free part of the southern and central Barents Sea, while there is little fishing activity in the Kara Sea.

In 2006, Norway adopted an integrated management plan for the Norwegian part of the Barents Sea and adjacent waters off the Lofoten Islands. In the preparatory work for this plan, an assessment of environmental impacts from shipping was carried out and valuable and vulnerable areas were identified. The plan established a forum on environmental risk management headed by the Norwegian Coastal Administration, which is tasked with providing better information on risk trends in the area, especially as regards acute oil pollution from ships and other sources. In July 2007, the IMO established regulations that require larger cargo vessels and tankers transiting the Norwegian coast of the Barents Sea to operate further away from the coast than in the past. This requirement is intended to allow a longer response time in case of accidents that could impact the Norwegian coastal environment and resources.

Vulnerable areas in the Barents and Kara seas have been identified in relation to oil and gas activities, based on where there are aggregations of animals that could potentially be impacted by oil spills or disturbances from activities. The Barents Sea holds more than seven million pairs of breeding seabirds, with major colonies on Svalbard, the western section of Novaya Zemlya off the coast of northern Russia and along the coast of northern Norway. The oceanographic polar front and the ice edge in the western and central Barents Sea is a concentrated zone of life in spring and summer with aggregations of seabirds and seals. The polar front area is also the wintering area for the large Barents Sea capelin stock and for

seabirds such as thick-billed murre. Svalbard and Franz Josef Land in the northern Barents Sea are important breeding and feeding areas for seabirds, walrus and seals, and denning areas for polar bear. The southern and eastern Barents Sea is a wintering area for many seabirds and sea ducks that breed further east in the Russian Arctic. The Pechora Sea area and the southern Kara Sea lie adjacent to tundra and wetlands that are important breeding grounds for geese, ducks and shorebirds. Many of these use coastal habitats for staging during spring migration and after breeding when they prepare for the fall migration out of the Arctic.

The southern Barents Sea is a rich fisheries area with large stocks of cod, haddock, capelin, juvenile herring and shrimp. A major stock of polar cod spawns under ice in the Pechora Sea region, and this region is also the main wintering area for white whales of the Karskaya population that is migratory between the Barents, Kara and Laptev seas. The smaller White Sea beluga population has its wintering area in the Voronka and Gorlo area at the entrance to the White Sea. The Barents Sea harp seal population has its whelping and molting areas on the ice also at the entrance to the White Sea. The Novaya Zemlya population of Atlantic walrus has its wintering area in the pack ice in the Pechora Sea region. White whales and walrus migrate north in spring following lead systems west of Novaya Zemlya, and the white whales continue east through the northern Kara Sea and into the western Laptev Sea in early summer. There are two subpopulations of polar bears in the Barents and Kara seas with seasonal migrations following the ice.

There are no documented negative impacts on animals in this area from shipping activities. Accidental oil spills have occurred and have been associated with high local mortality of seabirds. However, these incidents have not had material impacts at the population level for the affected species. Ship strikes of whales could occur in some areas but there are no reports to suggest that the level of impact is significant. The greatest concern is the threat from accidental oil spills that could have a large impact on seabirds and other marine birds, and also on marine mammals such as polar bear and on spawning polar cod. If shipping activities increase in the future, potential disturbance of wintering marine mammals and ship strikes of whales will become a concern.

and black carbon emissions were found in the Bering Sea region, around Iceland, along the Norwegian coast and in the Barents Sea. There are also moderate emissions along the western coast of Greenland.

Potential Disturbances from Ships and Shipping Activity in the Arctic

Sound and Noise Disturbance

All vessels produce sound as a by-product of their operation. Typically, vessels produce low frequency sound from the operation of machinery onboard, hydrodynamic flow noise around the hull and from propeller cavitation, which is typically the dominant source of noise. The sound a vessel produces relates to many factors including size, speed, load, condition, age and engine type. The larger the vessel and/or the faster it is moving, the more noise it produces. Many vessels also employ hydroacoustic devices such as commercial sonar, echosounders, side scan sonar for navigation, depth finding, seafloor mapping or to detect biologics as a regular part of their operations. These types of devices produce short pulses and use frequencies ranging from low to high, depending on their utility.

For most marine vertebrates, making, hearing and processing sounds serve critical biological functions. These include communication, foraging, reproduction, navigation and predator-avoidance. In particular, toothed whales have developed sophisticated biosonar capabilities to help them feed and navigate; large baleen whales have developed long-range communication systems using sound in reproductive and social interaction; and pinnipeds (i.e., seals, sea lion, walrus, etc.) make and listen to sounds for critical communicative functions. Many fish utilize sounds in mating and other social interactions.

The introduction of noise into the environment can adversely affect the ability of marine life to use sound in various ways and can induce alteration of behavior; reduction of communication ranges for social interactions, foraging, and predator avoidance; and temporary or permanent compromise of the auditory or other systems. In extreme cases, too much noise can lead to habitat avoidance or even death. Noise can also affect physiological functions and cause more generalized stress. Determining when impacts of noise exposure from any source become biologically significant to a species is often difficult. Nevertheless, this is an area where additional research is ongoing and needed in key areas.

Many environmental effects resulting from ship disturbances can be effectively mitigated through the use of best practices and the implementation of management measures.

Where there is an overlap between potential noise sources and the frequencies of sound used by marine life, there is particular concern as to how sound sources can interfere with important biological functions. The predominately low frequency sounds associated with large vessels is similar to the general hearing sensitivity bandwidths of large whales and many fish species. The ambient noise environment in the Arctic is more complex and variable than in many other ocean areas due to the seasonal variability in ice cover. In addition to natural sources contributing to background levels, anthropogenic sources, like vessel traffic, can also have a profound impact on these levels. In most regions in the northern hemisphere, shipping noise is the dominant source of underwater noise below 300 hertz.

Many environmental effects resulting from ship disturbances can be effectively mitigated through the use of best practices and the implementation of management measures. With regard to noise disturbances, such measures could include rerouting to avoid some areas in sensitive periods, lower speed, and alternative engine and hull designs to make ships more silent. There may be a need to plan potential future shipping lanes in the Arctic so as to avoid large seabird colonies, marine mammal haul-outs and other areas where animals are aggregated. In late 2008, the IMO's Marine Environment Protection Committee (MEPC) formed a correspondence group that is now working to identify and address ways to minimize the introduction of incidental noise into the marine environment from commercial shipping in order to reduce the potential adverse impact on marine life. This group aims to develop non-mandatory technical guidelines for ship-quieting technologies, as well as potential navigation and operational practices for all IMO member states. This work will be aimed at the global shipping industry and is not likely to contain Arctic specific considerations.

Icebreakers and Disturbance

All icebreaking operations, whether by independent commercial icebreaking ships or government icebreaker escort, can potentially cause disturbances to wildlife and local communities both through the noise they create and the trail of open water left astern. Compared to other vessels, icebreakers produce louder and more variable sounds. This is because of the episodic nature of the icebreaking, which involves ramming forward into the ice and then reversing to begin the process again. Some icebreakers are equipped with bubbler systems to aid in clearing ice from the vessel's path and these can create an additional noise source. Noise from bubbler systems and propeller cavitation associated with icebreaker movement has the potential to alter animal behavior and to disrupt the hearing ability and vocalization of marine mammals.

Wildlife has been found to exhibit a range of behavior in the presence of icebreakers. For example, beluga whales were found to be aware of the icebreaker vessels presence at distances of more than 80 kilometers away, and exhibit strong avoidance response at 35 to 50 km away. However, narwhal whales were found to display only subtle responses to the same disturbance.

The opening of channels through the ice by icebreaking vessels can impact Arctic residents and alter animal behavior. Open water channels take time to freeze and this can disrupt the movements of animals and people over the ice. In many areas of the Arctic in winter, the only naturally occurring ice openings are polynyas caused by winds or ocean currents. Artificially opened water channels can be problematic for marine mammals and other species, which confuse them for polynyas and can get trapped too far from the ice edge as the channel eventually refreezes.

Vessel Strikes on Marine Mammals

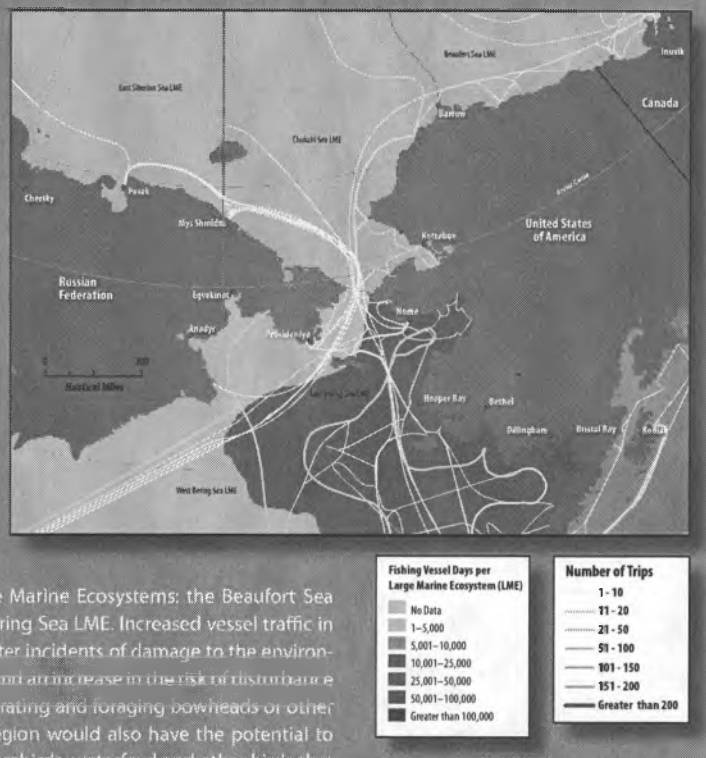
Vessel collisions, resulting in death or serious injury of marine mammals, are a threat to marine organisms worldwide. Vessel collisions or ship strikes occur mainly with large whale species, small cetaceans (i.e., dolphins, narwhal, beluga), marine turtles and sirenians (i.e., manatees, dugongs). Records indicate that nearly all large whale species are vulnerable to ship strikes. Vessel collisions with marine mammals can result in death, massive trauma, hemorrhaging, broken bones and propeller wounds.

Databases have been constructed which track the number of ship strikes occurring. These report more than 750 known cetacean vessel strikes through the world's oceans, including nearly 300 incidents involving large whales. Virtually all motorized vessel types, sizes and classes are represented in these databases. It should be noted, however, that any database will likely underestimate the number

Regional Environment Case Study

Bering Strait

Map 8.4 Bering Strait regional traffic and LME map. *Source: AMSA*



Current shipping activity in the Bering Strait and Chukchi Sea predominately comprises community re-supply and destinational traffic.

Traffic plying the Bering Strait, one of the narrowest sea lanes in the world, also traverses remote areas with difficult access for incident response, rescue and contaminant or debris cleanup. The U.S. Beaufort Sea coast has no port facilities or harbors suitable for refuge for medium to deep draft vessels and there are also very limited facilities on the Russian side of the strait. Given its restricted geographic nature, confounded by ice movement and strong ocean currents, the Bering Strait area is a major chokepoint for vessels transiting the region. The Aleutian Low creates persistent high winds and stormy conditions that elevate risk to vessels and cargo transiting the Aleutian and Commander islands area. These severe weather patterns may reduce the effectiveness of response to spills or other incidents.

This region includes four of the Arctic Large Marine Ecosystems: the Beaufort Sea LME, the Chukchi Sea LME, and East and West Bering Sea LME. Increased vessel traffic in the Beaufort and Chukchi seas may result in greater incidents of damage to the environment from ships, including pollutant discharges, and an increase in the risk of disturbance effects such as ship noise and ship strikes on migrating and foraging bowheads or other marine mammals. Any vessel incidents in this region would also have the potential to adversely affect major populations of nesting shorebirds, waterfowl and other birds that utilize breeding, nesting and foraging habitat along the coastal Beaufort and Chukchi seas and along the coast of western Alaska.

The eastern Bering Sea supports some of the largest commercial fisheries in the world. Increased vessel use of the eastern route that traverses the eastern Bering Sea may increase potentially adverse interactions with this region's rich fishery resources, fishing communities and hundreds of fishing vessels and support vessels. Spills due to accidental or illegal discharge from vessels could drift ashore to western Alaska areas where seasonal herring and salmon fisheries occur.

The Western Arctic stock of bowhead whales seasonally migrates through the Bering Strait, Chukchi and Beaufort seas. In the Bering Strait, they are physically constricted to a relatively small corridor, exposing them to increased interactions with vessels transiting this area during spring and fall. Bowhead whale migration could also potentially be disrupted by icebreakers. Whales could move further offshore following the open leads created by icebreaking vessels, putting them out of reach of coastal whaling communities. Any disruption of the spring and fall hunts, or any injury or mortality to bowheads would be considered a major issue to coastal Alaskan and Siberian communities.

Ice-dependent marine mammals in this region, such as polar bear, walrus and seals, already stressed due to sea ice retreat, may be at increased risk from any additional ship-sourced stressors or contamination, as populations will become increasingly concentrated around retreating sea ice.

Regional Environment Case Study

Canadian Arctic

For many years shipping has been the main link to the outside world for remote Arctic communities in Canada and yearly sealifts remain the key source of goods and necessities for many communities. Shipping in the Canadian Arctic has been occurring in a safe and relatively environmentally sustainable way for many years. This has been due to the historically low level of activity, as well as the regulatory restrictions that have been in place to protect Canadian Arctic waters from shipping since the 1970s in the form of the *Arctic Waters Pollution Prevention Act*. The types of shipping activity occurring in the Canadian Arctic during 2004 can be grouped into the following activities: community re-supply (i.e., tug-barge, cargo, fuel tankers), Canadian Coast Guard and research activity, cargo and re-supply support for resource development operations, cargo shipments in and out of the Port of Churchill and tourism.

The Canadian Arctic remains one of the last frontiers for natural resources and one of the last areas of relatively pristine wilderness on earth. It is a region with virtually no roads, no rail lines and where air services are infrequent and very costly. The lack of infrastructure and the extreme climate have, until recently, made this region uneconomical for large-scale resource development. Rising prices of oil, gas and other commodities and the changing climatic and geographic restraints may combine to allow significant and rapid increases in resource development

Map 8.5 Canadian Arctic regional traffic and LME map. *Source: AMSA*

activity in the Canadian Arctic which would lead to increased destinational shipping traffic in the region and intra-regional traffic. How this potential increase may impact the local environment is not known. However any increase in activity brings with it a corresponding increase in the risk of damage to the environment both from normal ship operations and accidents or emergencies. Due to the current relatively low levels of shipping activity occurring in the Canadian Arctic, any increase in activity in this region will be significant.

Currently four of the Arctic's 17 Large Marine Ecosystems occur in Canadian waters: Hudson Bay, Baffin Bay/Davis Strait, Arctic Archipelago and Beaufort Sea. The Canadian Arctic is home to a diverse range of wildlife that thrives across this variety of ecosystems. These populations are now under stress to varying degrees due to the changes occurring in the Arctic environment as a result of global climate change.

Areas that are vulnerable to new developments include wintering areas of bowhead and beluga in Hudson and Davis straits, spring migration routes for those whales into Hudson Bay and Foxe Basin and north into Lancaster Sound. Seabird breeding colonies and staging areas for migratory waterfowl and shorebirds occur in several locations throughout the region.

Specific adverse impacts associated with shipping activity that are of the most concern in the Canadian Arctic include the discharge of pollutants into the marine environment and the disruption or disturbance of migratory patterns of wildlife that would, in turn, impact indigenous hunting activity. In this region, icebreakers leave behind open water channels that may disrupt the movements of wildlife and people traveling on the ice. Icebreakers or other ships traveling through ice-covered waters where seals are whelping can impact nearby seals through flooding dens and wetting baby seals with their wakes. Marine mammals are known to congregate in shallow bays and migrate through the Canadian Arctic Archipelago. As shipping traffic increases in this region there will be increased potential for conflict between ships and marine mammals in narrow and geographically restrictive areas. Other ship impacts outlined in this section such as noise impacts, introduction of invasive species and ship emissions are also of concern.

of actual occurrences because many go either undetected or unreported. In some cases carcasses are found, but because injuries are internal or due to advanced decomposition, it may be difficult to determine cause of death. When large vessels are involved, the mariner may not be aware that a strike has occurred.

There are relatively few known incidents of Arctic or ice-adapted marine mammal species being involved in ship strikes. The relatively infrequent occurrence is a result of relatively lower vessel traffic in high latitudes as compared to major trading routes and human population centers in lower latitudes. However, of consideration is that certain Arctic species, such as the bowhead and Pacific right whale, have features that make them potentially vulnerable to ship strikes, particularly as vessel traffic increases in their waters. Arctic toothed whales, namely narwhals and beluga whales, are probably less vulnerable to ship strikes, given their greater maneuverability and social behavior that lends them to aggregating in large groups enhancing their detection. It should be noted, however, that records of roughly comparable mid-sized species such as pilot whales, killer whales and various species of beaked whales also appear in ship strike databases.

Vessel speed has been implicated as a key factor in the occurrence and severity of vessel strikes with large species. Several independent studies indicate that vessel speeds of 10-14 knots increase by one-half or greater the probability that a whale will survive a collision with a ship.

As vessel traffic increases in the Arctic, modifications to customary vessel operation in key cetacean aggregation areas or vessel speed restrictions can be an effective measure to mitigate potential impacts on vulnerable species such as bowhead whales and, to a lesser extent, narwhals, beluga whales and other Arctic marine organisms. Where feasible, vessel routing measures may also be applied in order for ships to avoid known cetacean aggregation areas. A number of steps have been taken by some states outside the Arctic region to reduce the threat of ship strikes to endangered large whale species, including shifting shipping lanes and applying to the IMO to establish a vessel "Area to be Avoided." The IMO's MEPC is currently working on development of a non-mandatory guidance document for minimizing the risk of ship strikes on cetaceans which will be aimed at the global maritime industry.

Light Disturbance

Birds of all species appear to be attracted to lights. This puts them at risk of collision with lighted structures. The attraction to light and resulting risk of collision varies depending on the weather, season and the age of the bird. The fall migration in the Arctic is

when most bird attraction and collision issues emerge, as young birds are traveling for the first time and inclement weather becomes more frequent. Light attraction of marine birds is not yet a significant issue in the Arctic. This is because most birds are in the Arctic in the summer months to breed, when there is little or no darkness; and most Arctic-breeding seabirds are diurnal and, therefore, less active at night.

Despite these factors, there are still risks. During the non-breeding period in ice-free waters and as the presence of lighted ships and structures increases, risks are heightened. A wide variety of nocturnal species nest in the North Pacific, especially in the Aleutian Islands. Storm-petrels are vulnerable in late summer and early fall, when hundreds have been known to pitch on a vessel during foggy conditions. These problems are not unique to the smaller nocturnal species. Common and king eiders, both large ducks, have collided with large shrimp vessels in waters off western Greenland, causing injury or death.

Research Opportunities

- Investigate the effects of ship noise and physical presence, including avoidance behavior on Arctic marine animals at the individual and population level. Such research would contribute to determining distances at which animals are disturbed from ships, the potential for ship strikes and assessment of the need for mitigation strategies if adverse effects are predicted.
- Complete regional modeling of ship emissions in order to investigate the current and potential impacts from these emissions along major routes and near key port regions in the Arctic. This will contribute to more accurate assessment of regional impacts on air quality, pollution, haze and visibility, and climate forcing due to the release and deposition of black carbon and other aerosols.
- Conduct baseline surveys of aquatic species in major recipient ports in the Arctic region and research the potential survival of species introduced through different vectors. Carry out a risk assessment of invasive species introduction under current international standards in order to determine the need for Arctic specific protections.
- Conduct further research on the transport, fate and effects of oil in ice-covered waters, and on technology, methods and procedures to clean-up and remove spilled oil to reduce environmental impacts.

Introduction of Invasive Species

The introduction and spread of alien invasive species is a serious problem that has ecological, economic, health and environmental impacts, including the loss of native biological diversity worldwide. Although the introduction of invasive species into the Arctic environment has been minimally studied, it is an issue that deserves further study in the context of a changing climate and potential increased shipping in the Arctic region.

The risk of introduction of invasive species will increase as shipping volume increases in this region. As with ship operations in non-Arctic areas, the threat of introduction comes from four sources: ballast water discharge, hull fouling, cargo operations and casualties or shipwrecks.

- **Ballast Water**
  The IMO's *International Convention for the Control and Management of Ships Ballast Water & Sediments* addresses ballast exchange and treatment. As of November 2008, 16 states including Norway, representing about 3.6 percent of the world's merchant shipping, have ratified this convention. Under the IMO convention standard, a small percentage of viable organisms will still be discharged.
- **Hull Fouling**
  In subarctic waters, transfer of aquatic invasive species on the hulls of ships has become a serious threat to the environment, rivaling ballast water discharge. However, hull coatings on ice-capable vessels may be effective antifouling agents, as would the scouring effects of passage through ice.
- **Cargo**
  Most international movements of goods are regulated by fumigation and biosecurity provisions to prevent the movement of invasive species in cargo. This is also applicable to the Arctic region. Much of the sealift and re-supply movements into the Arctic are palletized, increasing the potential for unwanted organisms to be entrained in the cargo.

MARPOL 73/78

Regular ship discharges are regulated through the IMO's *International Convention for the Prevention of Pollution from Ships, 1973, as Modified by the Protocol of 1978 Relating Thereto*

- **Casualty**
  Ship accidents and sinkings can introduce invasive species into the local environment. As an example, shipwrecks in the Aleutians have caused significant ecological damage through the introduction of predatory rat species onto islands that have large aggregations of nesting seabirds.

Due to climate change and the potential increase in shipping activity, the introduction of invasive species may require more attention than it has received in the past. In particular, trans-Arctic shipping between the North Atlantic and North Pacific could potentially represent a vector for transfer of species in ballast water or on hulls to new areas where the environmental conditions resemble those in their home waters. Introduction of rodent species to islands harboring nesting seabirds, as evidenced in the Aleutian Islands, can be devastating. With limited baseline data on what species might actually be at risk from ship operations such as ballast water discharge, the use of the precautionary approach and proactive preventative actions are encouraged.

Green Ship Technology in the Arctic

Technology has a role to play in the mitigation of environmental impacts in the Arctic and elsewhere. Many of the potential impacts from shipping that have been discussed in this assessment can be effectively reduced or eliminated through the use of current or developing technologies, as well as best practices. Examples include stack scrubbers that remove harmful substances such as sulfur and black carbon from a ship's emissions; water treatment systems for sewage, bilge water, ballast water and other discharges; technologies that harness wind or solar power to reduce fuel consumption; or the use of cleaner fuels that emit less harmful substances when burned. Given the sensitivity of the Arctic environment and the potential impacts from shipping, the development and application of green ship technologies should be a priority. These new technologies can be expedited through industry incentives, such as the green ship technology fund in Norway; or regulatory requirements, such as the IMO *International Convention for the Control and Management of Ships Ballast Water & Sediments.*

Selendang Ayu Impact

On December 8, 2004, the cargo ship *M/V Selendang Ayu* lost power as it was transiting the North Pacific's Great Circle Route and eventually came ashore near Dutch Harbor in the Aleutian Islands, where it broke into two sections (See page 88). Operations to rescue the crew from the *Selendang Ayu* resulted in loss of life for both rescuers and crew, increasing the adverse effects of this incident. Despite removal and recovery efforts, the ship eventually discharged its cargo of 66 million metric tons of soybeans, an estimated 1.7 million liters of intermediate fuel oil, 55,564 liters of marine diesel and other contaminants into the environment.

For three weeks the weather delayed response to the environmental hazards of the incident. Strong winds, rough seas and the remoteness of the spill stalled the clean-up and search for oiled animals.

To study the impact of the spill on shorebirds, the U.S. Fish and Wildlife Service released 162 bird-size blocks of wood from the grounding site more than a month after the incident. The blocks helped determine where contaminated dead birds might have drifted. The exercise led to the immediate recovery of 29 oiled birds, 19 that were dead or dying and 10 that were recovered and released. During the course of the clean-up, 1,603 bird carcasses and six sea otter carcasses were recovered. Because of the delay in the recovery efforts, it is likely the number of wildlife impacted was greater. By mid-February 2005, 38,000 bags of oily solid waste had been reclaimed. The clean-up effort was ongoing until June 2006, and the long term impacts on local populations are yet to be fully assessed. This information was drawn from a recent U.S. Fish and Wildlife Service report on the incident.

Findings

1] From an environmental point of view, Arctic shipping poses a threat to the region's unique ecosystems. This threat can be effectively mitigated through careful planning and effective regulation in areas of high risk.

2] Release of oil into the Arctic marine environment, either through accidental release, or illegal discharge, is the most significant threat from shipping activity.

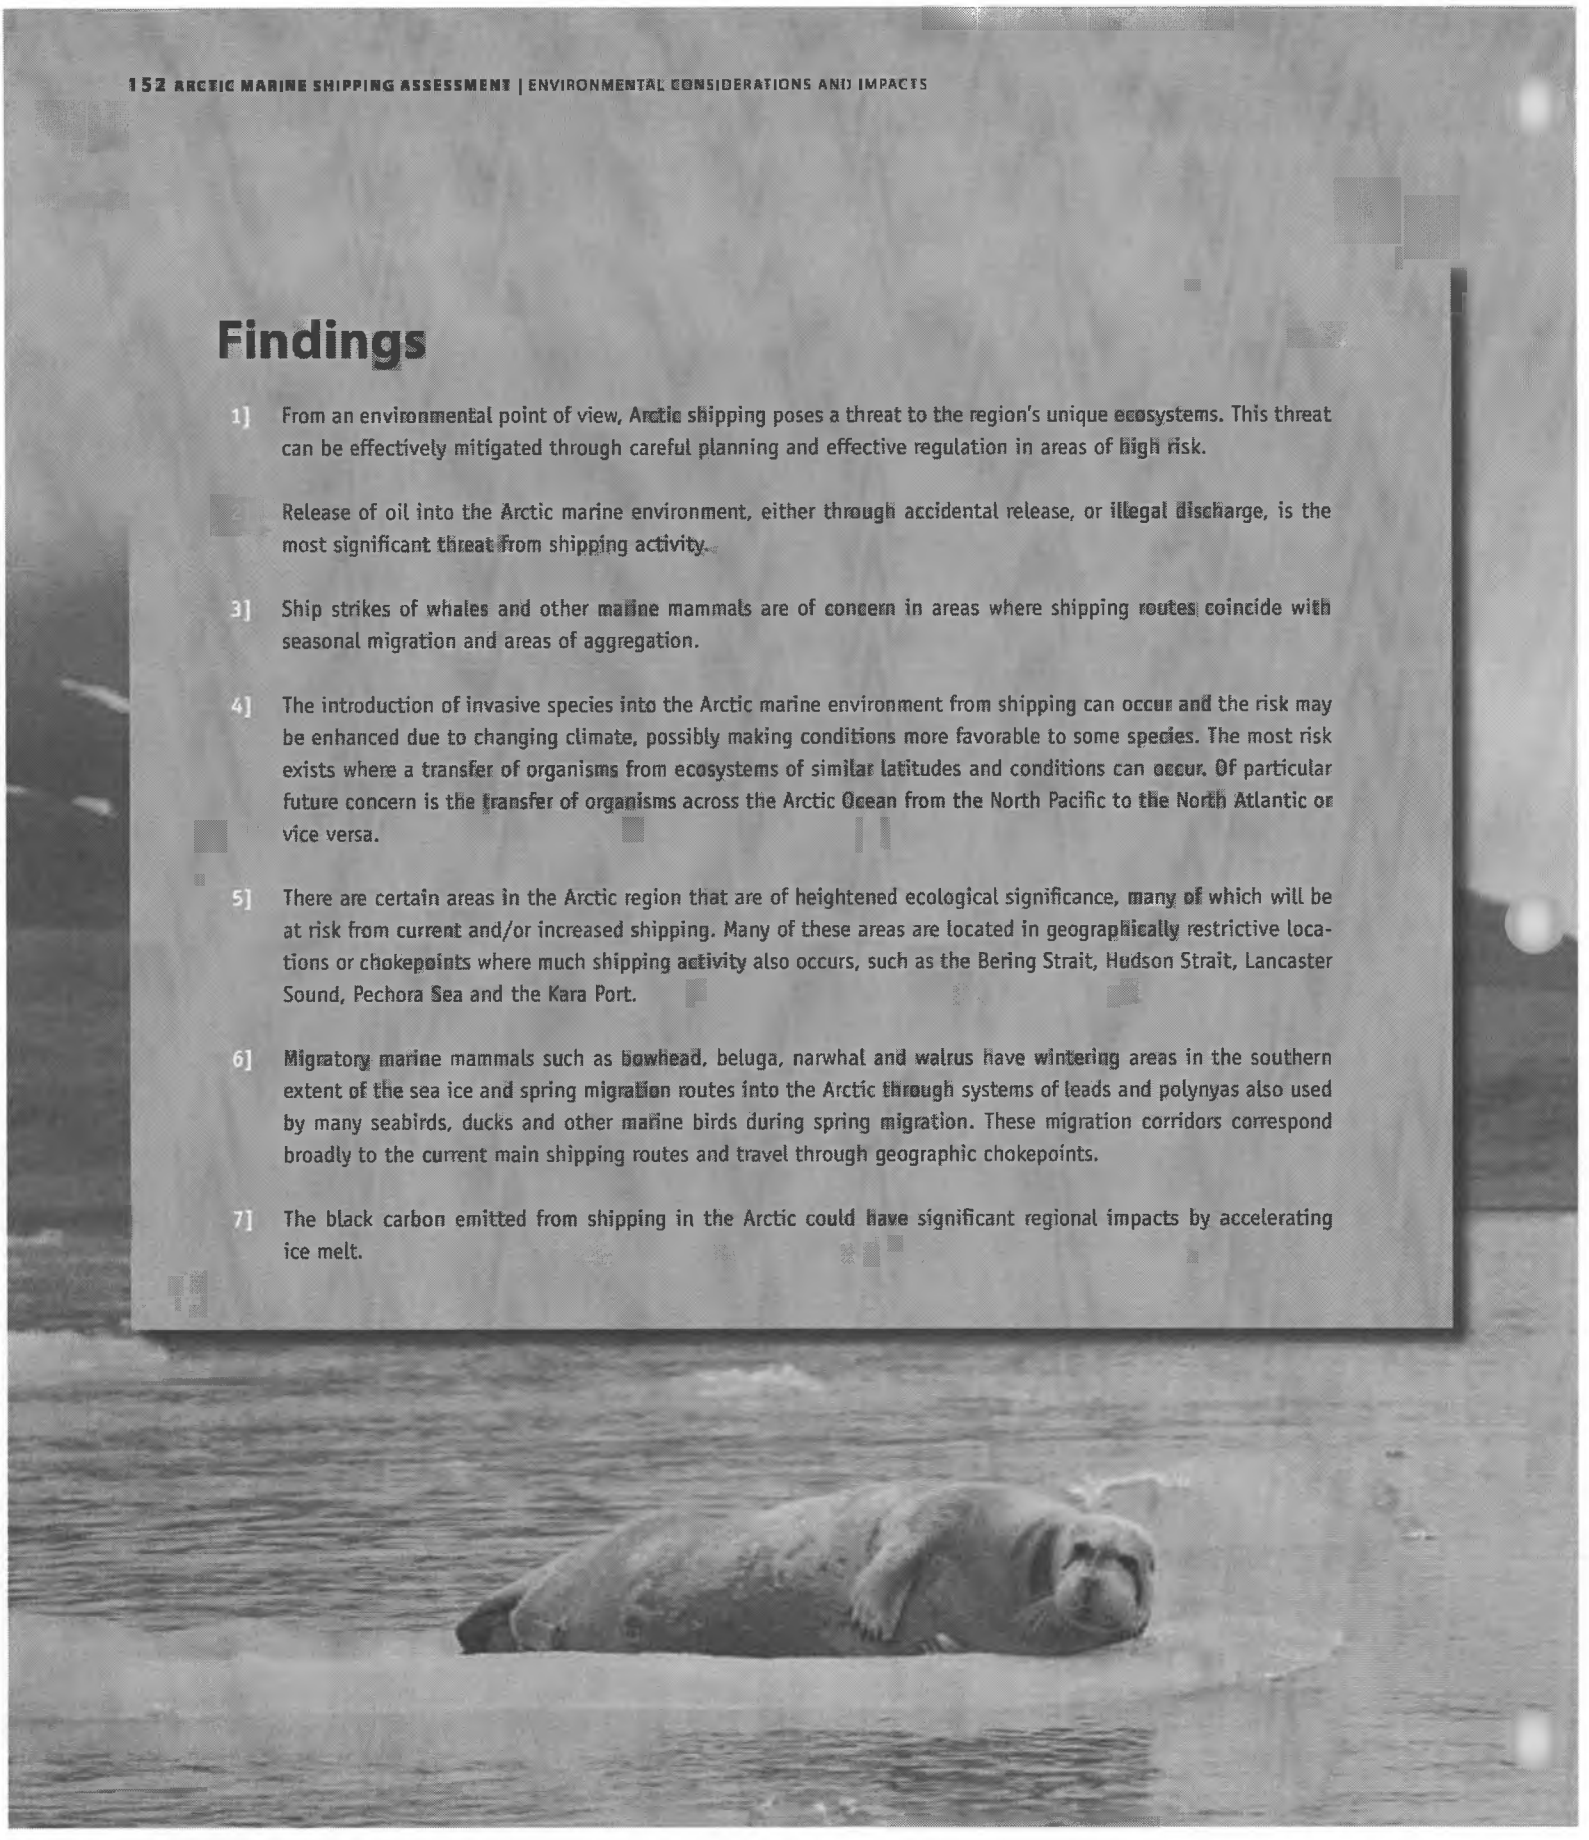
3] Ship strikes of whales and other marine mammals are of concern in areas where shipping routes coincide with seasonal migration and areas of aggregation.

4] The introduction of invasive species into the Arctic marine environment from shipping can occur and the risk may be enhanced due to changing climate, possibly making conditions more favorable to some species. The most risk exists where a transfer of organisms from ecosystems of similar latitudes and conditions can occur. Of particular future concern is the transfer of organisms across the Arctic Ocean from the North Pacific to the North Atlantic or vice versa.

5] There are certain areas in the Arctic region that are of heightened ecological significance, many of which will be at risk from current and/or increased shipping. Many of these areas are located in geographically restrictive locations or chokepoints where much shipping activity also occurs, such as the Bering Strait, Hudson Strait, Lancaster Sound, Pechora Sea and the Kara Port.

6] Migratory marine mammals such as bowhead, beluga, narwhal and walrus have wintering areas in the southern extent of the sea ice and spring migration routes into the Arctic through systems of leads and polynyas also used by many seabirds, ducks and other marine birds during spring migration. These migration corridors correspond broadly to the current main shipping routes and travel through geographic chokepoints.

7] The black carbon emitted from shipping in the Arctic could have significant regional impacts by accelerating ice melt.



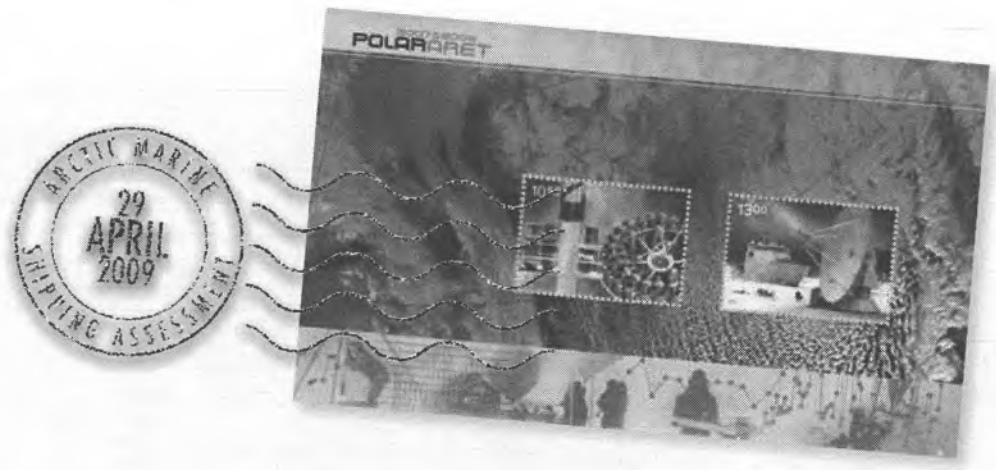
8] Ship emissions including greenhouse gases (GHGs), Nitrogen Oxides (NOx), Sulfur Oxides (SOx) and Particulate Matter (PM) may have negative effects on the Arctic environment and will increase in the Arctic region proportionately with increased shipping activity. Effective reduction of ship emissions can be achieved through the application of feasible and best available technologies, through air emissions reduction techniques and, most importantly, through effective implementation of relevant IMO regulations.

9] Sound is of vital biological importance to marine mammals and anthropogenic noise produced through shipping and other vessel activity can have various adverse effects on Arctic species.

10] Subarctic seas support some of the richest fisheries in the world in the Bering Sea and the Barents Sea. These two areas are also the location of the heaviest shipping traffic now occurring in the Arctic region. A potential accidental spill of oil or other hazardous and noxious substances in these areas could have large economic, social and environmental impacts.

11] Environmental effects on marine mammals, seabirds and fisheries from ship sourced disturbances, noise, or potential accidental/illegal release of oil and other hazardous and noxious substances may impact culturally and economically significant subsistence harvests of these animals.

12] The most immediate impacts of climate change in the Arctic will be the reduction of summer sea ice, longer open water seasons in the fall and the reduction of the year-round presence of multi-year ice. These changes may have far reaching implications for Arctic ecosystems and will also result in the lengthening of the current shipping season. Shipping in the future may be occurring much later into the fall and possibly earlier in the spring, thereby increasing the possibility of interaction between migrating and calving species and ships.



ARCTIC MARINE INFRASTRUCTURE

When compared with marine infrastructure in the world's other oceans, the Arctic is significantly lacking throughout most of the circumpolar north. The current increase in human activity in the Arctic is placing new demands on Arctic infrastructure needed to support safe marine shipping, protect the environment and respond to emergencies. Anticipated increases in Arctic marine shipping during the coming decades will place additional demands on infrastructure and require innovative, cooperative solutions that best use the limited resources available in this remote region.

The findings contained in this section are the result of extensive input received across a wide spectrum of interests from those experienced in Arctic marine operations, including representatives from the Arctic states. The analysis of current Arctic infrastructure included surveys based on information from the Arctic states regarding Arctic ports, capabilities for handling larger vessels, search and rescue assets and icebreaker capacity. In addition, an international workshop was held at the University of New Hampshire in March 2008 to consider infrastructure needs and gaps associated with emergency response to Arctic incidents. Workshop participants represented a broad spectrum of expertise including governmental agencies, industry, non-governmental organizations and indigenous people from the Arctic nations. The workshop, "Opening the Arctic Seas: Envisioning Disasters and Framing Solutions," considered five realistic emergency scenarios in diverse locations throughout the Arctic. Incidents envisioned involved vessels caught in ice or in a collision, oil spills, search and rescue, environmental damage and disruption of indigenous communities. The workshop report provides a qualitative analysis of risk factors for Arctic marine incidents likely to happen as shipping, tourism, exploration and development of natural resources such as oil, gas and minerals increase with the retreating ice cover (See page 176).

Major Arctic infrastructure themes emerged and are reflected throughout this section and its findings. Currently, vast areas of the Arctic have insufficient infrastructure to support safe marine shipping and respond to marine incidents in the Arctic. This includes such critical infrastructure components as the accuracy and availability of timely information needed for safe navigation; availability

of search and rescue assets, pollution response assets and supporting shoreside infrastructure to respond appropriately to marine incidents; port reception facilities for ship-generated waste; and availability of deepwater ports, places of refuge and salvage resources for vessels in distress. While there are notable exceptions, where infrastructure is more developed, they are the exception rather than the rule. To assist with ship navigation, locating refuges, pollution response and other activities, adequate weather forecasting and warning capabilities are essential and necessitate adequate observations, models and forecasts.

Emergency response is particularly challenging in the Arctic for a variety of reasons, including the remoteness and great distances that are often involved in responding; the impacts of cold, ice and a harsh operating environment on response personnel and equipment; and the lack of shoreside infrastructure and communications to support and sustain a response of any significant magnitude. Prevention of marine accidents, and actions designed to strengthen the effectiveness of preventive measures, are especially critical for Arctic marine shipping given the difficulties of responding once an incident has occurred. Preventive measures include ensuring that vessels operating in the Arctic meet appropriate design, construction and equipment standards; that vessel personnel have the specialized skills needed for operating in Arctic conditions, including operations in ice-infested waters where applicable; and that information needed for safe navigation is available, from accurate charts to timely information on meteorological and ice conditions and on other vessel traffic and activities in the area.

While there are many challenges associated with strengthening Arctic marine shipping infrastructure, there are also opportunities to develop measures to improve safe marine shipping operations and protect the Arctic environment in anticipation of the continuing increase in Arctic marine activity, rather than responding after an incident has occurred. Considering the long lead time to put marine infrastructure in place, this should be considered early in the prioritization process.

Systems Related to Safe Navigation

To the mariner, there are several environmental factors that make the Arctic uniquely difficult to navigate compared to temperate waters. These include: presence and movement of sea ice, icebergs, cold air and water temperatures, variable and often unpredictable severe weather, magnetic variation, solar flare activity and extended daylight or nighttime conditions. These environmental conditions, combined with the remoteness of the region from commercial shipping centers and shipping lanes, highlight the need for improved systems to support safe navigation in the Arctic region.

Arctic Charting

Hydrography is the oldest science of the sea. The earliest explorers were often hydrographers and cartographers who recorded their discoveries on marine charts, sometimes to claim new territory, and always to ensure safe passage.

Modern marine charts are compiled from accurate hydrographic surveys conducted onboard specialized vessels equipped with echo sounders that measure water depths and satellite navigation systems, such as the Global Positioning System (GPS), that determine the geographic positions of these soundings. Numerous other sources of information are used in the creation of charts, such as shoreline location, details of navigational aids, place names, conspicuous land-based features, overhead cables and underwater pipelines. Data on navigational charts are also corrected for the movement of tides, such that the depth portrayed is normally the minimum the mariner will find under the keel. Expert information specialists combine all these various sources of data into navigational charts, taking extreme care to ensure the information is clear and accurate for use by mariners. The collection of the hydrographic data required and the process to produce a new navigational chart can often take years.

In light of the limited amount of marine traffic, the historical survey methods (ship-based and ice-based) and the significant costs and the volatility of the weather conditions, hydrographic surveys in the Arctic have not achieved the same level of coverage and quality as surveys in southern latitudes. As a result, Arctic charting base hydrographic data is not adequate in most areas to support current and future marine activities. This situation could improve if collection methods and platforms were developed that would be minimally affected by the Arctic conditions of weather, ice and isolation.

For hundreds of years, navigation at sea has relied upon the manual plotting of vessel location on traditional paper charts. Modern Electronic Chart Display and Information Systems (ECDIS), combined with satellite-based positioning, bring hydrographic data into onboard computers, greatly improving the navigation information available to the mariner and potentially reducing the reliance on traditional aids, such as floating buoys and fixed lights. Advances are also being made in consolidating information such as weather and ice conditions into electronic charting systems, further assisting mariners.

Recognizing the benefits of electronic charts, the International Maritime Organization (IMO) has proposed compulsory carriage of ECDIS and Electronic Navigational Charts (ENCs) on high speed craft from July 1, 2008 onward for all new craft and from July 1, 2010 onward for existing craft. In addition, IMO's Safety of Navigation Subcommittee has reached consensus to implement the mandatory carriage of ECDIS on new passenger ships above 500 gross tonnage by 2012, with a broadening of this requirement in subsequent years.

Arctic nations report various levels of ENC coverage for their northern waters (Maps 9.1, 9.2, 9.3). The presence of an ENC does not guarantee adequate information for safe navigation, however, as they are normally created using the same information available on traditional charts. As previously mentioned, the hydrographic data in many Arctic locations is either non-existent or in serious need of improvement.

10%

The portion of the Canadian Arctic that the Canadian Hydrographic Service says has been surveyed to modern standards.

Arctic Marine Infrastructure Terminology

For the purpose of this assessment, "infrastructure" is defined broadly to address all major aspects of marine shipping, including vessels and crews, the systems needed to gather and supply accurate and timely information for safe navigation and operations, the personnel and resources needed to respond to a variety of potential emergencies, port reception facilities for ship-generated waste and the shoreside facilities needed to provide supplies and logistics in support of marine shipping and emergency response. "Vessels" include tankers, passenger vessels (ferries, large and small cruise ships) and pleasure craft, bulk carriers, container ships, fishing vessels, tug and barge combinations, offshore supply vessels, research ships, icebreakers and other watercraft. "Officers and crew" includes vessel personnel with special expertise for operations in cold and ice-infested waters, such as ice navigators or ice pilots, and considers the training, experience and expertise required for all vessel personnel when confronting the unique challenges of Arctic marine operations. "Emergency response resources" include response assets such as aircraft, vessels and specialized equipment; the logistics and supply chains needed to support these operations both at sea and ashore; and the availability of related shoreside facilities and resources such as port, medical, refueling facilities and living quarters to accommodate emergency responders. "Shoreside facilities" include ports and port facilities, particularly ports with adequate depth to accommodate larger vessels, potential places of refuge, airports and shoreside transportation systems.

© United States Coast Guard

Increased Arctic activity, coupled with the difficulties in deploying and maintaining navigational aids in the region, presents an opportunity to implement ECDIS to improve navigation safety and save costs. The benefits of ECDIS, however, are wholly dependent on the underlying hydrographic navigational charts and consequently the hydrographic data on which they are based. Coverage of GPS, or other means of positioning, is also crucial to take full advantage of the system.

Canada, the United States, the Russian Federation and Denmark are carrying out charting activities that include portions of the Northern Sea Route and the Northwest Passage. These countries, as well as Iceland and Norway, are all member states of the International Hydrographic Organization (IHO) whose mission "is to facilitate the provision of adequate and timely hydrographic information for worldwide marine navigation."

While there are published charts whose physical limits cover both the Canadian Northwest Passage and the Russian Northern Sea Route, the quality of the underlying data varies widely from modern, high resolution hydrographic surveys to no sounding information in some areas.

The quality and accuracy of navigational charts is entirely dependent on the hydrographic data used to compile them. Hydrographic surveys in the Arctic are logistically very complicated, expensive to undertake and highly dependent on weather and ice conditions. In addition, hydrographic offices normally prioritize their efforts based on a risk classification approach. Because the Arctic has traditionally seen smaller volumes of marine traffic, these risks have been perceived as low compared to other regions and progress in improving hydrographic coverage in the Arctic has been painstakingly slow.

IHO provides the current state of hydrographic surveys for member countries throughout the world. In Greenland, the limit for navigable waters has been set to 75 degrees northern latitude due to the permanent ice cover and the sparse population of its east coast. Within Canada, a high proportion of Arctic waters are inadequately surveyed or covered by frontier surveys only. A similar situation exists in the Russian Federation where ice conditions have precluded the systematic survey of the central parts of the Laptev and East Siberian seas. Only passage sounding

1933

The year the Russian Federal State Unitary "Hydrographic Enterprise" began conducting surveys.

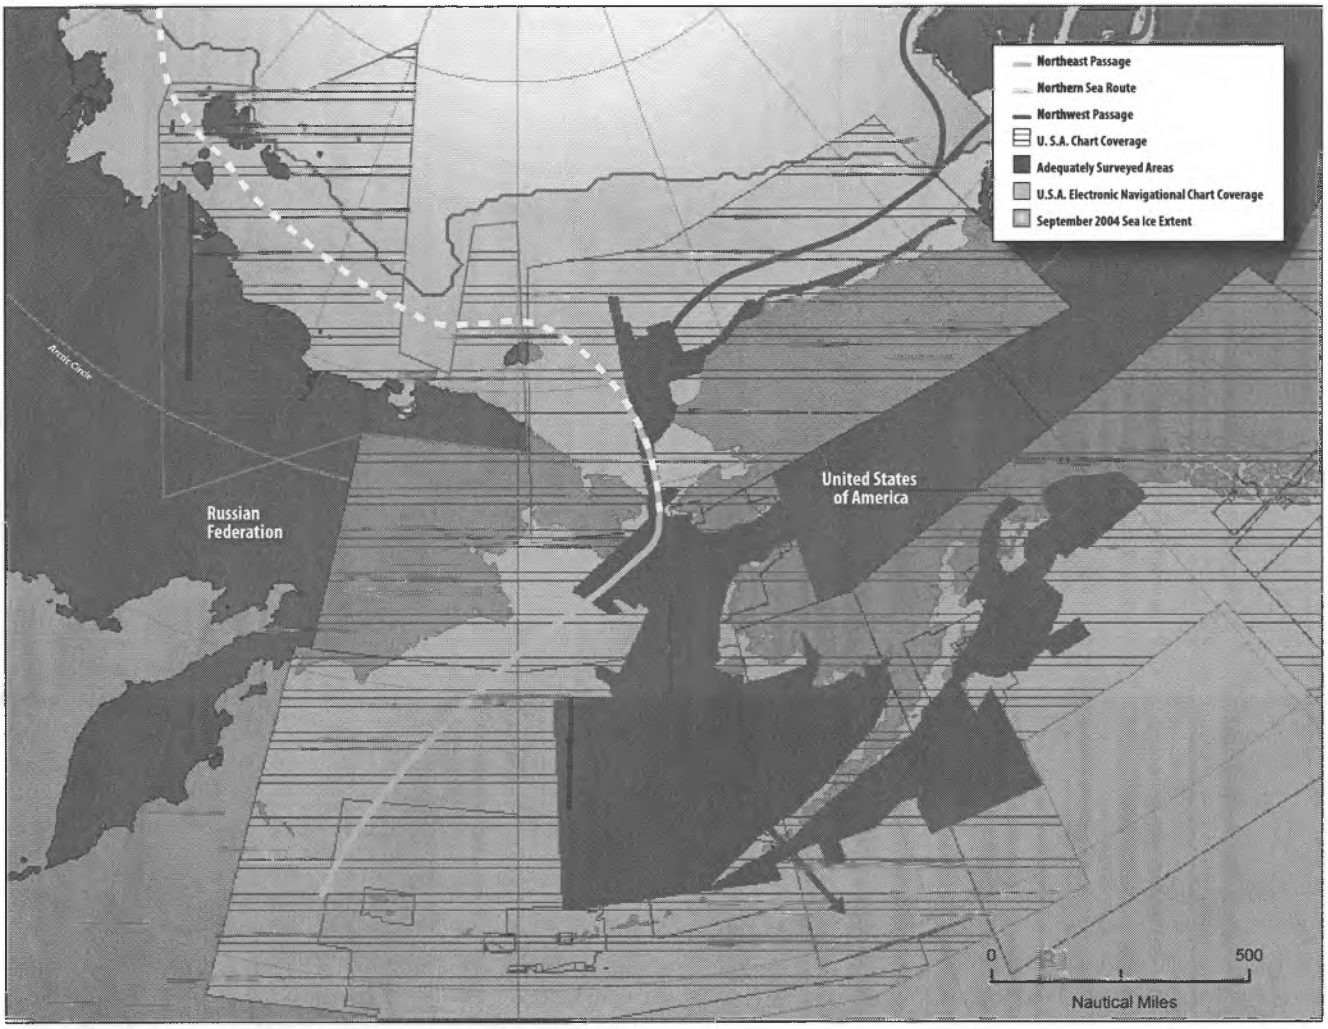
data is available for the deep water areas of the Sea of Okhotsk and the Bering Sea. The following figures illustrate the status of individual countries.

The Canadian Hydrographic Service reports that 10 percent of the Canadian Arctic has been surveyed to modern standards (Map 9.1). Coverage is often minimal and collected using rudimentary equipment and methods.

Surveys of the U.S. Arctic have been predominately along the northern coast of Alaska (Map 9.2).

The Russian Federal State Unitary "Hydrographic Enterprise" (SHD), formerly known as the Hydrographic Department, has conducted surveys since 1933. For the main areas of the Arctic shelf that cover 90 percent of the traditional navigation routes, detailed underwater topography is available (Map 9.3). Coastal surveys are completed for the Chukchi Sea, the East Siberian Sea, the Kara Sea, the navigable part of the Gulf of Ob', the shipping channel of the Yenisei River up to the port of Igarka, the shipping channel of the Khatanga and Kolyma rivers and the entrance of the Bykovsky waterway from the sea to the delta of the Lena River.

The SHD has set modern standards for Russian hydrographic surveys that recommend survey methods to ensure the detection of all



Map 9.2 U.S. charting and status of surveys in the Arctic. *Source: AMSA*

underwater obstacles on routes of intense navigation. To meet these modern standards, charts will need to be updated and, in the near future, an appreciable amount of work will have to be done. This includes detailed surveys of recommended shipping routes, harborages and anchorages for cargo operations using an instrumental area survey by special hydrographic equipment; regular measurement in areas not yet surveyed or surveyed with poor accuracy and details; and regular measurements in regions that are difficult to access because of ice conditions.

As mariners traverse the waters of nations around the world, they must be able to reliably interpret hydrographic products, independent of the country of origin. By becoming members of the International Hydrographic Organization, hydrographic offices agree to achieve uniformity in data quality and presentation standards. The emergence of digital products, most importantly electronic charts, has introduced a new aspect to the dissemination of hydrographic data. While a convergence of data sharing approaches is underway, significant inconsistencies remain. The Arctic provides an excellent opportunity to demonstrate the benefits of an open approach to data sharing in the international hydrographic community.

Sea ice is what sets the Arctic apart - what makes navigation in the Arctic especially unique and hazardous.

Ice Information in the Arctic

Without sea ice, the needs for environmental information in the Arctic would be little different from the world's other oceans - wind and weather, waves, tides, currents, etc. Sea ice is what sets the Arctic apart - what makes navigation in the Arctic especially unique and hazardous.

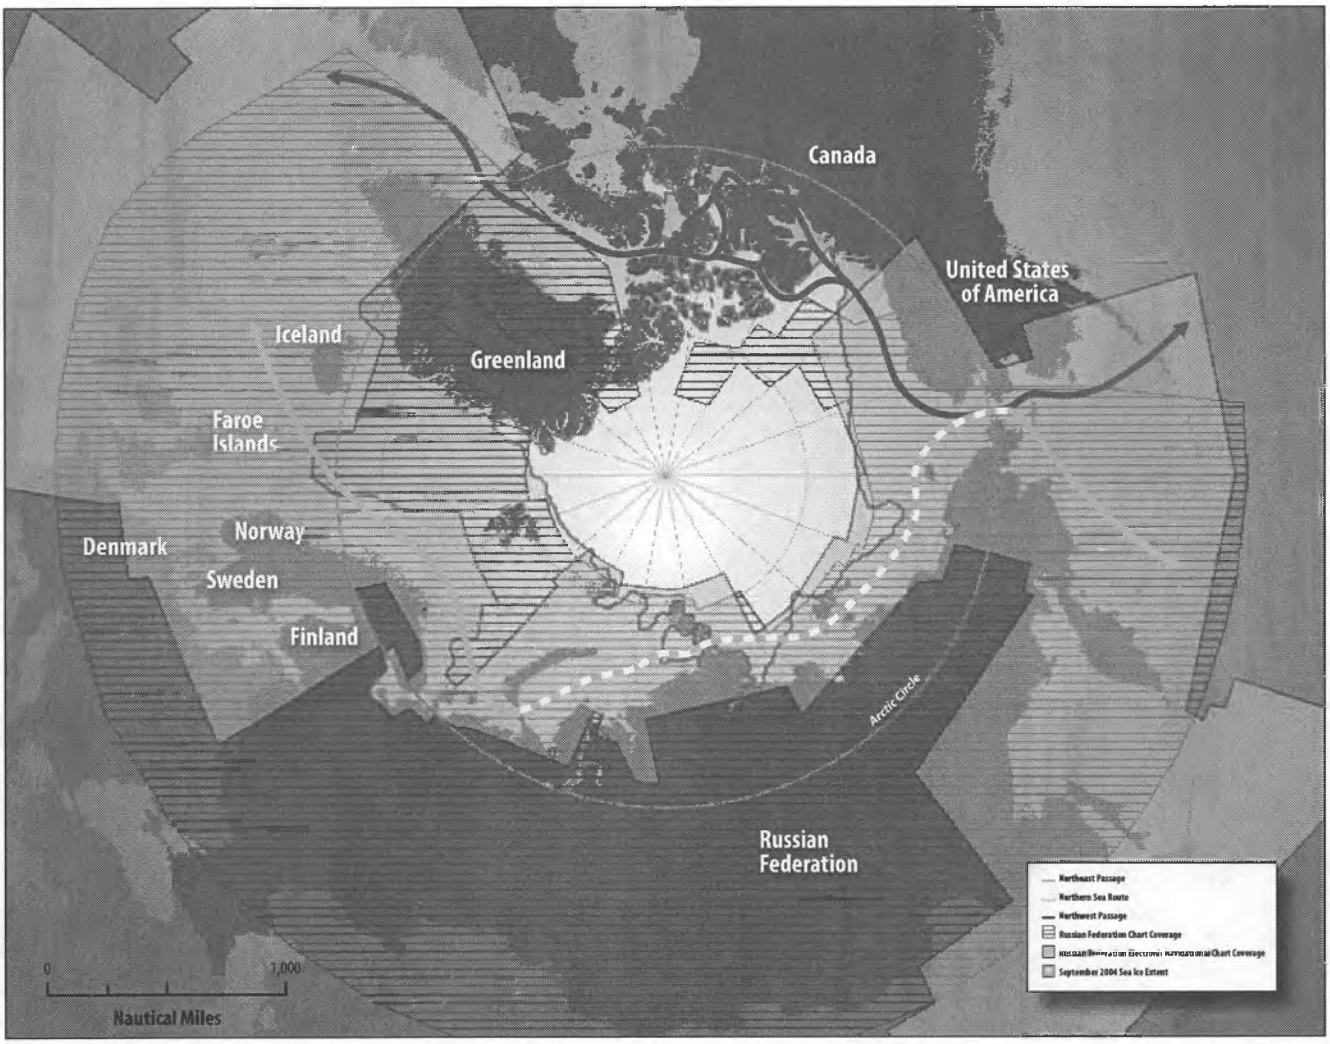
Sea ice in the Arctic has an annual cycle of freeze and melting that will not change in the future. When the sun goes down in the autumn and the extreme cold arrives, the ocean freezes. March is the month of maximum ice coverage. Through the summer months, the ice melts and retreats to a minimum extent in September.

It is generally agreed that the reduction in the thickness and extent of Arctic sea ice will continue into the future until, eventually, the Arctic will become free of sea ice in summer - much like the Baltic Sea, Sea of Okhotsk or the waters off the east coast of Canada. However, this will not eliminate the hazard that ice presents to Arctic shipping. There will still be a winter ice cover and significant inter-annual variability means that not all of the ice will melt every year, so scattered old ice floes will hide in the pack ice along with icebergs and ice island fragments. Moving ice driven by winds and currents will create a dynamic and hazardous operating environment. Variability in the onset of autumn freeze-up will present the risk of getting trapped in the Arctic over winter. Spring break-up to mark the start of summer navigation will vary and, as happens now in more southerly seas, shippers eager to start work will test the limits of their vessels in ice.

As more ships venture into the Arctic, the demand for ice information, as well as other ocean data, products and services, will continue to increase and the resources available to meet this increased demand will be stretched. The ice parameters needed in the future will not change significantly but will be required over larger geographic areas and longer periods of the year. Operators will still need to know where the ice is and isn't; where it's going to be, how closely packed it is and how thick and strong it is; generally, how difficult it will be to go around or, when necessary, go through. These parameters will be needed on a variety of space and time scales - from the hemispheric to the local, from months and weeks to daily or even hourly - to support tactical and strategic route planning for ships, scientific study and the development of policy and regulations to ensure safe marine practices.

The needs of mariners for ice information are currently met by a number of organizations, including national ice services that produce information for the Arctic that is generally freely available as a public service funded by tax-payers; academic institutions that provide ice information as part of an ongoing research program or to support field research campaigns; and commercial ice information services that provide services that are specific to individual clients with particular needs. As more ships venture into the Arctic and the demand for ice information and related services increases, there will be increasing pressure on the resources of ice information providers.

The national ice services collaborate in the Joint WMO-IOC Technical Commission for Oceanography and Marine Meteorology Expert Team on Sea Ice, the body that establishes and maintains the standards for ice information internationally; and in the International Ice Charting Working Group (IICWG), an ad hoc group



Map 9.3 Russian Federation chart and ENC coverage of the Northern Sea Route. *Source: AMSA*

that coordinates ice information services internationally and advises the Expert Team on Sea Ice. As a result of this collaboration, there is an internationally accepted nomenclature for ice in the ocean, common charting and coding practices and cooperative information sharing among the ice services.

Ice information products include ice charts depicting the distribution and characteristics of the sea ice in an area; satellite images of ice-infested waters, often with interpretative text added; and text messages describing ice conditions. There is a wide range of scales for these products - from hemispheric charts that are useful for long-range planning to the navigation scale to support tactical vessel movements.

It is certain that the needs for ice information will evolve as more Arctic shipping develops. It is impossible to predict exactly how that evolution will occur because it depends on many factors - how the ice distribution itself changes, where resources are found, what markets are developed, advances in ship design and improving technology to observe, produce and disseminate ice information. The following examples are intended to provide illustrations of the particular ice information needs for some probable scenarios.

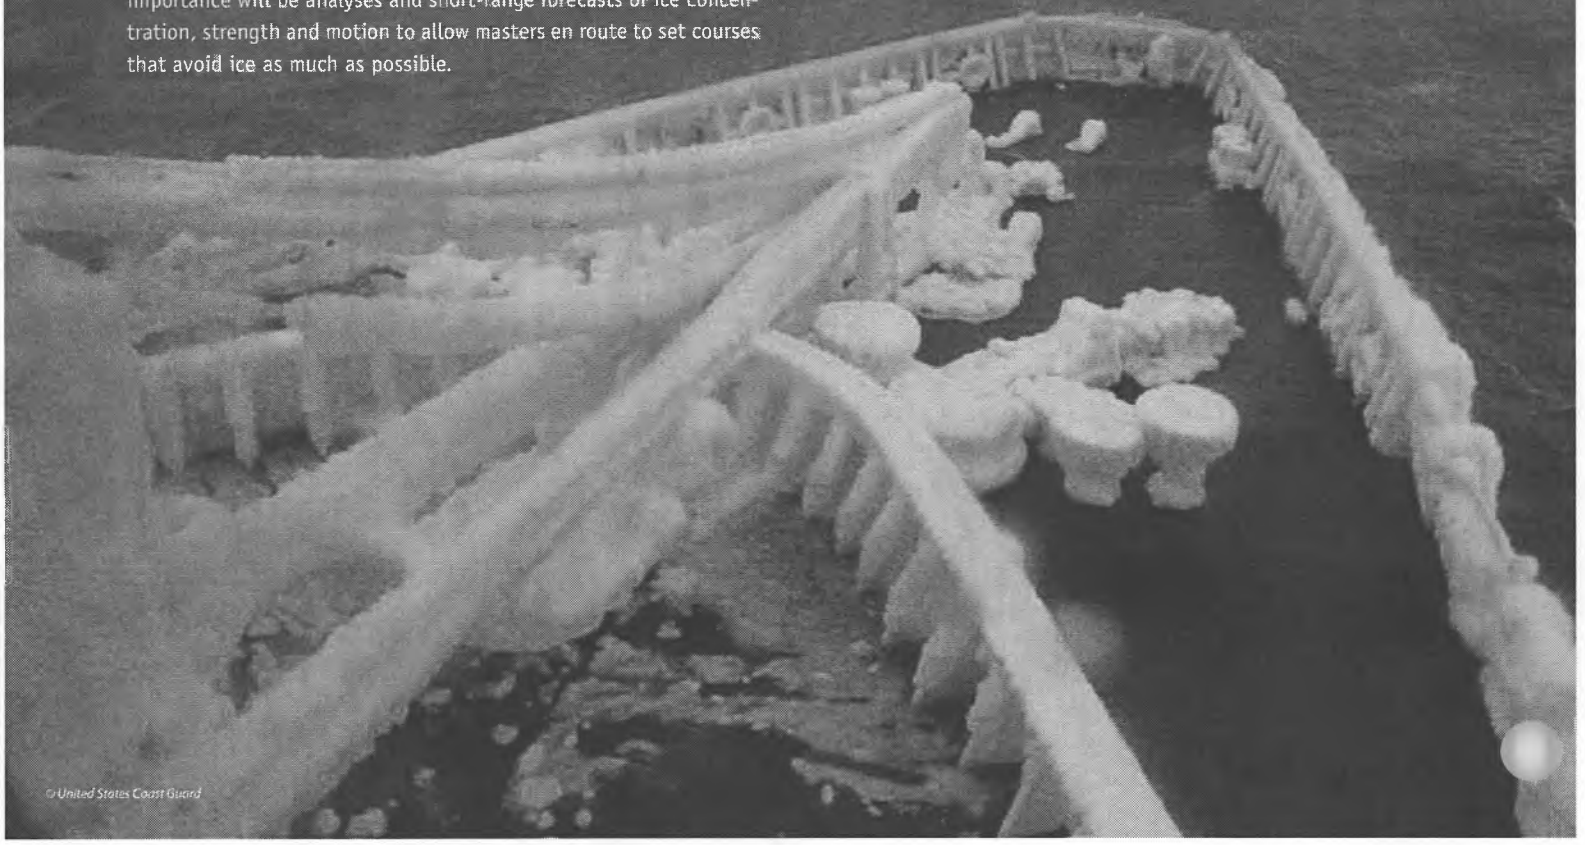
Potential shipping routes for extracting resources - principally oil, gas and minerals - will primarily be along shortest distance lines from the production sites to markets. It is likely the vessels used in this trade will be purpose-built for the trade in question and will operate year-round. They will be ice-strengthened and powered sufficiently to handle the most severe ice conditions encountered along the route. Ice information of most importance to these vessels will be that which can help them reduce time and fuel consumption en route as well as minimize the risks and delays that can be caused by difficult ice conditions around loading docks and piers.

Arctic transit shipping, using the Arctic Ocean as a short cut between Atlantic and Pacific, is not expected to become common because of the seasonal nature of the ice cover. Vessels designed to reliably pass through the winter Arctic ice cover will be greatly disadvantaged economically during the ice-free season. If transit shipping does occur in the Arctic, it will likely be limited to the summer season. These vessels will have some ice-strengthening to handle summer Arctic ice encounters but will not be able to deal with winter conditions. The most important ice information for this trade will be medium- and long-range forecasts of break-up and freeze-up to help companies decide when to head for the Arctic and when to get out in order to avoid being trapped over a winter. Close in the order of importance will be analyses and short-range forecasts of ice concentration, strength and motion to allow masters en route to set courses that avoid ice as much as possible.

Marine Weather Information for the Arctic

Modern weather information, including information for shipping, is based on numerical models. Numerical weather prediction analyses and forecasts are available for the Arctic from all of the major meteorological centers that run global models. States having the need for more detailed information for the Arctic areas have implemented high resolution models covering the Arctic region according to their needs.

In addition, Arctic coastal states provide marine weather information for their coastal waters. In most cases information for shipping is issued for large areas extending well offshore. Within the coverage of INMARSAT Global Maritime Distress Safety System transmissions, marine safety information in the form of gale and storm warnings is in place consistent with all other high sea areas in the world. However, no responsibility has yet been assigned for the high seas regions of the Arctic outside the coverage of INMARSAT, although an initiative is underway to do so by the World Meteorological Organization. Several states have offered to issue and/or prepare weather information for the Arctic. Progress in this initiative is expected and routine weather bulletins for the high Arctic areas may be in place in a few years. Prediction of the development and paths of lows giving rise to high winds is of particular concern for Arctic shipping. Accurate



© United States Coast Guard

forecasts of sea ice, wave height, wind direction and speed, visibility, temperature and superstructure icing are the most important routine forecast parameters for shipping - with at least the same accuracy and timeliness requirements as on the other oceans.

Although weather forecasts for the Arctic are based on the same tools using the same techniques as in other areas of the world, the scarcity of observations in the Arctic makes the monitoring of the weather more difficult than in areas with more observations. Meteorological observations in the Arctic rely on drifting buoys placed on top of the sea ice. A new generation of buoys that will withstand multiple freeze-thaw cycles is currently under development and is urgently needed to provide surface observations in the Arctic Ocean. The ability to measure the conditions of the atmosphere and ocean from satellites is, however, developing rapidly and, with adequate surface validation, the quality of weather forecasts will approach the quality used in other areas.

The future increase in human activity in the Arctic, including Arctic marine shipping and the continued overflight of the Arctic region by commercial aircraft, will place increasing demands on the SAR infrastructure.

Wave Information for the Arctic

Because of the ubiquitous presence of sea ice, waves have not been a major navigational hazard in the Arctic. However, with less sea ice to dampen the waves, this will no longer be the case in the future. Wave information is typically packaged along with marine weather information in sea ice-free areas. New operational modeling capability will be needed to deal with a partial ice cover and its effect on wave generation and transmission. Buoys that measure the wave heights and directions are essential for model validation but none of these exist in the Arctic for operational reporting. Because of the necessity to deal with winter ice, a new generation of buoys will have to be developed.

Marine Aids to Navigation

The safe and effective use of northern waters by maritime shipping relies heavily on such safety systems as fixed and floating aids to navigation, long-range aids to navigation (shore-based electronic or satellite-based), as well as safety and navigation information broadcasts. While southern waters and well-used maritime routes are well served by established systems, northern waters are served by a patchwork of these systems. Ships navigating in the Arctic encounter unique situations. Ships usually use a combination of satellite positioning and traditional navigation techniques.

Of the eight circumpolar countries, six have coastlines. Of these, Canada, Denmark, Norway, Iceland and the Russian Federation maintain active aids to navigation (ATON) networks. More specifically: The Canadian Coast Guard maintains a number of seasonal fixed and floating aids throughout the Canadian Arctic. These are placed around the last week in June by icebreakers in Ungava Bay, Hudson Strait, Frobisher Bay and in the western Arctic by the third week in July. There is an active aids program along the Mackenzie River, serviced by two CCG shallow draft tenders. These aids are then picked up and the fixed aids deactivated as the icebreakers leave the Arctic, generally by the last week in October.

Norway maintains aids to navigation along its entire coast and at Svalbard along the coast and in fjords. Of note are a number of fixed and floating aids to navigation in Svalbard internal waters. It is expected that the requirement for aids to navigation in the Svalbard area will increase based on analyses of both the changing traffic patterns and the utilization of better risk analysis methodology.

Denmark has a permanent system of radio communication and radar beacons (RACON) along the west coast of Greenland from Uummannarsuaq/Kap Farvel to Qeqertarsuup Tunual/Diskobugten, as well as a system of coastal fixed aids, such as daymarks, from Uummannarsuaq/Kap Farvel to Upernavik.

Iceland maintains a number of fixed and floating aids to navigation in its internal waters including a Digital Global Positioning System and RACON beacons and has a permanent system of radio communication for radio monitoring of its fishing fleet.

The Russian Federation has an extensive system of fixed and floating aids to navigation mainly in the harbors of the NSR, which also includes some lighted and unlighted beacons and daymarks along the coast between ports.

The United States has no aids to navigation along the north coast of Alaska. The current U.S. short-range ATON footprint in the

© German Shipowners' Association

Arctic extends a short distance north of the Bering Strait where the largest zinc mine in the world (Cominco's Red Dog mine) near Kivalina receives ore carriers. North of the Aleutians along the coast of the Bering Sea, the U.S. has some floating and fixed ATON near the Pribilof Islands and Bristol Bay for tug, barge and fishing vessel traffic. In the Aleutian chain, there are several areas where navigational aids are maintained for local traffic, as well as for the trans-Pacific shipping transiting this region.

Marine Communications, Traffic Monitoring and Control

The historical standard for communicating weather, wave and ice information to ships at sea is the radio facsimile broadcast. While its use is being eclipsed world-wide by digital communications, the analogue radio broadcast remains an important source of information in the Arctic. Radio stations in the United States, Canada, the United Kingdom, Denmark, Germany and the Russian Federation broadcast analysis and forecast charts for sea ice, icebergs, sea state and weather, as well as providing vessel traffic services and general marine communications.

Norway has established a very advanced system composed of Automatic Identification System (AIS) and Maritime Communications and Traffic Services along the Arctic coast. In January 2007, a Vessel Traffic Service (VTS) for the coast of northern Norway was established in Vardø, operated by the Norwegian Coastal Administration (NCA). The service is designed to monitor and guide vessels, to promote safe and efficient navigation, and to protect the marine environment against undesired events in the Barents Sea and along the Norwegian coast. The area of operation for Vardø VTS Center is the Norwegian Economic Zone (NEZ) outside the baseline, the area around Svalbard and the area outside Tromsø and Finnmark in northern Norway. The VTS Center interacts with vessels, other government agencies, the NCA duty team that is responsible for national response and with the Norwegian SAR for search and rescue services. The administration also coordinates, on a daily basis, the tugboat preparedness in North Norway in conjunction with Regional Headquarters North-Norway (Norwegian Armed Forces) and the NCA duty team.

The United States marine communications infrastructure in Alaska is concentrated where vessels operate the most. There is excellent very high frequency (VHF) coverage throughout southeast Alaska and into portions of the Bering Sea north to St. Paul and the Bristol Bay area. North of this region there is local VHF coverage at Nome, Kotzebue and Barrow. Barrow and Kotzebue, both north of the Bering Strait, also have high frequency (HF) NOAA radios. Mariners in these areas can speak directly to a weather expert via HF radio. Outside of VHF marine coverage, the U.S. Coast Guard relies on high frequency or satellite communications. Canada operates a seasonal system, while the Russian Federation is planning to augment their existing service during the next two years with further investment up to the 2020 timeframe. The Danish Navy operates a year-round high frequency radio station on the southwest coast of Greenland and maintains the IMO mandatory ship reporting system, GREENPOS, for all ships on voyage to or from Greenland ports and places of call. Furthermore, Denmark maintains a number of stations with limited communications capabilities in the south/southeast and lower western half of Greenland. Iceland has an advanced system of AIS along its coast with 23 base stations and repeaters with total coverage of the coastline. The maritime radio system has recently been renewed in VHF, MF (medium frequency) and HF bands and two new NAVTEX stations have been established. The traffic monitoring is carried out by the Maritime Traffic Service in Reykjavik operated by the Icelandic Coast Guard.

Communications using VHF, MF and HF as well as satellite are generally sufficient for the lower Arctic areas (Hudson Bay, Foxe Basin, southern Greenland waters and waters of the Northern Sea Route); however, once the high Arctic is reached, voice and data transmission become problematic.

Most modern ships are equipped with satellite digital communications equipment - not only for safety reasons but for the management and navigation of the ship. This equipment relies on geostationary INMARSAT satellites that do not provide service northward of about 80° N latitude. Other systems, such as the IRIDIUM constellation of 66 polar orbiting satellites, provide worldwide coverage including the Arctic. IRIDIUM is capable of providing a Ship Safety and Alerting System that meets IMO requirements but its data transfer rates are very low (less than 9.6 kb/s). The feasibility of communicating ice charts and satellite images to ships in the Arctic via the IRIDIUM system has been demonstrated but communications are limited and often interrupted. Other regional systems such as the Mobile Satellite System (MSAT) offer limited voice and data transfer capability only in North America including the Canadian Arctic Archipelago.

Improvements in capacity and reductions in cost are necessary for IRIDIUM and other regional systems to become a practical, widespread solution for the Arctic not only for voice, but more importantly for data transmission. The Russian Federation has been using communication satellites in highly elliptical orbits that provide long residence time over the Arctic ("Molniya" orbits) for television and other communications needs for several decades and, in 2007, pledged to improve radio and telecommunications in the Arctic.

It should be noted that the Canadian government has initiated a "Polar Communications and Weather space mission for Canada's North," (PCW) which is planning to provide robust 24/7 two-way satellite communications capability to all of the Canadian north for rapid high rate data transmission and information products, as well as low-data rate communications capability and also near-real time meteorological information products about the north to users throughout Canada.

© Neste Shipping Oy

Various maritime training institutions are developing, or have developed, ice navigation courses, employing full mission bridge simulators and associated software products.

Norway is in dialogue with the United Kingdom, Denmark (Greenland), Faroe Islands and Iceland with regard to establishing a regional North Atlantic AIS/VTMIS (Vessel and Traffic Monitoring and Information System). The system is planned to be in force in 2009, and will facilitate the implementation of Article 9 of the Directive 2002/59 and the establishment of the SafeSeaNet Tracking Identification Relay and Exchange System (STIRES) as presented in the STIRES study (Saab AB, PM PM 374185).

Satellites and aerial surveillance systems can improve monitoring capability and serve to improve compliance with state regulations such as those intended for pollution prevention, or traffic reporting schemes that consequently can help in protecting the environment. As shipping increases in the Arctic regions, the requirement for improved voice and data transmission coverage becomes paramount.

Personnel and Maritime Training

Considering the Arctic operational environment and the lack of infrastructure, safe navigation in the Arctic is often dependent on the skills of a limited number of seasoned northern mariners. The Arctic offers significant navigational challenges, especially to the uninitiated. For decades, safe navigation has rested in the hands of a small number of experienced officers in a few countries. Their training has mostly been on-the-job with relatively little in the way of formal ice navigation education except within the limited regular navigation curriculum. With increased shipping in the Arctic, the need for skilled mariners will increase. Earlier melt periods and later freeze-ups will allow a greater amount of multi-year ice and ice of land origin (iceberg fragments such as growlers and smaller pieces called bergy bits) into the shipping lanes of the Northern Sea Route and the Northwest Passage, as well as in Greenland waters. It should be noted that less ice does not mean less danger. Understanding of the special conditions influencing navigation in the Arctic is crucial to the maintenance of a safe shipping regime.

The IMO's *Guidelines for Ships Operating in Arctic Ice-covered Waters* and the *International Convention on Standards of Training, Certification and Watchkeeping of Seafarers* (STCW '95) call for specialized training for mariners in Arctic waters. The guidelines define an ice navigator as "any individual who, in addition to being qualified under the STCW Convention, is especially trained and otherwise qualified to direct the movement of a ship in ice-covered waters. It also states: "The Ice Navigator should have documentary evidence of having satisfactorily completed an approved training program in ice navigation. Such a training program should provide [the] knowledge, [the] understanding and proficiency required for operating a ship in Arctic ice-covered waters, including recognition of ice formation and characteristics; ice indications; ice maneuvering; use of ice forecasts, atlases and codes; hull stress caused by ice; ice escort operations; ice-breaking operations and effect of ice accretion on vessel stability." It also provides guidelines for companies operating in Arctic ice-covered waters to develop a training manual, including the development and inclusion of drills and emergency instructions, emphasizing changes to standard procedures made necessary by operations in Arctic ice-covered waters. These drills and emergency instructions would be incorporated into the routine vessel operational training.

The STCW includes mandatory training requirements for passage planning and ice navigation in ice-covered waters. This section also authorizes the use of approved training simulators to achieve the stated training requirements. The concept of an officer experienced in navigation in ice, as well as the qualifications required, forms part of various national legislation and rules among northern countries such as the Canadian *Arctic Waters Pollution Prevention Act* and its associated regulations: the *Joint Industry Coast Guard Guidelines* for the control and operation of oil tankers and bulk chemical carriers in ice control zones of Eastern Canada.

The Russian Federation has a modern Arctic maritime training regime concentrated in the following marine educational centers: the Admiral Makarov State Maritime Academy in St. Petersburg; the Admiral Nevelskoy Far East State Maritime Academy in Vladivostok; the regional center of continuing professional education at the Captain Voronin Maritime College in Arkhangelsk; the "MARSTAR" Academy in St. Petersburg; and the Primorsk Shipping Corporation training Center in Nakhodka.

These centers train prospective Arctic navigators using the "Preparation for Navigation in Ice Conditions" course developed by the Makharov Training Center. These courses are designed around three subdivisions: theoretical training, simulator training and practical training onboard a vessel. The courses follow the requirements

As more ships venture into the Arctic, the demand for ice information, as well as other ocean data, products and services, will continue to increase and the resources available to meet this increased demand will be stretched.

expressed in the IMO STCW 78/95 Requirements; the IMO's *Guidelines for Ships Operating in Arctic Ice-covered Waters* and finally those specified by the Russian *Rules of Navigation on the Seaways of the Northern Sea Route.*

The course trains officers in all aspects of operations in ice-covered waters, through theoretical and simulator-based training including: the preparation and planning for voyages in ice-covered waters; operating, navigating, maneuvering and escorting ships in Arctic ice-covered waters, including recognition of ice formation and its characteristics; features of maneuvering in ice of different density and thickness; communication between cargo vessels and icebreakers; and familiarization with emergency and search and rescue operations.

The prospective navigator must follow a practical regime composed of two phases that reinforces the theoretical and simulated aspects of the training already received, as well as knowledge passed on from more experienced operational personnel. These include practical navigation training where the student is taken onboard as a bridge officer trainee and is supervised by the navigating officers; and practical deck training where the student is taken onboard as a regular member of the ship's crew and studies features of ice operations from their point of view.

Certification of Ships' Officers and Crew

Maritime administrations around the globe are tasked with the certification process, which is linked to the maritime licensing programs for most countries. Several areas, such as vessel security officers, radar navigation and pilotage, have been fully addressed with special endorsements on individual licenses. Certification for tanker operations, vessel classification, vessel design and equipment for vessels operating in ice-covered waters has been established. Several regulations address oil spill response and environmental issues.

Various maritime training institutions are developing, or have developed, ice navigation courses, employing full mission bridge simulators and associated software products. The IMO has created a program of model training to assist institutions developing ice navigation courses with an emphasis on meeting STCW requirements. Several countries have instituted courses, including Finland and the Russian Federation, for the Baltic region, as well as Norway and Argentina. Canada has developed a model course using a simulator at the Marine Institute in St. John's, Newfoundland. While these classes begin to address the deficit in standardized ice navigation training, international harmonization is still necessary in order to provide the next generation of qualified northern navigators.

Incident Response and Capacity

As marine activity continues to expand in the Arctic, statistical trends indicate that the potential risk of vessel mishaps and marine pollution incidents also increases. The inherent navigational and environmental hazards and limited number of experienced personnel, combined with Arctic ecosystem sensitivity, heightens the need for greater incident response capacity and preparedness. It is important to learn, as soon as possible, what has been spilled, where and when in order to address it in an appropriate manner.

Protection of the Environment: Oil and Other Hazardous Spills Response

Marine incident prevention is based upon addressing four conditions that may result in pollution incidents:

- human error or failure caused by fatigue, malfeasance, unfamiliarity or other conditions either exclusively or in conjunction with each other;
- lack of operational readiness and preparedness caused by marginal or unprepared ship or crews;
- older vessel or vessel operating outside of operation parameters; and
- Arctic climate and situational unknowns caused by less predictable or rapidly changing weather, ice conditions, iceberg awareness or failure of mechanical systems unprepared for the rigors of Arctic operations.

Alone, or in combination, these conditions contribute to a myriad of scenarios for pollution and are the focus of the vast majority of preventive measures.

In addition, the variety of pollutant types and sub-types threaten the environment in different ways depending upon their chemical nature and how they behave when released. This may include circumstances such as waterway type, time of year, weather (wind, temperature) and local geography. Further adding to these circumstances are the variables associated with the potential impacts or sensitivities related to shoreline ecosystems, marine ecosystems, socio-economic systems or, in general terms, the overall exposed environments that would be lost or degraded.

Given the recognition that prevention may greatly diminish but not necessarily eliminate pollution threats, all maritime nations support preparedness and response activities. The challenge lies in the creation and sustainability of a preparedness and response regime that deals with the innumerable combinations and permutations possible.

While there are exceptions, there are few Arctic-based resources to address oil spills, especially the ability to recover trapped oil in hulls and compartments in both shallow and deep water.

Internationally, the Arctic countries are all signatories to MARPOL 73/78 (Annex I and II), COLREG Convention 72, STCW Convention 78 and Load Lines Convention 1966 and Protocol 1988, all of which fundamentally support the domestic legal frameworks for limiting vessel casualty situations. While these conventions apply internationally, the unique Arctic conditions relating to ice cover, weather fluctuation, limited basic infrastructure due to remoteness and particular biological susceptibilities increase the reliance on clear and robust prevention and preparedness regimes.

The Emergency Prevention, Preparedness and Response working group of the Arctic Council has created several products for dealing with oil spills in the Arctic. These products are available to the general public through http://eppr.arctic-council.org and include:

- an Arctic Guide referencing emergency systems and governmental contacts for all circumpolar nations that is updated annually;
- a Shoreline Cleanup and Assessment Manual (2004) for use in determining the most appropriate techniques for enhancing shoreline recovery;
- a series of Circumpolar Maps of Resources at Risk from Oil Spills in the Arctic (2002);
- a Field Guide (1998) for oil spills response referencing all manner of protection and recovery techniques; and
- an Environmental Risk Analysis (1998) of Arctic activities that indicates current potential spill sources.

Of particular note, the series of circumpolar maps, http://eppr.akvaplan.com, provides a first order overview of information for stakeholders to easily identify potential sources of spills and internationally important biological resources that could be at risk. The map catalogue includes thematic, regional and seasonal views including fish, bird, mammal, human population and protected areas.

A review of each Arctic state's response profile reveals a relatively consistent allocation of marine pollution interests from federal to local levels. In addition, there exists a number of longstanding bilateral agreements between adjacent countries that encourage cooperative efforts and transfer of best practices. For example, Norway and the Russian Federation have a bilateral oil spill response agreement for the Barents Sea that is exercised annually. There is no multilateral oil spill response agreement for the Arctic, but it may warrant an umbrella or multilateral agreement and/or a contingency planning process. Because of the diverse nature of the areas and interest, there is no particular advantage or disadvantage to any one model provided that entities share their objectives and communicate effectively.

In terms of current and future marine traffic, the Arctic is an immense, seasonally variable waterway with very little development along its shores. Despite the current disposition of resources and regimes, a more consistent country by country approach is required to address the pollution risk more effectively. Issues related to identifying risk areas, establishing timelines for response and ultimately designing a consistent response capacity remains a challenge.

Logistics - the procurement, maintenance and transportation of materials, facilities and personnel - are dependent upon existing Arctic infrastructure. This is a critical component of all Arctic operations. Sea-state and environmental exposure will place larger burdens on logistics supply lines. In the absence of shore-based infrastructure, longer range planning for refueling and replenishment are required. Distances between ports, coupled with the unpredictability of weather, may complicate access and supply, as well as removal of recovered product and waste. With public expectation of four season response capability for large or environmentally disastrous spills, the logistics infrastructure may need to be modified.

The issue of logistics is not surprisingly a significant and mostly limiting factor in facilitating an effective response. In remote areas, two distinct situations exist in relation to the provision of logistics: incidents within reasonable distances from established communities and those in more remote settings. Pre-existing infrastructure or pre-placement of response assets typically support this first scenario, while remote incident sites require the creation of infrastructure from the ground up. A mobile and relatively self-sustaining infrastructure is called for currently and likely into the foreseeable future. Selecting a site for this type of infrastructure becomes the key logistical issue facing a response and obtaining local knowledge of the areas is considered vital.

Oil spills in ice are more complicated to address than oil spills in open waters and there are several challenges connected with oil spill response in ice and snow and cold water. Apart from the normally long distances from existing infrastructure, the oil is less accessible in ice-covered waters. The oil can be spilled on ice or snow, in open pools between ice floes, in open channels behind vessels or even under the ice from pipelines or other sources.

There are some advantages in addressing oil spills in ice compared to open water. The weathering rate is normally much slower for an oil spill in ice as the emulsification rate is slower, resulting in an increased window of opportunity for use of most response techniques. The spreading of oil will be normally slower also, resulting in a large oil film thickness that may be favorable for oil spill response. The reduced weathering of oil in these conditions does, however, maintain the levels of its more toxic components for greater periods of time, thereby increasing the availability or risk of uptake by organisms.

Arctic Oil Spill Recovery Operations: Technology and Tactics

Effective Arctic oil spill recovery operations require advanced planning and international cooperation. All available methods must be available and considered for each situation although some methods have proven more effective in ice-covered waters. Along with planning and cooperation, training, incident communications and risk management are key elements to any oil recovery operation.

Mechanical recovery techniques combined with oil detection and tracking methods, currently dominate the in-field capabilities of most nations. However, tracking, detecting, as well as modeling oil in ice-covered waters has inherent environmental limitations. The mechanical methods are often considered the most environmentally friendly recovery methods. The concept is to create barriers via floating or alternative booms, recover the oil out of the sea with a mechanical skimmer and then do the post-treatment for the recovered oil in a controlled manner in environmentally safe conditions. However, the mechanical methods are laborious and time consuming and their efficiency is low. Further, mechanical methods often require complicated logistical support in the form of equipment and personnel transportation, which in remote or harsh conditions cannot easily be provided. Mechanical recovery in ice and snow conditions must meet challenges in terms of booming, skimming, recovery and pumping capabilities. Each of these areas has specific challenges to optimum recovery efforts.

Chemical dispersion can be utilized to promote the formation of oil droplets in order to accelerate the natural dispersion and biodegradation of spilled oil. Dispersants (surfactants) can be applied to control offshore slicks or oil that accumulates in coastal areas that have significant tidal or flushing action. In order for dispersion to be effective there needs to be limited weathering of the spilled oil, a cohesive slick, an oil within the viscosity ranges of dispersibility, an appropriate dispersant to oil ratio and turbulent mixing. Only a few research studies have been performed in the past 20 years regarding the use of dispersants on oil spills in ice-infested waters, either from an effectiveness or environmental-impact perspective, and these are of limited value in assessing the situation in realistic terms. Logistical support and effectiveness may also be a challenge when using dispersants. Limited studies such as the Joint Industry Program (JIP) on Oil in Ice, have followed the long-term fate of dispersed oil, but most impacts have been derived from laboratory studies.

In-situ burning, or ISB, is a treatment method that can be used for oil on open water, on ice and in broken ice, if adequate oil thickness can be achieved to sustain burning. This may require the use of booms or herding agents. While continued studies are needed to best determine the ISB effectiveness window of opportunity, for in-situ burning to be a viable option, planning, special equipment and training specific to ISB must be in place before the limited window of opportunity presents itself during a spill. Burnability is a function of oil type (chemical/physical factors), oil thickness on the interface and its state of weathering/degradation. While colder Arctic temperatures are a force to overcome for ISB in ice-covered waters, other natural degradation processes such as slower rates of spreading, evaporation and emulsification have supported burning.

450

The approximate number of lives saved in 2007 because of the Automated Mutual-Assistance Vessel Rescue System.

From the recovery rate point of view, in-situ burning seems to be the most effective method for clean-up of oil spills in ice and snow conditions. Furthermore, removal efficiency exceeding 90 percent can be achieved in ideal conditions (open water, fire booms and quiet conditions), but a burning rate of 60 to 70 percent can be considered as representative for burning on ice-free water. The burning rate can also be zero percent if the oil is not ignitable. ISB may be more limited due to weathering of the oil than the use of dispersants. This is significantly more effective than rates of 10 to 20 percent for mechanical recovery. Alternatively, in-situ burning will generate smoke and soot, thus moving part of the pollution from the sea to the air, and will leave a burn residue that must be recovered. Monitoring and assessment of these results is always necessary.

Oil may be removed by biological degradation. Oil-degrading bacteria naturally exist in the seas with oil, including the cold and icy waters. By adding oxygen and/or nutrients and/or bacteria a possible acceleration of this fundamentally natural process can occur. While bioremediation is an effective countermeasure for small spills with high surface areas (e.g., very thin staining or coating on shorelines), it is a relatively slow process, possibly requiring months if not years to fully accomplish and is best suited for post-spill response final treatment.

Protection of People and Property

The current search and rescue, or SAR, infrastructure in the Arctic, while varying between regions, is limited. For example, while there is a robust set of assets off the coast of Norway to respond in an emergency, there is little to no infrastructure along the coast of Greenland to respond to a passenger ship in distress. A survey of search and rescue resources among Arctic states indicates limited availability of fixed wing aircraft and helicopters in most of the region. Some survey responses included icebreakers and seasonal patrol vessels that can be used for SAR when near enough to an incident. However, in general, there are shortages of critical SAR response assets, such as long-distance, heavy-lift capacity helicopters. The usefulness of these assets is often limited by weather and other operating conditions. Emergency response efforts are further hampered in many regions by an insufficient shoreside infrastructure needed to provide basic logistics and support functions for SAR missions. The location and availability of SAR assets are often problematic given the vast distances and frequent harsh operating conditions typical in this region. In some instances, such as in connection with oil and gas activities, private industry addresses these gaps and shortfalls by providing its own supplemental SAR capacity

as part of its ongoing Arctic operations, but this remains the exception rather than the rule.

Arctic states have attempted to maximize the effectiveness of existing SAR resources by entering into bilateral and sub-regional SAR agreements with neighboring nations that have improved coordination of SAR responses in specific areas of the Arctic. For example, the Russian Federation, Canada and the United States have a search and rescue agreement. Norway and the Russian Federation have a bilateral search and rescue agreement for the Barents Sea that is exercised annually. There are also informal search and rescue arrangements with local governmental and private entities. There is no multilateral search and rescue agreement covering the entire Arctic region.

The future increase in human activity in the Arctic, including Arctic marine shipping and the continued overflight of the Arctic region by commercial aircraft, will place increasing demands on the SAR infrastructure. Many of the infrastructure deficiencies discussed in this report, such as the insufficient number of accurate charts or the need for better real-time information concerning the operational environment and communications difficulties, will also impact search and rescue efforts.

The need to strengthen search and rescue capabilities was specifically recognized by the representatives from the Russian Federation, Canada, the U.S., Denmark and Norway who met in Ilulissat, Greenland, in May 2008. "The increased use of Arctic waters for tourism, shipping, research and resource development also increases the risk of accidents and, therefore, the need to further strengthen search and rescue capabilities and capacity around the Arctic Ocean to ensure an appropriate response from states to any accident," states the Ilulissat Declaration. "Cooperation, including on the sharing of information, is a prerequisite for addressing these challenges. We will work to promote safety of life at sea in the Arctic Ocean, including through bilateral and multilateral arrangements between or among relevant states."

Passenger Vessel Safety in the Arctic

The most significant emerging challenge to the existing search and rescue infrastructure arises from the increase in marine tourism and passenger vessels operating in Arctic waters. As large passenger vessels continue to operate more frequently and farther north in the Arctic, the prospect of having to conduct mass rescue operations with limited SAR resources increases. Recent growth in Arctic marine tourism is outpacing infrastructure investment, development and support throughout the region. There are several potential problems associated with responding to an incident aboard a cruise ship. The potential number of people that would have to be rescued from a cruise ship far exceeds the capacity of most SAR response vessels and aircraft available in the Arctic. Cruise ships have a minimal capacity for self-rescue. Compliance with IMO guidelines for passenger

© Hapag-Lloyd Kreuzfahrten GmbH

Emergency response is particularly challenging in the Arctic for a variety of reasons, including the remoteness and great distances that are often involved in responding; the impacts of cold, ice and a harsh operating environment on response personnel and equipment; and the lack of shoreside infrastructure and communications to support and sustain a response of any significant magnitude.

vessels operating in remote areas is voluntary and, as a result, the planning and capability for self-rescue varies. Passengers are likely to be ill-prepared for the weather, which decreases their likelihood of survival if they are not rescued quickly. There are also a host of logistical challenges associated with the lack of shoreside infrastructure in most of the Arctic needed to accommodate and care for those that are rescued, including the lack of sufficient food, lodging and medical facilities. In many cases, the only available platform with capacity to feed and house rescued passengers would be another cruise ship.

A number of potential actions are available to address the challenges presented by emergency response to passenger vessel incidents in Arctic waters. First, ships intending to conduct passenger vessel transits in the Arctic would greatly improve the prospects for a successful rescue and survival of passengers and crew if they coordinated their transits with other passenger ships in the vicinity. In two incidents in the Antarctic, passengers and crew from stricken vessels were successfully transferred to other nearby passenger vessels. One of the stricken passenger vessels, the *M/V Explorer,* sank shortly after the transfer. Second, provisions in the *Enhanced Contingency Planning Guidance for Passenger Ships Operating in Areas Remote from SAR Facilities* (IMO 2006) provide valuable guidance for passenger vessels operating in remote areas such as the Arctic. The voluntary guidelines provide detailed information on emergency drills and inspections, and contain additional requirements for lifeboats, liferafts and survival kits that would allow passengers and crew to better survive the harsh Arctic environment until SAR response arrived on scene. The value of these guidelines is dependent in large part on the degree to which they are adopted and implemented. Third, search and rescue operations could be improved and limited resources used to best advantage by sharing information, lessons learned and best

© AP

practices arising from incidents that have already occurred in polar regions, including the two latest Antarctic incidents.

The advantages of mutual assistance between vessels operating in the Arctic, although particularly significant for passenger vessels, extend to all vessels. Voluntary systems have been established that allow search and rescue authorities to identify and request assistance from other vessels in the vicinity of a vessel in distress. The Automated Mutual-Assistance Vessel Rescue System (AMVER) is one such established system that can be accessed by Arctic SAR authorities to identify a possible source for assistance in any distress case in the Arctic region. There are more than 17,000 vessels enrolled in the AMVER network, representing 155 countries. On any given day, more than 3,500 vessels are available to divert and assist in a distress situation at sea. Approximately 450 lives were saved in 2007 because of AMVER. Participation is voluntary unless mandated by a vessel's flag state, shipping company or other authority.

€4.4B

The amount of money invested since 2004 to improve Murmansk's deepwater port facilities to include new oil, coal and container terminals as well as expanded rail lines.

Participating vessels provide regularly updated information on their SAR capabilities and intended track to rescue coordination centers. AMVER information is released only to recognized SAR agencies for safety-of-life-at-sea purposes, and provides rescue coordination centers with data on vessels in the vicinity of a SAR case that may be available to divert and assist.

Another example is the Russian Vessel Monitoring System, referred to as *VMS Victoria*. The system is intended for near real-time automated monitoring of vessels positions provided vessels are fitted with the ship satellite communication systems: INMARSAT-C or INMARSAT-D+, and for delivering the collected position reports data via Internet to remote users. *VMS Victoria* caters to the shipowners, operators and organizations responsible for control and surveillance of maritime vessels, as well as for search and rescue at sea. There are more than 1,200 vessels enrolled in the system, among them more than 600 foreign flag-state vessels. *VMS Victoria* operates constantly and allows its users: to track the movements of their fleets by receiving regular automated position reports from the vessels; to request an immediate position report from any vessel on demand if required; and to send short text messages and FleetNet broadcasts to a vessel/vessels. *VMS Victoria* processes messages in real time and then transmits them to INMARSAT. It is anticipated that the establishment of the LRIT-system will be an important system to identify ships in the vicinity of a distressed vessel, thereby requesting them to provide assistance.

Promoting the use of mutual vessel assistance systems such as AMVER or *VMS Victoria* would serve to supplement the extremely limited search and rescue resources and improve SAR capacity in the Arctic.

Although Arctic states often have existing agreements in place to coordinate SAR operations with neighboring nations, there are several advantages to creating a multilateral Arctic SAR agreement that would cover the entire northern region for both aeronautical and maritime SAR. A multilateral SAR agreement for the entire Arctic region would facilitate the most effective use of limited SAR resources throughout the Arctic and would ensure that available Arctic SAR facilities closest to a vessel or aircraft in distress are identified and respond first, regardless of nationality, in order to reduce response time and potentially save the most lives. A region-wide agreement would also improve SAR response by serving as the framework within which to conduct joint exercises and training; share information, lessons learned and best practices; and identify and improve mechanisms for mutual cooperation, coordination and support in search and rescue and emergency response.

The creation of a more comprehensive multilateral SAR agreement would build on existing proposals for an aeronautical Arctic SAR Memorandum of Agreement to include both aeronautical and maritime SAR, as encouraged by the *International Convention on Maritime Search and Rescue*, 1979, as amended; the *Convention on International Civil Aviation*, 1944 (Annex 12), as amended; and the *International Aeronautical and Maritime Search and Rescue Manual* (IAMSAR Manual). The proposed Arctic Region SAR agreement would identify aeronautical and maritime SAR region lines of delimitation; as affirmed in both conventions, such delimitation of SAR regions is not related to and would not prejudice the delimitation of any boundary between nations.

A multilateral SAR agreement would serve as the centerpiece of cooperation and coordination in support of Arctic emergency response operations while providing an important example of a mutually beneficial regional approach among Arctic nations to address important shared issues of concern.

Since Arctic and Antarctic emergency responses are similar in many ways, Arctic and Antarctic nations engaged in polar SAR could benefit from consultation and cooperation on issues of mutual concern and applicability. The five nations responsible for SAR in the Southern Ocean (New Zealand, Australia, Argentina, Chile and South Africa) currently meet to address many of the same challenges that face the eight Arctic Council nations concerning distance, harsh environment and limited SAR resources. In August 2008, New Zealand, Australia, Argentina, Chile, South Africa, United States, France, United Kingdom and the Council of Managers of National Antarctic Programs (COMNAP), met in Valparaiso, Chile, to discuss improving Antarctic SAR coordination and cooperation. One means of enhancing cooperation would be through mutual efforts of the Arctic Council and Antarctic Treaty Consultative Meetings. Future proposals and recommendations on polar SAR could be coordinated between both international fora to ensure continuity and standardization where appropriate.

Gaps in Preparedness and Response Operations

Remote surveillance and detection technologies (i.e., satellite communications, GPS availability, weather stations) are critical for establishing situational awareness for both preventive and response issues. This overall capability is limited in the Arctic due to a lack of coverage and the availability of real-time weather information.

Lightering in emergency situations and salvage typically represent two distinct marine activities that may be used in whole or in part to prevent and/or recover pollutants, and are considered in many cases synonymous with mechanical response capacities.

While all Arctic states individually support the overall strategic goal of limiting negative environmental impact and establishing

sustainable development, the potential for increased shipping has led to increased concern for threats, risk and evaluation of potential consequences worldwide. This leads to a high expectation by public and environmental groups for adoption of stringent preventive measures, as well as thorough mitigation and restoration measures in the event of an incident. This has also contributed to an increasing gap in maintaining realistic response expectations. To address this pressure many recent workshops and panel discussions have indicated a need for more harmonious pan-Arctic shipping rules. Cooperation at this level requires nations to develop common goals and objectives based upon mutually acceptable and scientific criteria. Ultimately the communication of these objectives is vital in maintaining realistic expectations.

While there are exceptions, there are few Arctic-based resources to address oil spills, especially the ability to recover trapped oil in hulls and compartments in both shallow and deep water. A multilateral oil spill contingency plan or an oil spill agreement may be options to address this issue.

Ports

In temperate maritime areas, deepwater ports and the services they provide are typically relatively close to global maritime shipping and often taken for granted. The situation in the Arctic is quite different. Deepwater ports, places of refuge, marine salvage, adequate port reception facilities for ship-generated waste and towing services are rarely available. The availability of port infrastructure and support directly influences the level of risk associated with transiting a particular waterway and corresponds to the levels of marine insurance rates.

Ports and Intermodal Transport Links

There are few deepwater ports in U.S. or Russian waters near the Bering Strait. The closest U.S. harbor with deep water is Dutch Harbor in the southern Bering Sea. On the Russian Federation side, the nearest deepwater port is Provideniya. Other Russian ports near the Bering Strait that are closed to foreign ships are Egvekinot, Anadyr and Beringovsky.

Arctic Marine Incidents Workshop

A key AMSA workshop, Opening the Arctic Seas: Envisioning Disasters and Framing Solutions, was held in March 2008 at the Coastal Response Research Center of the University of New Hampshire. The center, a partnership between the U.S. National Oceanic and Atmospheric Administration and UNH, develops new approaches to spill response and restoration through research and synthesis of information.

In cooperation with the U.S. Coast Guard and U.S. Arctic Research Commission, the center hosted the workshop to identify key strategies, action items and resource needs for preparedness and response to potential Arctic marine incidents. The 50 workshop participants represented a spectrum of constituencies and expertise including government agencies, the marine industry, Arctic indigenous groups, academia and non-governmental organizations. Experts from the U.S., Denmark, Canada, Russian Federation, Norway and Finland and one non-Arctic state, South Africa, participated.

The workshop focused on the qualitative risk factors for five plausible Arctic marine incidents developed by the organizing committee and bear some similarities with incidents that have already occurred in polar waters. The incidents were designed to explore: spill response; search and rescue; firefighting and salvage; communications; governance and jurisdiction; and legal issues. The five incidents were:

- **Cruise ship grounding in the west coast of Greenland**
  Mid-September grounding in a fjord of a cruise ship with 1,400 passengers. Progressive flooding makes the ship unstable and all passengers and crew must abandon ship.

- **Bulk carrier trapped in ice in the central Arctic Ocean**
  September/late season crossing of the Arctic Ocean en route to the Bering Strait and the Pacific Ocean. Ice damages the ships' rudder and propeller. The ship's non-ice strengthened hull makes wintering impossible. Rescue operations are challenging due to the remote location and changing sea ice cover.

- **Fire and collision in offshore operations in the Beaufort Sea**
  In late winter, a drill ship, two oil spill response vessels and one ice management icebreaker are conducting exploratory drilling operations in 50 meters of water 20 nautical miles offshore within the disputed U.S.-Canada border area in the Beaufort Sea. An engine room fire on the icebreaker causes it to lose control and collide with the drill ship, rupturing a ballast tank. The drill ship empties 700 barrels of Arctic grade diesel fuel to maintain stability; 300 barrels of diesel fuel are also spilled because of the fire on the ice management ship. Crew members on both vessels suffer injuries.

- **Oil tanker and fishing vessel collision in the Barents Sea**
  The collision occurs in near-zero visibility within the disputed Russia-Norway border in the Barents Sea. The tanker releases 25,000 barrels of crude oil in the water and must be towed to a place of refuge to avoid potentially spilling its remaining cargo. The fishing vessel sinks making salvage impractical.

- **Tug and barge grounding on St. Lawrence Island in the Bering Sea** In May in broken ice conditions, a tug loses power while towing a barge laden with mining explosives and other containerized cargo for several Arctic communities. Pushed by a storm surge, the tug and barge are grounded in an area that was a critical habitat for threatened and endangered species and a haul-out location for Pacific walrus. The tug and barge are separated by several miles, the tug ruptures a fuel tank, containers are in the water and some wash onshore.

Workshop participants were divided into five groups each working on a single, plausible incident. Four questions were addressed by each group: If this incident happened today in the Arctic, how would we respond? How would we prefer to respond? What are the gaps and needs that exist today that prevent us from responding in the preferred manner? What do we need to do to address those needs and fill the gaps?

The exercise yielded the following themes:

(A) Ports and Waterways Management

- Designate potential places of refuge in the Arctic and develop guidelines for their use; an international effort should also rank them by seasonal environmental conditions.
- Establish policies and systems to control ship movements such as route planning; use of Automatic Identification Systems on all Arctic ships; vessel tracking systems and designation as Particularly Sensitive Sea Areas from IMO.

(B) Vessels and Crew Safety

- Institute mandatory safety regulations for Arctic operations; the current IMO Guidelines for Ships Operating in Arctic Ice-Covered Waters address specific construction, fire safety, lifesaving, navigational, operational and crew training issues, but they are voluntary; mandatory training for ice navigation and emergency response in polar environments is necessary; a non-binding regulatory framework seems inconsistent with the hazards of Arctic navigation and the potential for environmental damage in the Arctic Ocean.

(C) Response Agreements and Plans

- Existing search and rescue and pollution contingency plans do not provide enough detailed information to facilitate an effective response; there is a need for Arctic-wide agreements for SAR and pollution response; agreements and response plans should

designate which nations respond in specific areas and clarify operations in disputed regions; agreements and response plans should also ensure foreign responders can participate in operations unimpeded by customs and immigration issues; Arctic states could establish an integrated response management center to manage the execution of agreements and facilitate the decision-making process.

(D) Strategies to Improve Prevention and Preparedness

- Conduct comprehensive environmental risk assessments and impact assessments to assist in decision-making, route planning, emergency response, etc.
- Increase emergency response assets, equipment and supplies in the Arctic, placing emphasis on regions of active development; self-sustaining, forward-operating response bases should be established.
- Improve knowledge for Arctic incident response through training and engagement of the local community; responders and the maritime industry. Arctic indigenous people should be trained in response and local communities must participate in response operations.

(E) Strategies to Improve Response

- Consider alternative countermeasures for oil spill cleanup; mechanical measures in ice-covered waters may be impractical and alternative response options should be considered (dispersants, chemical herders, sinking agents, in-situ burning, etc.).
- Expand communications capabilities throughout the Arctic; expanded shore based (VHF and HF) and satellite systems are required.
- Improve logistical support capabilities for responders; support for response personnel in remote Arctic regions must be brought to the region of operations.

(F) Strategies to Foster Community Involvement

- Involve indigenous peoples and local communities in planning, response, recovery and restoration decisions and operations.
- Conduct outreach to local communities and keep all stakeholders well informed.

(G) Strategies to Ensure Availability of Funds for Response

- Establish an international Arctic response fund to offset the costs of SAR and pollution response.
- Increase penalties and insurance requirements for ships operating in the Arctic to ensure response funding and act as a deterrent.

The workshop identified three key areas of data and research needs: (1) the updating of weather data due to a lack of overall information, and investment to update navigational charts for Arctic regional seas, ports and waterways; (2) studies on the behavior of oil in cold water and technologies for spill response (including the detection of oil under ice as well as cleanup measures for oil in ice); and (3) improving the baseline information for Arctic resources (biological/ecological resources and areas important for human use and cultural significance) that could be affected by potential marine incidents.

Two themes resonated throughout the workshop: The Arctic states need to foster and enhance their cooperation to improve joint contingency plans and multinational agreements, as well as to agree to develop mandatory safety regulations for Arctic marine operations. The proper management of risk using appropriate policies and strategies, supported by scientific research, can lead to reduced risk for loss of life and environmental damage.

© Ben Ellis

This situation differs with the region between the Atlantic and Arctic oceans, where there are many Norwegian, Icelandic and Russian deepwater ports. There are a number of deepwater ports along the west coast of Greenland. In the Arctic, there are essentially no deepwater ports along the North Slope of Alaska or throughout the Canadian Archipelago, except for that of Tuktoyaktuk, which, while having a relatively deepwater port, suffers from a shallow approach channel and a high degree of in-fill silting, situated as it is in the delta of the Mackenzie River. Mention should also be made of the limited port facilities at Resolute Bay, in the middle of the archipelago, which acts as a center of transportation, communications and administration for the high Arctic but which can only handle ships of 5m draft alongside a sunken barge used as a dock. Ships of deeper draft must anchor in an open roadstead.

In Hudson Bay, the Port of Churchill is Canada's only northern deepwater seaport with well sheltered, along-side berthing facilities. It provides access, via rail, to the interior of Canada and North America in general. The growing Port of Churchill offers four berths for the loading and unloading of grain, general cargo and tanker vessels. The Port can efficiently load Panamax size vessels. The link between Murmansk and Churchill has become known as the "Arctic Bridge" since it requires sea and rail systems to complete the transport of goods to North American destinations. The use of the Port of Churchill eliminates time-consuming navigation, additional handling and high-cost transportation through the Great Lakes and St. Lawrence Seaway. The current shipping season runs from mid-July to the beginning of November. The use of icebreakers could significantly lengthen the shipping season. Another significant port in the Eastern Canadian Arctic is Iqaluit, which requires that ships anchor and use barges to land their cargo and features some of the highest tides on the planet as well as one of the largest tidal ranges in existence.

The Canadian government has recently proposed an upgrade to the rail link to Churchill, as well as the development of a deepwater port at the old mining town of Nanisivik in Nunavut on Baffin Island, to be used primarily by the Department of National Defence. It is unclear what facilities this port will have since it is not situated near a major population center, major shipping route or railroad. In addition to the proposed port at Nanisivik, future planned development on Baffin Island also includes the iron-ore mine at Mary River under construction by Baffinland Iron Mines Corporation that will include a railroad to the planned port at Steensby Inlet.

In contrast, the northern coast of the Russian Federation has several deepwater ports that have been supported by the Northern Sea Route Authority and fleet of icebreakers for several decades. Murmansk is well known for being the largest deepwater port north of the Arctic Circle that is ice-free throughout the year. Murmansk also provides intermodal access to northern European and Asian

industrial centers. In recent years, Russian Arctic ports in the Barents Sea, including Murmansk, have expanded significantly as offshore oil and ore production have increased in the region. Since 2004, more than €4.4 billion have been invested in improving Murmansk's deepwater port facilities to include new oil, coal and container terminals as well as expanded rail lines. Murmansk port capacities are projected to increase to an annual 28.5 million tonnes by 2010 and 52 million tonnes by 2020. Other Russian Arctic ports along the Northern Sea Route include Pevek, Tiksi, Igarka, Dudinka, Dikson, Vitino, Arkhangelsk and Novy. These ports are well-established and supported by the Russian icebreaker fleet, although many require long river transits to access.

Unique to the region is the Port of Varandey on the Pechora Sea coast. As oil production expands in the Russian Arctic, LUKOIL, in cooperation with ConocoPhillips, has developed Varandey into a deepwater oil export terminal. The Varandey facility consists of an onshore tank farm with a total rated capacity of 325,000 cubic meters (2,000,000 barrels); and an innovative fixed ice-resistant oil terminal 14 miles offshore, with a height of more than 160 feet. The terminal includes living quarters and a mooring cargo handling system with a jib and a helicopter platform; two underwater pipelines, connecting the onshore tank battery and the offshore oil terminal; and an oil metering station, auxiliary tanks, pumping station and power supply facilities. Sovkomflot has one new 70,000 DWT ice-strengthened oil tanker in operation and two being built in South Korean shipyards, to shuttle oil to Murmansk, as well as other locations in Europe and North America.

There are likely to be significant practical difficulties to be encountered in finding and supporting suitable places of refuge for ships in need of assistance in the Arctic and in providing such ships with adequate support.

© Canadian Coast Guard

Places of Refuge

The Ilulissat Declaration outlined the need to cooperate to improve search and rescue and disaster response capability in the Arctic as marine activity increases. Central to this objective is the need for deepwater places of refuge and marine salvage/support capability.

According to IMO's *Guidelines on Places of Refuge for Ships in Need of Assistance*, a place of refuge means a location where a ship in need of assistance can take action to enable it to stabilize its condition and reduce the hazards to navigation, and to protect human life and the environment. A ship in need of assistance means a ship in a situation, apart from one requiring rescue of persons on board, which could give rise to the loss of the vessel or an environmental or navigational hazard.

With an increase in international Arctic shipping, it is likely that ships in need of assistance may need to request refuge in sheltered waters of the Arctic states. There are likely to be significant practical difficulties to be encountered in finding and supporting suitable places of refuge for ships in need of assistance in the Arctic and in providing such ships with adequate support. In the Arctic, harsh environmental conditions and increasing marine traffic densities make this course of action even more critical. Potential place of refuge guidelines detail the process by which port authorities decide where to allow a damaged ship to berth. In an attempt to balance shipping interests with the protection of natural and cultural resources, selection of such places should incorporate input from potentially affected governments, communities, the shipping industry and other stakeholders. Authorities should also rank places based on seasonal environmental conditions.

The European Union Places of Refuge Framework provides a model for the development of potential place of refuge guidelines by Arctic nations. Western Norway has an established system for places

of refuge based on IMO guidelines and the EU framework, including predefined places if applicable. The system will be expanded to include the entire Norwegian coast, including Svalbard, by late 2009 or early 2010. The places of refuge are evaluated based on the EU Safety at Sea project.

Other Infrastructure Components

Arctic marine infrastructure includes components not required or taken for granted in temperate waters. Polar icebreakers and marine salvage capability are risk mitigators from the perspective of marine insurance companies. If a vessel navigating in the Arctic has readily available polar icebreaker and/or marine salvage support, the risk to the vessel and corresponding financial risk to owners and insurers is substantially reduced.

Icebreakers

Government and private icebreakers are a key resource in the development of the Arctic. Generally, icebreakers are able to carry out the following roles: maintenance of shipping tracks in ice-covered waters, close escort of shipping in ice, provision of ice information, sovereignty support/representation, search and rescue, environmental response, command platform for emergency response, medical evacuation in remote areas, harbor breakout, electrical power supply, science platform, constabulary function (maritime security), transporting cargo (northern re-supply and logistic support) and fisheries conservation and protection.

There are some 50 icebreakers in the world fleet. The Russian fleet is by far the largest and most powerful, counting icebreakers powered by nuclear power plants, with five of 75,000 shaft horsepower (shp). The Russian Federation recently announced the allocation of some 15 billion rubles to build another 75,000 shp icebreaker. The next largest

The world's icebreaker fleets are aging and will require significant investment during the coming years to maintain their effectiveness and capability.

fleet of Arctic-class icebreakers is that of the Canadian Coast Guard. The Canadian Government recently announced an investment of $C720 million to provide an Arctic-class replacement for the *CCGS Louis S. St-Laurent*. Most other countries that operate icebreakers own one or two, other countries such as Denmark and Norway have small fleets of ice-strengthened vessels generally intended for fisheries patrol and interdiction. The world's icebreaker fleets are aging and will require significant investment during the coming years to maintain their effectiveness and capability. For instance, Canadian icebreakers are on the average 30-plus years old, while those of the U.S. are 30 years old, with the exception of the *USCGC Healy*, which was built in 2000. Of note is the recently issued report, *Polar Icebreakers in a Changing World*, which is a needs analysis of U.S. icebreaking requirements in the coming years. In addition, it is also known that a number of other countries are either building or planning construction of new icebreakers primarily intended for science research, namely the European Union and South Korea.

Icebreaker construction is very specialized and very expensive. Steel is thicker and stronger than that required for normal cargo ship construction. In addition, there are other necessary specific features, such as horizontal and vertical construction members that are deeper and stronger, reinforced icebelts and redundant features. These details are specified in a number of national regulations governing construction of ice-class ships, namely those of the Russian Federation, Canada, Finland and Sweden; as well as classification societies such as the American Bureau of Shipping, Det Norske Veritas, Germanischer Lloyd and Lloyd's Register. Recently, the International Association of Classification Societies approved their *Polar Class* construction standard as one of a number of "Unified Requirements." Classification societies have one year to enter the new requirement in their respective rules. Classification societies have the new requirements in their respective rules, and some are expected to keep their existing rules.

© German Shipowners' Association

Marine Salvage Support

In the Arctic Ocean, with the exception of Norway, Iceland and ports along the Northern Sea Route, there are few places of refuge or government/commercial salvage response to support commercial shipping. Generally, there are limited ship repair and/or salvage infrastructure and pollution countermeasures capabilities based around the Arctic basin. This lack of an Arctic salvage capability is a concern to the marine insurance industry.

There is inadequate port, salvage, towing and other necessary marine infrastructure support for the growing amount of commercial traffic transiting the Great Circle Route through the Aleutian Islands. This was highlighted by the 2004 *M/V Selendang Ayu* engine failure and subsequent grounding with a spill of more than 1 million liters of fuel oil along the northern side of Unalaska Island (See page 88). This incident could have been prevented if large tugs and adequate salvage support were nearby; instead, the nearest tugs capable of handling this type of emergency were in Seattle, Washington. After the 738 ft *M/V Selendang Ayu's* engine broke down in gale-force Bering Sea winter weather, several efforts to tow it by small tugs based out of Dutch Harbor failed.

Baltic Sea Case Study

Introduction

As the Arctic Ocean becomes seasonally ice-covered, coupled with the likelihood of increased marine shipping activity, an evaluation of the Baltic Sea marine shipping regime could be considered as a model for ship operations, information systems, incident response and harmonization of regulations.

The countries of the Baltic Sea Area work to protect the marine environment of the Baltic Sea from all sources of pollution through intergovernmental cooperation under the Convention on the Protection of the Marine Environment of the Baltic Sea Area and its governing body, the Baltic Marine Environment Protection Commission (HELCOM). All detailed information of the HELCOM activities is placed on website www.helcom.fi.

The Baltic Sea area is a sensitive marine ecosystem that needs comprehensive nature conservation and protection measures. The Baltic Sea states within the framework of HELCOM designated 89 areas as Baltic Sea Protected Areas (BSPAs) on the basis of their significance for marine nature conservation and protection of habitat and species. Work is still ongoing to designate other offshore areas as BSPAs. In order to harmonize the approaches and implementation process for marine protected areas (MPAs) in the Northeast

© Aker Arctic Technology

Atlantic and the Baltic Sea, HELCOM and the OSPAR Commission, the governing body of the Convention for the Protection of the Marine Environment of the North-East Atlantic, have developed a detailed work program on marine protected areas closely linked to the European Union network for the protection of European fauna and flora, the so-called NATURA 2000 network.

The Baltic Sea States are dependent upon safe, secure and sustainable sea transports. The maritime traffic in the Baltic Sea area is dense and has increased notably since the beginning of the 1990s. The annual turnover for oil and oil products in the Baltic Sea is calculated to be approximately 160 million tonnes. On top of that, 500 million tonnes of other goods are annually transported by ships within the Baltic Sea area. Therefore an extensive regime of protective measures consisting of both international and national regulations is in place inside and adjacent to this semi-enclosed sea; examples of relevant measures are compulsory reporting and traffic surveillance, routing systems, compulsory pilotage and the designation of the area as a Special Area under Annexes I and V; and as a SOx Emission Control Area under Annex VI of the MARPOL 73/78 Convention.

Navigation Systems and Ship Operations

The Baltic Sea has some of the densest maritime traffic in the world. More than 2,000 ships are en route in the Baltic on an average day, not including ferries, smaller fishing boats or pleasure craft. Among those 2,000 ships, some 200 are oil tankers with a cargo up to 150,000 tonnes.

Several ferry lines connect the states in the Baltic proper. Some of the world's biggest ferries are transporting goods and people

between Sweden and Finland and there are several other ferry lines; i.e., between Sweden and Germany, Denmark and Germany, and between Denmark and Sweden. Most of the year intensive fishing for herring, cod and salmon takes place, sometimes in close vicinity to the major shipping lanes. Incidents are not rare considering that up to 2,000 fishing boats could be at sea on an average day. In summer, large numbers of cruise ships from all over the world enter the Baltic Sea area to visit the many coastal cities of cultural interest, such as Helsinki, St. Petersburg, Tallinn, Riga, Gdansk, Rostock, Lübeck, Copenhagen, Visby and Stockholm. Also numerous pleasure craft are sailing between the more than 500 ports or between different archipelago areas in the Baltic Sea. Oil and gas activities are for the time being few, but are expected to grow in the southern section of the area.

Compulsory Reporting and Traffic Surveillance

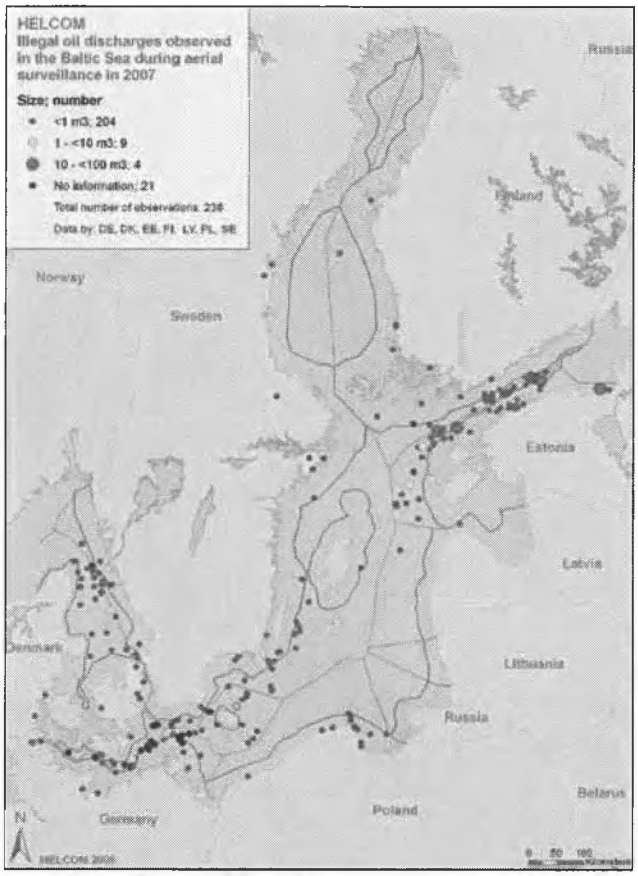
When ships enter the Baltic Sea they have to go through the Kattegat and the Great Belt or the Sound. There is intense traffic in the northern part of the area, where an extensive part of the traffic goes to and from Denmark as well as to and from the Baltic Sea. Large vessels follow the traffic lane Route T.

It is recommended that all ships of 20,000 gross tonnage and above navigating Route T should participate in the radio reporting service SHIPPOS together with all ships with a draft of 11 meters and more; loaded oil-, gas- and chemical tankers of 1,600 gross tonnage and above; and all ships carrying radioactive cargoes.

The system provides beneficial information to ships about other ship movements in the area. IMO has adopted a mandatory ship reporting system in the Great Belt Traffic Area. Ships with a gross tonnage equal to or exceeding 50 and all ships with a draft of 15 meters or more are required to submit a ship report to the VTS Centre.

Mandatory ship reporting systems have been established nationally by the Baltic Sea states in approaches to oil terminals and other ports. Article 4 of the EU directive 2002/59/EC of June 27, 2002, establishing a community vessel traffic monitoring and information system, states the operator, agent or master of a ship bound to a port of a member state shall report information to the port authority at least 24 hours in advance or in certain cases earlier. The information includes ship identification, port of destination, estimated time of arrival, etc.

A new mandatory reporting system has been introduced in the Gulf of Finland using the Gulf of Finland Mandatory Reporting System, GOFREP. In accordance with the IMO resolution, Finland, Estonia and the Russian Federation require that all vessels exceeding



Map 9.5 Location of oil spills observed in the Baltic Sea area in 2007. *Source: HELCOM*

300 gross tonnage are required to participate in the GOFREP system when sailing in the international waters in the Gulf of Finland. This reporting system will allow automatic reporting with AIS and automatic response from the GOFREP.

IMO resolution MSC.138(76) recommends masters use new and improved navigation equipment including Electronic Chart Display and Information System (ECDIS) onboard ships navigating Route T with a draft of 11 meters or more; oil tankers navigating the Sound with a draft of seven meters or more; chemical tankers; gas carriers; and ships carrying a shipment of irradiated nuclear fuel, plutonium and high level radioactive wastes (INF cargoes) irrespective of size. ECDIS supports plotting and automatically monitoring ships' positions throughout their voyage. The risk of collisions and groundings will be reduced by superimposing AIS and radar information on the electronic chart display.

Research Opportunities

- Research to advance the convergence of critical navigational information including hydrography (ENCs), weather, ice conditions and other data into integrated shipboard navigation systems.
- Research into technologies for hydrographic data collection, especially for adaptation to the Arctic environment. This should include the use of unmanned, underwater (under-ice) vehicles, multibeam technology, through-the-ice data collection, and airborne systems for the collection of nearshore depths and for shoreline identification.
- Research on satellite remote sensing and surface validation to develop means of monitoring ice thickness across the Arctic Ocean.
- Simulated conditions or field testing of oil spills and other pollutants to determine behavior including fate and effects. This should include improvements in remote surveillance and detection technologies; improved oil-in-ice modeling capabilities and long-term fate and effects of lingering oil.
- Focus on further development and improvement of ice service products and services on ice thickness, iceberg detection, forecasting of ice drift and drift of icebergs.
- Research on behavior of oil in cold, ice infested areas including establishing forecasting models to compute the drift of oil in such waters.
- Further development of satellite based oil detection algorithms for ice-covered areas.
- Research on effective response techniques and technology for oil spill recovery on ice, broken ice and cold water.

Routing Systems

A transit route (Route T) through the Kattegat, the Great Belt and the Western Baltic has been established for deep draft ships. Routing systems have been established for ships navigating the Sound. A deepwater route (DW) from Bornholm, south of the Hoburgen bank and up to the border with the Estonian Economic Zone fulfilling the IHO S44 standard for hydrographic surveying has been established. With a clearance of 10 nautical miles to the banks, this will allow a ship with, for example, an engine failure, ample time for speed reduction to be able to drop anchor.

Fifteen traffic separation schemes are established and adopted by IMO in eight parts of the Baltic Sea Area. Two schemes are established in Samsø Belt/Great Belt, two in the Sound, one off Kiel lighthouse, one south of Gedser, one south of Öland Island, one south of Gotland Island, two in the entrance to the Gulf of Finland and five in the Gulf of Finland.

Pilotage

Pilotage services are established locally by the port states and are normally compulsory for ships over certain sizes.

Due to the *Copenhagen Treaty 1857*, ships sailing to or from the North Sea to the Baltic Sea are not required to use pilots. The IMO recommends that when navigating the entrances to the Baltic Sea, local pilotage services should be used by ships as identified in Resolution MSC.138 (76). Certified pilots for the entrances to the Baltic Sea are available in Denmark and, for ships passing through the Sound, in Sweden. Certified Baltic Sea deep-sea pilots are available in all Baltic Sea States.

Weather and Wave Information Systems

Weather and wave monitoring and information systems have been established by the Baltic Sea States in the Baltic Sea area. Weather and wave information is available for seafarers at all times.

Ice Information Systems

Baltic Icebreaking Management (BIM) is an organization with members from all the Baltic Sea states: Denmark, Estonia, Finland, Germany, Latvia, Lithuania, Norway, Poland, the Russian Federation and Sweden. The overall objective of BIM is to ensure a well functioning, year-round maritime transport system in the Baltic Sea through the enhancement of strategic and operational cooperation between the Baltic Sea countries in the area of winter navigation assistance.

The Internet site, www.Baltice.org, is a single access point to reliable and up-to-date information related to winter navigation in the Baltic Sea area.

Protection of People and Property: Incident Response and Overall Coordination

Search and rescue at sea means saving and protecting lives of persons in distress in the sea area. This includes many different duties like assisting vessels and boats in distress at sea, preventing disasters, searching for missing people and performing medical transport in the archipelago and sea area. The basis for carrying out these duties is enacted in international treaties and decrees. All authorities operating in the Baltic Sea area carry out SAR at sea. Also participating are merchant shipping and voluntary organizations. For example, in Finland, the Border Guard is responsible for SAR service at sea and the Maritime Rescue Coordination Centre and maritime rescue sub-centers lead SAR operations. When the persons or environment are no longer in danger, commercial companies carry out the salvage of vessels and cargo.

Protection of the Environment: Oil and Other Hazardous Spills Response

The cooperation in combating spillages of oil and other harmful substances in the Baltic Sea area is based on the Helsinki Convention and HELCOM Recommendations on combating matters, adopted by the Helsinki Commission.

In accordance with the Helsinki Convention the Contracting Parties shall maintain the ability to respond to spillages of oil and other harmful substances into the sea threatening the marine environment of the Baltic Sea area. This ability shall include adequate equipment, ships and manpower prepared for operations in coastal waters as well as on the high seas.

According to the Helsinki Convention, the Contracting Parties shall agree bilaterally or multilaterally on those regions of the Baltic Sea Area in which they should conduct aerial surveillance and take action for combating or salvage activities whenever a significant spillage of oil or other harmful substance or any incident causing or likely to cause pollution within the Baltic Sea area has occurred or is likely to occur.

In cases where a Contracting Party is not able to cope with a spillage by the sole use of its personnel and equipment, the Contracting Party in question can request combating assistance from other Contracting Parties, starting with those who seem likely also to be affected by the spillage.

Monitoring / Enforcing Compliance with Marine Regulation

Port State Control

Port State Control systems have been established by the Baltic Sea States in all Baltic Sea ports in accordance with the Paris Memorandum of Understanding.

Aerial Surveillance

By international law, any release of oily wastes or oily water from ships is prohibited in the Baltic Sea, where oil pollution can affect sensitive ecosystems for long periods. But ships persist in making illegal discharges, despite improvements in port reception facilities and a harbor fee system, which means there is no financial gain to be had from polluting the sea. Every year national surveillance aircraft detect several hundred illegal oil discharges in the Baltic Sea. The actual number of illegal discharges is probably much higher than this. In fact, during most years more oil is released on purpose around the Baltic Sea than is spilled accidentally.

Internationally Coordinated Surveillance Flights

The HELCOM states endeavor to fly, at a minimum, twice per week over regular traffic zones including approaches to major sea ports, as well as in regions with regular offshore activities; and once per week over the regions with sporadic traffic and fishing activities. Twice a year, several Baltic Sea states jointly organize surveillance flights (24 to 36 hours): one covering the southern part of the Baltic Sea and another flight over waters further north.

Arctic Maritime Training

Maritime training in ice conditions is available by private companies in the Baltic Sea area.

The content of the courses includes ice characteristics and ice classifications, ice charts, ice classes, winterization, ship operations in ice, independent navigation in ice, icebreaker operations and ice navigation in convoy. Training of ship maneuvering in ice is done in a full-mission simulator.

Findings

1] Considering the Arctic operational environment and the lack of infrastructure, safe navigation in the Arctic is often dependent on the skills of a limited number of seasoned northern mariners. The demand for skilled mariners is increasing, the number of experienced Arctic mariners is decreasing and there are no universal or mandatory formal education, training and certification requirements in place for ice navigators or crew to prepare them for Arctic marine operations.

2] Based on the information provided, significant portions of the primary Arctic shipping routes do not have adequate hydrographic data, and therefore charts, to support safe navigation. This appears most critical in the Canadian Archipelago and the Beaufort Sea and possibly other areas in the Arctic; at the same time the Russian Federation has broadly identified a requirement for updated hydrography in its Arctic waters. In addition, expansion of the current routes is required to allow alternative courses when hazardous ice conditions are encountered, for entry to points of refuge when necessary, and to support access to natural resources.

3] Electronic Chart Display and Information Systems (ECDIS), especially when coupled with Digital Global Positioning System, improves navigational safety by providing precise, real-time positioning along with holistic display of navigation and environmental information critical for safe navigation in the Arctic. ECDIS may also reduce the requirements and costs associated with deploying and maintaining traditional aids to navigation systems. This creates a high expectation that hydrographic offices will have electronic charts ready for use in the primary navigation routes in the Arctic by 2012. However, the use of ECDIS is wholly dependent on the availability of accurate navigational charts, which rely on comprehensive hydrographic surveys and data.

4] Arctic Maritime Traffic Awareness - There are few systems to monitor and control the movement of ships in ice-covered Arctic waters as an effective way to reduce the risk of incidents, particularly in areas deemed sensitive for environmental or cultural reasons.

5] There are serious limitations to radio and satellite communications for voice or data transmission in the Arctic because there is not complete satellite coverage of the region.

6] There is no binding requirement to implement the recently developed and adopted International Association of Classification Societies (IACS) Unified Requirements concerning *Polar Class* and the December 2002 IMO *Guidelines for Ships Operating in Arctic Ice-covered Waters;* consequently polar vessel construction standards are unevenly applied.

7] For safe operations, ships navigating in the Arctic need the same suite of meteorological and oceanographic data, products and services as in the other oceans plus a comprehensive suite of data, products and services related to sea ice and icebergs. As the shipping season becomes extended, significant increases in resources will be needed to expand the information services accordingly.

8] Emergency response capacity for saving lives and pollution mitigation is highly dependent upon a nation's ability to project human and physical resources over vast geographic distances in various seasonal and climatic circumstances. The current lack of infrastructure in all but a limited number of areas, coupled with the vastness and harsh environment, makes carrying out a response significantly more difficult in the Arctic. Without further investment and development in infrastructure, only a targeted fraction of the potential risk scenarios can be addressed.

9] The operational network of meteorological and oceanographic observations in the Arctic, essential for accurate weather and wave forecasting for safe navigation, is extremely sparse.

© United States Coast Guard

The Arctic Council's Arctic Marine Shipping Assessment was a four-year, multinational-led project, under the direction of the Protection of the Arctic Marine Environment (PAME) working group, that included more than 185 experts in maritime and related fields; 13 major workshops in Canada, Finland, Iceland, the Russian Federation and the United States; and 14 town hall meetings in selected Arctic communities, supported by the Permanent Participants of the Arctic Council. Funding for the *AMSA 2009 Report* was a public-private partnership effort.

Report details next steps in arctic shipping policies

FOR IMMEDIATE RELEASE: Sept. 15, 2010
CONTACT: Marmian Grimes, UAF information officer, 907-474-7902, marmian.grimes@alaska.edu

Fairbanks, Alaska—As the climate warms and global commerce grows, the prospect of an arctic shipping route becomes more tangible. A new report released by the University of Alaska Fairbanks offers international policymakers guidance for navigating the political and practical ramifications of shipping in the Arctic.

The report, "Considering a Roadmap Forward: The Arctic Marine Shipping Assessment," is the result of a workshop hosted by UAF in October 2009 as part of the University of the Arctic's Institute for Applied Circumpolar Policy. The workshop drew nearly 70 experts from Canada, China, Denmark, Japan, Norway, the United Kingdom and the United States to examine the 17 recommendations outlined in the Arctic Council's 2009 Arctic Marine Shipping Assessment.

"The workshop report takes the key AMSA recommendations and provides to the arctic community a list of action items to consider as we collectively navigate a future of change," said Mike Sfraga, head of the UA Geography Program and UAF vice chancellor for students.

Sfraga co-chairs the Institute for Applied Circumpolar Policy with Kenneth Yalowitz of Dartmouth College. Yalowitz is director of the Dickey Center for International Understanding at Dartmouth.

"The future of shipping in the Arctic is one of the most important issues resulting from climate change in the North," Yalowitz said.

The three-day October 2009 workshop focused on three themes: enhancing arctic marine safety, protecting arctic people and the environment, and building the arctic marine infrastructure. The 24-page report offers dozens of proposed actions, many of which will require public or private funding. Among the highest-priority policy issues are:

- A mandatory International Maritime Organization Polar Code.
- Full tracking and monitoring of arctic commercial ships.
- An arctic search and rescue agreement (underway).
- Surveys of indigenous marine use.
- A circumpolar response capacity agreement among the arctic states.
- Implementation of an arctic observing network to support science and marine operations.

"The working groups identified a roadmap, actions and a set of key issues for each of AMSA's recommendations," said UAF geography professor Lawson Brigham, who led the original AMSA effort for the Arctic Council.

Sfraga presented the report at an Institute for Applied Circumpolar Policy workshop in Rovaniemi, Finland, last week. UAF Chancellor Brian Rogers is sharing the report with members of the University of the Arctic, Arctic Council and Arctic Parliamentarians in Brussels this week. It is available online at http://www.snap.uaf.edu/downloads/arctic-marine-shipping-assessment. The workshop report will also be widely distributed to the global maritime and arctic communities.

Considering a Roadmap Forward: The Arctic Marine Shipping Assessment

WORKSHOP REPORT

University of Alaska Fairbanks
October 22-24, 2009

University of the Arctic ~ Institute for Applied Circumpolar Policy

Editors: Lawson W. Brigham and Michael P. Sfraga

University of Alaska Geography Program
School of Natural Resources & Agricultural Sciences

UNIVERSITY OF ALASKA FAIRBANKS

Greetings from the University of Alaska Fairbanks - America's Arctic University. I am pleased that UAF is a founding member, along with our partner Dartmouth College, of the University of the Arctic Institute for Applied Circumpolar Policy. The Institute was established to explore, inform, and shape policy issues that impact residents of the North. It is with this background that I share with you the findings of the Institute's 2nd workshop held at the University of Alaska Fairbanks entitled "Considering a Roadmap Forward: The Arctic Marine Shipping Assessment."

As Chancellor of the University of Alaska Fairbanks and member of the University of the Arctic's Board of Governors, I believe universities throughout the North have a responsibility to study and consider issues that impact the people of the North. The Arctic Council's Arctic Marine Shipping Assessment (AMSA), published in April of 2009, is a path-breaking report that will have far-reaching impacts on Northern communities well into the future. This report's long-term importance is the reason the Fairbanks workshop considered the implications and challenges of the AMSA and its related recommendations.

It takes many partners to conduct a successful program. In addition to the participants, I want to highlight Victor Santos-Pedro, David Jackson, Margaret Williams, and Bob Pawlowski, who tirelessly led the program's three working groups. I would like to thank Holland America Lines and the United States Arctic Research Commission for their generous support of the workshop.

I am confident that "Considering a Roadmap Forward: The Arctic Marine Shipping Assessment" will further inform stakeholders, policy makers, industry, and the people of the North as they consider the challenges in our unique, dynamic, fragile, and powerful Arctic of the future.

Brian Rogers, Chancellor

Recommended Citation: Brigham, L. and M. Sfraga (Editors), 2010. *Creating a Roadmap Forward: the Arctic Marine Shipping Assessment* . Workshop Report for October 22-24, 2009, University of Alaska Fairbanks and the University of the Arctic Institute for Applied Circumpolar Policy.

Introduction and Workshop Objectives

This is a report of an Arctic policy workshop hosted by the University of Alaska Fairbanks on 22-24 October 2009. It forms an important contribution to the University of the Arctic's Institute for Applied Circumpolar Policy (IACP), a collaboration between Dartmouth College, the University of Alaska Fairbanks (UAF), and the University of the Arctic (UArctic). ICAP is co-directed by Dr. Michael Sfraga, University of Alaska Fairbanks and Former U.S. Ambassador Kenneth Yalowitz, Dartmouth College. IACP is the first formal institute sanctioned by UArctic member institutions and its mission is to promote discussion and analysis of critical issues facing the circumpolar region and its people. IACP has also been established to provide educational opportunities and policy-oriented advice as northern peoples face the challenges resulting from rapid climate change and other drivers of change in the Arctic such as natural resource development and globalization.

IACP has initially focused its efforts on a series of conferences and workshops that will hopefully improve public and private understanding of the policy implications resulting from circumpolar change, especially climate change and the human dimension. These gatherings bring together representatives of governments, non-governmental organizations, Arctic indigenous peoples, industry, and research organizations to discuss, identify, and prioritize issues and policy-related research. The outcomes of these meetings will help develop the agendas for governments to address pressing policy issues in the Arctic. The first IACP venue was held at Dartmouth College 1-3 December 2008 with a focus on climate change and Arctic security issues; a report, *The Arctic Climate Change and Security Policy Conference - Final Report and Findings*, was released in June 2009 at the Carnegie Endowment for International Peace in Washington, DC. The second IACP venue is the subject of this workshop report regarding the Arctic Council's Arctic Marine Shipping Assessment (AMSA). A third venue will be organized at the Arctic Centre in Rovaniemi, Finland in September 2010 focusing on climate change and human security in the Arctic.

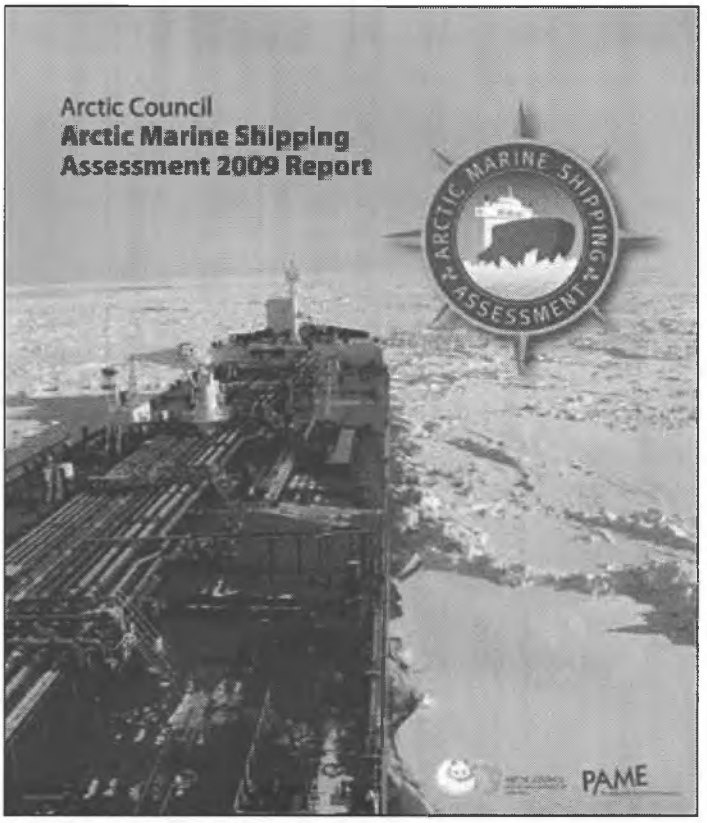
The topic for this workshop report, the Arctic Council's Arctic Marine Shipping Assessment (AMSA), came about because of the April 2009 release of the *AMSA 2009 Report*. AMSA has clear policy implications for the Arctic and the global maritime industry, and UArctic and UAF recognized the relevance of these issues to the mission of IACP. Nearly seventy experts from Canada, China, Denmark, Japan, Norway, the United Kingdom and the United States participated; participants included representatives from the Arctic states, non-governmental organizations, indigenous groups, marine companies, maritime organizations, and academic institutions.

The objectives of the Fairbanks workshop were to explore the implications of the AMSA recommendations using three working groups of experts, and discuss the challenges ahead for implementation of the outcomes of AMSA. The working groups identified a roadmap and actions, and a set of key issues for each of AMSA's recommendations. Further discussions focused on funding and financial issues, and the key policy issues that are of the highest priority in addressing Arctic marine safety and marine environmental protection. The workshop agenda, included as Appendix 2, also indicates nine workshop presentations that highlighted significant policy issues being faced today by the Arctic states and indigenous communities throughout the North. It is anticipated that the results of this workshop will be used by the Arctic Council and its working groups, the Permanent Participants on the Council, the maritime industry, and many other stakeholders to assist in shaping future use of the Arctic Ocean.

© U.S. Coast Guard

Background ~ The Arctic Marine Shipping Assessment

On 29 April 2009 at the Arctic Council Ministerial meeting in Tromso, Norway, the Arctic Ministers approved a key study for the future of the region, the Arctic Marine Shipping Assessment (AMSA). AMSA is the culmination of work by nearly 200 experts under the Council's working group Protection of the Arctic Marine Environment (PAME). AMSA was led by Canada, Finland and the United States during 2005-2009 and is a follow-on effort to the Council's Arctic Climate Impact Assessment and the Arctic Marine Strategic Plan, both released in 2004 and each indicating increases in Arctic marine operations. AMSA is an assessment of current and future Arctic marine activity with a focus on Arctic marine safety and marine environmental protection. These themes are consistent with the Arctic Council's key mandates of environmental protection and sustainable development. Overall, the *AMSA 2009 Report* is a message by the Arctic states to the world with a framework to address the many, complex challenges of protecting Arctic people and the environment in an era of expanding use of the Arctic Ocean.



AMSA can be viewed in three ways:

- A **baseline assessment** of Arctic marine activity early in the 21st century using the 2004 AMSA database as an historic snapshot of marine use;
- A **strategic guide** for a host of Arctic and non-Arctic actors and stakeholders;
- A **policy document of the Arctic Council**, since the *AMSA 2009 Report* was negotiated and consensus for its approval was reached by the eight Arctic states within the Council.

The *AMSA 2009 Report* is a key Arctic Council policy document that contains some elements of scientific research, especially those topics related to environmental impacts. However, AMSA is much broader than science and includes such topics as geography, law of the sea, scenarios of the future, marine infrastructure, globalization of the Arctic, indigenous community viewpoints, natural resource development, and other practical issues of Arctic marine navigation; 96 findings are presented in the assessment. The *AMSA 2009 Report* and *AMSA Background Research Documents* (research papers not approved or negotiated by the Arctic Council) can be found on the PAME web site (www.pame.is).

The key outcomes of AMSA are 17 recommendations agreed to by the Arctic states in the *AMSA 2009 Report* under three, inter-related themes: Enhancing Arctic Marine Safety, Protecting Arctic People and the Environment, and Building the Arctic Marine Infrastructure. The full AMSA recommendations are included in Appendix I of this report. These 17 recommendations were the focus of the Fairbanks workshop expert discussions and resulted in a roadmap ahead and key issues for each, and identification of funding challenges and policy issues that require attention. As with AMSA itself, the workshop experts recognized that implementation of the AMSA recommendations would require extensive international cooperation and public-private partnerships.

Guidance to the Workshop Working Groups

AMSA Workshop Working Groups:

I. Enhancing Arctic Marine Safety
II. Protecting Arctic People and the Environment
III. Building the Arctic Marine Infrastructure

- ✓ Please read recommendations specific to your AMSA theme.
- ✓ Please address the five tasks listed below.
- ✓ Provide bulleted answers – followed by a brief narrative that summarizes the overall "roadmap" response to each recommendation.

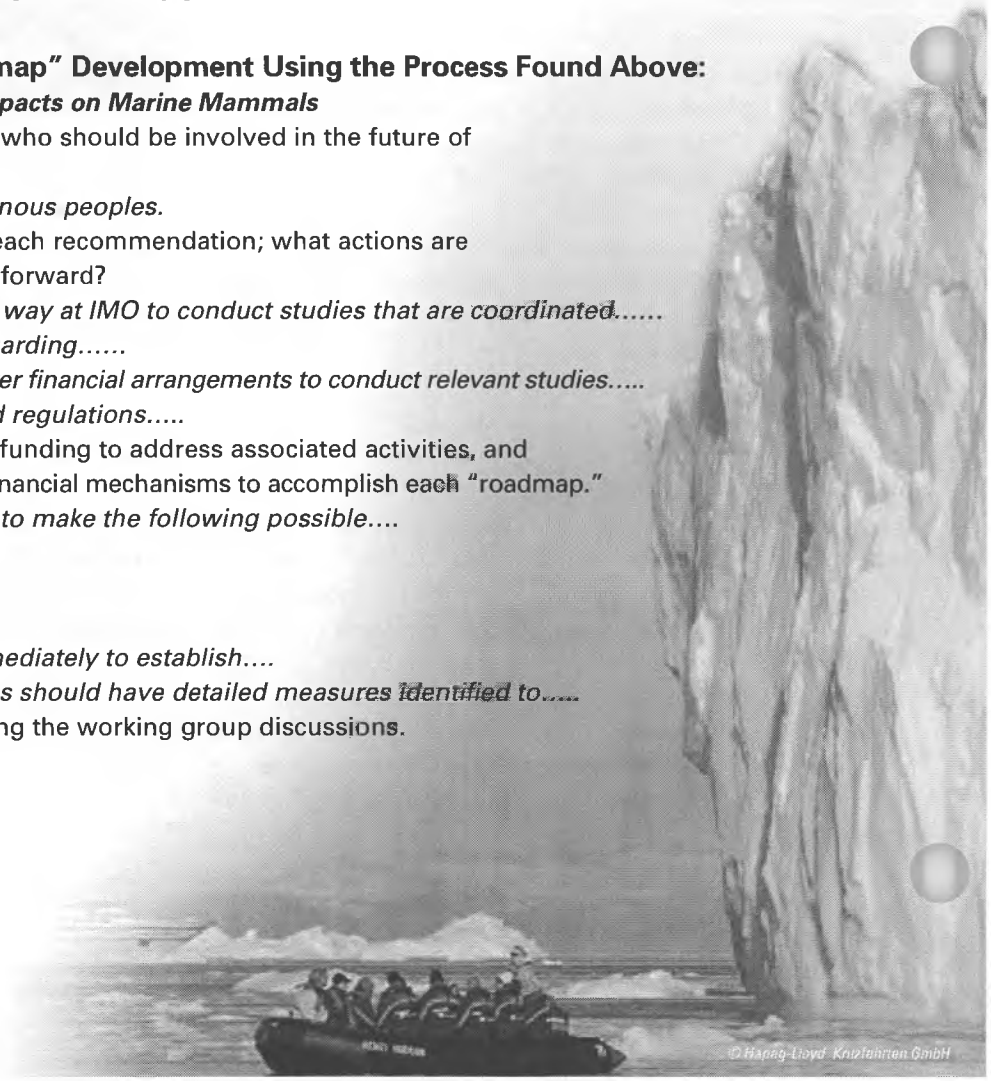
Tasks:

1) Identify primary stakeholders and actors who should be involved in the future of this recommendation.
2) Develop "roadmap" or "roadmaps" for each recommendation; what actions are required to move each recommendation forward?
3) For each "roadmap" identify sources of funding to address associated activities, and recommend any possible new or special financial mechanisms to accomplish each "roadmap."
4) Establish a timeline for each "roadmap."
   a. Less than 2 years
   b. Beyond 2 years
5) Identify other key issues discovered during the working group discussions.

Example Recommendation and "Roadmap" Development Using the Process Found Above:

AMSA Recommendation II G: Addressing Impacts on Marine Mammals

1) Identify primary stakeholders and actors who should be involved in the future of this recommendation.
   - *IWC, IMO, Maritime agencies, Indigenous peoples.*
2) Develop "roadmap" or "roadmaps" for each recommendation; what actions are required to move each recommendation forward?
   - *Arctic nations should act in a unified way at IMO to conduct studies that are coordinated.....*
   - *Consult with Arctic Communities regarding.....*
   - *Arctic Council, SDWG, etc. should foster financial arrangements to conduct relevant studies.....*
   - *Establish international standards and regulations.....*
3) For each "roadmap," identify sources of funding to address associated activities, and recommend any possible new or special financial mechanisms to accomplish each "roadmap."
   - *Establish new financial mechanisms to make the following possible....*
4) Establish a timeline for each "roadmap."
   a) Less than 2 years
   b) Beyond 2 years
      - *Technical groups must begin immediately to establish....*
      - *In two year's time, working groups should have detailed measures identified to.....*
5) Identify other key issues discovered during the working group discussions.



Identifying the Stakeholders and Actors

Experts in the three Workshop Working Groups (Enhancing Arctic Marine Safety, Protecting Arctic People and the Environment, and, Building the Arctic Marine Infrastructure) identified a host of stakeholders and actors who are believed to have some involvement and influence in AMSA and in the future of Arctic marine activity. As might be expected, there were significant overlap among the working group listings, and discussions on who might be relevant stakeholders and actors. The primary decision-makers and 'players' in this review are considered to be the eight Arctic sovereign states, the flag states, and the indigenous groups who make up the six Permanent Participants of the Arctic Council. The below should be considered examples of the key stakeholders & actors, however, not an exhaustive list.

~ **Sovereign States** (Regulatory and response agencies; regional authorities; national hydrographic services; national ice services; national pollution funds); Flag States; ~ **Indigenous Groups** (including domestic tribal groups and Arctic Council Permanent Participants)

~ **International Governmental Organizations:** International Maritime Organization; International Hydrographic Organization; International Maritime Satellite Organization; World Meteorological Organization; International Whaling Commission; International Association of Marine Aids to Navigation and Lighthouse Authorities; International Oil Pollution Compensation Funds; International Telecommunication Union; International Oceanographic Commission; International Ice Charting Working Group; The World Bank

~ **Maritime Industry:** Shipping companies; Offshore drilling companies; Ship classification companies; International Association of Classification Societies (IACS); Intertanko, Bimco; Cruise Lines International Association; Oil Companies International Marine Forum; Offshore Marine Services Association; International Oil and Gas Products; SIGTTO; International Association of Drilling Contractors; International Association of Arctic Expedition Cruise Operators; Passenger Vessel Association; International Association of Antarctic Tour Operators; Fishing industry; marine pilots; Oil spill response organizations; International Tanker Owners Pollution Federation; Local marine suppliers and engineering/technical support firms

~ **Marine Insurers:** Marine insurance companies; International Union of Marine Insurance; American Institute of Marine Underwriters

~ **Private/Independent:** NGOs; Non-profit foundations; academic & training institutions; research organizations (public and private)

© Harald Finkler

Results of the Working Group Discussions on the AMSA Recommendations:

Roadmap and Actions & Key Issues for

I ~ Enhancing Arctic Marine Safety

II~ Protecting Arctic People and the Environment

III ~ Building the Arctic Marine Infrastructure

© Fednav, Ltd.

I. Enhancing Arctic Marine Safety

I.A. Linking with International Organizations

ROADMAP AND ACTIONS	KEY ISSUES

• PAME to bring together experts on shipping from the Arctic states to identify common interests and develop unified positions and approaches.
• Identify an Arctic state lead country to facilitate an IMO meeting of experts on Arctic safety issues.
• For a consistent approach on Arctic shipping issues, the Arctic states should coordinate:
  ○ Input from all actors and stakeholders in each state including regional interests.
  ○ Input from different government agencies who attend various international organizations (for example IMO, ILO and WMO).
  ○ Input from stakeholders and government departments who attend a particular organization (such as IMO).
	• Taking into consideration the opinions and ideas of other interested stakeholders before approaching international organizations (such as IMO), the Arctic states may have a potential agreed position.
	• Knowing who is and is not represented at the international organizations.
	• Early, proactive actions will improve communications on all Arctic shipping issues

I.B. IMO Measures for Arctic Shipping

ROADMAP AND ACTIONS	KEY ISSUES
• Guidelines have been updated to become the IMO 'Guidelines for ships operating in polar waters.' • Arctic Council to send a letter to Arctic marine interests as a whole to promote the December 2009 IMO Assembly resolution applying guidelines to polar waters. • Arctic states to promote the application of the polar guidelines with industry and others as appropriate, to national and international interests. • IMO Maritime Safety Committee (MSC) has tasked the Design and Equipment Subcommittee to develop a mandatory polar code in 3 sessions (Feb 2010, Autumn 2010, and Spring 2011). • Adoption will be by tacit or implied amendment to SOLAS and MARPOL Conventions. • Having agreed the polar code is to become mandatory, the Arctic states encourage other interested states/ parties to participate, engage and support adoption and implementation of the polar code. • Influential for communication and consensus building for the mandatory polar code are the Consultative Parties of the Antarctic Treaty.	• These Guidelines now apply to Arctic and Antarctic waters whether ice-covered or not. • Polar code will have a mandatory Part A and recommendations in Part B. • Construction requirements (hull and machinery) will be in both the polar code and International Association of Classification Societies (IACS) rules. • Ice navigator competence requirements must be clearly defined in STCW Convention; requirements to have an ice navigator aboard will be in the polar code. • Need for a model ice navigation course and to establish acceptance criteria for simulations as partial training fulfillment. • Need for theoretical training, including the incorporation of contemporary local knowledge, together with practical experience in ice. • Lack of Arctic marine infrastructure needs to be considered for independent operations. • Endorsement of certificates to include bridge and engineering personnel; desirable for operators to be familiar with ship conditions when operating in remote and ice-covered waters.

I.C. Uniformity of Arctic Shipping Governance

ROADMAP AND ACTIONS	KEY ISSUES
• PAME to conduct a survey/inventory of national or regional regulations, standards and guidelines with the aim of harmonizing safety and pollution prevention measures in keeping with UNCLOS. • Required surveys and inventories from the AMSA research agenda include: 1. Comparative study of how Arctic states address liability and compensation, especially for bunker fuel spills and hazardous/noxious substance incidents. 2. Survey of existing and potential fee systems for icebreaking and other Arctic services, such as navigational aids, charting, SAR, and ice information services, provided by the Arctic states. 3. Survey of ballast water practices and invasive species threats from Arctic shipping and a comparison of Arctic state approaches to ballast water exchanges and treatments. 4. Review of how bilateral and regional cooperation in addressing Arctic marine operations might be enhanced using other international approaches and experiences. • Draft language for a potential international agreement or designation (PSSA) in keeping with UNCLOS on safety and pollution prevention measures in regions of the central Arctic Ocean beyond coastal state jurisdiction for consideration by IMO.	• Key examples of Arctic state regulations for possible integration in the harmonization of measures: ○ *Canada:* Reporting scheme; guidelines for cruise ship operation; ballast guidelines for tankers and barges; equivalent standards for construction of Arctic class ships; Arctic shipping/waters pollution prevention regulations; oil transfer guidelines. ○ *Russia:* Guidelines for operation on the Northern Sea Route; Arctic port regulations. ○ *United States:* Marine Mammal Protection Act; cruise ship discharge regulations in Alaska. ○ *Greenland:* mandatory reporting scheme; regulations for the safety of navigation. ○ *Norway and Russia:* Results of Barents 2020. ○ WWF-Gap Analysis study. ○ Industry and NGO surveys and standards.

I.D. Strengthening Passenger Ship Safety in Arctic Waters

ROADMAP AND ACTIONS	KEY ISSUES
• Include in an Arctic Council letter (for distribution of polar guidelines to operators), the IMO enhanced contingency guidance for cruise ships in polar waters. • Request cruise ship associations (CLIA and AECO) to develop harmonized best practices for operating in remote and ice-covered conditions (for example, mother ship and tenders). • Invite cruise ship associations to make presentations to PAME and Arctic expert meetings at IMO. • Organize an international workshop/conference on cruise ship safety in Arctic waters with cruise operators and regulators.	• Need to encourage the formation of cruise ship organizations that cover all Arctic waters, such as IAATO in Antarctic waters. • Urge passenger ship operations in polar waters to be carried out in tandem with sufficient capacity for mutual rescue. • Passenger ship operators to document and mitigate risks and hazards associated with potential grounding in poorly charted waters.

I.E. Arctic Search and Rescue (SAR) Instrument

ROADMAP AND ACTIONS	KEY ISSUES
• U.S. currently chairing an Arctic Council task force to draft a multinational Arctic SAR agreement; to be completed by 2011 for signature by the Arctic Ministers; first meeting December 2009. • Coordinate the use of existing resources and deploy them in the most effective manner that will cover any response gaps. • Arctic Council to urge all Arctic states, and EPPR, to participate in the process for a SAR agreement.	• Requirement for a comprehensive review of current, national SAR (maritime and aviation) capabilities for the Arctic. • Evaluation of the adequacy of cooperative SAR agreements and arrangements for addressing increasing commercial use of the Arctic Ocean and Arctic airspace.

II. Protecting Arctic People and the Environment

II.A. Survey of Arctic Indigenous Marine Use

ROADMAP AND ACTIONS	KEY ISSUES
• Feasibility and design of a survey should be regional and national, not one unified circumpolar effort. • Development of a survey must have early communications and develop trust with indigenous communities. • Surveys to be based on scientific methods with verifiable data; data needs to be accessible in a synthesized format for review. • Survey characteristics: relate risk to communities, resource and traditional ways; build on existing information/past surveys; structured for acceptability; administered with trust and believability; sustainable for future use and comparison; cover general areas and patterns rather than specific tracks. • Surveys must recognize changes: increased access for shipping; boundary changes with climate change; marine values associated with resource access; differences in stakeholder perspectives of the circumpolar region; importance of today's decisions and the future.	• Must identify who to communicate with including organizations, community leaders, and spokespersons. • Must determine what information is important for operations, development, and regulatory regimes. • Survey must insure: scientific methodology; verifiability; accuracy; and usability for the intended purpose. • Survey data must be formatted and mapped for accessibility by many. • More synthesized information will have greater value in decision-making; level of resolution of data also key for users.

II.B. Engagement with Arctic Communities

ROADMAP AND ACTIONS	KEY ISSUES
• Community engagement long before regional/local development or ship arrivals. • Communication of near-term Arctic marine operations, such as cruise ships, allows preparedness for community opportunities to show cultural pride and traditional lifestyle, to provide arts and crafts, and for local job development. • Early communication of marine operations can enhance coordination of traditional uses of ice-covered waterways with ship uses/tracks. • Future planning for Arctic ports and ship support requires community involvement with socio-economic aspects and an understanding of traditional uses of the waterways and local coastal areas. • Recognition that future Arctic port site selection (and limited funds for infrastructure) will create competition between communities; evaluation of gains and losses within communities and needs for investment. • Future development will require mandated environmental assessment processes involving: community engagement, national standards, international coordination, and transparency of findings. • New Arctic marine developments will require risk assessments involving community engagement and reporting of results.	• Need to keep Arctic communities engaged; Permanent participants at the Arctic Council can monitor progress and mechanisms for engagement. • Determination of the level of public process mandated for each region. • Stressing the importance of ongoing dialogue and government consultation with a goal of enhanced community engagement. • Fostering conflict avoidance and communicating the importance of building trust among the actors. © Ross MacDonald

II.C. Areas of Heightened Ecological and Cultural Significance, and II.D. Specially Designated Arctic Marine Areas

ROADMAP AND ACTIONS	KEY ISSUES
• **For Archaeological and Cultural Sites:** o Develop site management plans with: location identification; community engagement; identification of stresses on the site (tourism, offshore operations, and climate change); rules for numbers of visitors, type of access, and type of facilities allowed; guidelines for waste management offshore. o Develop site response plans to: offshore anchoring, discharges from ships, cargo loss, oil spills and hazmat spills. o Site response plans would be nested in larger, regional response plans. • **For Migratory Route Protection and Preservation:** o Measures include: regulating ship speeds; establishing areas to be avoided; ship routing; establishing financial responsibility for liability and compensation. o Monitoring and designating reporting areas are key elements to evaluating mitigation effectiveness.	• Local site management should not conflict with MARPOL or UNCLOS navigation rights. • Consideration of climate change impacts and the resulting movement of cultural and ecological sites. • Should management regimes be mobile as well as protected sites with changing climate? • How to pay for response activities; the need for an international regime (civil liability). • Movement of marine species with changing Arctic climate. • Sorting out the relationship between changing access for shipping and the impacts of climate change on migratory routes. • Range of objectives, from allowing no shipping to creating a balance between shipping and environmental protection measures. • Multiple strategies available to minimize marine use impacts; options available to communities to be pro-active rather than reactive to future Arctic marine uses.

II.E. Protection from Invasive Species

ROADMAP AND ACTIONS	KEY ISSUES
• Ratification of IMO Ballast Water Convention (for the global oceans) not enough and there is a need for tighter, Arctic-specific measures/requirements. • Beyond ballast water there are hull fouling and cargo riders as potential sources of invasive species. • Requirement for an Arctic prevention plan, perhaps a Hazard Analysis and Critical Control Points (HACCP) evaluation program (Australia has developed invasive species transfer avoidance measures for a range of marine activities). • Require further Arctic shipping scenarios and projections to frame the risks of invasive species. • Need more baseline surveys, especially in the areas of concentrated marine activity. • Require expanded monitoring, protocols for comparability, and the involvement of local residents with traditional knowledge who will be first to see changes. • As part of a response capacity there is a need for agreed upon emergency treatment options. • Shipwreck response and rapid response (eradication) capacities in shallow waters and on land (rats).	• Rapid ratification of the IMO Ballast Water Convention required, especially by the 8 Arctic states. • IMO movement on creating measures for the Arctic under the Ballast Water Convention and the other agreements. • Potential incentives for shipbuilders and ship operators to improve prevention effectiveness. • Application of same regulations for international shipping to Arctic coastwise trade. • Require research/testing and personnel expertise ~ capacity building in the Arctic. 
II.F. Oil Spill Prevention

ROADMAP AND ACTIONS	KEY ISSUES
• Most significant strategy remains keeping oil contained ashore and within ships - the prevention of Arctic oil spills. • Initiate a comparative evaluation of Arctic state schemes including: strength of prevention regime; liability standard; damage compensation; preparedness laws; fuel transfer standards; compliance; enforcement of regulations. • Enhanced cooperation and dialogue on unified standards of prevention and levels of tolerance/enforcement. • Initiate an effectiveness evaluation of training, systems, technology and environmental knowledge. • Conduct response gap analysis with a view to required research and capacity-building. • Explore the possibility of marine areas or zones where there is restricted traffic for tankers & LNG ships. • Development of a potential liability incentive fund for prevention.	• Development of trust among the many stakeholders on prevention issues. • Establishing strategic communication among the states and conducting oil spill tests and experiments with international consensus. • Required funding of basic research for systems improvements.

II.G. Addressing Impacts on Marine Mammals

ROADMAP AND ACTIONS	KEY ISSUES
• Research on improving baseline information on migratory routes required: added challenge are route changes and distinguishing between climate change impacts and increased marine activities. • Industry representatives must be involved in discussions for mitigation measures from the earliest development. • Preferred strategy is to separate ship traffic and marine mammals in space and time; where separation is not feasible, restrictions on ship speeds can help reduce mammal strikes. • Completion of an AIS receiver network in the Arctic is high priority; linkages between AIS and marine mammal awareness need to be developed. • Spatial distance is key for other disturbances: mating, migration, resting, calving, feeding and haul out areas; seasonal deflection from normal migratory routes can impact food security, subsistence lifestyles and the social structure of communities. • Develop lighting measures to reduce light disturbance to birds. • Research on noise from marine operations: deflection causes; masking (mammal communications); potential physiological damage. • Develop 'sound budgets' to review the cumulative effects of various marine operations.	• Cultural-subsistence awareness training should be developed for regional operators. • Restrictions and measures impacting navigation should be linked to the evolution of special marine areas and mapping efforts to plot changing marine ecosystems. • Vessel routing and speed restrictions are effective measures to mitigate impacts on marine mammals. • Many Arctic regions are not currently regulated; potential mechanisms and use of possible technologies are pathways forward.

II.H. Reducing Air Emissions

ROADMAP AND ACTIONS	KEY ISSUES
• Development at IMO of uniform standards. • Recognition that the global marine industry and IMO are developing regulations and uncertainty surrounds future standards. • Air quality agencies of the Arctic states should address this issue at a meeting with marine operators; potential for future negotiated acceptable levels of emissions for the Arctic. • Assessment of black carbon impacts in the Arctic important. • Arctic-specific standards may be requested in the the future at IMO.	• New control technologies may be available to mitigate ship emissions in the Arctic. • Different, more stringent emissions standards may be required for the Arctic Ocean and entire Arctic region. • Monitoring and tracking of future emissions will be essential for enforcement.

III. Building the Arctic Marine Infrastructure

III.A. Addressing the Infrastructure Deficit

ROADMAP AND ACTIONS	KEY ISSUES
• Institute an 'infrastructure deficit awareness program.' • Industry notification of communities at all stages. • Port and shore side development plans in all Arctic states. • Coordinate and identify public and private/industry funding. • Survey existing ports and port needs. • Develop national Arctic port strategies. • Explore 'tiered-port' (primary & secondary) approach. • Match government and industry priorities enhancing cooperation. • International conference of Arctic, Northern and Gateway ports and infrastructure. • Review linkages between large ports, small ports, and river infrastructure. • Launch an Arctic aids-to-navigation requirements review. • Prioritization of areas for hydrographic resurvey. • Review and assess Arctic long-range electronic navigation requirements. • Continue harmonization of national ice services and products. • Continued research on Arctic sea ice thickness and improved remote sensing tools for thickness. • Explore concept of 'virtual' ice center for the Arctic Ocean. • Improved sea ice type and iceberg detection (satellite and radar).	• Prioritizing hydrographic surveys. • Industry funding identification for public-private partnerships. • Development of new schemes for cost recovery of all marine infrastructure. • Icebreaker fleet renewal (public and private/ industry fleets). • Survey and enumeration of Arctic places of refuge. • Holistic Arctic port planning – closer Arctic state cooperation and coordination.  © Neste Shipping Oy

III.B. Arctic Marine Traffic Systems

ROADMAP AND ACTIONS	KEY ISSUES
• Mandatory Automatic Identification System (AIS) carriage. • Mandatory commercial traffic reporting. • Assessment of potential vessel traffic separation schemes in selected Arctic waterways. • Assessment of Arctic state ability to enforce mandatory reporting. • Potential harmonization of mandatory reporting systems (for example, between the Northern Sea Route, Canadian Arctic and Bering Strait regions). • Comprehensive examination of crossing maritime borders: examining the practical issues (ease of crossing, logistical support, SAR, emergency response, communications). • Develop consolidated coast pilot & sailing directions for the Arctic Ocean (one-stop shopping and available electronically in multiple languages).	• Identification of potential marine protected areas; timing key for infrastructure and navigation systems development. • Status of endangered species legislation that could impact traffic schemes. • Sharing traffic information with regional governments and local communities. © Fednav, Ltd.

III.C. Circumpolar Environmental Response Capacity

ROADMAP AND ACTIONS	KEY ISSUES
• Primary goal of all Arctic rules and regulations: spill prevention. • Enhanced R&D for: recovery of oil in ice; trajectory modeling; remote sensing detection. • Harmonization of minimum standards for oil spill legislation. • Extend best practices and R&D to all Arctic states. • Comprehensive analyses of projected marine areas of high risk. • Enhanced analyses and reviews of appropriate response strategies based on geography. • Continued close cooperation among the Arctic states in: R&D, spill response exercises, and exchange of information and best practices. • Encourage regional, bilateral response agreements (for example, Canada/Denmark, US/Russia). • Assessment and augmentation of emergency and rapid transportation capability for oil spill response equipment. • Initiate Arctic discussions regarding hazardous material and chemical spills in the Arctic.	• Responses to incidents involving naval vessels in the Arctic Ocean. • Need for an Arctic oil spill liability trust fund; potential joint Arctic state-industry collaboration. • Role of Arctic communities in emergency response capability. • Increased frequency of Arctic emergency response joint exercises. • Potential for an Arctic state agreement on circumpolar, environmental response capabilities and capacities; could be an Arctic Council initiative following Arctic SAR agreement.

III.D. Investing in Hydrographic, Meteorological and Oceanographic Data

ROADMAP AND ACTIONS	KEY ISSUES
• Improved quality of regional and circumpolar weather forecasting. • Improved and refined met-ocean-ice forecasts and modeling techniques. • Improved training for Arctic forecasters (link met training to sea ice training; increased field training). • Improved access throughout the Arctic Ocean (including EEZs) for real-time met-ocean-ice data. • PAME/Arctic Council to approach the World Meteorological Organization (WMO) to expand Arctic states' participation in WMO activities. • WMO conference for met-ocean-ice cooperation in the Arctic. • Arctic Council and Arctic states to coordinate increased cooperation for observations. • Increased reporting of local weather observations by all ships in the Arctic Ocean (a function of the ice navigator). • Enhanced iceberg monitoring in the Arctic Ocean. • New observing systems with free and open access to environmental satellite information.	• Requirements for adequate polar communication to handle new, large information flow. • Cost recovery of data and information (user fees possible). • Status and future of observing networks resulting from IPY cooperation. • Cost and access to SAR data for ice information. • Improving transfer of met-ocean-ice information to indigenous populations and communities for hunting and fishing.  *© Canadian Coast Guard*

Funding Issues

Key issues not addressed in AMSA are the broad financial and funding concerns linked to each of the AMSA recommendations. The Fairbanks workshop experts identified several significant areas that require near-term funding and also reviewed issues related to the need for liability and compensation mechanisms in the Arctic.

Indigenous Marine Use Surveys ~ A key requirement in most regions of the Arctic, and one of the AMSA recommendations, is the need for surveys of indigenous marine use. Up-to-date baseline data on regional and local patterns of indigenous use of Arctic waters is necessary to assess the impacts from increasing Arctic marine operations. Significant discussions were held on this topic in Fairbanks due to the complexities and sensitivities of conducting such human use surveys. There was general agreement that the surveys could not be conducted in one unified circumpolar effort (although the baseline data could be merged later to construct a unified 'picture'). Public appropriations from national and regional governments are key since these surveys relate to subsistence living, marine safety, environmental protection and multiple use management of Arctic marine waterways. Broad scale surveys are nominally the responsibility of governments, national and regional. However, private sources of funding, such as from NGOs and nonprofit foundations, could also be important at the local, community level for detailed studies and surveys. Grants or surveys from industry sources (for example, natural resource developments related to mining) could be used to support surveys in preparation of new marine transportation systems and navigation in local waterways.

Marine Infrastructure Elements ~ The lack of adequate marine infrastructure in most of the Arctic (except for the Norwegian coast and northwest Russia) to support current and future levels of Arctic marine activity is a key finding of AMSA. Large public and private investments will be necessary to provide an adequate safety net for marine operations and environmental protection. Public and private funding for satellite communications and environmental monitoring are urgently required to fill existing Arctic gaps in coverage. Enhancing environmental response capacity may require public-industry funding of equipment to be cached in remote Arctic locations. A mandatory ship tracking and monitoring system will require public appropriations and the potential for pooling funding among the Arctic states. Public funding of enhanced Arctic weather and sea ice information may also mandate cost recovery schemes. Hyrographic surveys and charting are urgent requirements and these activities need significant national investments; cost recovery through industry user fees may be necessary, for example, in remote Arctic regions of seasonal marine traffic. The World Bank and other international financial institutions should be considered for Arctic port facilities and overall marine infrastructure. Coordinated investments for such elements as ports and aids to navigation should be discussed by the Arctic states.

Liability and Compensation Challenges ~ Robust, effective oil spill liability trust funds are required in the Arctic; funds can come from public-private partnerships and they could be based on regional or bi-lateral agreements. Two national models are Canada's Ship-source Oil Pollution Fund and the U.S. Oil Pollution Act of 1990. A conference on liability-compensation issues for Arctic marine incidents should be organized by the Arctic states and industry interests.

© ConocoPhillips

Summary ~ Key Policy Issues Ahead

During the course of the workshop discussions revealed a number of high priority issues as critical outcomes of AMSA. The Co-editors of this report have developed a list of key policy issues from the discussions in Fairbanks that require attention in the near-term to enhance Arctic marine safety and marine environmental protection. Throughout the workshop the highest priority issue consistently noted was the urgent need for a mandatory Polar Code developed by the International Maritime Organization. Implementation of mandatory rules for polar ship construction, design, equipment, operations and ice navigator competency was considered by the workshop participants as the crucial first step for protecting Arctic people and the environment in an era of increased marine operations in the Arctic Ocean.

The following lists are provided as summaries of Arctic policy issues derived from the expert discussions of the AMSA Workshop:

© Fednav, Ltd.

I. <u>Highest Priority</u> Arctic Policy Issues Related to AMSA:

- A mandatory Polar Code developed by the IMO.
- Full tracking and monitoring of Arctic commercial ships (mandatory AIS).
- An Arctic SAR agreement ~ an ongoing Arctic Council SAR Task Force is to produce a binding agreement by spring 2011.
- Surveys of indigenous marine use so that multiple use strategies in Arctic waterways can be developed.
- A circumpolar response capacity agreement ~ an agreement among the Arctic states (and possibly non-Arctic states) for pooling resources and enhancing regional capacity.
- Implementation of an Arctic Observing Network among the 8 Arctic states and non-Arctic states ~ a network to support scientific research and marine operations.

II. <u>High Priority</u> Arctic Policy issues Related to AMSA:

- A critical Arctic marine infrastructure requirement ~ increased hydrography and surveying of Arctic waters for enhanced navigation charts.
- Oil spill research on prevention best practices and responses to oil released in Arctic ice-covered waters.
- Enhanced research, including mitigation measures, on the impacts on marine mammals, and other migratory fauna, of increased Arctic marine operations.
- Identification of specific ballast water/invasive species issues and prevention strategies related to Arctic marine operations.
- A comprehensive study to identify potential Arctic marine areas, including the central Arctic Ocean, for possible designation as IMO Particularly Sensitive Sea Areas (PSSAs).
- Marine industry development of harmonized best practices for all cruise ships operating in Arctic waters, including operational strategies for mutual rescue.
- Studies on the application of ecosystems-based management to Arctic coastal regions.
- A comparative study of Arctic state liability and compensation strategies for marine incidents with a view to developing future uniform measures.
- Fully developed IMO ice navigator competency requirements included in the STCW; mandatory requirement for onboard ice navigator as part of the Polar Code.
- Enhanced marine communications systems in the Arctic, including full coverage satellite communications in the central Arctic Ocean.

APPENDIX 1:
The Arctic Marine Shipping Assessment Recommendations

The focus of the AMSA is marine safety and marine environmental protection, which is consistent with the Arctic Council's mandates of environmental protection and sustainable development. Based on the findings of the AMSA, recommendations were developed to provide a guide for future action by the Arctic Council, Arctic states and many others. The AMSA recommendations are presented under three broad, inter-related themes that are fundamental to understanding the AMSA: Enhancing Arctic Marine Safety, Protecting Arctic People and the Environment, and Building Arctic Marine Infrastructure. It is recognized that implementation of these recommendations could come from the Arctic states, industry and/or public-private partnerships.

I. ENHANCING ARCTIC MARINE SAFETY

A. Linking with International Organizations: That the Arctic states decide to, on a case by case basis, identify areas of common interest and develop unified positions and approaches with respect to international organizations such as: the International Maritime Organization (IMO), the International Hydrographic Organization (IHO), the World Meteorological Organization (WMO) and the International Maritime Satellite Organization (IMSO) to advance the safety of Arctic marine shipping; and encourage meetings, as appropriate, of member state national maritime safety organizations to coordinate, harmonize and enhance the implementation of the Arctic maritime regulatory framework.

B. IMO Measures for Arctic Shipping: That the Arctic states, in recognition of the unique environmental and navigational conditions in the Arctic, decide to cooperatively support efforts at the International Maritime Organization to strengthen, harmonize and regularly update international standards for vessels operating in the Arctic. These efforts include:

---Support the updating and the mandatory application of relevant parts of the *Guidelines for Ships Operating in Arctic Ice-covered Waters* (Arctic Guidelines); and,

---Drawing from IMO instruments, in particular the Arctic Guidelines, augment global IMO ship safety and pollution prevention conventions with specific mandatory requirements or other provisions for ship construction, design, equipment, crewing, training and operations, aimed at safety and protection of the Arctic environment.

C. Uniformity of Arctic Shipping Governance: That the Arctic states should explore the possible harmonization of Arctic marine shipping regulatory regimes within their own jurisdiction and uniform Arctic safety and environmental protection regulatory regimes, consistent with UNCLOS, that could provide a basis for protection measures in regions of the central Arctic Ocean beyond coastal state jurisdiction for consideration by the IMO.

D. Strengthening Passenger Ship Safety in Arctic Waters: That the Arctic states should support the application of the IMO's *Enhanced Contingency Planning Guidance for Passenger Ships Operating in Areas Remote from SAR Facilities*, given the extreme challenges associated with rescue operations in the remote and cold Arctic region; and strongly encourage cruise ship operators to develop, implement and share their own best practices for operating in such conditions, including consideration of measures such as timing voyages so that other ships are within rescue distance in case of emergency.

E. Arctic Search and Rescue (SAR) Instrument: That the Arctic states decide to support developing and implementing a comprehensive, multi-national Arctic Search and Rescue (SAR) instrument, including aeronautical and maritime SAR, among the eight Arctic nations and, if appropriate, with other interested parties in recognition of the remoteness and limited resources in the region.

II. PROTECTING ARCTIC PEOPLE AND THE ENVIRONMENT

A. Survey of Arctic Indigenous Marine Use: That the Arctic states should consider conducting surveys on Arctic marine use by indigenous communities where gaps are identified to collect information for establishing up-to-date baseline data to assess the impacts from Arctic shipping activities.

B. Engagement with Arctic Communities: That the Arctic states decide to determine if effective communication mechanisms exist to ensure engagement of their Arctic coastal communities and, where there are none, to develop their own mechanisms to engage and coordinate with the shipping industry, relevant economic activities and Arctic communities (in particular during the planning phase of a new marine activity) to increase benefits and help reduce the impacts from shipping.

C. Areas of Heightened Ecological and Cultural Significance: That the Arctic states should identify areas of heightened ecological and cultural significance in light of changing climate conditions and increasing multiple marine use and, where appropriate, should encourage implementation of measures to protect these areas from the impacts of Arctic marine shipping, in coordination with all stakeholders and consistent with international law.

D. Specially Designated Arctic Marine Areas: That the Arctic states should, taking into account the special characteristics of the Arctic marine environment, explore the need for internationally designated areas for the purpose of environmental protection in regions of the Arctic Ocean. This could be done through the use of appropriate tools, such as "Special Areas" or Particularly Sensitive Sea Areas (PSSA) designation through the IMO and consistent with the existing international legal framework in the Arctic.

E. Protection from Invasive Species: That the Arctic states should consider ratification of the IMO International Convention for the Control and Management of Ships Ballast Water and Sediments, as soon as practical. Arctic states should also assess the risk of introducing invasive species through ballast water and other means so that adequate prevention measures can be implemented in waters under their jurisdiction.

F. Oil Spill Prevention: That the Arctic states decide to enhance the mutual cooperation in the field of oil spill prevention and, in collaboration with industry, support research and technology transfer to prevent release of oil into Arctic waters, since prevention of oil spills is the highest priority in the Arctic for environmental protection.

G. Addressing Impacts on Marine Mammals: That the Arctic states decide to engage with relevant international organizations to further assess the effects on marine mammals due to ship noise, disturbance and strikes in Arctic waters; and consider, where needed, to work with the IMO in developing and implementing mitigation strategies.

H. Reducing Air Emissions: That the Arctic states decide to support the development of improved practices and innovative technologies for ships in port and at sea to help reduce current and future emissions of greenhouse gases (GHGs), Nitrogen Oxides (NOx), Sulfur Oxides (SOx) and Particulate Matter (PM), taking into account the relevant IMO regulations.

III. BUILDING THE ARCTIC MARINE INFRASTRUCTURE

A. Addressing the Infrastructure Deficit: That the Arctic states should recognize that improvements in Arctic marine infrastructure are needed to enhance safety and environmental protection in support of sustainable development. Examples of infrastructure where critical improvements are needed include: ice navigation training; navigational charts; communications systems; port services, including reception facilities for ship-generated waste; accurate and timely ice information (ice centers); places of refuge; and icebreakers to assist in response.

B. Arctic Marine Traffic System: That the Arctic states should support continued development of a comprehensive Arctic marine traffic awareness system to improve monitoring and tracking of marine activity, to enhance data sharing in near real-time, and to augment vessel management service in order to reduce the risk of incidents, facilitate response and provide awareness of potential user conflict. The Arctic states should encourage shipping companies to cooperate in the improvement and development of national monitoring systems.

C. Circumpolar Environmental Response Capacity: That the Arctic states decide to continue to develop circumpolar environmental pollution response capabilities that are critical to protecting the unique Arctic ecosystem. This can be accomplished, for example, through circumpolar cooperation and agreement(s), as well as regional bilateral capacity agreements.

D. Investing in Hydrographic, Meteorological and Oceanographic Data: That the Arctic states should significantly improve, where appropriate, the level of and access to data and information in support of safe navigation and voyage planning in Arctic waters. This would entail increased efforts for: hydrographic surveys to bring Arctic navigation charts up to a level acceptable to support current and future safe navigation; and systems to support real-time acquisition, analysis and transfer of meteorological, oceanographic, sea ice and iceberg information.

APPENDIX 2: Workshop Agenda & Presentations

THURSDAY, OCTOBER 22, 2009

9:00 am **Welcome**
- Mike Sfraga, Director, UA Geography Program, Associate Dean, School of Natural Resources and Agricultural Sciences
- Brian Rogers, Chancellor, University of Alaska Fairbanks
- Mead Treadwell, Chairman, United States Arctic Research Commission
- Denise Michels, Inuit Circumpolar Council Representative, Mayor of Nome
- Lars Kullerud, President, University of the Arctic
- Ross Virginia, Director, Institute of Arctic Studies, Dartmouth College

9:45 am **Opening Presentations**
- *Economic Development, Community Sustainability, and Future Arctic Marine Use,* Denise Michels, Mayor of Nome, Vice President Kawerak Native Corporation, ICC Representative
- *Arctic Climate Modeling,* Scott Rupp and John Walsh, University of Alaska Fairbanks
- *Research Challenges in the Arctic Ocean – The Marine Mammal Protection Act and Geophysical Research,* Bernard Coakley, University of Alaska Fairbanks
- *Outcomes of the Arctic Marine Shipping Assessment,* Lawson Brigham, University of Alaska Fairbanks and Chair, AMSA

12:00 pm **Lunch**
- *The International Maritime Organization's Arctic Initiatives,* Victor Santos-Pedro, Transport Canada

1:30 pm **Charge to the Working Groups:** Mike Sfraga, Lawson Brigham, Ben Ellis
Outline Major Issues/Questions; Introduce Working Group Leads

2-5:00 pm **Working Groups and Leads in Session,** I. Enhancing Arctic Marine Safety , II. Protecting Arctic People and the Environment, and III. Building the Arctic Marine Infrastructure

6:30 pm **Welcome Dinner and Presentation**
- North by 2020: Hajo Eicken, Professor of Geophysics and Amy Lovecraft, Associate Professor of Political Science, University of Alaska Fairbanks

FRIDAY, OCTOBER 23, 2009

9:00 am **Working Group Leads Report to Participants and Discussion:** Lawson Brigham

10:00 am **Working Groups Reconvene**

12:00 pm **Lunch**
- *Governance Issues in the Arctic Ocean* – Betsy Baker, Vermont Law School and Dartmouth College
- *Regulating Arctic Ships and Operations* - Des Upcraft, Lloyd's Register, UK

1:30-5 pm **Working Groups Reconvene**

6:30 pm **Chancellor's Reception** – Sponsored by Holland America Lines
University of Alaska Museum of the North, Entertainment: Pavva Inupiaq Dancers
***Buses Depart Princess Lodge at 6:00 pm** ***Buses Depart Museum at 8:30 pm**

SATURDAY, OCTOBER 24, 2009

9:00 am **Working Groups Reconvene:** Mike Sfraga, Lawson Brigham

12:00 pm **Lunch**
- *Monitoring Ships in the Alaskan Arctic* – John Adams, Marine Exchange of Alaska

1:00 pm **Working Group Reports:** Group Leads, 30 minutes per group

3:00 pm **Synthesis Activity**

3:30 pm **Program Reflection, Next Steps**
- Draft document prepared
- Schedule for Report Writing, Participant Distribution, Editing, etc.
- Timing and plans for Report Distribution, etc.

APPENDIX 3: Workshop Participants

Michael Baffrey	U.S. Department of Interior, Alaska
Betsy Baker	Vermont Law School and Dartmouth College
Lawson Brigham	University of Alaska Fairbanks and AMSA Chair / Workshop Co-Leader & Report Co-Editor
Pablo Clemente-Colon	U.S. National Ice Center
Bernard Coakley	University of Alaska Fairbanks
Craig Dorman	University of Alaska
Hajo Eicken	University of Alaska Fairbanks
Ben Ellis	Ben Ellis & Company / Workshop Co-Leader
Pierre-Andres Forest	University of the Arctic
Victoria Gofman	Aleut International Association
Larry Hartig	Commissioner, Alaska State Department of Environmental Conservation
William Hill	Crowley Marine Services, Anchorage
Rob Huebert	University of Calgary
Layla Hughes	WWF-Alaska
Henry Huntington	PEW Environment Group
Michael Inman	U.S. Coast Guard Seventeenth District, Juneau
David Jackson	Canadian Coast Guard / Leader, Workshop Working Group III
Jay Jerome	U.S. Coast Guard Sector, Anchorage
John Kaighin	Shell Exploration & Production Company, Anchorage
John Kelley	University of Alaska Fairbanks
Katie Kennedy	University of Alaska Fairbanks
Hiromitsu Kitagawa	Ocean Policy Research Foundation, Tokyo, Japan
Pia Kohler	University of Alaska Fairbanks
Lars Kullerud	President, University of the Arctic
Denny Lassuy	U.S. North Slope Science Initiative, Anchorage
Thomas Laughlin	International Union for Conservation of Nature, Washington, DC
Carol Lewis	University of Alaska Fairbanks
Patrick Lewis	WWF Arctic, Oslo, Norway
Amy Lovecraft	University of Alaska Fairbanks
Ken MacInnis	Marine and Environmental Law Institute, Dalhousie University, Halifax, Canada
Molly McCammon	Alaska Ocean Observing System, Anchorage
Earl McDowell	U.S. Navy
Elizabeth McLanahan	U.S. National Oceanic & Atmospheric Administration, Washington, DC
Denise Michels	Mayor of Nome, Alaska
Sharry Miller	Alaska State Department of Environmental Conservation
Sherry Modrow	University of Alaska Fairbanks
William Morani Jr.	Holland America Lines, Seattle
Tom Moyer	Office of U.S. Senator Mark Begich of Alaska
Patricia Opheen	U.S. Army Corps of Engineers, Alaska
Bob Pawlowski	Denali Commission, Anchorage / Co-Leader, Workshop Working Group II
Jackie Poston	Alaska State Department of Environmental Conservation
Brian Rogers	Chancellor, University of Alaska Fairbanks
Tracy Rogers	University of Alaska Fairbanks
Cheryl Rosa	U.S. Arctic Research Commission
Scott Rupp	University of Alaska Fairbanks
Warren Sanamo Jr.	Edison Chouest Offshore, Galliano, Louisiana
Victor Santos-Pedro	Transport Canada, Ottawa and AMSA Co-lead / Leader, Workshop Working Group I
Mike Sfraga	University of Alaska Fairbanks / Workshop Co-Leader & Report Co-Editor
Virgil "Buck" Sharpton	University of Alaska Fairbanks
Per Sønderstrup	Danish Maritime Authority, Copenhagen, Denmark
Wanda Tangermann	University of Alaska Fairbanks
Nancy Tarnai	University of Alaska Fairbanks
Michael Terminel	Edison Chouest Offshore, Anchorage
Dennis Thurston	U.S. Minerals Management Service, Alaska Region
Mead Treadwell	Chairman, U.S. Arctic Research Commission
Carl Uchytil	U.S. Coast Guard Seventeenth District, Juneau, Alaska
Des Upcraft	Lloyd's Register, London, United Kingdom
Ross Virginia	Dartmouth College
John Walsh	University of Alaska Fairbanks
Hanling Wang	Chinese Academy of Social Sciences, Beijing
John Whitney	U.S. National Oceanic & Atmospheric Administration, Anchorage
Denis Wiesenburg	University of Alaska Fairbanks
Margaret Williams	WWF-Alaska / Co-Leader, Workshop Working Group II
Shiji Xu	Chinese Arctic and Antarctic Administration, Beijing

Acronyms

AECO ~ Association of Arctic Expedition Cruise Operators
AIS ~ Automated Identification System
AMSA ~ Arctic Marine Shipping Assessment
CLIA ~ Cruise Lines International Association
EEZ ~ Exclusive Economic Zone
EPPR ~ Emergency Prevention, Preparedness and Response
HACCP ~ Hazard Analysis and Critical Control Points
IAATO ~ International Association of Antarctica Tour Operators
IACP ~ Institute for Applied Circumpolar Policy
IACS ~ International Association of Classification Societies
ILO ~ International labor Organization
IMO ~ International Maritime Organization
IPY ~ International Polar Year (2007-08)
IWC ~ International Whaling Commission
LNG ~ Liquefied Natural Gas
MARPOL ~ International Convention for the Prevention of Pollution from Ships
NGO ~ Non-governmental Organization
PAME ~ Protection of the Arctic Marine Environment
PSSA ~ Particularly Sensitive Sea Area
R&D ~ Research and Development
SAR ~ Search and Rescue
SDWG ~ Sustainable Development Working Group
SOLAS ~ International Convention for the Safety of Life at Sea
STCW ~ International Convention on Standards of Training, Certification and Watchkeeping for Seafarers
UAF ~ University of Alaska Fairbanks
UArctic ~ University of the Arctic
UNCLOS ~ United Nations Convention on the Law of the Sea
WMO ~ World Meteorological Organization

The United Nations Convention on the Law of the Sea lays down a comprehensive regime of law and order in the world's oceans and seas establishing rules governing all uses of the oceans and their resources. It enshrines the notion that all problems of ocean space are closely interrelated and need to be addressed as a whole.

The Convention was opened for signature on 10 December 1982 in Montego Bay, Jamaica. This marked the culmination of more than 14 years of work involving participation by more than 150 countries representing all regions of the world, all legal and political systems and the spectrum of socio/economic development. At the time of its adoption, the Convention embodied in one instrument traditional rules for the uses of the oceans and at the same time introduced new legal concepts and regimes and addressed new concerns. The Convention also provided the framework for further development of specific areas of the law of the sea.

The Convention entered into force in accordance with its article 308 on 16 November 1994, 12 months after the date of deposit of the sixtieth instrument of ratification or accession. Today, it is the globally recognized regime dealing with all matters relating to the law of the sea.

The Convention (full text) comprises 320 articles and nine annexes, governing all aspects of ocean space, such as delimitation, environmental control, marine scientific research, economic and commercial activities, transfer of technology and the settlement of disputes relating to ocean matters.

Some of the key features of the Convention are the following:

* Coastal States exercise sovereignty over their territorial sea which they have the right to establish its breadth up to a limit not to exceed 12 nautical miles; foreign vessels are allowed "innocent passage" through those waters;
* Ships and aircraft of all countries are allowed "transit passage" through straits used for international navigation; States bordering the straits can regulate navigational and other aspects of passage;
* Archipelagic States, made up of a group or groups of closely related islands and interconnecting waters, have sovereignty over a sea area enclosed by straight lines drawn between the outermost points of the islands; the waters between the islands are declared archipelagic waters where States may establish sea lanes and air routes in which all other States enjoy the right of archipelagic passage through such designated sea lanes;
* Coastal States have sovereign rights in a 200-nautical mile exclusive economic zone (EEZ) with respect to natural resources and certain economic activities, and exercise jurisdiction over marine science research and environmental protection;
* All other States have freedom of navigation and overflight in the EEZ, as well as freedom to lay submarine cables and pipelines;
* Land-locked and geographically disadvantaged States have the right to participate on an equitable basis in exploitation of an appropriate part of the surplus of the living resources

of the EEZ's of coastal States of the same region or sub-region; highly migratory species of fish and marine mammals are accorded special protection;
* Coastal States have sovereign rights over the continental shelf (the national area of the seabed) for exploring and exploiting it; the shelf can extend at least 200 nautical miles from the shore, and more under specified circumstances;
* Coastal States share with the international community part of the revenue derived from exploiting resources from any part of their shelf beyond 200 miles;
* The Commission on the Limits of the Continental Shelf shall make recommendations to States on the shelf's outer boundaries when it extends beyond 200 miles;
* All States enjoy the traditional freedoms of navigation, overflight, scientific research and fishing on the high seas; they are obliged to adopt, or cooperate with other States in adopting, measures to manage and conserve living resources;
* The limits of the territorial sea, the exclusive economic zone and continental shelf of islands are determined in accordance with rules applicable to land territory, but rocks which could not sustain human habitation or economic life of their own would have no economic zone or continental shelf;
* States bordering enclosed or semi-enclosed seas are expected to cooperate in managing living resources, environmental and research policies and activities;
* Land-locked States have the right of access to and from the sea and enjoy freedom of transit through the territory of transit States;
* States are bound to prevent and control marine pollution and are liable for damage caused by violation of their international obligations to combat such pollution;
* All marine scientific research in the EEZ and on the continental shelf is subject to the consent of the coastal State, but in most cases they are obliged to grant consent to other States when the research is to be conducted for peaceful purposes and fulfils specified criteria;
* States are bound to promote the development and transfer of marine technology "on fair and reasonable terms and conditions", with proper regard for all legitimate interests;
* States Parties are obliged to settle by peaceful means their disputes concerning the interpretation or application of the Convention;
* Disputes can be submitted to the International Tribunal for the Law of the Sea established under the Convention, to the International Court of Justice, or to arbitration. Conciliation is also available and, in certain circumstances, submission to it would be compulsory. The Tribunal has exclusive jurisdiction over deep seabed mining disputes.

A Historical Perspective

The oceans had long been subject to the freedom of-the-seas doctrine - a principle put forth in the seventeenth century essentially limiting national rights and jurisdiction over the oceans to a narrow belt of sea surrounding a nation's coastline. The remainder of the seas was proclaimed to be free to all and belonging to nc While this situation prevailed into the twentieth century, by mid-century there was an impetus to extend national claims over offshore resources. There was growi concern over the toll taken on coastal fish stocks by long-distance fishing fleets and over the threat of pollution and wastes from transport ships and oil tankers ca noxious cargoes that plied sea routes across the globe. The hazard of pollution was ever present, threatening coastal resorts and all forms of ocean life. The navies maritime powers were competing to maintain a presence across the globe on the surface waters and even under the sea.

A tangle of claims, spreading pollution, competing demands for lucrative fish stocks in coastal waters and adjacent seas, growing tension between coastal nation rights to these resources and those of distant-water fishermen, the prospects of a rich harvest of resources on the sea floor, the increased presence of maritime pow and the pressures of long-distance navigation and a seemingly outdated, if not inherently conflicting, freedom-of-the-seas doctrine - all these were threatening to transform the oceans into another arena for conflict and instability.

In 1945, President Harry S Truman, responding in part to pressure from domestic oil interests, unilaterally extended United States jurisdiction over all natural resources on that nation's continental shelf - oil, gas, minerals, etc. This was the first major challenge to the freedom-of-the-seas doctrine. Other nations soon follo suit.

In October 1946, Argentina claimed its shelf and the epicontinental sea above it. Chile and Peru in 1947, and Ecuador in 1950, asserted sovereign rights over a 2 mile zone, hoping thereby to limit the access of distant-water fishing fleets and to control the depletion of fish stocks in their adjacent seas.

Soon after the Second World War, Egypt, Ethiopia, Saudi Arabia, Libya, Venezuela and some Eastern European countries laid claim to a 12-mile territorial se clearly departing from the traditional three-mile limit.

Later, the archipelagic nation of Indonesia asserted the right to dominion over the water that separated its 13,000 islands. The Philippines did likewise. In 1970, Canada asserted the right to regulate navigation in an area extending for 100 miles from its shores in order to protect Arctic water against pollution.

From oil to tin, diamonds to gravel, metals to fish, the resources of the sea are enormous. The reality of their exploitation grows day by day as technology opens ways to tap those resources.

In the late 1960s, oil exploration was moving further and further from land, deeper and deeper into the bedrock of continental margins. From a modest beginni 1947 in the Gulf of Mexico, offshore oil production, still less than a million tons in 1954, had grown to close to 400 million tons. Oil drilling equipment was already as far as 4,000 metres below the ocean surface.

The oceans were being exploited as never before. Activities unknown barely two decades earlier were in full swing around the world. Tin had been mined in the shallow waters off Thailand and Indonesia. South Africa was about to tap the Namibian coast for diamonds. Potato-shaped nodules, found almost a century earlie lying on the seabed some five kilometres below, were attracting increased interest because of their metal content.

And then there was fishing. Large fishing vessels were roaming the oceans far from their native shores, capable of staying away from port for months at a time. Fish stocks began to show signs of depletion as fleet after fleet swept distant coastlines. Nations were flooding the richest fishing waters with their fishing fleets virtually unrestrained: coastal States setting limits and fishing States contesting them. The so-called "Cod War" between Iceland and the United Kingdom had brought about the spectacle of British Navy ships dispatched to rescue a fishing vessel seized by Iceland for violating its fishing rules.

Offshore oil was the centre of attraction in the North Sea. Britain, Denmark and Germany were in conflict as to how to carve up the continental shelf, with its rich oil resources.

It was late 1967 and the tranquillity of the sea was slowly being disrupted by technological breakthroughs, accelerating and multiplying uses, and a super-Power rivalry that stood poised to enter man's last preserve - the seabed.

It was a time that held both dangers and promises, risks and hopes. The dangers were numerous: nuclear submarines charting deep waters never before explored; designs for antiballistic missile systems to be placed on the seabed; supertankers ferrying oil from the Middle East to European and other ports, passing through congested straits and leaving behind a trail of oil spills; and rising tensions between nations over conflicting claims to ocean space and resources.

The oceans were generating a multitude of claims, counterclaims and sovereignty disputes.

The hope was for a more stable order, promoting greater use and better management of ocean resources and generating harmony and goodwill among States that would no longer have to eye each other suspiciously over conflicting claims.

Third United Nations Conference on the Law of the Sea

On 1 November 1967, Malta's Ambassador to the United Nations, Arvid Pardo, asked the nations of the world to look around them and open their eyes to a looming conflict that could devastate the oceans, the lifeline of man's very survival. In a speech to the United Nations General Assembly, he spoke of the super-Power rivalry that was spreading to the oceans, of the pollution that was poisoning the seas, of the conflicting legal claims and their implications for a stable order and of the rich potential that lay on the seabed.

Pardo ended with a call for "an effective international regime over the seabed and the ocean floor beyond a clearly defined national jurisdiction". "It is the only alternative by which we can hope to avoid the escalating tension that will be inevitable if the present situation is allowed to continue", he said.

Ambassador Tommy Koh, President, UN Convention on the Law of the Sea. *(UN Photo)*

Pardo's urging came at a time when many recognized the need for updating the freedom-of-the-seas doctrine to take into account the technological changes that had altered man's relationship to the oceans. It set in motion a process that spanned 15 years and saw the creation of the United Nations Seabed Committee, the signing of a treaty banning nuclear weapons on the seabed, the adoption of the declaration by the General Assembly that all resources of the seabed beyond the limits of national jurisdiction are the common heritage of mankind and the convening of the Stockholm Conference on the Human Environment. What started as an exercise to regulate the seabed turned into a global diplomatic effort to regulate and write rules for all ocean areas, all uses of the seas and all of its resources? These were some of the factors that led to the convening of the Third United Nations Conference on the Law of the Sea, to write a comprehensive treaty for the oceans.

The Conference was convened in New York in 1973. It ended nine years later with the adoption in 1982 of a constitution for the seas - the United Nations Convention on the Law of the Sea. During those nine years, shuttling back and forth between New York and Geneva, representatives of more than 160 sovereign States sat down and discussed the issues, bargained and traded national rights and obligations in the course of the marathon negotiations that produced the Convention.

- Protection of the Marine Environment
- Marine Scientific Research
- Settlement of Disputes

The Convention

Navigational rights, territorial sea limits, economic jurisdiction, legal status of resources on the seabed beyond the limits of national jurisdiction, passage of ships through narrow straits, conservation and management of living marine resources, protection of the marine environment, a marine research regime and, a more unique feature, a binding procedure for settlement of disputes between States - these are among the important features of the treaty. In short, the Convention is an unprecedented attempt by the international community to regulate all aspects of the resources of the sea and uses of the ocean, and thus bring a stable order to mankind's very source of life.

"Possibly the most significant legal instrument of this century" is how the United Nations Secretary-General described the treaty after its signing. The Convention was adopted as a "Package deal", to be accepted as a whole in all its parts without reservation on any aspect. The signature of the Convention by Governments carries the undertaking not to take any action that might defeat its objects and purposes. Ratification of, or accession to, the Convention expresses the consent of a State to be bound by its provisions. The Convention came into force on 16 November 1994, one year after Guyana became the 60th State to adhere to it.

Across the globe, Governments have taken steps to bring their extended areas of adjacent ocean within their jurisdiction. They are taking steps to exercise their rights over neighbouring seas, to assess the resources of their waters and on the floor of the continental shelf. The practice of States has in nearly all respects been carried out in a manner consistent with the Convention, particularly after its entry into force and its rapid acceptance by the international community as the basis for all actions dealing with the oceans and the law of the sea.

The definition of the territorial sea has brought relief from conflicting claims. Navigation through the territorial sea and narrow straits is now based on legal principles. Coastal States are already reaping the benefits of provisions giving them extensive economic rights over a 200-mile wide zone along their shores. The right of landlocked countries of access to and from the sea is now stipulated unequivocally. The right to conduct marine scientific research is now based on accepted principles and cannot be unreasonably denied. Already established and functioning are the International Seabed Authority, which organize and control activities in the deep seabed beyond national jurisdiction with a view to administering its resources; as well as the International Tribunal for the Law of the Sea, which has competence to settle ocean related disputes arising from the application or interpretation of the Convention.

Wider understanding of the Convention will bring yet wider application. Stability promises order and harmonious development. However, Part XI, which deals with mining of minerals lying on the deep ocean floor outside of nationally regulated ocean areas, in what is commonly known as the international seabed area, had raised many concerns especially from industrialized States. The Secretary-General, in an attempt to achieve universal participation in the Convention, initiated a series of informal consultations among States in order to resolve those areas of concern. The consultations successfully achieved, in July 1998, an Agreement Related to the Implementation of Part XI of the Convention. The Agreement, which is part of the Convention, is now deemed to have paved the way for all States to become parties to the Convention.

Setting Limits

The dispute over who controls the oceans probably dates back to the days when the Egyptians first plied the Mediterranean in papyrus rafts. Over the years and centuries, countries large and small, possessing vast ocean-going fleets or small fishing flotillas, husbanding rich fishing grounds close to shore or eyeing distant harvests, have all vied for the right to call long stretches of oceans and seas their own.

Conflicting claims, even extravagant ones, over the oceans were not new. In 1494, two years after Christopher Columbus' first expedition to America, Pope Alexander VI met with representatives of two of the great maritime Powers of the day - Spain and Portugal - and neatly divided the Atlantic Ocean between them. A Papal Bull gave Spain everything west of the line the Pope drew down the Atlantic and Portugal everything east of it. On that basis, the Pacific and the Gulf of Mexico were acknowledged as Spain's, while Portugal was given the South Atlantic and the Indian Ocean.

Before the Convention on the Law of the Sea could address the exploitation of the riches underneath the high seas, navigation rights, economic jurisdiction, or any other pressing matter, it had to face one major and primary issue - the setting of limits. Everything else would depend on clearly defining the line separating national and international waters. Though the right of a coastal State to complete control over a belt of water along its shoreline - the territorial sea - had long been recognized in international law, up until the Third United Nations Conference on the Law of the Sea, States could not see eye to eye on how narrow or wide this belt should be.

At the start of the Conference, the States that maintained the traditional claims to a three-mile territorial sea had numbered a mere 25. Sixty-six countries had by then claimed a 12-mile territorial sea limit. Fifteen others claimed between 4 and 10 miles, and one remaining major group of eight States claimed 200 nautical miles.

Traditionally, smaller States and those not possessing large, ocean-going navies or merchant fleets favoured a wide territorial sea in order to protect their coastal waters from infringements by those States that did. Naval and maritime Powers, on the other hand, sought to limit the territorial sea as much as possible, in order to protect their fleets' freedom of movement.

As the work of the Conference progressed, the move towards a 12-mile territorial sea gained wider and eventually universal acceptance. Within this limit,

States are in principle free to enforce any law, regulate any use and exploit any resource.

The Convention retains for naval and merchant ships the right of "innocent passage" through the territorial seas of a coastal State. This means, for example, that a Japanese ship, picking up oil from Gulf States, would not have to make a 3,000-mile detour in order to avoid the territorial sea of Indonesia, provided passage is not detrimental to Indonesia and does not threaten its security or violate its laws.

In addition to their right to enforce any law within their territorial seas, coastal States are also empowered to implement certain rights in an area beyond the territorial sea, extending for 24 nautical miles from their shores, for the purpose of preventing certain violations and enforcing police powers. This area, known as the "contiguous zone", may be used by a coast guard or its naval equivalent to pursue and, if necessary, arrest and detain suspected drug smugglers, illegal immigrants and customs or tax evaders violating the laws of the coastal State within its territory or the territorial sea.

The Convention also contains a new feature in international law, which is the regime for archipelagic States (States such as the Philippines and Indonesia, which are made up of a group of closely spaced islands). For those States, the territorial sea is a 12-mile zone extending from a line drawn joining the outermost points of the outermost islands of the group that are in close proximity to each other. The waters between the islands are declared archipelagic waters, where ships of all States enjoy the right of innocent passage. In those waters, States may establish sea lanes and air routes where all ships and aircraft enjoy the right of expeditious and unobstructed passage.

Navigation

Perhaps no other issue was considered as vital or presented the negotiators of the Convention on the Law of the Sea with as much difficulty as that of navigational rights.

Countries have generally claimed some part of the seas beyond their shores as part of their territory, as a zone of protection to be patrolled against smugglers, warships and other intruders. At its origin, the basis of the claim of coastal States to a belt of the sea was the principle of protection; during the seventeenth and eighteenth centuries another principle gradually evolved: that the extent of this belt should be measured by the power of the littoral sovereign to control the area.

In the eighteenth century, the so-called "cannon-shot" rule gained wide acceptance in Europe. Coastal States were to exercise dominion over their territorial seas as far as projectiles could be fired from a cannon based on the shore. According to some scholars, in the eighteenth century the range of land-based cannons was approximately one marine league, or three nautical miles. It is believed that on the basis of this formula developed the traditional three-mile territorial sea limit.

By the late 1960s, a trend to a 12-mile territorial sea had gradually emerged throughout the world, with a great majority of nations claiming sovereignty out to that seaward limit. However, the major maritime and naval Powers clung to a three-mile limit on territorial seas, primarily because a 12-mile limit would effectively close off and place under national sovereignty more than 100 straits used for international navigation.

A 12-mile territorial sea would place under national jurisdiction of riparian States strategic passages such as the Strait of Gibraltar (8 miles wide and the only open access to the Mediterranean), the Strait of Malacca (20 miles wide and the main sea route between the Pacific and Indian Oceans), the Strait of Hormuz (21 miles wide and the only passage to the oil-producing areas of Gulf States) and Bab el Mandeb (14 miles wide, connecting the Indian Ocean with the Red Sea).

At the Third United Nations Conference on the Law of the Sea, the issue of passage through straits placed the major naval Powers on one side and coastal States controlling narrow straits on the other. The United States and the Soviet Union insisted on free passage through straits, in effect giving straits the same legal status as the international waters of the high seas. The coastal States, concerned that passage of foreign warships so close to their shores might pose a threat to their national security and possibly involve them in conflicts among outside Powers, rejected this demand.

Instead, coastal States insisted on the designation of straits as territorial seas and were willing to grant to foreign warships only the right of "innocent passage", a term that was generally recognized to mean passage "not prejudicial to the peace, good order or security of the coastal State". The major naval Powers rejected this concept, since, under international law, a submarine exercising its right of innocent passage, for example, would have to surface and show its flag C an unacceptable security risk in the eyes of naval Powers. Also, innocent passage does not guarantee the aircraft of foreign States the right of overflight over waters where only such passage is guaranteed.

In fact, the issue of passage through straits was one of the early driving forces behind the Third United Nations Conference on the Law of the Sea, when, in early 1967, the United States and the Soviet Union proposed to other Member countries of the United Nations that an international conference be held to deal specifically with the entangled issues of straits, overflight, the width of the territorial sea and fisheries.

The compromise that emerged in the Convention is a new concept that combines the legally accepted provisions of innocent passage through territorial waters and freedom of navigation on the high seas. The new concept, "transit passage", required concessions from both sides.

The regime of transit passage retains the international status of the straits and gives the naval Powers the right to unimpeded navigation and overflight that they had insisted on. Ships and vessels in transit passage, however, must observe international regulations on navigational safety, civilian air-traffic control and prohibition of vessel-source pollution and the conditions that ships and aircraft proceed without delay and without stopping except in distress situations and that they refrain from any threat or use of force against the coastal State. In all matters other than such transient navigation, straits are to be considered part of the territorial sea of the coastal State.

Back to the contents

Exclusive Economic Zone

The exclusive economic zone (EEZ) is one of the most revolutionary features of the Convention, and one which already has had a profound impact on the management and conservation of the resources of the oceans. Simply put, it recognizes the right of coastal States to jurisdiction over the resources of some 38 million square nautical miles of ocean space. To the coastal State falls the right to exploit, develop, manage and conserve all resources - fish or oil, gas or gravel, nodules or sulphur - to be found in the waters, on the ocean floor and in the subsoil of an area extending 200 miles from its shore.

The EEZs are a generous endowment indeed. About 87 per cent of all known and estimated hydrocarbon reserves under the sea fall under some national

jurisdiction as a result. So too will almost all known and potential offshore mineral resources, excluding the mineral resources (mainly manganese nodules and metallic crusts) of the deep ocean floor beyond national limits. And whatever the value of the nodules, it is the other non-living resources, such as hydrocarbons, that represent the presently attainable and readily exploitable wealth.

The most lucrative fishing grounds too are predominantly the coastal waters. This is because the richest phytoplankton pastures lie within 200 miles of the continental masses. Phytoplankton, the basic food of fish, is brought up from the deep by currents and ocean streams at their strongest near land, and by the upwelling of cold waters where there are strong offshore winds.

The desire of coastal States to control the fish harvest in adjacent waters was a major driving force behind the creation of the EEZs. Fishing, the prototypical cottage industry before the Second World War, had grown tremendously by the 1950s and 1960s. Fifteen million tons in 1938, the world fish catch stood at 86 million tons in 1989. No longer the domain of a lone fisherman plying the sea in a wooden dhow, fishing, to be competitive in world markets, now requires armadas of factory-fishing vessels, able to stay months at sea far from their native shores, and carrying sophisticated equipment for tracking their prey.

The special interest of coastal States in the conservation and management of fisheries in adjacent waters was first recognized in the 1958 Convention on Fishing and Conservation of the Living Resources of the High Seas. That Convention allowed coastal States to take "unilateral measures" of conservation on what was then the high seas adjacent to their territorial waters. It required that if six months of prior negotiations with foreign fishing nations had failed to find a formula for sharing, the coastal State could impose terms. But still the rules were disorderly, procedures undefined, and rights and obligations a web of confusion. On the whole, these rules were never implemented.

The claim for 200-mile offshore sovereignty made by Peru, Chile and Ecuador in the late 1940s and early 1950s was sparked by their desire to protect from foreign fishermen the rich waters of the Humboldt Current (more or less coinciding with the 200-mile offshore belt. This limit was incorporated in the Santiago Declaration of 1952 and reaffirmed by other Latin American States joining the three in the Montevideo and Lima Declarations of 1970. The idea of sovereignty over coastal-area resources continued to gain ground.

As long-utilized fishing grounds began to show signs of depletion, as long-distance ships came to fish waters local fishermen claimed by tradition, as competition increased, so too did conflict. Between 1974 and 1979 alone there were some 20 disputes over cod, anchovies or tuna and other species between, for example, the United Kingdom and Iceland, Morocco and Spain, and the United States and Peru.

And then there was the offshore oil.

The Third United Nations Conference on the Law of the Sea was launched shortly after the October 1973 Arab-Israeli war. The subsequent oil embargo and skyrocketing of prices only helped to heighten concern over control of offshore oil reserves. Already, significant amounts of oil were coming from offshore facilities: 376 million of the 483 million tons produced in the Middle East in 1973; 431 million barrels a day in Nigeria, 141 million barrels in Malaysia, 246 million barrels in Indonesia. And all of this with barely 2 per cent of the continental shelf explored. Clearly, there was hope all around for a fortunate discovery and a potential to be protected.

Today, the benefits brought by the EEZs are more clearly evident. Already 86 coastal States have economic jurisdiction up to the 200-mile limit. As a result, almost 99 per cent of the world's fisheries now fall under some nation's jurisdiction. Also, a large percentage of world oil and gas production is offshore. Many other marine resources also fall within coastal-State control. This provides a long-needed opportunity for rational, well-managed exploitation under an assured authority.

Figures on known offshore oil reserves now range from 240 to 300 billion tons. Production from these reserves amounted to a little more than 25 per cent of total world production in 1996. Experts estimate that of the 150 countries with offshore jurisdiction, over 100, many of them developing countries, have medium to excellent prospects of finding and developing new oil and natural gas fields.

It is evident that it is archipelagic States and large nations endowed with long coastlines that naturally acquire the greatest areas under the EEZ regime. Among the major beneficiaries of the EEZ regime are the United States, France, Indonesia, New Zealand, Australia and the Russian Federation.

But with exclusive rights come responsibilities and obligations For example, the Convention encourages optimum use of fish stocks without risking depletion through overfishing. Each coastal State is to determine the total allowable catch for each fish species within its economic zone and is also to estimate its harvest capacity and what it can and cannot itself catch. Coastal States are obliged to give access to others, particularly neighbouring States and land-locked countries, to the surplus of the allowable catch. Such access must be done in accordance with the conservation measures established in the laws and regulations of the coastal State.

Coastal States have certain other obligations, including the adoption of measures to prevent and limit pollution and to facilitate marine scientific research in their EEZs.

Continental Shelf

In ancient times, navigation and fishing were the primary uses of the seas. As man progressed, pulled by technology in some instances and pushing that technology at other times in order to satisfy his needs, a rich bounty of other resources and uses were found underneath the waves on and under the ocean floor - minerals, natural gas, oil, sand and gravel, diamonds and gold. What should be the extent of a coastal State's jurisdiction over these resources? Where and how should the lines demarcating their continental shelves be drawn? How should these resources be exploited? These were among the important questions facing lawyers, scientists and diplomats as they assembled in New York in 1973 for the Third Conference.

Given the real and potential continental shelf riches, there naturally was a scramble by nations to assert shelf rights. Two difficulties quickly arose. States with a naturally wide shelf had a basis for their claims, but the geologically disadvantaged might have almost no shelf at all. The latter were not ready to accept geological discrimination. Also, there was no agreed method on how to define the shelf's outer limits, and there was a danger of the claims to continental shelves being overextended - so much so as to eventually divide up the entire ocean floor among such shelves.

Although many States had started claiming wide continental-shelf jurisdiction since the Truman Proclamation of 1945, these States did not use the term "continental shelf" in the same sense. In fact, the expression became no more than a convenient formula covering a diversity of titles or claims to the seabed and

subsoil adjacent to the territorial seas of States. In the mid-1950s the International Law Commission made a number of attempts to define the "continental shelf" and coastal State jurisdiction over its resources.

In 1958, the first United Nations Conference on the Law of the Sea accepted a definition adopted by the International Law Commission, which defined the continental shelf to include "the seabed and subsoil of the submarine areas adjacent to the coast but outside the area of the territorial sea, to a depth of 200 metres, or, beyond that limit, to where the depth of the superjacent waters admits of the exploitation of the natural resources of the said areas".

Already, as the Third United Nations Conference on the Law of the Sea got under way, there was a strong consensus in favour of extending coastal-State control over ocean resources out to 200 miles from shore so that the outer limit coincides with that of the EEZ. But the Conference had to tackle the demand by States with a geographical shelf extending beyond 200 miles for wider economic jurisdiction.

The Convention resolves conflicting claims, interpretations and measuring techniques by setting the 200-mile EEZ limit as the boundary of the continental shelf for seabed and subsoil exploitation, satisfying the geologically disadvantaged. It satisfied those nations with a broader shelf C about 30 States, including Argentina, Australia, Canada, India, Madagascar, Mexico, Sri Lanka and France with respect to its overseas possessions C by giving them the possibility of establishing a boundary going out to 350 miles from their shores or further, depending on certain geological criteria.

Thus, the continental shelf of a coastal State comprises the seabed and its subsoil that extend beyond the limits of its territorial sea throughout the natural prolongation of its land territory to the outer edge of the continental margin, or to a distance of 200 miles from the baselines from which the territorial sea is measured, where the outer edge of the continental margin does not extend up to that distance.

In cases where the continental margin extends further than 200 miles, nations may claim jurisdiction up to 350 miles from the baseline or 100 miles from the 2,500 metre depth, depending on certain criteria such as the thickness of sedimentary deposits. These rights would not affect the legal status of the waters or that of the airspace above the continental shelf.

To counterbalance the continental shelf extensions, coastal States must also contribute to a system of sharing the revenue derived from the exploitation of mineral resources beyond 200 miles. These payments or contributions - from which developing countries that are net importers of the mineral in question are exempt C are to be equitably distributed among States parties to the Convention through the International Seabed Authority.

To control the claims extending beyond 200 miles, the Commission on the Limits of the Continental Shelf was established to consider the data submitted by the coastal States and make recommendations

Deep Seabed Mining

Deep seabed mining is an enormous challenge that has been compared to standing atop a New York City skyscraper on a windy day, trying to suck up marbles off the street below with a vacuum cleaner attached to a long hose.

Mining will take place at a depth of more than fifteen thousand feet of open ocean, thousands of miles from land. Mining ships are expected to remain on station five years at a time, working without a stop, and to transfer the seabed minerals they bring up to auxiliary vessels.

At the centre of the controversy were potato-sized manganese nodules found on the deep ocean floor and containing a number of important metals and minerals.

On 13 March 1874, somewhere between Hawaii and Tahiti, the crew of the British research vessel HMS *Challenger*, on the first great oceanographic expedition of modern times, hauled in from a depth of 15,600 feet a trawl containing the first known deposits of manganese nodules. Analysis of the samples in 1891 showed the Pacific Ocean nodules to contain important metals, particularly nickel, copper and cobalt. Subsequent sampling demonstrated that nodules were abundant throughout the deep regions of the Pacific.

In the 1950s, the potential of these deposits as sources of nickel, copper and cobalt ore was finally appreciated. Between 1958 and 1968, numerous companies began serious prospecting of the nodule fields to estimate their economic potential. By 1974, 100 years after the first samples were taken, it was well established that a broad belt of sea floor between Mexico and Hawaii and a few degrees north of the equator (the so-called Clarion Clipperton zone) was literally paved with nodules over an area of more than 1.35 million square miles.

In 1970 the United Nations General Assembly declared the resources of the seabed beyond the limits of national jurisdiction to be "the common heritage of mankind". For 12 years from then, up to 1982 when the Convention on the Law of the Sea was adopted, nothing tested so sorely the ability of diplomats from various corners of the world to reach common ground than the goal of conserving that common heritage and profiting from it at the same time.

Back to the contents

The Exploitation Regime

Having established that the resources of the seabed beyond the limits of national jurisdiction are the common heritage of mankind, the framers of the treaty faced the question of who should mine the minerals and under what rules. The developed countries took the view that the resources should be commercially exploited by mining companies in consortia and that an international authority should grant licenses to those companies. The developing countries objected to this view on the grounds that the resource was unique and belonged to the whole of mankind, and that the most appropriate way to benefit from it was for the international community to establish a public enterprise to mine the international seabed area.

Thus, the gamut of proposals ran from a "weak" international authority, noting claims and collecting fees, to a "strong" one with exclusive rights to mine the common heritage area, involving States or private groups only as it saw fit. The solution found was to make possible both the public and private enterprises on one hand and the collective mining on the other - the so-called "parallel system".

This complex system, though simplified to a great degree by the Agreement on Part XI, is administered by the International Seabed Authority, headquartered in Jamaica. The Authority is divided into three principal organs, an Assembly, made up of all members of the Authority with power to set general policy, a council, with powers to make executive decisions, made up of 36 members elected from among the members of the Authority, and a secretariat headed by a secretary-general.

Back to the contents

Technological Prospects

Unfortunately, the road to the market is long, hard and expensive. The nodules lie two to three miles - about 5 kilometres - down, in pitch-black water where pressures exceed 7,000 pounds per square inch and temperatures are near freezing. Many of the ocean floors are filled with treacherous hills and valleys. Appropriate deep-sea mining technology must be developed to accommodate this environment.

Many mining systems have been tried, and some have appeared more promising than others. For a while, hydraulic suction dredge airlifts and a continuous-line bucket system were thought to be a promising answer to the mining dilemma. Another system, the so-called shuttle system, involves sending down a remotely operated, Jules Verne-like vehicle, with television "eyes" and powerful lights, to crawl over the ocean floor, gobble up and crush nodules and resurface with its catch.

Today, the continuous-line bucket system, where empty buckets are lowered to the bottom of the ocean and later raised, partially filled with nodules, has been discarded because of low recovery rates. The shuttle system has been shelved because its operational and investment costs far exceeded the costs of more conventional approaches. However, this system is thought to be the technology of the future. Thus, the current focus is on the hydraulic suction and dredge method. But there are a number of technological problems to be worked out before it will be ready for commercial application.

Keeping a steady ship position, since a vessel cannot anchor 5 kilometres above the sea floor and making sure that the pipe does not snap or that the recovery vehicle is not lost or permanently stuck on the ocean floor are among the many headaches involved in developing the necessary technology for commercial exploitation.

Extracting metals from the nodules is another task altogether. All agree that this phase will be the most expensive, even if only at the initial investment stage. Technologically, however, processing does not pose as much of a challenge as the recovery of manganese nodules. That is because it is thought that the two processing techniques applied to land-derived ores - heat and chemical separation of the metals - will apply just as well to the seabed resources.

Because of their porous nature, recovered nodules retain a great deal of water. Heat processing would therefore require a great amount of energy in order to dry the nodules prior to extracting the metals. It is for that reason that some believe that chemical techniques will prove to be the most efficient and least costly.

Moreover, processing would involve such waste that special barren sites would have to be found to carry out operations. Yet, others believe that the economic viability of seabed mining would be greatly enhanced if a method is devised to process the nodules at sea, saving enormous energy costs involved in the transfer of nodules to land-based processing plants.

Back to the contents

The Question of Universal Participation in the Convention

Prospects for seabed mining depend to a large degree on the market conditions for the metals to be produced from seabed nodules. While one of the driving forces behind the Convention on the Law of the Sea was the prevailing belief in the 1970s that commercial seabed mining was imminent, today the prospects for the inherently expensive process of mining the seabed have greatly receded with changing economic and other conditions since the early 1980s. Indeed, some experts predict that commercial mining operations are not likely to begin until well after the year 2000.

A number of important political and economic changes have taken place in the 10 years that have elapsed since the adoption of the Convention, some directly affecting the deep seabed mining provisions of the Convention, others affecting international relations in general. In the meantime, the prevailing economic prognosis on which the seabed mining regime was built has not been realized.

The Convention on the Law of the Sea holds out the promise of an orderly and equitable regime or system to govern all uses of the sea. But it is a club that one must join in order to fully share in the benefits. The Convention - like other treaties - creates rights only for those who become parties to it and thereby accept its obligations, except for the provisions which apply to all States because they either merely confirm existing customary law or are becoming customary law.

However, as its preamble states, the Convention starts from the premise that the problems of ocean space are closely interrelated and need to be considered as a whole. The desire for a comprehensive Convention arose from the recognition that traditional sea law was disintegrating and that the international community could not be expected to behave in a consistent manner without dialogue, negotiations and agreement.

In this context, it must be underscored that the Convention was adopted as a "package deal", with one aim above all, namely universal participation in the Convention. No State can claim that it has achieved quite all it wanted. Yet every State benefits from the provisions of the Convention and from the certainty that it has established in international law in relation to the law of the sea. It has defined rights while underscoring the obligations that must be performed in order to benefit from those rights. Any trend towards exercising those rights without complying with the corresponding obligations, or towards exercising rights inconsistent with the Convention, must be viewed as damaging to the universal regime that the Convention establishes.

The adoption of the Agreement on Part XI has eliminated this threat. With nearly all States now adhering, even on a provisional basis pending ratification or accession, to the Convention, the threat to the Convention has been eliminated. The Agreement has particularly removed those obstacles which had prevented the industrialized countries from adhering to the Convention. Those same countries have either ratified the Convention or submitted it for their internal legislative procedures. Even more important, is their active participation in the institutions created by the Convention and their strong support for the regime contained in it.

Back to the contents

Pioneer Investors

The Preparatory Commission for the International Seabed Authority and for the International Tribunal for the Law of the Sea was established, prior to the entry into force of the Convention, to prepare for the setting up of both institutions. The Preparatory Commission proceeded with the implementation of an interim regime adopted by the Third United Nations Conference on the Law of the Sea, designed to protect those States or entities that have already made a large investment in seabed mining. This so-called Pioneer Investor Protection regime allows a State, or consortia of mining companies to be sponsored by a State, to be registered as a Pioneer Investor. Registration reserves for the Pioneer Investor a specific mine site in which the registered Investor is allowed to explore for, but

not exploit, manganese nodules. Registered Investors are also obligated to explore a mine site reserved for the Enterprise and undertake other obligations, including the provision of training to individuals to be designated by the Preparatory Commission.

The Preparatory Commission had registered seven pioneer investors: China, France, India, Japan, the Republic of Korea, and the Russian Federation, as well as a consortium known as the Interoceanmetal Joint Organization (IMO). With the Convention in force and the International Seabed Authority being functioning, those pioneer investors will become contractors along the terms contained in the Convention and the Agreement, as well as regulations established by the International Seabed Authority.

Protection of the Marine Environment

Thor Heyerdahl, sailing the Atlantic in his papyrus raft, Ra, found globs of oil, tar and plastics stretching from the coast of Africa to South America. Parts of the Baltic, Mediterranean and Black Sea are already so polluted that marine life is severely threatened. And waste dumped in the Pacific and Atlantic Oceans has washed up on the shores of Antarctica.

In the United States, long stretches of beaches are often closed because of medical and other waste washing up on shore. And every time an oil tanker is involved in an accident, the world's pulse quickens a bit in fear of a major catastrophe, In fact, every time a tanker cleans its tanks at sea, every time a factory channels toxic residues to coastal waters or a city conveniently releases raw sewage into the sea, every time a service station changes the oil of an automobile and pours the waste oil into the sewers, the oceans become a little more polluted. Eventually, scientists fear, the oceans' regenerative capacity will be overwhelmed by the amount of pollution it is subjected to by man. Signs of such catastrophe are clearly observed in many seas—particularly along the heavily populated coasts and enclosed or semi-enclosed seas.

There are six main sources of ocean pollution addressed in the Convention: land-based and coastal activities; continental-shelf drilling; potential seabed mining; ocean dumping; vessel-source pollution; and pollution from or through the atmosphere.

The Convention lays down, first of all, the fundamental obligation of all States to protect and preserve the marine environment. It further urges all States to cooperate on a global and regional basis in formulating rules and standards and otherwise take measures for the same purpose.

Coastal States are empowered to enforce their national standards and anti-pollution measures within their territorial sea. Every coastal State is granted jurisdiction for the protection and preservation of the marine environment of its EEZ. Such jurisdiction allows coastal States to control, prevent and reduce marine pollution from dumping, land-based sources or seabed activities subject to national jurisdiction, or from or through the atmosphere. With regard to marine pollution from foreign vessels, coastal States can exercise jurisdiction only for the enforcement of laws and regulations adopted in accordance with the Convention or for "generally accepted international rules and standards". Such rules and standards, many of which are already in place, are adopted through the competent international organization, namely the International Maritime Organization (IMO).

On the other hand, it is the duty of the "flag State", the State where a ship is registered and whose flag it flies, to enforce the rules adopted for the control of marine pollution from vessels, irrespective of where a violation occurs. This serves as a safeguard for the enforcement of international rules, particularly in waters beyond the national jurisdiction of the coastal State, i.e., on the high seas.

Furthermore, the Convention gives enforcement powers to the "port State", or the State where a ship is destined. In doing so it has incorporated a method developed in other Conventions for the enforcement of treaty obligations dealing with shipping standards, marine safety and pollution prevention. The port State can enforce any type of international rule or national regulations adopted in accordance with the Convention or applicable international rules as a condition for the entry of foreign vessels into their ports or internal waters or for a call at their offshore terminals. This has already become a significant factor in the strengthening of international standards.

Finally, as far as the international seabed area is concerned, the International Seabed Authority, through its Council, is given broad discretionary powers to assess the potential environmental impact of a given deep seabed mining operation, recommend changes, formulate rules and regulations, establish a monitoring programme and recommend issuance of emergency orders by the Council to prevent serious environmental damage. States are to be held liable for any damage caused by either their own enterprise or contractors under their jurisdiction.

With the passage of time, United Nations involvement with the law of the sea has expanded as awareness increases that not only ocean problems but global problems as a whole are interrelated. Already, the 1992 United Nations Conference on Environment and Development (UNCED) held in Rio de Janeiro, Brazil in 1992, placed a great deal of emphasis on the protection and preservation of the oceans' environment in harmony with the rational use and development of their living resources, thus establishing the concept of "sustainable development" embodied in Agenda 21, the programme of action adopted at the Conference.

The necessity to combat the degradation and depletion of fish stocks, both in the zones under national jurisdiction and in the high seas and its causes, such as overfishing and excess fishing capacity, by-catch and discards, has been one of the recurrent topics in the process of implementation of the programme of action adopted in Rio de Janeiro.

In this respect, among the most important outputs of the Conference was the convening of an intergovernmental conference under United Nations auspices with a view to resolving the old conflict between coastal States and distant-water fishing States over straddling and highly migratory fish stocks in the areas adjacent to the 200 nautical-mile exclusive economic zones. This Conference adopted the 1995 Agreement on Straddling Fish Stocks and Highly Migratory Fish Stocks which introduces a number of innovative measures, particularly in the area of environmental and resource protection obliging States to adopt a precautionary approach to fisheries exploitation and giving expanded powers to port States to enforce proper management of fisheries resources.

Back to the contents

Marine Scientific Research

With the extension of the territorial sea to 12 miles and the establishment of the new 200-mile EEZ, the area open to unrestricted scientific research was circumscribed. The Convention thus had to balance the concerns of major research States, mostly developed countries, which saw any coastal-state limitation on research as a restriction of a traditional freedom that would not only adversely affect the advancement of science but also deny its potential benefits to all nations in fields such as weather forecasting and the study of effects of ocean currents and the natural forces at work on the ocean floor.

On the other side, many developing countries had become extremely wary of the possibility of scientific expeditions being used as a cover for intelligence gathering or economic gain, particularly in relatively uncharted areas, scientific research was yielding knowledge of potential economic significance.

The developing countries demanded "prior consent" of a coastal State to all scientific research on the continental shelf and within the EEZ. The developed countries offered to give coastal States "prior notification" of research projects to be carried out on the continental shelf and within the EEZ, and to share any data pertinent to offshore resources.

The final provisions of the Convention represent a concession on the part of developed States. Coastal State jurisdiction within its territorial sea remains absolute. Within the EEZ and in cases involving research on the continental shelf, the coastal State must give its prior consent, However, such consent for research for peaceful purposes is to be granted "in normal circumstances" and "shall not be delayed or denied unreasonably", except under certain specific circumstances identified in the Convention. In case the consent of the coastal State is requested and such State does not reply within six months of the date of the request, the coastal State is deemed to have implicitly given its consent. These last provisions were intended to circumvent the long bureaucratic delays and frequent burdensome differences in coastal State regulations.

Back to the contents

Settlement of Disputes

Provisions for the settlement of disputes arising out of an international treaty are often contained in a separate optional protocol. Parties to the treaty could choose to be bound by those provisions or not by accepting or not accepting the Protocol. The Convention on the Law of the Sea is unique in that the mechanism for the settlement of disputes is incorporated into the document, making it obligatory for parties to the Convention to go through the settlement procedure in case of a dispute with another party.

During the drafting of the Convention, some countries were opposed in principle to binding settlement to be decided by third party judges or arbitrators, insisting that issues could best be resolved by direct negotiations between States without requiring them to bring in outsiders. Others, pointing to a history of failed negotiations and long-standing disputes often leading to a use of force, argued that the only sure chance for peaceful settlement lay in the willingness of States to bind themselves in advance to accept the decisions of judicial bodies.

What emerged from the negotiations was a combination of the two approaches, regarded by many as a landmark in international law.

If direct talks between the parties fail, the Convention gives them a choice among four procedures - some new, some old: submission of the dispute to the International Tribunal for the Law of the Sea, adjudication by the International Court of Justice, submission to binding international arbitration procedures or submission to special arbitration tribunals with expertise in specific types of disputes. All of these procedures involve binding third-party settlement, in which an agent other than the parties directly involved hands down a decision that the parties are committed in advance to respect.

The only exception to these provisions is made for sensitive cases involving national sovereignty. In such circumstances, the parties are obliged to submit their dispute to a conciliation commission, but they will not be bound by any decision or finding of the commission. The moral pressure resulting was argued as being persuasive and adequate to ensure compliance with the findings. The Convention also contains so-called "optional exceptions", which can be specified at the time a country signs, ratifies or accedes to the Convention or at any later time. A State may declare that it chooses not to be bound by one or more of the mandatory procedures if they involve existing maritime boundary disputes, military activities or issues under discussion in the United Nations Security Council.

Disputes over seabed activities will be arbitrated by an 11-member Seabed Disputes Chamber, within the International Tribunal for the Law of the Sea. The Chamber has compulsory jurisdiction over all such conflicts, whether involving States, the International Seabed Authority or companies or individuals having seabed mining contracts.

The United Nations and the Law of the Sea

Throughout the years, beginning with the work of the Seabed Committee in 1968 and later during the nine-year duration of the Third United Nations Conference on the Law of the Sea, the United Nations has been actively engaged in encouraging and guiding the development and eventual adoption of the Law of the Sea Convention. Today, it continues to be engaged in this process, by monitoring developments as they relate to the Convention and providing assistance to States, when called for, in either the ratification or the implementation process.

The goal of the Organization is to help States to better understand and implement the Convention in order to utilize their marine resources in an environment relatively free of conflict and conducive to development, safeguarding the rule of law in the oceans.

In this context, the Division for Ocean Affairs and the Law of the Sea (DOALOS) of the United Nations Office of Legal Affairs helps to coordinate the Organization's activities and programmes in the area of marine affairs. It is active in assisting and advising States in the integration of the marine sector in their development planning. It also responds to requests for information and advice on the legal, economic and political aspects of the Convention and its implications for States. Such information is used by States during the ratification process, in the management of the marine sector of their economies and in the development of a national sea-use policy.

The United Nations also gives assistance to the two newly created institutions - the International Seabed Authority and the International Tribunal for the Law of the Sea.

The Future

The entry into force of the Convention, together with extended jurisdiction, new fields of activity and increased uses of the oceans, will continue to confront all States with important challenges. These challenges will include how to apply the new provisions in accordance with the letter and spirit of the Convention, how to harmonize national legislation with it and how to fulfil the obligations incumbent upon States under the Convention.

Another major challenge will be to provide the necessary assistance, particularly to developing States, in order to allow them to benefit from the rights they

have acquired under the new regime. For example, a great many of the States that have established their EEZs are not at present in a position to exercise all their rights and perform duties under the Convention. The delimitation of EEZ, the surveying of its area, its monitoring, the utilization of its resources and, generally speaking, its management and development are long-term endeavours beyond the present and possibly near-term capabilities of most developing countries.

The United Nations will continue to play a major role in the monitoring of, collection of information on and reporting on State practice in the implementation of the new legal regime. It will also have a significant role to play in reporting on activities of States and relevant international organizations in marine affairs and on major trends and developments. This information will be of great assistance to States in the acceptance and ratification of the Convention, as well as its early entry into force and implementation.

A number of new duties falls upon the Secretary-General of the United Nations. These include the depositing of charts and coordinates showing the maritime limits of coastal States and servicing of the Commission on the Limits of the Continental Shelf The Secretary-General is also called upon to convene meetings of States Parties to elect the members of the International Tribunal for the Law of the Sea and to adopt its budget. Meetings of States Parties may also be called for a Review Conference dealing with the provisions on deep seabed mining or for amending the Convention.

The United Nations will continue to strengthen the cooperation that has developed over the last two decades among the organizations in the United Nations system involved in marine affairs. Such close cooperation would be of great benefit to States, since it would avoid duplication and overlapping of activities. It would also help to coordinate multidisciplinary activities related to the management of marine affairs.

With the passage of time, United Nations involvement with the law of the sea is expected to expand as awareness increases that not only ocean problems but also global problems as a whole are interrelated.

United States Arctic Research Commission Report

US ARCTIC RESEARCH COMMISSION

REPORT ON

GOALS AND OBJECTIVES FOR ARCTIC RESEARCH 2009–2010

FOR THE US ARCTIC RESEARCH PROGRAM PLAN

ABOUT THE US ARCTIC RESEARCH COMMISSION

The US Arctic Research Commission is an independent federal agency created by the Arctic Research and Policy Act (ARPA) of 1984, as amended. It consists of a nonpartisan advisory body of scientists, physicians, indigenous leaders, and industry representatives appointed by the President of the United States and supported by staff located in Washington, DC, and in Anchorage, AK. In addition to establishing the goals in this report, the Commission sets US Arctic research policy and builds cooperative links in Arctic research, from the US Arctic research program, to international partners, and to the State of Alaska. The law requires the Commission to comment to Congress on the progress of the Executive Branch in reaching goals set by the Commission and on their adoption by the Interagency Arctic Research and Policy Committee (IARPC). The Commission plays an active role in the work of several interagency committees, including the Arctic Policy Group, chaired by the US Department of State, which oversees US participation in the eight-nation Arctic Council. The Commission is a statutory member of the North Pacific Research Board and the North Slope Science Initiative, and is a member of various committees of the National Ocean Governance Structure, the interagency Extended Continental Shelf Task Force, the Scientific Ice Expeditions Interagency Committee, involving US Navy nuclear submarines in the Arctic, the Alaska Ocean Observing System, the International Permafrost Association, and the Consortium for Ocean Leadership, among others.

HOW THIS REPORT WAS COMPILED

Under ARPA, the US Arctic Research Commission biennially recommends key goals and objectives for the US Arctic Research Program Plan (hereinafter referred to as the "Plan"). The goals report was released after the Commission collected substantial input from scientific researchers, policymakers, and the public in Alaska, throughout the United States, and in the growing number of nations with Arctic interests. The Commission cosponsored a number of scientific meetings and workshops to help define its research goals and policy, including a June 2009 workshop in Anchorage with the National Institutes of Health's Fogarty International Center, to help understand the basis for the remarkably high rate of behavioral and mental health problems in the Arctic, including suicide, alcoholism, and spousal and child abuse. During the last two years, the Commission led special initiatives and reports, including the *Arctic Marine Shipping Assessment*, an Arctic Council agenda for shipping research, and a white paper on oil spill response research. The Commission occasionally writes "white papers" on other subjects as well, which are posted on the Commission's web site, www.arctic.gov.

WHERE THIS REPORT GOES FROM HERE

Under ARPA, IARPC is charged with revising the nation's five-year Arctic Research Program Plan in order to achieve the goals of this report. The recommendations in this report were conveyed, as required by law, in 2009, and this report elaborates upon those goals as a starting point for IARPC's work to revise the Plan. Federal agencies have been identified to lead revisions under each theme in this goals report and to undertake new initiatives; this report contains specific recommendations for federal agencies and other partners in the US Arctic Research Program. The White House Office of Science and Technology Policy (OSTP) and the Office of Management and Budget (OMB) also play major roles in formulating a federal policy and budgets to carry out the plan adopted in response to this goals report.

During 2010, in preparation for the 2011 goals report, the Commission will work closely with OMB, OSTP, and IARPC member agencies to summarize the work of each agency's Arctic research program, including developing the best possible information on the Plan's current budget, estimated at approximately $400 million per year.

US ARCTIC RESEARCH COMMISSION

REPORT ON

GOALS AND OBJECTIVES FOR ARCTIC RESEARCH 2009–2010

FOR THE US ARCTIC RESEARCH PROGRAM PLAN

Mr. President and Members of Congress:

The Arctic region, and Alaska—America's Arctic—provides tremendous value to the United States. Without a significant Arctic Research Program, however, those things we value in and from the Arctic—energy, food, security, biodiversity, fresh water, carbon sinks, pristine wilderness, more direct transport routes, rich indigenous cultures—cannot contribute as well or be sustained. There is little human activity we know of in the Arctic that is not "knowledge based." The Arctic continues to be rich in mysteries that can only be solved with pioneering, exploration and research. With greater knowledge, the Arctic region can contribute more to both the global economy and the environment. Knowledge about Arctic processes can help protect the world from expensive, unnecessary, and destructive climate change.

The US Arctic Research Commission is pleased to present goals it has established for the nation's Arctic Research Program. In developing these goals, we have listened, widely. We are grateful for the advice we have received from Arctic residents, the American public at large, the State of Alaska, the academic community, federal agencies who manage our Arctic assets, and international partners. Since the basic goals we set here remain the same as those set in 2007, much work has begun at the Interagency Arctic Research Policy Committee to see that this research actually happens. What we present now urges an acceleration of that work, and new emphases to mesh with current national priorities related to energy and climate, ocean policy, health, national and homeland security, and keeping the US competitive in the world economy. To highlight a few:

- Fresh with the completion of the 2007–2009 International Polar Year, the first since 1957, the Arctic science community is better prepared now to establish a sustained Arctic observing network. As the world works to create an effective mitigation scheme to reduce greenhouse gas emissions, monitoring will help us understand potentially overwhelming "feedbacks" in the Arctic that could counter those efforts.

- Federal agencies are paying much more attention to the great health disparities and tragic, alarming youth suicide rates experienced by Arctic residents. We must now begin rigorous research to support US-funded clinical efforts to stem suicide rates in the Arctic. A generation of youth is at risk, and new research initiatives could not be more vital.

- Resource managers are more aware of the need to catalogue all our resources, and to expand efforts to map parts of the Arctic for the first time. These programs, tied with pending US accession to the United Nations Convention on the Law of the Sea, can expand US territory in the Arctic. We must be aware that our neighbors also see the same Arctic opportunities in new territory, expanding fisheries, shipping routes, and oil and gas, and only with an active Arctic presence will the United States help shape new patterns of activity in the Arctic to our liking. When it comes to work related to protection of threatened species, the federal government needs better partnerships with the State of Alaska, indigenous peoples who subsist on these resources, and international partners.

- Federal and state agencies responsible for building infrastructure must direct more research to help Arctic residents adapt to climate change. As the Arctic Ocean becomes more accessible, it is also essential that we meet the promise of the Oil Pollution Act of 1990, and have an oil spill research program that will assure

Arctic residents that meaningful improvements and reduction of risk are underway. The American public pays a tax of eight cents a barrel of oil used to reduce spill risks, yet the government cannot be said to have a competitive research program of the scope we promised ourselves after the Exxon Valdez Oil Spill in 1989.

- An Arctic Ocean baseline science plan will enable the policy goals of ecosystem-based management and marine spatial planning called for by the President's Ocean Policy Task Force. But, appropriate funding is needed for science to provide that essential knowledge from the Arctic Ocean. We also need to work with our neighbors in the Arctic to ensure that we have access for science throughout the Arctic Ocean. Too often in recent years, legitimate science has been denied permission to collect data in vast parts of this ocean, and with new territorial claims in the Arctic, the situation could get worse.

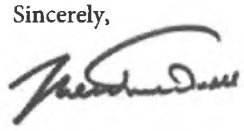
- Finally, we need to light a fire under Arctic research efforts in the humanities: educators, museums, researchers, and native leaders must come together to apply research to the goal of protecting indigenous language, identities, and culture. Without that, we stand to lose huge knowledge—forever—as living generations pass away.

The Commission, the Interagency Arctic Research and Policy Committee, the White House Office of Science and Technology Policy, and the Office of Management and Budget must work together to see that the US Arctic Research Program is better integrated and more transparent, as called for in the Arctic Research and Policy Act of 1984. We are delighted that the United States has, since our recommendation in 2007, reviewed policy at the Presidential level, resulting in US Arctic policy NSPD-66/HSPD-25, and that agencies across the government are paying closer attention to the opportunities and challenges of a newly accessible, rapidly changing Arctic region. It is also good to report that the nation is moving ahead with construction of an Alaska Region Research Vessel, recently named "R/V *Sikuliaq*," funded by the National Science Foundation with stimulus money. Credit is due to many—in the public, the Executive Branch, and the Congress—for making these things happen.

We look forward, soon we hope, to a decision to replace the nation's aging pair of polar icebreakers: with a changed Arctic Ocean, no other platform can provide the nation what it needs for research, law enforcement, environmental protection, emergency response, search and rescue, maritime commerce, national and homeland security.

We thank you for the opportunity to work with some of the most fascinating people in one of the most unique and strategic places on Earth. Our enthusiasm for the Arctic region only grows with what we've been privileged to learn and privileged to do. Godspeed to those who continue to advance the world's knowledge of the Arctic.

Sincerely,



Mead Treadwell, Chair

EXECUTIVE SUMMARY

This report conveys to President Barack Obama, Congress, and the American people the nation's highest-priority goals and objectives for Arctic research. These goals are established by the US Arctic Research Commission (USARC) under the authority of the Arctic Research and Policy Act (ARPA) of 1984, as amended.

THE STRATEGIC ARCTIC

Arctic assets are strategic to our nation. Without a strong Arctic research program, the United States cannot be the best steward of these assets. Arctic research plays a key role in addressing fundamental scientific issues and in helping the nation meet its security needs, its economic aspirations, and its responsibilities as an Arctic nation. Polar research allows the nation to exercise global leadership in adapting to and mitigating climate change.

RESEARCH GOALS

The US Arctic Research Program must strengthen its efforts on five central and crosscutting themes.

1. Environmental Change of the Arctic, Arctic Ocean, and Bering Sea

- With international partners, we must continue to develop and "operationalize" SAON (Sustaining Arctic Observing Network) to gain greater understanding of pan-Arctic change. Relevant entities: NOAA, NSF, DOI, DOD, NSSI, DOS, USCG, NPRB, AOOS, OSRI, and BASC.
- The federal interagency initiative, SEARCH (Study of Environmental ARctic CHange), must further address the causes, and global implications of Arctic sea ice reduction, melting ice sheets and glaciers, ocean acidification, methane flux to the atmosphere, and black carbon deposition. These factors can "make or break" the effectiveness of a global climate change mitigation regime. Relevant entities: NOAA, NSF, DOI, DOD, NSSI, DOS, USCG, NPRB, AOOS, OSRI, and BASC.
- President Obama has indicated that the United States will be a leader in global efforts to mitigate climate change and new national initiatives are underway to bolster US adaptation strategies. Arctic research in these areas needs to be mindful of and a contributor to national and global adaptation and mitigation efforts.
- The "newly accessible" Arctic Ocean is inviting to commercial fishing, shipping, tourism, mineral, and energy extraction interests. The United States has barely begun the baseline oceanographic research necessary to support US and Arctic Council goals for ecosystem-based management in the Arctic Ocean. This research should move ahead, patterned to support "marine spatial planning," a tool that enables integrated, forward-

looking, and consistent decision making on the use of the sea. Relevant entities: NSF, NOAA, NPRB, OSTP, NSTC, CEQ, Federal Ocean Governance Structure, DOT/MARAD, USFWS, DOS, and local subsistence-based co-management groups.

2. Arctic Human Health

- Arctic residents face a number of health issues, but in this report, and as a gateway to other topics, we focus on suicide, given the extraordinarily high and increasing rates. The rate is greatest among indigenous youth, and is higher than in any other select population within our nation. Clinical and community intervention researchers must be brought together to better address this epidemic. The Commission proposes support for the National Academy of Sciences (Institute of Medicine and Polar Research Board) to convene a meeting of health researchers, caregivers, indigenous leaders, and experts from a wide range of disciplines to develop a rigorous, evidence-based, and recurring assessment of scientific research and intervention efforts to reduce suicide and other severe and related behavioral problems, including alcoholism, and spousal and child abuse. To be most effective, this assessment must be repeated every decade to enhance Arctic mental health research, to review intervention results, and to guide the scaling up of successful efforts within Arctic communities.

- Domestic abuse is another serious problem that is over-represented in Alaska's rural communities. It is strongly linked to child abuse and is often associated with alcohol abuse. Women in isolated, rural communities are especially vulnerable. Developing a multidisciplinary, coordinated approach to addressing domestic violence and child abuse is critical to improve Arctic human health and social stability in rural Arctic villages. Behavioral and mental health are just one aspect of Arctic human health; other foci include chronic, infectious, and zoonotic diseases, food safety and contaminants, and diet and lifestyle changes, among others. Relevant entities: DHHS (CDC, NIH, SAMHSA, ACF, IHS, and others) NIMH, tribal organizations (e.g., ANTHC and Southcentral Foundation), and the State of Alaska.

3. Civil Infrastructure

- The State of Alaska has developed an adaptation research agenda to respond to the dramatic effects of climate change. The emerging federal research program in this area should integrate with and support these efforts, which include protecting communities from erosion, and adapting buildings and civil infrastructure to thawing permafrost. Relevant entities: Denali Commission, USACE, DOT, HUD, State of Alaska, and USGS.

- The Interagency Coordinating Committee on Oil Pollution Research (ICCOPR) has not met the promise of the Oil Pollution Act of 1990 (OPA90). The Commission urges a significant new funding stream to support improvements in prevention, response, and remediation of oil spills in ice-covered waters. IARPC and ICCOPR must work together. Relevant entities: USCG, NOAA, OSRI, CRRC, MMS, Navy SupSalv, NIST, EPA, and OSTP.

- The *Arctic Marine Shipping Assessment* (AMSA, 2009), completed by the eight Arctic nations in spring 2009, identifies the research necessary to address the opportunities and challenges of Arctic shipping. IARPC, in conjunction with the Committee on Marine Transportation Systems and USARC, should develop an implementation plan. Relevant entities: DOT, USCG, DOS, NOAA, and the State of Alaska.

- Conventional and renewable energy potential in the Arctic has recently been assessed and is considerable. In 2009, the first comprehensive assessment of Arctic oil and gas deposits revealed that the region accounts for about 13% of the undiscovered oil, 30% of the undiscovered natural gas, and 20% of the undiscovered natural gas liquids in the world (Gautier et al., 2009). On the renewable side, over 90% of the United States' tidal energy potential is in Alaska. The Commission recommends that the Department of Energy prepare an Arctic research plan that addresses the nation's energy security interest in developing Alaska's huge renewable and nonrenewable energy potential for export to the lower 48 states, and that also recognizes the importance of providing affordable energy to Alaska's remote villages. Given the links between energy and the environment, the plan should

also address DOE's climate research interests in the Arctic, such as the Atmospheric Radiation Measurement Program. The Commission further urges continued support for the DOE Arctic Energy Office, with emphasis on methane hydrate research (both onshore and offshore), and on tundra travel research, such as the impacts of water withdrawal from tundra for ice road construction, lake recharge, and ground hardness and elasticity over a range of temperatures. The DOE National Renewable Energy Laboratory has established a research program in Alaska that can examine the substantial wind, wave, tidal, geothermal, and biomass potential for serving the many Arctic communities "off the grid" with stable-cost power, with the possibility of exporting renewable energy from the Arctic. Relevant entities: DOE, DOI/USGS, State of Alaska, USDA, and CCHRC.

4. Natural Resource Assessment and Earth Science

- The Commission applauds the leadership taken by the federal government's interagency Extended Continental Shelf (ECS) Task Force to identify claims that the United States may make to considerably increase its territory in the Arctic Ocean. The Commission has urged Senate ratification of the United Nations Convention on the Law of the Sea. If the United States is not party to this treaty, US scientists may not formally review and assess the claims of other nations in the Arctic. Relevant entities: ECS Task Force agencies, US Congress.

- The Alaska Mineral Resource Assessment Program, required by the Alaska National Interest Lands Conservation Act of 1980, should be funded in core agency budgets.

- Federal and state efforts to cooperate in providing an imagery database and digital elevation model are promising and could be successful in bringing Alaska's maps up to the standard of the rest of the nation. Both federal and state governments are urged to agree upon and fund a coherent plan for mapping the US Arctic that federal and state agencies, the research community, and the public can rely on. Relevant entities: DOD/NGA, DOI/BLM/USGS, State of Alaska, DHS, and NASA.

5. Indigenous Languages, Cultures, and Identities

- The Commission recommends that federal agencies continue, through IARPC, to develop and fund a research plan to help prevent extinction of the diverse languages spoken by Arctic peoples. In two meetings of IARPC principals, a commitment to this goal has been agreed upon. It is time to develop an integrated plan that is funded. Relevant entities: NSF, NEH, SI, BIA, HHS, ED, USDA, the State of Alaska, and Native Alaskan organizations.

RESEARCH INFRASTRUCTURE

To have an effective Arctic research program, the United States must invest in human capital, research platforms, and infrastructure, including new polar class icebreakers, and sustained sea, air, land, space, and social observing systems. The value of Arctic research is based on the quality of its researchers and the support of the public. Our research programs must work hand in hand with educators, support improved Arctic and ocean "literacy," and support training of young scientists with a focus on the Arctic. We must also enhance the educational "pipeline" that renews and sustains the research community examining Arctic problems and helps keep America competitive. The United States must renew international partnerships, strengthen and stabilize competitive funding for academic research, and build closer ties with the Arctic's indigenous residents. Relevant entities: OSTP, NSF, NOAA, NASA, USCG, Navy, and Native Alaskan organizations.

The Commission urges the President and Congress to commit to replacing the nation's two polar class icebreakers. Further, we call upon all agencies involved in Arctic research, through IARPC, to restore support for the Alaska Native Science Commission (ANSC) and the Barrow Arctic Science Consortium (BASC). NSF previously funded these programs to support its own logistics needs, but the benefits of both are enjoyed by many federal agencies that conduct Arctic research. Both served as key vehicles for involving Alaska Natives in the US Arctic Research Program. The Commission also encourages additional US and Japanese government support for the International Arctic Research Center (IARC), which serves as an international nexus for integrating and synthesizing Arctic climate change research. Relevant entities: NSF, DOC/NOAA, USCG, DOS, NASA, DOI, and DOD/USACE.

RESEARCH POLICY

The Arctic Research and Policy Act (ARPA) of 1984, as amended, established Arctic scientific research policy for the United States. This law promises much that has yet to be delivered. USARC, IARPC leadership, and the White House Offices of Science and Technology Policy and Management and Budget must work together, with Congress, to see that Arctic research policy is robust, and is translated into an effective, integrated, and forward-looking national Arctic Research Program Plan and associated budget as promised in ARPA. The new US Arctic policy (NSPD-66/HSPD-25) is a good start, but much work remains.

As called for in the Arctic Research and Policy Act of 1984, the Commission will continue to work for greater cooperation and coordination with other nations and the State of Alaska. Simply put, IARPC needs to meet regularly and produce the integrated plans and reports called for in ARPA.

As the federal government fulfills its responsibilities to manage lands, oceans, wildlife, and resources under its jurisdiction in the Arctic, we urge full funding of the North Slope Science Initiative (NSSI) and the Alaska Ocean Observing System (AOOS) as mechanisms for bringing appropriate stakeholders to the table. Appropriate federal-state scientific cooperation can help avoid expensive lawsuits over matters such as offshore drilling and Endangered Species Act determinations.

Internationally, USARC particularly emphasizes strengthening Arctic science cooperation with Russia. We urge the United States to continue its initiative to assure access to the Arctic Ocean for scientific researchers and to be mindful in its visa and immigration policy of the needs of students and researchers to cross national borders, regularly and predictably, to conduct their work.

USARC intends, as it develops its 2011 goals report, to further discuss and revise US Arctic research policy. Solid efforts are now underway to include local and traditional knowledge in US Arctic research. Support for marine mammal co-management programs will benefit by developing a joint USARC/IARPC research policy. The federal government spends approximately $400 million per year on Arctic research, and the results have helped identify important changes in the Arctic environment, enabling policymakers to respond to them.

The US Arctic Policy (NSPD-66/HSPD-25) has helped agencies identify their roles in America's new Arctic policy. Each of those agencies is likely to find new research needs as a result of those efforts. USARC looks forward to working with IARPC, OMB, and OSTP to bring about the integrated Arctic research program plan and budget called for in the ARPA.

INTRODUCTION

THE STRATEGIC ARCTIC

Arctic assets are strategic to our nation. Without a strong Arctic research program, the United States cannot be the best steward of these assets. Arctic research plays a key role in addressing fundamental scientific issues and in helping the nation meet its security needs, its economic aspirations, and its responsibilities as an Arctic nation. Polar research allows the nation to exercise global leadership in adapting to and mitigating climate change.

America became an Arctic nation in 1867, with the purchase of Alaska. Although Arctic assets such as whale oil and seal fur helped fuel the US economy before 1867, history recounts that bringing Alaska into the United States, and later into the Union, was not without controversy. Many citizens thought that Alaska had no value at all, or, at the time of Statehood, no capability to support itself.

Today, the value of the Arctic is much more evident to Americans. Arctic assets help defend our continent, and are key to the security of European and Asian nations as well. In global commerce, the Arctic region helps feed our nation and the world with its robust fisheries. The Arctic fuels life on three continents with its oil, natural gas, and, increasingly, its huge potential hydro, wave, wind, tidal, geothermal, and biomass resources. Likewise, the Arctic plays a strategic role in global air and sea transport, and telecommunication, and as the Arctic Council's recently completed *Arctic Marine Shipping Assessment* (AMSA, 2009) showed, shipping might play an even greater role in the future.

Life on Earth itself might not exist without the shielding of solar radiation provided by the magnetosphere, created by the North and South magnetic poles. Global climate is moderated by Arctic cold. Polar sea ice and adjacent snow cover on land reflect major amounts of solar radiation back into space, cooling the planet. Boreal forests and permafrost underlying the taiga and tundra are major storehouses of carbon that might, in a warmer climate, be released into the atmosphere, exacerbating warming.

In addition to feeding, powering, defending, and protecting us, Arctic assets inspire us and teach us. From the smallest organisms at the base of the food chain, to the larger seals, birds, walrus, and bears at the top, Arctic living resources are diverse, sought after, and appreciated, and they are a popular tourist attraction. The Arctic's indigenous peoples contribute to global culture and knowledge in ways that are increasingly necessary and valuable. Today's Arctic residents continue to consider themselves pioneers, and are known in popular circles for exploration and discovery, and also in television shows such as the History Channel's "Ice Road Truckers," and the Discovery Channel's "The Deadliest Catch."

These Arctic assets are strategic, useful, and sustainable, but only if they are understood. To this end, the United States and other nations are engaged in research in Arctic science, history, medicine, social science, law, and other disciplines. In this US Arctic Research Commission report, we demonstrate that further, important research is required to better understand and protect our Arctic assets.

RESEARCH GOALS

The US Arctic Research Program must strengthen its efforts on five central and crosscutting themes:

1. *Environmental Change of the Arctic, Arctic Ocean, and Bering Sea*
2. *Arctic Human Health*
3. *Civil Infrastructure*
4. *Natural Resource Assessment and Earth Science*
5. *Indigenous Languages, Cultures, and Identities*

The Commission identified these five themes for the US Arctic Research Program in its 2007 goals report. The Interagency Arctic Research and Policy Committee (IARPC) adopted this report in 2007, and since then, the Commission and IARPC have been working together to revise the US Arctic Research Program's Five Year Plan that is called for in the Arctic Research and Policy Act of 1984, as amended. This plan will have up-to-date, integrated objectives in five areas outlined below. The development of each of these programs is at a different level of maturity. The Commission has modified the environmental change theme to include a new emphasis on the Arctic Ocean, which requires a new plan and commitment of resources.

The dramatic environmental changes occurring in the Arctic, which result from a changing climate, impact all five of these goals. Thus, USARC calls for a commitment to long-term and stable funding of research to ensure that appropriate observations are made in Arctic networks, and that the resulting time-series data are collected, distributed, and analyzed. These data will allow scientists to identify and better understand longer-term trends in climate, and to differentiate them from annual variability in weather. Although NSF and international partners have made progress in designing SAON, a strong need remains for further institutional commitment by NOAA and NASA, among other agencies, to finance and operate the system in the long term within the context of the Global Ocean Observing System and Global Climate Observing System. Such a need, on a broader scale, could be addressed by creating a National Climate Service, analogous to the National Weather Service, as has recently been proposed.

RESEARCH INFRASTRUCTURE

To have an effective Arctic research program, the United States must invest in human capital, research platforms, and infrastructure, including new polar class icebreakers, and sustained sea, air, land, space, and social observing systems. The value of Arctic research is based on the quality of its researchers and the support of the public. Our research programs must work hand in hand with educators, support improved Arctic and ocean "literacy," and support training of young scientists with a focus on the Arctic. We must also enhance the educational "pipeline" that renews and sustains the research community examining Arctic problems and helps keep America competitive. The United States must renew international partnerships, strengthen and stabilize competitive funding for academic research, and build closer ties with the Arctic's indigenous residents. Relevant entities: OSTP, NSF, NOAA, NASA, USCG, Navy, and Native Alaskan organizations.

The Commission finds that the US Arctic Research Program's core asset—its people—needs attention and greater support. Comparing the first half of this decade (2001–2004) with the preceding one (1991–1995), NSF found that although 11% more bachelor's degrees were awarded in the earth, atmospheric, and ocean sciences in the most recent period, the number of doctoral degrees in these fields fell by 11%. Science and engineering doctorate production has depended heavily upon foreign students, who earn 33% of the total science doctorates and more than half of those in engineering (National Science Board, 2006).

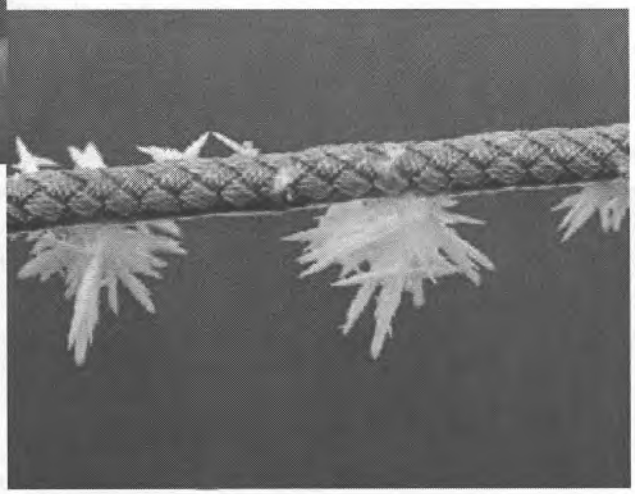
As we complete the International Polar Year (2007–2009), we hope the nation will develop a new generation of polar researchers to carry on this vital work. The Commission calls on federal agencies and Congress to address this goal head on, with clearer, sustainable commitments to extramural funding of Arctic research programs. Outreach and education programs, which saw new initiatives during the International Polar Year, should be continued. Programs such as the Alaska Native Science and Engineering Program (ANSEP) at the University of Alaska help mentor native Alaska Native students of high-school age to join undergraduate and graduate programs at the university level. The Centers for Ocean Science Education Excellence (COSEE), including, COSEE Alaska, also play a critical role in bringing together the ocean sciences research community with educators and the general public, thereby encouraging new collaborations to create and disseminate knowledge, increase public understanding of scientific discovery, and enhance educational opportunities.

The Commission also acknowledges the success of two other programs. The NSF ADVANCE program, designed to recruit and retain women in science and engineering careers within universities, has significantly addressed the gender balance in academia. On an international scale, the Commission acknowledges the success of the Association of Polar Early Career Scientists (APECS). APECS is an international and interdisciplinary organization for young researchers (ranging from undergraduates to early faculty members, educators, and others with interests in polar regions) that stimulates research collaborations and develops leadership by facilitating networking, providing opportunities for professional development, and promoting education and outreach.

In addition to people, Arctic research relies heavily upon infrastructure such as satellites with sophisticated sensor packages, icebreakers with research equipment and laboratories, field stations and laboratories, networks of monitoring stations, buoys and cabled marine observatories, permafrost boreholes and tunnels, and autonomous unmanned vehicles.

Since the Commission's 2007 goals report, significant new investments have been made—or commitments are in place—for a new Alaska Region Research Vessel (R/V *Sikuliaq*), SAON, and new laboratories, including the Barrow Global Climate Change Research Facility on Alaska's North Slope, and NOAA's $51M Ted Stevens Marine Research Institute in Juneau, Alaska.

LEFT. Growlers. (Photo credit: K. Crane)
BELOW. Ice crystals. (Photo credit: M. Dunn)



The US government owns and operates three icebreakers capable of operating in the Arctic Ocean, two of which (*Polar Sea* and *Polar Star*) are considered "polar class." These vessels, essential platforms from which to conduct Arctic research, as well as to conduct many other critical missions, are both over 30 years old, beyond their service lives, and many reports (e.g., NRC, 2007a) have called for them to be replaced. The Chair of the National Academies study, Dr. Anita Jones wrote, "Our committee reaffirmed the value and efficacy of the USCG/research community partnership and recommended replacing the aging icebreakers with new ships, designed with research community involvement. The Coast Guard should be funded to build and operate the new ships" (Jones, 2007). A more recent report, from the Congressional Research Service (O'Rourke, 2009), recommends that Congress do the following:

- Approve the Coast Guard's current plan to study requirements for future icebreakers and then derive an acquisition strategy based on the results of these studies—a plan that might result in an initial replacement icebreaker entering service 8 to 10 years from now.
- Hold hearings to solicit additional information on the issue of polar icebreaker modernization; or direct the Coast Guard to provide such information.
- Direct the Coast Guard to include the option of nuclear power in its studies of requirements and design options for future icebreakers.

The Commission also highlights the need for stronger international and interagency partnerships. In some cases, US-Russian programs are failing due to a lack of high-level commitment and attention, and because of difficulties experienced by scientists in gaining access to certain areas, such as the offshore Russian Exclusive Economic Zone. Although important bilateral research programs exist with many nations, this report highlights the value of improving our joint work with Japan (which has put a strong priority on Arctic research climate change and in methane hydrates), Iceland (whose experience in alternative energy can help the United States achieve climate goals and sustain US Arctic residents), Norway (where government and industry supported oil-in-ice programs are vital to improving the safety of transportation and energy development throughout the Arctic), and Canada (where common work on ocean floor bathymetry and geology are helping both nations prepare extended continental shelf claims under the United Nations Convention on the Law of the Sea).

RESEARCH POLICY

The Arctic Research and Policy Act (ARPA) of 1984, as amended, established Arctic scientific research policy for the United States. This law promises much that has yet to be delivered. USARC, IARPC leadership, and the White House Offices of Science and Technology Policy and Management and Budget must work together, with Congress, to see that Arctic research policy is robust, and is translated into an effective, integrated, and forward-looking national Arctic Research Program Plan and associated budget as promised in ARPA. The new US Arctic policy (NSPD-66/HSPD-25) is a good start, but much work remains.

The Arctic Research and Policy Act requires federal agencies and the White House to present a clear, integrated Arctic research budget to the Congress and the public. The Commission is taking steps to see that this requirement is realized. Greater transparency of our Arctic science programs should quantify the balance between the government's internally conducted science, and that of extramural competitive science—and help the Commission, IARPC, and Congress determine whether that balance should shift.

The Commission calls for a strengthening of IARPC's ties to the National Science and Technology Council. It calls upon the US Coast Guard to reactivate the moribund Interagency Coordinating Committee on Oil Pollution Research (ICCOPR), created by Congress in the Oil Pollution Act of 1990 (OPA90). It calls for continued work on the US Ocean Action Plan, predicated on the work of the US Commission on Ocean Policy, and on the new results from President Obama's Ocean Policy Task Force. And throughout, the Commission urges federal agencies to clearly identify and sustain competitive funding opportunities for the academic research sector, the nation's most vital resource in Arctic research.

With respect to international aspects of Arctic research, the Commission continues to encourage the US Senate to ratify the United Nations Convention on the Law of the Sea and the Stockholm Convention on Persistent Organic Pollutants treaty. The work of the eight-nation Arctic Council has been, and remains, vital to international collaborative efforts on scientific research. The call for research cooperation in the 2008 Ilulissat Declaration, issued by the five Arctic coastal States (United States, Canada, Russia, Norway, and Denmark), is also strongly supported by the Commission. The declaration states:

The five coastal states currently cooperate closely in the Arctic Ocean with each other and with other interested parties. This cooperation includes the collection of scientific data concerning the continental shelf, the protection of the marine environment, and other scientific research. We will work to strengthen this cooperation, which is based on mutual trust and transparency, inter alia, through timely exchange of data and analyses.

Inherent in the ability to conduct international research in the Arctic is the issue of access. If scientists are denied the ability to enter to the Exclusive Economic Zones of Arctic coastal states to conduct marine scientific research, or face insurmountable obstacles associated with national visa and immigration policies, or in the ability to bring equipment into and out of countries, then research is stymied, to the benefit of none. The Commission has witnessed many examples where international cooperation and coordination of Arctic research not only successfully addresses key scientific issues, but also serves as a means of building positive relationships among countries, furthering understanding, and improving diplomacy among nations. The 2004 Arctic Coring Expedition of the international Integrated Ocean Drilling Program is a perfect example.

CONCLUSION

The Commission's 2009–2010 report coincides with the conclusion of the first International Polar Year (IPY) in 50 years. Although the 2007–2008 IPY has drawn to a close, we must continue the research momentum begun during this period. Scientific results are still coming in, and will be reported at upcoming international conferences. Cooperation must be maintained. Infrastructure, as well as knowledge and understanding, must be the IPY legacy.

This Commission strongly endorses President Obama's address to the members of the National Academies, on April 27, 2009, where he called science "more essential for our prosperity, our security, our health, and our environment than it has ever been," and promised to make major investments—more than 3% of the gross domestic product—in research and innovation, exceeding what was invested in 1964, at the height of the space race. He also emphasized the importance of using funds to encourage high-risk, high-return research and to support researchers at the beginning of their careers.

The Commission urges enhanced levels of stable funding, especially for large interdisciplinary research facilities in the Arctic. These facilities form the long-term base of cutting-edge scientific research in these inhospitable areas. Antarctic research has profited from such a base of support for facilities and equipment, allowing initial laboratory analyses of collected samples to be conducted in the field. The Arctic needs a similar US science commitment. Such funding is also needed to remediate the unfunded mandates of several federal agencies, with the notable exception of NSF, to participate in supporting the IPY's legacy. The last Polar Year, which expanded into the International Geophysical Year in 1957, initiated decades of sustained scientific research on Earth processes and provided the data and technologies responsible for revealing the magnitude of our current environmental changes. Sadly, the recently completed IPY is unlikely to repeat this achievement, as the funding not only did not increase, but for many agencies it decreased.

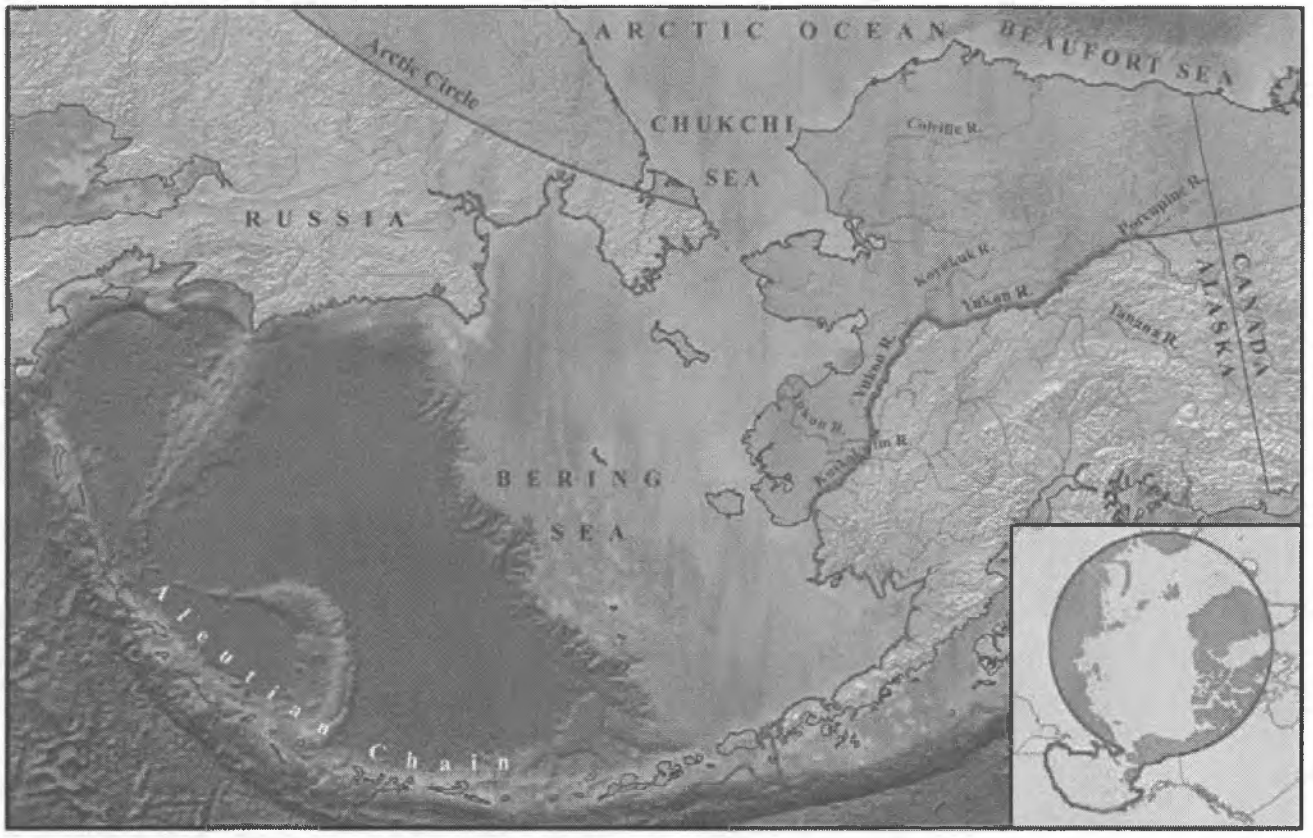
ARCTIC BOUNDARY AS DEFINED BY THE ARCTIC RESEARCH AND POLICY ACT (ARPA)

All United States and foreign territory north of the Arctic Circle and all United States territory north and west of the boundary formed by the Porcupine, Yukon, and Kuskokwim rivers; all contiguous seas, including the Arctic Ocean and the Beaufort, Bering, and Chukchi seas; and the Aleutian chain.[1]



ACKNOWLEDGEMENT: Funding for this map was provided by the National Science Foundation through the Arctic Research Mapping Application (http://armap.org) and Contract #0520837 to CH2M HILL for the Interagency Arctic Research Policy Committee (IARPC).
MAP AUTHOR: Allison Gaylord, Nuna Technologies. May 27, 2009.

MAJOR RESEARCH PROGRAM RECOMMENDATIONS

The US Arctic research program must strengthen its efforts on five central and crosscutting themes.

1. Environmental Change of the Arctic, Arctic Ocean, and Bering Sea
2. Arctic Human Health
3. Civil Infrastructure
4. Natural Resource Assessment and Earth Science
5. Indigenous Languages, Cultures, and Identities

In 2007, the USARC *Report on Goals and Priorities for US Arctic Research* focused on building a robust and effective interagency program based on these five major themes. They span a wide range of basic and applied research topics, from Earth system science, to human health initiatives, to the social sciences, to engineering and technology development. Arctic change and its relation to global climate change is a thread that weaves these five themes together. In 2007, we added theme five—research related to indigenous languages, cultures, and identities. It represents the first research goal brought forward in the Commission's history with a basis in the humanities and social sciences rather than in the physical, biomedical, or geophysical sciences, or in applied engineering.

In 2009, we urge IARPC to continue its work to revise and strengthen the US Arctic Research Program's five-year plan along the same five themes. We applaud IARPC's work to make a new start on themes two through five, and its work to develop SAON as a major contribution to theme one. As noted above, we modified the first theme to include a new emphasis on the Arctic Ocean. In this report, we also recommend a series of new or renewed initiatives under each of the five themes, several of which have a strategic, immediate impact upon the nation. Our recommendations are included below in the discussion of each theme.

1 ENVIRONMENTAL CHANGE OF THE ARCTIC, ARCTIC OCEAN, AND BERING SEA

INITIATIVES RECOMMENDED BY THE COMMISSION

- With international partners, continue to develop and "operationalize" SAON to gain greater understanding of pan-Arctic change.

- SEARCH must further address the troubling lack of understanding of global climate impacts from processes such as Arctic sea ice reduction, melting glaciers and ice sheets, ocean acidification, methane release, and black carbon deposition. These factors can make or break the effectiveness of a global climate change mitigation regime.

- The "newly accessible" Arctic Ocean is inviting to commercial fishing, shipping, tourism, mineral, and energy extraction. The United States has barely started the baseline oceanographic research necessary to support US and Arctic Council goals for ecosystem-based management in the Arctic Ocean. This research should move forward, patterned to support marine spatial planning, a tool that enables integrated, forward-looking and consistent decision making on the use of the sea. Although legislation is pending in Congress to help plan this study effort through a National Research Council process, we urge IARPC to work with its members, the North Pacific Research Board, the Alaska Ocean Observing System (AOOS), and the North Slope Science Initiative (NSSI) to develop a plan and new sources of funding for an Arctic Ocean initiative similar to the Bering Sea Ecosystem Program-Bering Sea Integrated Ecosystems Research Program (BEST-BSIERP), the historic partnership between the National Science Foundation and the North Pacific Research Board. In this vein, the President's Ocean Policy Task Force heard widespread calls for better Arctic Ocean baseline research during its field visit to the Arctic and first regional public meeting in Anchorage, August 18, 2009.

Within the US Arctic Research Program Plan, the largest focus of current work is on understanding climate change. Work in the Arctic has made major contributions to global climate change science, both through the US Climate Change Science Program (CCSP) and the United Nation's Intergovernmental Panel on Climate Change (IPCC). Observing systems established in the Arctic are set to make major data set contributions to the Global Earth Observing System of Systems (GEOSS). Likewise, these observing systems have contributed to and have benefitted from emerging local observing systems and science programs, such as AOOS, NSSI, and the Barrow Environmental Observatory (BEO).

Below, we suggest ways to further improve the process of building SAON and we suggest ways SEARCH can put those observations to work with immediate benefits to global efforts to mitigate climate change.

SUSTAINING ARCTIC OBSERVING NETWORK (SAON)

In April 2007, and in response to the recommendation of this Commission, IARPC called for the development of a government-wide Arctic Observing Network to observe key parameters of Arctic climate and society, and to allow us to begin to understand the causes and consequences of Arctic change. As a basis for this work, in 2006, the National Academy of Sciences prepared a report, *Toward an Integrated Arctic Observing Network* (NRC, 2006). In 2007, with leadership from NOAA and NSF, IARPC prepared a summary, *Arctic Observing Network (AON): Toward a US Contribution to Pan-Arctic Observing* (Jeffries et al., 2007), which reviewed ongoing and future federal Arctic observing activities and developed a strategy to enhance, coordinate, and integrate US observing efforts.

Twice now, foreign ministers of the Arctic Council's eight nations committed support for an international SAON effort; the US participates in an international initiating group to enhance cooperation. The greatest source of extramural funding for US principal investigators to develop projects in support of pan-Arctic observing has been NSF's Office of Polar Programs, which initiated this support prior to the present IPY, and continues it from the core NSF budget and the 2009 economic stimulus package. Enhanced coordination and integration of observing activities, and management of data and information, are now enabling scientists to respond with increased agility to many of the questions posed by SEARCH, IPCC, and others.

RECOMMENDATIONS

The Commission recommends that IARPC make a long-term commitment to an operational SAON. To date, most of the AON/SAON work has been conducted through NSF-funded short-duration research grants, with specifically designed, hypothesis-driven research objectives. For the long-term, AON/SAON needs a "home" and a commitment to provide continuing funding because the power and value of Arctic observations are inherently linked with the consistency and length of time over which they are made. The question of how this enduring effort will be structured and financially supported has yet to be fully answered within the United States, specifically within IARPC, or within the international SAON initiating group. All of the following entities need to be part of the enduring picture: NOAA, NASA, NSF, the State of Alaska, the University of Alaska's facilities, including Toolik Field Station, research programs such as the NPRB, and core interagency efforts in Alaska, such as AOOS, BEO, NSSI, and the Prince William Sound Oil Spill

BELOW. Drilling through ice. (Photo credit: M. Dunn)

Recovery (OSRI). For example, support for AOOS would be a valuable US investment in ocean research and monitoring that would help us understand sea ice variability, cross-shelf ecosystems, and climate change.

To help achieve sustained funding, both in the United States and internationally, AON/SAON organizers need to develop a specific list of gaps in their capability to monitor high-priority science objectives. How many rivers are yet to be gauged for water flow? How many buoys are needed to define Arctic Ocean circulation patterns, sea ice thickness and distribution, and changing atmospheric temperatures and pressures? What new satellites are needed to collect required data sets? The Commission is prepared to advocate funding or partnerships to fill these gaps, when such a list is produced. We recommend that the next revision of the US Arctic Research Plan include specific, hard sensor and data management targets to make capitalization and operating cost targets of the observing network far more transparent.

When fully implemented, AOOS will be able to detect changes in the marine environment, in marine ecosystems, and in living resources. These abilities will be critical in the Arctic, such as in the Bering Strait region and off the North Slope of Alaska. The information from this system will also be used to predict future changes and their consequences. Because of the pivotal role of the Bering Strait in AON and in the nation's ocean monitoring network within the highly productive Bering Sea ecosystem, the Commission stresses the need for long-term support for AOOS as a line item in either the NOAA or ONR budget.

From a scientific standpoint, the Commission further recommends that AON/SAON work closely with predictive modeling efforts, marine spatial planners, and resource and wildlife managers to ensure that the data being collected meet the needs of these downstream users. A working group empaneled by the Commission to look at scaling issues has identified a set of questions to be considered as data collected on a small, local scale are extrapolated to form regional or global predictions. Also, model predictions on large or even global scales need to be modified to provide output on smaller scales. The working group report on scaling issues will be posted at http://www.arctic.gov after publication in 2010.

STUDY OF ENVIRONMENTAL ARCTIC CHANGE (SEARCH)

SEARCH is a comprehensive US national initiative to study Arctic climate change (SEARCH SSC, 2001). To date, it is the most robust interagency program convened by IARPC in response to Commission goals, and the program has made major contributions. Over 70 projects have been funded by several different agencies. These projects are focusing on the nature, extent, and possible future system-scale change in the Arctic environment by observing, understanding, and ultimately responding to environmental change. The science conducted by SEARCH spans terrestrial, oceanic, atmospheric, and social systems in the Arctic. Given the nature of the initiatives, SEARCH and AON are closely linked. Some consider AON the "front-end" observing component of SEARCH, which includes understanding and responding as two major programmatic goals.

SEARCH focuses on four major activities:

- Long-term observations to detect and monitor environmental change
- Modeling to synthesize observations, test hypotheses, and attempt to predict future change
- Process studies to understand the science behind environmental forces, interactions, and feedback
- Helping citizens and governments respond to the impact of change on ecosystems and societies by providing an understanding of what has been learned

Careful planning of SEARCH was required given the broad interdisciplinary science agenda, interagency interests, long time horizon, and international aspects. These program attributes have permitted evolution of a science advisory structure comprised of a committee with three panels: (1) Observing Change, (2) Understanding Change, and (3) Responding to Change. Thus, while the initiative is fundamentally science-driven, it also informs policymakers. The implementation blueprint is presented in *SEARCH: Plans for Implementation During the IPY and Beyond*, published in 2005. Each panel's agenda is distilled into a series of specific tasks and actions:

OBSERVING. Activities include: data rescue; improving observation density, collocation, and integration; improving coverage to close observation gaps; developing optimal observation and sampling strategies; observing key processes and studying feedbacks; acquiring paleoclimate and paleoenvironmental data over critical time periods; developing networks; developing data archival and distribution systems; and using innovative technologies.

Caribou trophies.
(Photo credit: J. Farrell)

UNDERSTANDING. Types of activities include: model-based assimilation of currently available observations; improving and expanding model capabilities; model simulations for forecasting and for guiding observing system design; developing and using of proxy records; diagnostic analyses of synthesized observations and paleoreconstructions; and studying interactions between the Arctic environment and socioeconomic and cultural changes.

RESPONDING. Types of activities include: providing stakeholder-driven guidance to observe and identify useful predictions; interpreting modeling/analysis results in the context of local knowledge; assessing responsiveness and effectiveness of institutions in addressing social and economic concerns about climate change; and developing community-based networks and cooperatives to facilitate these activities.

RECOMMENDATIONS

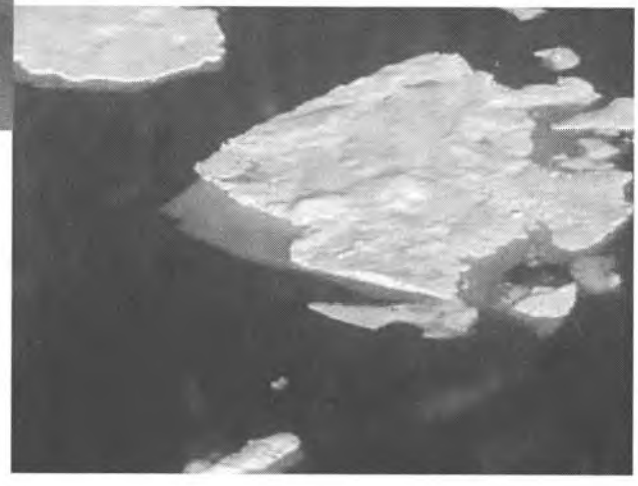
First, expeditiously, SEARCH must further address the lack of understanding of the global climate impacts from Arctic sea ice reduction, melting glaciers and ice sheets, ocean acidification, methane release, and black carbon deposition. These factors significantly impact the effectiveness of any global climate change mitigation regime. These questions gain importance as the United States prepares for future Conferences of the Parties in the United Nations Framework Convention on Climate Change, such as the recently held conference in Copenhagen.

Key science questions include: What is the contribution to Earth's heat budget from lost reflection of Arctic sea ice? Is it true that "Arctic amplification," where temperatures rise in northern latitudes to a much greater degree than global averages, means a large volume of greenhouse gases are set to be released from decomposing organic matter in warming permafrost? If so, will those gases "overpower" any mitigation scheme adopted to reduce anthropogenic greenhouse gas emissions? Do scientific results back up the hypothesis, embodied in the Arctic Council's Task Force on Black Carbon and other short-term forcers of climate change, that reducing methane and black carbon emissions could help slow the retreat of sea ice?

Second, SEARCH is the best example of both the success and the shortcomings of the current coordination process of US Arctic research. Although the Arctic Research and Policy Act requires an integrated Arctic research budget, IARPC, OMB, and OSTP have not produced one. That breach should be rectified, not only to gauge SEARCH's progress toward its objectives, but also to provide greater transparency for this important program. Lacking this information, neither the Commission nor Congress can conclude what kind of further funding is needed.

Third, US agencies supporting climate related research in the Arctic region should make sure that their Arctic programs are integrated with SEARCH. NSSI, NPRB, and AOOS activities, conducted outside direct agency command and control, should also be included. Likewise, SEARCH activities should be clearly recognized and integrated into any upcoming revisions of national climate change science programs and ocean science programs, as well as international, pan-Arctic climate research programs such as the International Study of Arctic Change (ISAC), under the aegis of the International Arctic Science Committee (IASC) and the Arctic Council's Arctic Monitoring and Assessment Program (AMAP).

Fourth, the Commission commends the process used to date by IARPC's lead agency, NSF, to outsource coordination of SEARCH activities to the Arctic Research Consortium of the United States (ARCUS). ARCUS leadership of SEARCH efforts has helped keep extramural climate research (that performed by academic institutions rather than government agencies) strong, and has supported a bottom-up, rather than top-down, process for setting research priorities. We urge the continuation of this leadership model, and its replication, where possible, with IARPC's other thematic



LEFT. Mountains from above. (Photo credit: J. Farrell)
BELOW. Sea ice. (Photo credit: J. Farrell)

programs. It is also critical to engage the private sector, which has commercial interests in the nature of Arctic change, for example, through policy forums and funded research avenues (e.g., Small Business Innovation Research).

Fifth, we urge SEARCH to respond further to the increasing need for more precise modeling of climate change in the Arctic region. Resource management decisions ranging from the Endangered Species Act status of polar bears, oil and gas development, fisheries openings and closures, shipping regulations, and onshore tundra travel, among others, rely on high-quality regional as well as global assessments and predictions.

Sixth, the Commission applauds the active, continuing synthesis and outreach components of SEARCH embodied in the *State of the Arctic Report* (Richter-Menge et al., 2008) and the continuing Arctic Report Card, annual Web-based updates (e.g., Richter-Menge and Overland, 2009). SEARCH findings played an important part of IPY outreach programs as well, and those outreach programs should continue. We recommend regular SEARCH synthesis workshops to help integrate SEARCH efforts across the government.

RUSSIAN-AMERICAN LONG-TERM CENSUS OF THE ARCTIC (RUSALCA)

The RUSALCA program makes long-term observations in US and Russian territorial waters to better understand the causes and consequences of the reduction in sea ice cover in the northern Bering and Chukchi seas. Among the "consequences" is the rapid change in the marine ecosystem that is being observed, coincident with the retreat of sea ice. The program is based on a memorandum of understanding (MOU), beginning in 2003, between NOAA and the Russian Academy of Sciences.

Support for RUSALCA Bering Strait oceanographic moorings (that monitor currents, temperature, salinity, productivity, and nutrients) in Russian and American waters are funded annually by NOAA, NSF, and Russia's Roshydromet. As an integral part of AON, long-term support for these moorings is an essential part of our IPY legacy. Scientific data derived from this effort help us understand how climate change will affect storms in our coastal communities, how marine mammal and fisheries resources will vary, and how transportation needs in the Arctic will evolve.

The RUSALCA program began in summer 2004 with a multidisciplinary cruise on the Russian R/V *Khromov* to investigate seawater-column physics, nutrient chemistry, and biology. Moorings deployed in the western Bering Strait in 2004 have been recovered and redeployed annually. Beginning in 2007, the RUSALCA program has planned joint annual cruises focusing on the physics in the Bering Strait region, and an even more extensive multidisciplinary cruise was carried out in 2009 and will be repeated in 2012. The 2008 field program successfully recovered and redeployed eight moorings across the entire Bering Strait and retrieved oceanographic data confirming a record warm Pacific water flux in 2006 and 2007. On August 22, 2009, the RUSALCA mission embarked from Nome, Alaska, on the R/V *Khromov* for a 40-day voyage into the Bering Strait and northward to the Pacific side of the Arctic Ocean. Due to the severe reduction in sea ice cover, the expedition was able to take the first fish trawl at 77°N above the Chukchi Plateau, about 300 km north of the 2004 northernmost site.

RECOMMENDATION

USARC strongly urges an immediate appropriation of funding to NOAA's Arctic and Ocean Exploration programs, including a line item for the RUSALCA program, to honor the MOU between the governments of Russia and the United States, through NOAA. Failure to regularly fund the American contribution to this joint research effort jeopardizes future access to Russian territorial waters and opportunities to share sampling platforms. Elsewhere in this report, the Commission recommends further work to strengthen US-Russian cooperation in Arctic research.

BERING SEA AND ARCTIC OCEAN ECOSYSTEM STUDIES

In every biennial USARC *Report on Goals and Objectives for Arctic Research* (herein referred to as USARC Goals Report) since 1995, a key priority has been research in the Bering Sea. For several reasons, most related to the greater accessibility and human use of the Arctic Ocean, we expand that priority to include the Arctic Ocean, especially the Chukchi and Beaufort seas off the US coast.

BERING SEA

Information from the Bering Sea research effort helps support management decisions associated with this highly productive ecosystem. The Bering Sea contains vast numbers of marine birds and mammals as well as productive commercial fish and shellfish species that total to more than 50% of all landings (by volume) in the United States. The Bering Sea also provides over 25 million pounds of subsistence foods used by nearly 55,000 Alaskan Native residents, primarily in small rural communities.

Prior USARC goals reports expressed concern about the deficiency of integrating observations and data from many projects and programs, and emphasized our lack of ability to predict changes occurring in the Bering Sea system resulting from natural and human factors. Since then, considerable attention has been directed toward these priorities. Many of the key agencies and institutions that support such research joined in a Bering Sea Interagency Working Group (BIAWG), created by IARPC, which meets annually. BIAWG has drafted a strategy to coordinate and integrate research of the Bering Sea ecosystem and its living marine resources. The working group report (BIAWG, 2006) focused on four core questions:

1. How does the Bering Sea ecosystem respond to climate change and variability?
2. Is the current warming of the Bering Sea due to decadal variability, or a result of a long-term secular trend?
3. Can we predict the effects that the warming and changing sea-ice dynamics will have on the biological resources of the Bering Sea (commercial, subsistence, ecological, and protected)?
4. What measurable factors (physical, chemical, and biological) serve as the best indicators of ecosystem change at different trophic levels and different spatial/temporal scales?

Organizations represented on the BIAWG, their areas of interest or responsibility, and their budgetary commitments are:

- ALASKA OCEAN OBSERVING SYSTEM (NOAA/AOOS) anticipates a Bering Sea monitoring program expenditure of > $1M per year (subject to congressional approval).

- BERING ECOSYSTEM STUDY (BEST, NSF) has $21M of extramural research, including $11M for ship time over four years of expeditions, and resources for a subsequent year of analysis and reporting. During the expeditions, support is budgeted for two to three months of icebreaker time and three to four months of ice-strengthened ship time annually.

- ALASKA FISHERIES SCIENCE CENTER (AFSC, NOAA NMFS) conducts studies mandated by the Magnuson-Stevens Fishery Conservation and Management Act, the National Environmental Policy Act, and the Marine Mammal Protection Act. AFSC conducts routine surveys and assessment studies on Bering Sea living marine resources, including groundfish, rockfish, juvenile salmon, forage fish, crab, Steller sea lion, northern fur seal, harbor seal, ice seal, gray whale, northern right whale, and humpback whale. NOAA provides ship time on its research vessels *Miller Freeman* and *Oscar Dyson*. AFSC scientists are also responsible for two interagency coordinated research efforts:

  - NORTH PACIFIC CLIMATE REGIMES AND ECOSYSTEM PRODUCTIVITY (NPCREP) project (FY07 $2M, FY08 $4M, level funds thereafter) detects and measures ecosystem changes. NPCREP will expand existing, and initiate new, long-term observing sites on the Bering Sea shelf and, upstream, in the Gulf of Alaska.

  - LOSS OF SEA ICE (LOSI), proposed in FY08 ($2M), extends fish assessment surveys farther north, initiates annual assessments for ice-dependent seals, and models the population dynamics of new species that may be managed if fishing is extended northward. Scientists from AFSC, PMEL, and NPRB drafted the LOSI implementation plan with a targeted start date of spring 2009.

- PACIFIC MARINE ENVIRONMENTAL LABORATORY (PMEL, NOAA) PMEL scientists partner with AFSC scientists and compete for NPRB and NOAA grants.

- NORTH PACIFIC RESEARCH BOARD (NPRB) provided $16M in extramural funding for the Bering Sea Integrated Ecosystems Research Program (BSIERP), including funds for ship time for six fiscal years starting in 2007. NPRB anticipates a planning year, three major field seasons during calendar years 2008–2010, and two years of analysis and reporting.

- UNIVERSITY OF ALASKA FAIRBANKS (UAF), School of Fisheries and Ocean Science (SFOS) faculty members, among others in the nation, compete for BEST, NPRB, and NOAA funds to support researches on the Bering Sea ecosystem.

- US FISH AND WILDLIFE SERVICE (USFWS) has management responsibilities for sea otters, Pacific walrus, and polar bears, and manages refuges in and adjacent to the Bering Sea. USFWS is also the trust agency for all migratory birds and regulates and monitors their spring and sport harvest. USFWS also manages threatened, endangered, and at-risk species. USFWS and USGS conduct seabird counts.

- NORTH PACIFIC FISHERIES MANAGEMENT COUNCIL (NPFMC) has implemented an Arctic Fisheries Management Plan that covers the offshore area from 3–200 miles into the Chukchi and Beaufort seas. We recognize the growing contributions of community-based groups earning funds through the North Pacific Fishery Management Council's Community Development Quota (CDQ), and urge their integration into the science program.

- USARC provides advice and makes recommendations to the President and Congress on Arctic research needs.

In 2007, NSF and NPRB formalized a $52M joint management plan for a six-year study of the Bering Sea ecosystem, a partnership to support a comprehensive, vertically integrated study, during 2007–2012, through NSF's BEST and NPRB's BSIERP programs. The plan concentrates research efforts on the eastern Bering Sea shelf between the Aleutian Islands and St. Lawrence Island. NSF provides support for the lower trophic levels, up to and including macrozooplankton and benthic infauna, and supports social science projects focusing on the relationships between a changing marine environment and the adjacent communities. NPRB supports studies of the upper trophic levels, macrozooplankton and benthic fauna, up the food

RIGHT. Kivalina resident. (Photo credit: J. Farrell)

chain to include humans, their communities, and social and economic impacts. Protocols for jointly considering the scientific proposals to the two organizations, as well as coordinated planning efforts and data sharing protocols assure coordinated research.

Recommendations

USARC applauds this ground-breaking cross-agency collaboration between NSF and NPRB, and now urges Congress and NSF to support the alignment and overall synthesis of the BEST and BSIERP programs, such as through an NSF announcement of opportunity, to ensure the greatest return on the initial investment.

In response to a NPRB request for proposals, the North Pacific Marine Science Organization (PICES) released PICES Scientific Report No. 33 (Kruse et al., 2006), which addressed the previously articulated USARC need for research on the ability to predict changes occurring in the Bering Sea from natural and human-induced causes. Some recommendations resulting from the workshop echo concerns shared by USARC, and include:

1. Ecosystem-level and community-level conservation thresholds are relatively new ideas in marine conservation. Because they will require new kinds of indicators, research is needed to develop and apply them in the Bering Sea.

2. New research is needed to understand how to synthesize the large set of Bering Sea data records into a reasonable number of ecosystem status indicators.

3. Enhancements to the ocean/ecosystem monitoring network are needed to fill ecological data gaps at several points (plankton, benthic infauna and epifauna, seasonal species interactions and movements, small pelagics, and cephalopods) to improve predictive models and the development of ecosystem indicators.

4. A healthy relationship between Alaska Native communities and the marine ecosystem requires a high level of attention. Socioeconomic objectives related to the marine environment should be developed for the region, along with their indicators and reference points. Effective solutions will likely require policy that is formulated from the integration of traditional ecological knowledge (TEK) with complementary scientific research from a variety of disciplines, such as biology, ecology, economics, political science, and sociology. Co-management groups funded by NOAA and USFWS, including the Alaska Sea Otter and Sea Lion Commission, the Alaska Nanuuq (polar bear) Commission, the Eskimo Walrus Commission, the Alaska Eskimo Whaling Commission, and other marine

USARC Chair Mead Treadwell and USCG Avionics Electrical Technician First Class Jody Sullens on a USCG Hercules C-130 Arctic Domain Awareness flight over the Beaufort Sea. (Photo credit: J. Farrell)

mammal commissions, can provide important observational data through TEK, which is crucial to maintaining and incorporating Alaska Native involvement and partnership, and closely link scientific research to support socioeconomic and social-ecological goals.

5. Plans should be developed to better communicate results to scientists, policymakers, and decision makers, and the general public.

USARC welcomes the lead that NPRB has taken in soliciting international input in developing ecological indicators for the Bering Sea and in reiterating the need for dedicated federal funding to each of the collaborating BIAWG programs. NPRB is also commended for successful outreach activities and encouragement of TEK.

Finally, USARC recommends support to develop AOOS in the Bering Strait region as described in the Bering Strait Regional Case Study in the *Arctic Marine Shipping Assessment* (AMSA, 2009).

ARCTIC OCEAN

Significant research in the Arctic Ocean has been funded by DOI's Minerals Management Service (MMS), NOAA, NSF, private oil and gas exploration enterprises, and others. NPRB and AOOS are poised to provide funding for Arctic Ocean research, subject to developing an integrated science plan. The North Pacific Fisheries Management Council's moratorium on commercial fishing in the US Arctic Ocean Exclusive Economic Zone points out the need for good baseline ecosystem studies in the area. Oil and gas exploration plans, and greater shipping use of this ocean, further point out the need for solid understanding of the biology of this region to avoid adverse impacts. Internationally, many policy analysts and decision makers have suggested the Arctic Ocean is a good place to apply marine spatial planning and ecosystem-based management across national jurisdictions and in the high seas. Such an effort requires an enhanced understanding of the Arctic ecosystem rooted in multiyear data sets.

How do we get there? The Commission thanks AOOS and NPRB for its leadership in convening experts on this question. A workshop on Arctic Research and Monitoring on January 23, 2009 followed an initial Arctic Research and Monitoring Collaboration Roundtable held in the summer of 2008 (Dorman, 2009). The goal was "*to share information and promote collaboration among the many entities with increasing activities in marine research and monitoring in the Alaska maritime Arctic (Chukchi and Beaufort Seas), including the oil and gas industry, local, state and federal agencies, and nongovernmental and academic organizations.*"

Two researchers presenting at the workshop, Russ Hopcroft and John Walsh, were cited in the workshop report as having a common conclusion: "*...although the anthropogenic and natural forces driving climate change in the Chukchi and Beaufort largely come from outside the area, the impacts have*

already started, will be large, fundamental, and irreversible, will require more precise coupling of models (atmosphere, snow, sea ice and ecosystem), and will necessitate significant adaptation by virtually all trophic levels in the ecosystem, from microbes to man."

A number of organizational steps were discussed at the workshop. Most current "investors" in Chukchi and Beaufort research from federal, state, private industry, and academic institutions were present, and collaboration in data sharing was increased as a result. An integrated science plan should be produced by an active group of stakeholders who represent these broad constituencies.

USARC has cosponsored several workshops, symposia, conferences (such as the annual Alaska Marine Science Symposium), and other efforts on Arctic Ocean research, and will continue to do so.

Recommendations

First, IARPC, in the context of the national review of ocean policy called for by President Obama, should establish an umbrella science plan for the Arctic Ocean, and put a structure in place with clear research objectives. As a guide, we recommend that IARPC use the report from the workshop on Arctic Research and Monitoring sponsored by AOOS and NPRB (Dorman, 2009) and the NPRB Arctic synthesis report by Hopcroft and others (Hopcroft et al., 2006).

Second, a research plan for the Arctic Ocean should be patterned to support marine spatial planning. We recognize the newly accessible Arctic Ocean is inviting to commercial fishing, shipping, tourism, mineral, and energy extraction. The United States has barely started the baseline oceanographic research necessary to support US and Arctic Council goals for ecosystem-based management in the Arctic Ocean.

Third, USARC recommends that NSF and NPRB move forward together and obtain support from other groups such as AOOS and NSSI to create and support an initiative to understand the Arctic Ocean marine ecosystem similar to their joint effort on the Bering Sea ecosystem through the six-year, $52M BEST-BSIERP effort.

Fourth, recent studies have begun examining the impact of environmental pollutants, bioaccumulation, and climate change on food safety and health. Because the Arctic is a unique and to a great extent an unexplored or measured environment with regard to health issues, it requires a specialized research approach to meet the health care needs of its people. To the end, the Commission calls on the US Senate to ratify the Persistent Organic Pollutants treaty. Arctic indigenous residents unfairly endure multiple health disparities; research into such ailments should appeal to a wide variety of institutes and centers at NIH and NIMH as well as the Fogarty International Center. For example, infectious diseases, cancer, heart disease, obesity, diabetes, and various mental health issues are overrepresented in Arctic populations.

Fifth, consistent with the recommendations from the first International Arctic Fisheries Symposium, held in Anchorage in October 2009, the Commission calls for increased cooperative research as a basis upon which decisions will be made for future Arctic fisheries. The symposium should also be reconvened regularly so that scientists and policymakers from several countries, representing different perspectives, may come together and discuss common issues.

Sixth, international focus on ocean acidification must include the current and potential impacts on the ecosystems of the Bering Sea and the Arctic Ocean, which contain waters that are already more corrosive to carbonate (i.e., lower carbonate ion concentration) than in the equivalent Arctic water masses in the Atlantic sector. What is the current impact of acidification on species that are particularly susceptible to dissolution, such as pteropods (among the food sources for salmon), or on larval blue king crab, or on shellfish, such as scallops? In the United States, funding has been provided to NOAA, NSF, and EPA to focus greater attention on ocean acidification, and the National Academy of Sciences and The Oceanography Society recently released publications on this topic (see December 2009 issue of *Oceanography* at http://tos.org/oceanography/issues/issue_archive/22_4.html). The impacts of acidification on Arctic waters must be an integral part of these activities and reports.

2 ARCTIC HUMAN HEALTH

US Arctic residents suffer from a wide range of severe physical and behavioral health issues with a far higher incidence in comparison to their counterparts in the lower 48 states. Life expectancy among the Alaskan indigenous population (approximately 15% of the total Alaskan population, or 100,000 people, according to the US Census Bureau) can be short and tragic. Death rates due to accidents and suicides of young adults are the most frequent and infant mortality rates are higher (Wigle et al., 2005) than for natives in the lower 48 states. Over one-third of rural Alaskan women become victims of an intimate partner (Wagner et al., 1995). Although the transition from a traditional subsistence lifestyle and socioeconomic system toward a cash economy has brought rapid economic change and new technologies, it has also markedly increased the prevalence in the native population of acute and chronic diseases such as cancer, diabetes, hypertension, obesity, cardiovascular diseases, alcoholism and drug abuse, as well as domestic violence, child abuse, accidents, and mental illness, including mood disorders, and suicide.

The US Arctic Research Program needs to make a generational commitment to conduct research to improve the plight of Alaska's native people, described in the Pulitzer Prize winning series, "A People in Peril" (1988, *Anchorage Daily News*). Despite over 20 years of public awareness of the health problems of indigenous people in Alaska, and meritorious attempts at prevention and control of some of these diseases by the health agencies of the State of Alaska, the Indian Health Service, and more recently the empowered tribal health consortia, there are precious few examples of improvement and, instead, there has been a progressive increase in the rates of suicide, alcoholism, and accidents in Alaska Natives. In addition, their death rate from lung cancer is increasing. The Arctic's First People have many threats and challenges before them.

As IARPC establishes its priorities for US Arctic Human Health research, DHHS has designated the Fogarty International Center at the National Institutes of Health (NIH) as the point of contact for Arctic health research matters. We applaud the leadership Fogarty has given in responding to the Commission and the IARPC mandate to develop an Arctic Health Research Program Plan. We encourage other federal agencies dealing with Arctic health research issues—the Department of Health and Human Services (e.g., Centers for Disease Control and Prevention [CDC], individual NIH institutes, the Substance Abuse and Mental Health Services Administration [SAMHSA]), EPA, DOI, and others—to dedicate more resources to Arctic health research.

CDC and the various institutes and centers at NIH spend approximately $24M annually on research activities in Alaska, and a portion is directed to assessing and improving human health. For example, studies of the weight, nutrition, and health of Alaska Natives are conducted by the UAF Center for Alaska Native Health Research (CANHR), which was established through a grant awarded by NIH's National Center for Research Resources (NCRR). Because Arctic residents unfairly endure multiple health disparities, and are considered "underserved" in the majority of rural areas, research into such ailments should appeal to a wide variety

of institutes and centers at NIH. For example, infectious diseases, cancer, heart disease, and mental health all have their unique aspects within Arctic populations.

There is a growing circumpolar collaboration in Arctic health research, supported by the work of the International Union for Circumpolar Health (IUCH), the Arctic Council's Sustainable Development Working Group, and the individual efforts of Arctic nations and research institutions. Unfortunately, despite the enormous toll on the people of Alaska and the Arctic, there are no NIH-sponsored studies of depression, alcoholism, suicide, or cancer in Alaska Natives. The Commission has identified several research approaches to improve health in Native communities. These include expanding the understanding of traditional healing methods and improving more clinically based approaches. Further investigation of genetic factors may assist in identifying and understanding any propensity that may exist for cancer, other chronic diseases, or mental health problems in indigenous populations.

Inupiat living in Northwest Alaska have one of the highest youth suicide rates in the world (Wexler, 2006). This situation is an unacceptable expression of the depression and alcoholism caused by a variety of known and unknown malignant factors, including cultural and language devaluation, loss of cultural identity, climate change, and the lack of jobs and work in native communities. Other countries (e.g., New Zealand) have faced similar problems in their native population and have succeeded in reducing the suicide rates. We need to make Alaska a healthier place for Alaska Natives to live in. The Commission has found that the nation's medical researchers, with specific expertise in these health problems, do not have enough awareness of the health challenges faced by Alaska Natives. NIH and the National Institute of Mental Health (NIMH), while sympathetic to these problems, have told the Commission that more proposals are necessary from the national medical research community in order to see more funding directed to research in this area. The Commission calls upon NIH and NIMH to work together with the NAS/IOM and the research community as a whole and Alaska Native researchers and practitioners to expand Arctic health research. Toward this end, and at the request of and with support from the Commission, on June 2 and 3, 2009, the Fogarty International Center of the National Institutes of Health convened a workshop on suicide and other behavioral health issues in Anchorage, and the proceedings from this workshop were published in early 2010 (Levintova et al., 2010). Specialists from a variety of Arctic disciplines, indigenous leaders, and representatives from various NIH institutes and centers attended.

Part of the discussion focused on a Commission recommendation, stated below, that NIH, NIMH, the National Institute on Alcohol Abuse and Alcoholism (NIAAA), the National Center on Minority Health and Disparities (NCMHD), the National Institute on Child Health and Development (NICHD) and other appropriate government agencies support a "decadal" review on Arctic human mental health research to be conducted by both the National Academies' Institute of Medicine and Polar Research Board. This review and Institute of Medicine report would empanel experts from many different disciplines. It would work closely with the Arctic region's indigenous leaders, health researchers and practitioners, state officials and others to bring research, intervention, and clinical work together. The workshop discussion showed that an appropriate review would focus on the epidemiology and causes of the excessive morbidity and mortality caused by suicide, domestic violence, addictions, and other mental and behavioral conditions so frequent among Arctic populations. This review should also identify methods for future genetic, genomic, and functional imaging studies of natives living at high latitudes to learn if the strategies for enhancing the resilience of the native population can benefit from preventive and interventional methods that are more developed and successful with other at-risk populations elsewhere.

RECOMMENDATIONS

First, the Commission recommends that IARPC follow through on its commitment to develop an overarching US Arctic human health research plan. This plan should include state-of-the-art advances in genomics and genetics. Further, it should encourage the study of high-latitude physiological

differences, improve the knowledge of Arctic epidemiology, and integrate work across the various centers and institutes of NIH, with the work funded by other agencies, such as CDC, SAMHSA, EPA, DOI (including USGS, BIA, USFWS), Food and Drug Administration (FDA), NOAA, and Alaska and tribal healthcare providers

Second, we must immediately bring research to bear on a deadly problem with causes and treatments that may be unique to the Arctic. Suicide rates in the Arctic are appalling, and greater among indigenous Arctic youth than any other group within our nation. Clinical research and community intervention efforts must come together to address this epidemic. The Commission urges the National Academy of Sciences, through the Institute of Medicine and Polar Research Board, to bring together health researchers and practitioners, indigenous leaders, and experts from a wide range of disciplines to develop a rigorous, evidence-based, iterative, and recurring assessment of intervention efforts. To be most effective, this effort must be decadal, to establish research priorities, review results, guide the scaling up of successful pilot programs into widespread clinical interventions, and to track the progress and success of the research agenda.

Third, the Arctic Human Health Initiative (AHHI), a US-led contribution to IPY has been a significant contributor to international coordination of Arctic health research. The Commission calls for continuation and greater funding of this CDC-affiliated initiative so that it may conduct, to a much greater extent, the research that the proposal calls for. Leadership from NIH, CDC, and SAMHSA will be essential in this effort. Because the Arctic is a unique and to a great extent an unexplored or unmeasured environment with regard to health issues, it requires a specialized research approach to meet the health care needs of its people. Genetic analysis has shown that Arctic indigenous peoples are significantly different from those at lower latitudes. An IARPC health plan needs to coordinate closely with each working group of the Arctic Council toward this objective.

Fourth, recent studies have begun examining the impact of environmental pollutants and climate change on food safety and health. We applaud work that EPA has done in this area, and also the Alaska Department of Environmental Conservation (ADEC), Division of Environmental Health, through a new initiative to monitor fish for heavy metals such as mercury. State and federal research and mission agencies need to strengthen cooperation with Alaska tribes and subsistence communities as these efforts continue.

Fifth, the Arctic presents itself as an ideal location for the development of innovative technologies for medicine-at-a-distance or telemedicine and telepsychiatry. The Commission recommends supporting and promoting such innovation by grants from NIH and other agencies. These innovations could have broad value to other parts of the nation and the world. Initial work on this subject, supported by the State of Alaska and the US Department of State, and conducted by Hild et al. (2000), should be updated, advanced, and implemented.

3 CIVIL INFRASTRUCTURE

Arctic climate and conditions have always called for unique methods in transportation, housing, telecommunications, sanitation, energy production, navigation, and mapping. As climate change impacts the Arctic, thawing permafrost, reducing sea ice, strengthening storms, and eroding coastlines, civil infrastructure is facing new challenges. Long-held engineering standards assumed that the permafrost regime would be perpetually stable. Realization that permafrost might thaw significantly during the lifespan of a building, a pipeline, or a road system requires research to develop new methods of design and construction. Seasonal restrictions adopted to protect tundra and permafrost during road construction, pipeline building, and oil exploration have expanded as winters have become milder or shorter; that, too, has caused a need to reexamine methods.

As protective winter sea ice retreats from the coastlines, storm surges reach the shore, making it vulnerable to erosion. For example, in the village of Shishmaref, inhabited for 400 years, climate change is destroying homes, water, sanitation systems, and other infrastructure, which requires relocation of the entire village. Shishmaref is not an isolated example; the village of Kivalina is another case where, for example, fuel depots are perilously close to the approaching erosional front.

Research and innovative engineering solutions are needed to create new infrastructure to accommodate the demands of an Arctic that is increasingly accessible, whether by land, sea, or air. The Commission has long recommended infrastructure research within the US Arctic Research Program. Since the 2007 goals report, and with the leadership of the US Army Corps of Engineers Cold Regions Research and Engineering Laboratory (CRREL), IARPC has committed to develop an integrated plan. At the start, the Commission recommended that infrastructure research cover a wide variety of topics, such as permafrost, shoreline erosion, construction techniques, and building codes, methods to reduce the cost of living (primarily housing) in Alaska, oil spills, energy use, and marine transportation. Such a program plan will serve as intellectual underpinning for broad research on civil infrastructure in the Arctic.

CRREL, in coordination with the University of Alaska Fairbanks and the Denali Commission, conducted a USARC-sponsored workshop toward an infrastructure research program plan in April 2010, in Fairbanks, Alaska. The focus of the workshop was to identify state, national, and international partners, prioritize actions in each field, and identify pilot projects and other opportunities to test the feasibility of larger research efforts.

USARC has encouraged the participation and cooperation of other agencies to work with CRREL in this process. For civil work, sanitation, and housing, we will continue to discuss the roles that the Department of Transportation (DOT), Federal Aviation Administration (FAA), Denali Commission, State of Alaska, Department of Housing

and Urban Development (HUD), Department of Energy (DOE), NSSI, and USGS can play. For oil spill research, in this report, we are recommending a second set of collaborations. Two interagency entities created by law, IARPC, and the Interagency Coordinating Committee on Oil Pollution Research (ICCOPR), chaired by the US Coast Guard, in the Department of Homeland Security, have responsibility to work in this area. Specific recommendations on ways to better ways to implement oil spill research are described in a USARC white paper (see http://www.arctic.gov for the white paper). The scientific community has suggested that one of the greatest needs in responding to oil spills is understanding where the oil will go (e.g., spill trajectories, ocean circulation models) in the event of a spill. Clearly, current research has just begun, and a more comprehensive initiative is needed by entities such as AOOS, MMS, other ICCOPR agencies, and industry.

For shipping research identified by the *Arctic Marine Shipping Assessment* (AMSA, 2009), we recommend a third collaboration, with the participation of DOT, MARAD, the Committee on Marine Transportation Systems, the National Academies Transportation Research Board, the US Coast Guard, and others.

For energy research unique to Arctic assets and conditions, we have encouraged DOE to maintain funding for the Arctic Energy Office, and to remove restrictions to allow work on renewable energy as well as fossil fuels. DOE has responded by staffing a representative of the National Renewable Energy Laboratory (NREL) in Alaska and has begun developing a renewable energy research plan. Such a plan will become an integral component of a climate mitigation strategy.

For telecommunications, we convened a workshop on the use of the Iridium network in high Arctic research (no other system is available to civil users at high latitudes), and we encouraged the Arctic Council's Arctic telecommunications assessment.

For Alaska's Arctic mapping needs, the Commission encouraged collaboration among the Statewide Digital Mapping Initiative (SDMI), federal geographic data committees, and the Civil Applications Committee, which is a "window" for the use of classified assets such as spy satellites by civil government agencies.

CRREL and IARPC are encouraged to work together with two centers addressing civil infrastructure research that have been established on the UAF campus. The Alaska Center for Climate Assessment and Policy, funded by NOAA, is one of a national group of Regional Integrated Sciences and Assessments programs. It is a partnership among scientists at UAF and University of Alaska Anchorage, state and local planners, including those at the National Weather Service and United States Army Corps of Engineers, and stakeholder groups, including Alaska Native tribal governments, industries, and nongovernmental organizations. A third civil infrastructure center at UAF, focused on energy, is authorized but not funded.

The Alaska Aviation Safety Project, funded at Alaska's Department of Transportation through NASA, is a second source of collaboration in research to improve mapping, aviation safety, and use of new telecommunications and navigation techniques. Its sister project, Capstones, funded by FAA, used remote Arctic conditions to develop a new method of air-traffic control, automatic dependent surveillance-broadcast, which is being implemented over time across the United States and in other nations. In 2008, the National Aeronautic Association awarded the academic, government, and industry team (Commercial Aviation Safety Team), which pioneered this technology, aviation's highest honor, the Robert J. Collier Trophy, joining the ranks of others who had reached aerospace milestones, including Orville Wright, Howard Hughes, Chuck Yeager, and the crew of Apollo 11. The Commission congratulates these applied research programs for their work, and encourages further research by DOT and NASA to improve safety of aviation in the Arctic. The Cold Climate Housing Research Center (CCHRC) is a partnership between the university and industry to conduct research to advance understanding and application of cold climate housing principles. CCHRC's own research plan can support the IARPC approach.

The Commission includes baseline mapping of the Arctic in the topic of "civil infrastructure" for obvious reasons, such as the impact, over time, of erosion, storm surge, and inundation of coastlines. Maps provide essential data necessary to conduct scientific research in support of civil infrastructure. The State of Alaska created SDMI and charged it with developing and implementing a plan to upgrade the state's digital imagery and elevation data. Currently, these framework data sets for Alaska are well below national quality standards and are outdated; the most recent statewide aerial imagery acquisition occurred in the early 1980s. New and higher-quality imagery is essential for understanding landscape changes that have occurred due to climate warming and development, and provide a needed current baseline against which future change can be assessed. The only statewide digital topographic data for Alaska was generated by digitizing 1950s vintage USGS quadrangle-scale map products and have local horizontal errors that exceed 1 km. SDMI received state support over the last three years during which it collected all available digital high-resolution imagery and elevation data and lifted licenses so that all state and federal agencies, native organizations, educators, and researchers have access to these data sets through the Web. Given the early and significant success of this program, USARC encourages Alaska to continue to fund SDMI and to broaden the program's scope such that it becomes an integral component of SAON and AON activities as appropriate.

With respect to oil spills, the Commission has worked not only to identify a research agenda, but also a potential source of funding—the Oil Spill Liability Trust Fund—which is authorized to support US oil spill research programs but is seldom used to any great degree. We also learned that the OPA90's ICCOPR, chaired by USCG, seldom meets, does not publish its meeting agenda or minutes, and does not have an updated national research plan, as called for by OPA90. Yet, when an Arctic Ocean offshore lease sale commands $2.7 billion in bids, as it did in early 2008, the nation should certainly find the means to improve spill prevention and response techniques and to have better baseline research on the fate and effects of oil spills, and the restoration of Arctic environments.

The Commission has engaged in constructive dialogue with many players, and concludes that an oil spill research agenda would be relatively easy to put together if funding for research is made available (see white paper on this topic at http://www.arctic.gov). Participants that would be involved in such a program include USCG, NOAA, NSSI, MMS, OSRI, NOAA, DOT's Office of Pipeline Safety, and the State of Alaska.

The Commission chair and staff visited with principal investigators at the Joint Industry Program at SINTEF, Trondheim, Norway, where oil spill response techniques were tested in spring of 2009 in ice-covered waters, with the support of the US government and industry. Former Commissioner Walter Parker attended the 2009 Arctic Marine Oil Pollution conference, hosted by Canada, on the Commission's behalf. In March, 2008, as part of the *Arctic Marine Shipping Assessment* (AMSA, 2009), the NOAA Coastal Response Research Center (CRRC) at the University of New Hampshire held a workshop, "Opening the Arctic Seas: Envisioning Disasters, Framing Solutions," with the encouragement and support of the Commission and other agencies. The Commission helped organize a US-Canadian conference held in Anchorage in October 2008 called, "Northern Oil and Gas Research Forum '08, Current Status and Future Directions for the Beaufort Sea, North Slope and Mackenzie Delta," to bring researchers on this topic and others together.

And, finally, on the topic of marine transportation, USARC has devoted a significant amount of time to identifying needs for Arctic research. We have held extended conversations with MARAD, USCG, and others, and worked with MARAD on a 2008 Arctic Transportation Conference. We have worked extensively with the US Navy/NOAA/USCG Joint office and the National Ice Center to sponsor three symposia on "Impacts of an Ice-Diminishing Arctic on Naval and Maritime Operations." The Commission is proud to have provided, with our former Deputy Director Dr. Lawson Brigham, leadership for the Arctic Council Protection of the Arctic Marine Environment Working Group's *Arctic Marine Shipping Assessment*, available at the USARC Web site http://www.arctic.gov. We have been briefed by Congressman Don Young on his sponsorship of implementing legislation for the *Arctic Marine Shipping Assessment*, and appreciates how it would support research for "safe, secure, and reliable" Arctic shipping.

The creation, by the Department of Homeland Security, of a new Center of Excellence for Island, Maritime, and Extreme Environment Security (CIMES) is a promising step toward ensuring security and disaster mitigation as marine transportation continues to expand across trans-arctic routes. CIMES is a partnership among the University of Hawaii, UAF, and University of Puerto Rico Mayagüez, with UAF holding the role of developing monitoring capabilities to discriminate and track marine vessels and oil spills in ice-laden waters and under extreme conditions of cold and dark.

RECOMMENDATIONS

First, USARC commends IARPC for commissioning and CRREL for leading the development of an integrated Arctic infrastructure research plan. We urge that process to continue to completion with the broad participation discussed in this report, and to provide good targets for congressional funding in years to come. Infrastructure research should include government staff scientists, engineers, and contractors, "extramural" competitively funded university researchers, and private industry. As government agencies fund much of the infrastructure needs of the Arctic, we encourage these agencies to adopt research findings through pilot projects in their normal course of business.

Second, the Commission recommends IARPC work with the State of Alaska to support the State's adaptation research agenda to respond to the dramatic effects of climate change.

The emerging federal research program in this area should integrate with and support these efforts, which include protecting communities from erosion, and adapting buildings and civil infrastructure to thawing permafrost. Information on the process and findings can be reached at http://climatechange.alaska.gov.

Third, the Commission recommends the President, Congress, NOAA, and USCG take steps to ensure the US oil spill research program meets the promise of the Oil Pollution Act of 1990. The Commission urges use of the Oil Spill Liability Trust Fund, which collects eight cents per barrel on domestic oil production and imports, as authorized, to support a significant new funding stream for oil spill research in the Arctic. We recommend a target of at least $10M per year, to be made competitively available, for Arctic/Subarctic spill research on an agenda to be adopted jointly by IARPC, ICCOPR, with the participation of the State of Alaska, the North Slope and Northwest Arctic Boroughs, OSRI, CRRC, and industry operating in the Arctic region. This research should support improvements in prevention, response, and remediation of oil spills in ice-covered waters and help resource management agencies integrate spatial planning into spill prevention and response in the Arctic Ocean.

We have urged Congress to "inflation proof" the OSRI "endowment" in the Oil Spill Liability Trust Fund, to raise its principal from the $23 million set aside in 1990 to at least $35 million.

We urge Congress not to change the leadership of the ICCOPR, but to use its oversight to make sure it meets regularly, is transparent in its deliberations and decisions, and that a national plan as well as an Arctic regional plan are developed and funded. If Congress chooses to create a Regional Citizens Advisory Committee for the Arctic Region, as it has with Prince William Sound and Cook Inlet, we would urge that committee to include USARC representation, to have a science budget, and to work closely with entities planning and carrying out oil spill research in the Arctic region.

Fourth, the *Arctic Marine Shipping Assessment*, completed by the eight Arctic nations in spring 2009, identifies the research necessary to address the opportunities and challenges of Arctic shipping (AMSA, 2009). IARPC should include this research in its infrastructure research plan, and US DOT and other agencies should identify means to provide competitive extramural funding to carry out the research.

Fifth, since the Commission's 2007 goals report, the conventional and renewable energy potential of the Arctic has been further assessed and shown to be dramatic. The Commission recommends that DOE include the Arctic Energy Office in its core budget, and that it be placed within the DOE organization such that it has authority to continue sponsoring fossil energy research as well as to expand its role into sponsoring renewable energy research. (The Commission was not consulted by DOE when it cut funding for the Arctic Energy Office, though that consultation is required by law.) Through this office and other DOE programs, the Commission urges research related to capture and production of Arctic methane and methane hydrates (both onshore and offshore). Five of the eight Arctic nations, including the United States, are members of the International Partnership for the Hydrogen Economy. Given the challenges of dealing with Arctic marine oil spills and black carbon in the Arctic, and given that Arctic shipping requires specialized vessels to begin with, the Commission urges the United States and its partners to institute pilot projects on alternative-fueled fishing and commercial vessels in the Arctic region. Finally, the Commission acknowledges that NREL has established an Alaskan research program that can further address the dramatic wind, wave, tidal, geothermal, and biomass potential to serve the many "off the grid" Arctic communities with stable-cost power and to provide new methods to export energy from the Arctic. We urge appropriate funding of that program once a plan is developed.

Sixth, federal and state efforts to cooperate in providing an imagery database and digital elevation model are promising and could be successful in bringing Alaska's maps up to the standard seen by the rest of the nation. Federal and state governments are urged to agree upon and fund a coherent plan for mapping the US Arctic that federal and state agencies, the research community, and the public can rely on.

4 NATURAL RESOURCE ASSESSMENT AND EARTH SCIENCE

As has been clear since the 1968 discovery of North America's largest oil and gas reservoir at Prudhoe Bay in the Alaskan Arctic, subsequent discoveries and a recent assessment of oil and gas potential by the USGS, the Arctic is rich in conventional energy. Arctic tidal, geothermal, wind, wave and biomass energy potential are also strong. There are large deposits of mineral deposits in the Arctic, including gold, diamond, lead, zinc, nickel, iron ore, and molybdenum. The Arctic's living resources are diverse, with some the largest mammals (Moore and Huntington, 2008), biggest herds, richest fisheries (as the Bering Sea is in the "Arctic"), and longest migrating species of birds making their homes there. Most of these resources are found on public lands. As a significant owner of Arctic resources, the United States has a responsibility to know what it owns, to understand basic biology, geology, and natural history of its assets, and to understand the population dynamics of the living resources it manages—alone, or in concert with the State of Alaska and other nations.

Toward this end, the Commission recommended first in its 2003 goals report that IARPC adopt a Resource Assessment Theme in the US Arctic Research Program. In later reports, the Commission amended this theme to include basic earth science. Leadership within IARPC for developing this research plan was taken on since the last goals report by USGS.

The Commission, in its deliberations with the public, industry, government, and academic community, finds at least three elements that should be in a resource assessment and earth science research plan, including:

- An assessment of the mineral and energy resources of the Arctic region, especially those on public lands of the United States and Alaska
- An assessment of the living resources of the Arctic region, especially those on the public lands of the United States and Alaska, and those that migrate across national borders
- An earth science plan that takes into account the major geographic and geophysical "unknowns" of the Arctic region, including the geology and tectonics of the Arctic Ocean and the Bering Sea, and studies of the magnetic pole and the magnetosphere

The Commission finds that the US government has a spotty record of keeping one research promise required by the Alaska National Interest Lands Conservation Act (ANILCA) of 1980. That act, which ended one of the loudest environmental debates in Congress, set aside large areas in Alaska for national parks, monuments, wildlife refuges, and wild and scenic rivers. Set as a compromise while millions of acres were set aside from development, ANILCA calls for a continuing Alaska Mineral Resource Assessment Program (AMRAP) to determine the mineral potential of Alaska's public lands. Our recommendation that DOI restore core

funding for this program, and that IARPC include AMRAP in an Arctic Research Program Plan, is based on the requirements of this law.

Earth science initiatives should continue to incorporate fundamental geophysical and geological research (especially in the Arctic Ocean) so that as a nation, we understand our land, its value, and the extent of our offshore sovereignty beyond the current EEZ. The United States and the four other Arctic coastal nations are currently in the midst of drawing new sovereign borders in the Arctic Ocean, and the United States may gain an area of Arctic undersea territory that is roughly the size of California. In this vein, USARC supports US accession to the United Nations Convention on the Law of the Sea, and the interagency Extended Continental Shelf Mapping Initiative.

The Commission continues to urge the Obama Administration, the Department of Defense (especially the Navy), and affiliated entities to continue efforts to declassify military data for civilian scientific purposes. Declassification of bathymetric (water depth) data, collected by US nuclear submarines, has significantly improved our understanding of the Arctic Ocean, and the construction of maps, and to help define the nation's offshore sovereign boundary. The Central Intelligence Agency's recent resurrection of the scientific group MEDEA (Measurements of Earth Data for Environmental Analysis), which searches intelligence data archives for information that can be publicly released in order to shed light on environmental change, is also an encouraging development.

While we have addressed Arctic mapping and gas hydrates research in the Arctic Infrastructure portion of this report, it may be appropriate for those research objectives to join the Resource Assessment and Earth Science program plan as well. Our recommendation for core DOI and congressionally created long-term funding for NSSI will support resource assessment and earth science under this theme, as well as the climate and infrastructure research programs covered by other themes. The Commission was not consulted, as the Arctic Research and Policy Act requires, when the government's FY 2009 spending plan for NSSI was revised down and the 2010 budget for NSSI was significantly cut.

Since the last USARC goals report, the Commission has worked with and heard from leaders of the Integrated Ocean Drilling Program (IODP), which conducts deep ocean drilling for earth science and deep biosphere science objectives around the world. The Commission notes with dismay the challenges IODP has had in gaining access to Bering Sea drill sites within the Russian Arctic EEZ to conduct

RIGHT. Picking berries. (Photo credit: B. Molnia)
BELOW. Piloting C-130. (Photo credit: J. Farrell)

marine scientific research, and in the science infrastructure recommendations, the next section of this report, we recommend diplomatic approaches to solving this problem.

In 2008, the Commission visited the HIPAS Observatory, outside of Fairbanks. There, we were briefed on magnetosphere and aurora studies, including research on the exchange of ionized particles to and from the atmosphere though the workings of lines of force emanating from the magnetic north pole. The Commission has also been briefed during its field visits to Svalbard and meetings on the Oregon State University campus on other magnetosphere research being conducted into the Arctic. The polar regions are the only venue on Earth where some of this research may be conducted. Development and incorporation of a magnetosphere research plan under this theme will be useful in determining our research infrastructure and funding goals for the coming years.

DOI committed USGS employees in Anchorage to take a leadership role in developing this thematic research plan for IARPC. Their effort is supported within the larger DOI. To obtain information from others, USGS will send survey letters to the appropriate federal and state agencies to better understand each organization's 20-year vision for resource assessment, the level of support for such assessment, partnerships, staff levels, and the requisite infrastructure. The results of this information-gathering effort were discussed at DOI meetings in 2009, and will be turned into an integrated plan to report to IARPC.

RECOMMENDATIONS

First, the Commission commends the DOI's USGS for its leadership in assembling a research plan under the theme Resource Assessment and Earth Science, and urges it to include assessments of Arctic energy and minerals, assessments of Arctic onshore living resources, and an Arctic earth science plan, with clear goals allowing appropriate funding decisions to be made.

Second, the Commission applauds the leadership taken by the federal government's interagency ECS Task Force to identify claims the United States may make to dramatically increase its territory in the Arctic Ocean. The Commission has urged ratification of the United Nations Convention on the Law of the Sea so that US scientists may be part of reviewing other nations' claims in the Arctic.

Third, the AMRAP, required by ANILCA, should be funded in core agency budgets of the nation's public land management agencies within the Departments of Interior, Agriculture, Defense.

Fourth, the Commission urges DOI to institute and maintain a basic level of funding for this NSSI program. Congress created NSSI as a collaborative research program to support integrated, ecologically sensitive land management on the North Slope of Alaska. The Commission thinks the government should find a "dedicated" source for NSSI as it has for the NPRB, the Prince William Sound OSRI, and the Denali Commission so that long-term science commitments can be made.

5 INDIGENOUS LANGUAGES, CULTURES, AND IDENTITIES

Language helps us define the cultural diversity of our planet and serves as the strongest pillar to our diverse cultural heritage. Language is a fundamental indication of who we are, that is, of our identity. Although critical, language is one of the most vulnerable elements of our cultural being. Some languages expand and grow, so that their speakers number in many millions, whereas many minority languages decline and even become extinct, such as when the last native speaker of the Alaskan language Eyak died in January 2008. Of the thousands of known languages, fewer than 10 are used by nearly 60% of the global population and more than 500 are extinct. When speakers of endangered minority languages switch to other languages as their mode of communication and education, huge amounts of cultural information can be lost forever, including historical data, place names, and clues to changing natural phenomena, such as climate conditions or wildlife population levels. A peoples' cultural identity is endangered by language loss.

In the US Arctic, language vulnerability is especially acute in the current generation. Indigenous people are being separated from their cultural past. As many indigenous languages do not have long-standing written traditions, the cultural legacy they carry—as well as the languages themselves—are poorly recorded. Languages passed down by the spoken word, rather than the spoken and written word, cannot be easily enhanced via the most common societal means, such as formal education, public programs, book printing, and writing. This creates a volatile mix, and the loss of language invariably impacts cultural tradition, human history, and traditional ecological knowledge. These losses prompt a shift in the cultural and identity of younger generations.

Without a research plan to address Arctic language, cultural preservation, and revitalization, the path to language extinction in the North is likely to shorten. The thematic addition of languages, identities, and cultures to the US Arctic Research Program Plan should address the following goals, originally proposed in the Commission's 2007 goals report:

- Regular, permanent census processes to understand the diversity of languages spoken by Arctic people, and the viability of those languages for future generations
- Documented procedures to ensure that languages and place names spoken and given by Arctic people are recorded, preserved, and transmitted
- Defined policy options and processes for language preservation that have succeeded in the Arctic and elsewhere are made available to Arctic policymakers and residents

RECOMMENDATIONS

First, the Commission applauds IARPC for the attention it has given the goal of developing a research plan and program for indigenous languages, identities, and cultures. The Commission urges one agency among likely participants—NSF, the National Endowment for the Humanities, the Department of Education, DOI's Bureau of Indian Affairs, the Smithsonian Institution—to take clear leadership in establishing this research plan. IARPC is behind in meeting even its initial target of a status report on common goals and objectives in the area of indigenous languages and cultures, set for September 2007. A research program plan can take advantage of congressional initiatives supporting immersive language study of indigenous languages in the nation's schools, an Arctic Council initiative to derive best practices around the North, and other efforts by United Nations agencies such as UNESCO to help preserve cultural heritage in the North.

Second, to better achieve these goals, the Commission proposes the following new tactics and strategies:

- DEVELOP NEW APPROACHES: Promote new interdisciplinary and cross-agency initiatives that integrate language documentation with language support, education, heritage preservation, cultural and museum research, outreach and public programs. An excellent example of this is the "Endangered Languages and Indigenous Knowledge" initiative of the National Museum of Natural History and the Smithsonian Institution. With respect to research, this effort will coordinate the study and promotion of indigenous languages by Smithsonian scholars in understanding the world's cultural and natural diversity, its origins, and functions on a variety of scales, focusing specifically on indigenous systematics, classifications, and natural world observations; the analysis of language structures, especially the general principles of human language and most clearly seen in endangered languages; and documentation and broadly accessible databases.

- COLLABORATE AND SHARE: Create a database of current programs run by various federal agencies in support of northern indigenous languages, cultures, community health and wellness, sustainable ways of living; expand interagency and inter-program collaboration, data and resource sharing; make information about ongoing efforts and opportunities at the federal (and state) level available to prospective users, researchers, and communities.

- MAKE GOOD USE OF AVAILABLE RESOURCES AND BEST-WORKING PROGRAMS: Identify resources that are critical to the efforts in support of indigenous languages, cultures, and identities (e.g., certain libraries, museums, archives, heritage databases, public programs, individual elders, and knowledge keepers); research policy options and processes for language/culture preservation that have succeeded in the Arctic and elsewhere, so that they can be made available to Arctic policymakers and residents.

- INCREASE VISIBILITY: Put support for local languages, cultures, identities, and community well-being firmly among the priorities of federal programs focused on the North; measure program success by the products with the lasting impact on the ground rather than by the amount of money spent.

- INCLUDE STAKEHOLDERS IN THE DECISION MAKING: Expand the role of local/indigenous advisers to federal programs in support of northern languages, cultures, and community well-being; use local offices of federal agencies for public outreach and feedback, including tribal consultation, to the many ongoing efforts.

INITIATE RESEARCH ON EMERGING TOPICS

The rapidly evolving Arctic region presents a wide variety of important topics that require scientific research in order to provide information to decision makers. Such topics include:

- ALASKA NATIVE POPULATION STATISTICS. What are the key causes of death in Alaska Natives and especially in youth? What is the true incidence of suicidal behavior, self-destructive acts, and alcoholism? What is the death rate of Alaska Natives and the rate of migration to urban settings? Why is the incidence of alcoholism so high in indigenous peoples? What are the effects when multiple stressors, such as socioeconomic pressures and high-latitude conditions, that are evolving in response to climate change? What are the best counter-measures to reduce alcoholism and suicide in this vulnerable population? What techniques are most successful throughout the world to sustain native populations and how might they best and most expediently be adapted to the US Arctic population?

- CARBON SINKS, SOURCES, AND FLUXES IN THE ARCTIC. Given the large and increasingly active reservoirs of carbon in the Arctic, such organic carbon locked in permafrost, and methane sequestered in gas hydrate deposits, scientists need to develop a better understanding of carbon cycling, and its associations with climate and environmental change. Attention must also be paid to understanding and mitigating the impacts of black carbon in the Arctic and to quantifying, by monitoring, the efflux of carbon to the atmosphere from Arctic environments.

- ARCTIC FISHERIES. Climatic-induced changes in ocean temperatures and other properties are changing the ecosystem, and may be contributing to the migration of fish stocks. Our understanding of the standing stock of fish in the Arctic is minimal. What's there now? What stocks are moving in, or out? What is the health of the stocks and what threats do they face? What are the needs of subsistence fishermen?

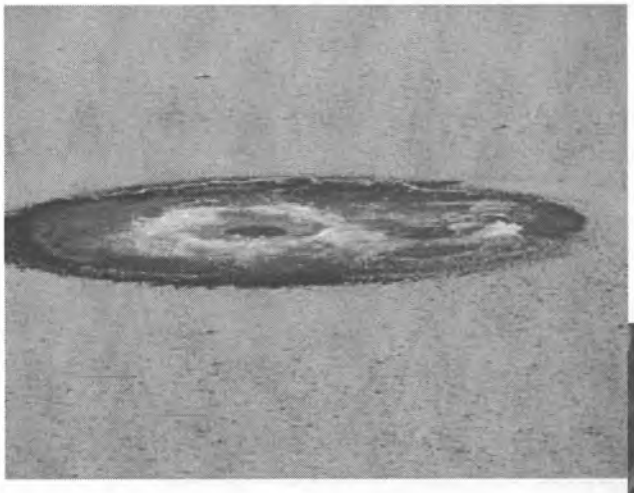
- AUTONOMOUS UNMANNED SYSTEMS. Application of these aerial and marine technologies has great promise in the Arctic given the remoteness of the region, and the difficult and dangerous operating environment. Specific applications include surveying for forest fires, observing marine mammals in a nonintrusive manner, and making environmental observations over much greater areas than previously possible. Research into increasing endurance, expanding operational environments, developing sensors and detectors, and developing novel deployment and retrieval methods are a few lines of inquiry.

- RENEWABLE ENERGY. Energy costs are volatile in the short run, but are increasing overall, which places greater emphasis on developing renewable energy, particularly in remote Arctic environments. Research needs to be conducted on how to adapt renewable technologies, such as solar power, wind power, hydroelectricity, micro hydro, hydrokinetic, biomass, and biofuels, to and for Arctic environments. Research is also needed to address issues such as "next generation" batteries that can work effectively in cold weather conditions, and the effective electrification of off-road vehicles such as all-terrain vehicles, snow machines, and small boats and outboard motors.

- NOVEL APPROACHES TO FOSSIL ENERGY. Fossil fuel development is core to the economies of most Arctic nations, and directed research can reduce the impact of Arctic fossil fuel development on the environment. Promising new or alternative methods of exploration, production, transportation, and carbon sequestration that were presented to the Commission in the last two years include advances in directional drilling, efforts to reduce noise or change the seasons for seismic surveying, prospects for using tunneling and other mining techniques to take oil development underground, eliminating the need for above-ground facilities in wildlife refuges, and an expanding practice in offshore Arctic underwater oil and gas production facilities. Transport improvements that may be attainable include novel means to protect subsea pipelines from ice scour, the use of rigid airships (developed, in part so far, with NASA and DOD funds) to move heavy equipment and materials into remote sites, and use of remotely piloted vehicles for wildlife monitoring. Potential Arctic-specific carbon capture and sequestration techniques have also been shown to the Commission. Given that much of the oil, heavy oil, gas, shale gas and gas hydrates, coal, and coalbed methane deposits to be found in the US Arctic are on federal lands, the Commission thinks research into these promising techniques should be undertaken in concert with industry, the State of Alaska, and international partners in producing and consuming countries.

- EMERGING INFECTIOUS DISEASES. The risks from an avian flu, and from other new, previously unknown, and in some cases drug-resistant infectious diseases pose a significant threat to global health. Such diseases have emerged in Alaska, and elsewhere in the Arctic, and in some cases vector through the Arctic via migrating populations. Some Arctic birds are thought to harbor bacteria that carry antimicrobial drug-resistant determinants.

- BIOACCUMULATION OF TOXINS. Research is required to assess and monitor the levels of toxins, such as mercury, and other contaminants in game and fish stocks, most recently halibut, heavily relied upon by Alaskans for food, and ultimately to determine methods to minimize such contamination.



ABOVE. Seal hole. (Photo credit: M. Dunn)
RIGHT. Bering Strait starfish. (Photo credit: K. Crane)

- ARCTIC BIOPROSPECTING. A report by the United Nations University Institute of Advanced Studies reports that private entities are searching for and developing products and treatments from DNA found in Arctic plants and animals. New products include ice cream and anti-stroke medications. One company has used "antifreeze proteins" collected from Arctic organisms to improve the texture, taste, and safety of frozen foods. Another company is attempting to use proteins from the arctic squirrel, which can lower its temperature to below freezing, to help stroke victims recover more quickly.

- MARINE MAMMAL RESEARCH. Biologists contend that the rapid decrease in summer sea ice extent and thickness, particularly over the last few years, is negatively impacting marine mammal populations. Research is needed to better understand whale, walrus, polar bear, and seal populations, and how they are responding to their changing environments. Issues that need to be addressed include: determining populations, their sustainability, and "take" levels; developing better means to collaborate and cooperate with indigenous peoples in marine mammal research; developing new methods to track the movements of individuals and populations; better projecting climate change, environmental conditions, migration routes, and food habitats; and obtaining more frequent population counts.

- GLACIER AND ICE SHEET DYNAMICS. Recent observations of smaller glaciers and the larger Greenland ice sheet suggest that climate warming is resulting in a much more complex set of dynamical processes than previously thought. Because the melting of this ice has the capacity to significantly impact global sea levels, research needs to address questions regarding the processes and rates of the dynamics in this part of the global cryosphere.

- SCALING ARCTIC RESEARCH. The scientific community has a rich legacy of studies focused on local, place-based studies. Although these studies are an important foundation for scientific understanding of the Arctic, there are a growing number of techniques and approaches that enable researchers to observe, simulate, and analyze trends over much large spatial scales, including the domain of the full pan-Arctic. Tangible strategies to bridge scales and to ensure a consistency of conclusions obtained from studies cast over often disparate temporal and spatial domain scales will be necessary before a full understanding of the behavior of the full Arctic system can be secured.

- ARCTIC EARTH SYSTEM MODELS. Many of the most critical strategic decisions facing policymakers involve the behavior of a highly coupled Arctic system, in terms of its biogeophysical as well as its human dimension elements. How well the scientific community can develop a coherent picture of how the full system behaves in response to continued greenhouse warming, loss of sea ice, and the implications of potential interventions associated with geoengineering—among many other rapid changes—will dictate the capacity of policymakers to mitigate, respond, and adapt to change. Due to its richness of processes, close coupling of subsystems, and sharp time and space boundaries, the Arctic portion of the Earth system becomes a particularly challenging one to simulate. Next-generation Arctic Earth System Models are stimulating new advances in process field studies, observational network deployments, and numerical and cyberinfrastructure capabilities, which together will improve the fidelity of these computer simulations and also enhance their capacity to create policy-relevant scenarios of the future.

- OBSERVING AND MODELING ARCTIC SEA ICE. Although this subject is not necessarily new, it demands greater attention given the overall decline, and the dramatic changes in sea ice extent and thickness over the past 30 years.

- GEOENGINEERING. We encourage and support international efforts to conduct research into the potential of climate intervention techniques, more commonly referred to as "geoengineering," for example, methods for carbon capture and storage and for solar radiation management. Research needs to assess how such techniques may be used to respond to climate change, and how to reduce the risks of deployment. It is imprudent to wait until there is a crisis before identifying potential climate intervention processes. Advanced study will help reduce the risk of such techniques, if and when it is necessary to use them. Such research does not alleviate the need to conserve resources, reduce greenhouse gas emissions, or to create clean technologies.

RESEARCH INFRASTRUCTURE

REINVEST IN ARCTIC RESEARCH

FEDERAL AGENCY SUPPORT FOR EXTRAMURAL RESEARCH

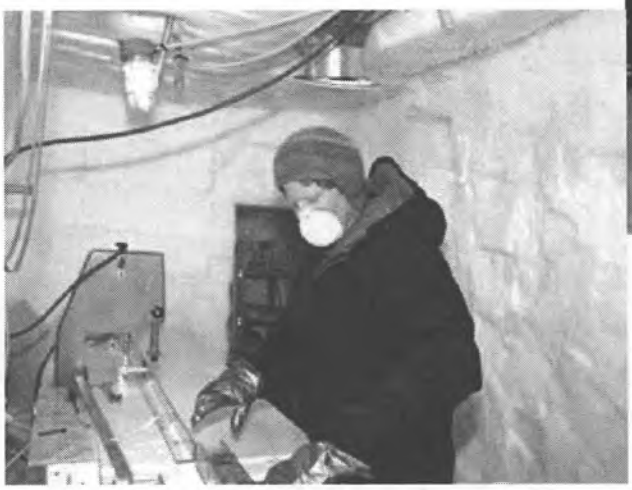
Sustaining a strong and vital government-sponsored Arctic research program requires federal agencies to set clear goals and objectives, establish robust leadership, and develop long-term, coordinated extramural support for research conducted by academic scientists. In light of budget challenges, however, many of the mission-focused government agencies have retrenched, and have cut support for extramural programs, or reorganized, in order to maintain internal initiatives. These changes do not necessarily serve the greater interests of Arctic research, especially in terms of educating and training future researchers and managers to deal with the challenges facing the Arctic.

The Commission reminds agencies of the following clause in public law: "All Federal agencies shall consult with the Commission before undertaking major Federal actions relating to Arctic research" (*Arctic Research and Policy Act*, SEC. 105. (c)). USARC will redouble efforts to work closely with agencies to encourage greater balance between extramural and intramural Arctic research. USARC commits to working with IARPC to ensure that this aspect of the law is followed, calling for an open budget process and a comprehensive and balanced approach.

SUSTAINABLE RESEARCH PROGRAMS BUILD HUMAN CAPACITY

It's all about people. A nation's most valuable resource is the vitality of its scientific workforce. Research requires scientists and technology experts. Despite broad and continued support for the President Bush's 2006 American Competitiveness Initiative, and Congress's America COMPETES Act to promote excellence in technology, education, and science, there has been, until 2009, a major, overall decline in the level of federal funding for peer-reviewed, investigator-driven, extramural Arctic research in Earth and ocean observations and marine ecosystem dynamics at a time when ocean policy, climate change adaptation, and sustainable fisheries management all require more.

This trend has been especially troubling because many educators and resource managers are approaching retirement and sufficient new scientists are not being taught and trained. Only a vibrant research and educational enterprise with consistent funding will attract a new generation of scientists to Arctic research that is critical to dealing with change already occurring in the Arctic. USARC asserts that Arctic research is essential in order for the United States to



LEFT. Mark Twickler, University of New Hampshire, working on chemical samples in the science trench at GISP2. (Photo credit: R. Alley)
ABOVE. Viewing sea ice from a USCG Hercules C-130. (Photo credit: J. Farrell)

adapt to change while simultaneously achieving its national competitiveness goals. Priority needs to be given to funding projects that help build the human capacity to conduct scientific research.

FUNDING AMERICA'S ARCTIC SCIENCE

Generally, as national science funding expands across the board, greater resources are available for the Arctic Research Program. In 2009, President Obama and Congress worked to expand financial support for scientific research, including that associated with the Arctic. The FY09 operating budget, and the President's FY10 budget both included significant increases in scientific research budgets, and the American Recovery and Reinvestment Act of 2009 (ARRA) also provided a significant boost for research. In particular, NSF's first ARRA-identified expenditure was funding for the Alaska Regional Research Vessel, recently named the R/V *Sikuliaq* [pronounced [see-KOO-lee-auk], an Inupiaq word meaning "young sea ice," an initiative that the Commission has long supported. Will this recent support endure? A recent history of appropriations provides appropriate, longer-term context for consideration.

The omnibus FY08 appropriations bill was passed by Congress and signed by the President in December 2007. For the fourth year in a row, federal investment in research declined in real dollars. Of particular concern in the development of this budget was that going into the House-Senate joint conference, increases of approximately 10% were requested for many of the various federal research agencies. The negotiations, however, resulted in only a 1.1% increase for one of the nation's key science support agencies, NSF. Given an expected inflation rate of 2.4%, there was a loss of 1.3% within this agency in real dollars. Similar decreases occurred at NIH and other agencies that sponsor extramural research.

These cuts were particularly troublesome during the first IPY since 1958, with the potential to mark a new milestone in Arctic research. Many IPY aspirations for new US research activities were not met, and these research needs continue.

The United States must fully address the research funding goals that President Obama presented in *The Audacity of Hope,* and that the previous president and the Congress endorsed in the American Competitiveness Initiative and the America COMPETES Act. USARC joins the American Association for the Advancement of Science in drawing attention to this serious condition. We encourage the President and Congress to continue their recent turn around in support, and to make it enduring.

Recommendation

President Obama's recent commitment (April 27, 2009 speech at the National Academy of Sciences Annual Meeting) to invest more than 3% of the gross domestic product in research and innovation is most promising, and the Commission strongly encourages Congress to help him achieve this goal.

DEVELOP AND SUSTAIN ARCTIC RESEARCH INFRASTRUCTURE

The term "Arctic research infrastructure" covers a wide range of basic physical and organizational structures integral to the scientific research enterprise. Below, we address a variety of observing networks, vessels, satellites, laboratories, research centers, and emerging technologies, such as autonomous vehicles used under the sea, and in the air. A great challenge in scientific research is maintaining an appropriate balance in financial support for infrastructure, and the associated management and operations budgets, compared to budgets to conduct the scientific research with data collected from such infrastructure.

Arctic Observing Network (AON)

As described earlier, USARC supports implementation and further growth of AON, and recommends collaboration with other Arctic nations and the International Arctic Science Committee (IASC) to integrate AON into the international global observing and data management systems, up to, and including GEOSS. Key government decisions are necessary now to implement the AON vision of the Committee on Designing an Arctic Observing Network (NRC, 2006).

Polar Icebreakers

USARC has long supported a strong and viable national icebreaker fleet, and has been an ardent advocate of a timely and rational replacement program for the aging vessels *Polar Sea* and *Polar Star*. All of USARC's key points in this regard were communicated to the NRC Committee on the Assessment of US Coast Guard Polar Icebreaker Roles and Future Needs. USARC is pleased to see that these points were incorporated into the report published by the Council in 2007 (NRC, 2007a).

- The United States should continue to project an active and influential presence in the Arctic to support its interests. This presence requires a US government polar icebreaking capability to assure year-round access throughout the region.
- National interest in the polar regions require that the United States immediately program, budget, design, and construct two new polar icebreakers to be operated by the US Coast Guard.
- Polar icebreakers are essential instruments of US national policy in the changing polar regions. To assure adequate national icebreaking capability into the future, a presidential decision directive should be issued to clearly align agency responsibilities and budgetary authorities.

These recommendations are consistent with NSPD-66/HSPD-25, released in 2009. Further, in 2010, after additional cost-benefit studies are complete, USARC urges the President and the Congress to commit to building two new polar class icebreakers to meet US needs in the polar regions.

Earth Observing Satellites

In concert with the latest NRC study (NRC, 2007b) on what AAAS calls "the crisis in Earth observation from space," USARC also expresses grave concern that the network of satellites upon which the United States and the world have relied upon for global observations is at great risk. These observations are critical for anticipating the impacts of global change as well as being essential for weather forecasting; hurricane and storm warning; management of agriculture, forestry, and fisheries; and national security. Budget cuts and reallocations at NASA and NOAA will decrease satellite missions by 40% by the end of the decade. As noted in the NRC study, this trend toward a sharply diminished US capacity in Earth observations had also resulted from an explicit redirection of NASA's priorities away from Earth observations and toward missions to the Moon and Mars.

USARC supports recommendations of the NRC study for restoring US capabilities in Earth observations from space to acceptable levels, including:

- Reconstituting specific key observation capabilities that have recently been deleted from scheduled NOAA satellite series
- Accelerating NASA's current launch schedule to shrink the data gaps implied by current plans

- Committing to the 17 highest-priority new Earth-observation missions, out of more than 100 candidates evaluated for the 2010–2020 time period

The study concluded that its recommendations could be funded until 2020 by returning the Earth science budget at NASA to its FY1998–2000 level and stabilizing the budget of NOAA's National Environmental Satellite, Data, and Information Service at only slightly above the FY07 level, adjusted for inflation.

The February 2008 news release by the Office of Science and Technology Policy about the Bush Administration's plans to significantly enhance the nation's civil Earth observation capabilities was encouraging. Reinstating critical climate measurement capabilities (once part of the National Polar-Orbiting Operational Environmental Satellite System effort) and funding a new set of space research missions in NOAA and NASA to advance our understanding of changes in Earth's climate, ocean, and land surfaces is a welcomed development that USARC encourages Congress and this administration to support.

Other Emerging Technologies and Observatories

As noted in the above-mentioned NRC reports, Arctic scientific research objectives frequently depend on platforms such as observatories, ships, submarines, satellites, aircraft, and other technologies to detect natural phenomena and to collect data. The Arctic presents a wealth of opportunities to test and employ research platforms on land, in the sea, and in the air. Much of this infrastructure, however, lacks support and long-term commitment. The need is especially keen when international consensus and investments are involved. Coordination will reduce costs and increase effectiveness. Therefore, USARC recommends that IARPC help lead an international assessment of Arctic research infrastructure needs, and then work with public and private institutions to make appropriate investments in new platforms to support the nation's Arctic research program.

The Commission supports the following infrastructure opportunities as vital. Some of these elements have been addressed (NRC, 2006) as AON elements, and others have recently been funded, such as the Alaska Regional Research Vessel:

- Alaskan Permafrost Observatory
- Barrow and Bering Sea Cabled Observatories
- Barrow Arctic Research Center
- Hydrological Sensor Systems
- Technologies—Telemedicine, Communications, and Wireless Sensing Networks
- Unmanned Autonomous Aircraft and Underwater Systems
- Alaska Regional Research Vessel (ARRV)

REINVIGORATE THE INTERAGENCY ARCTIC RESEARCH POLICY COMMITTEE (IARPC)

The primary objective of the 1984 Arctic Research and Policy Act was to produce and implement a comprehensive national policy and plan for Arctic scientific research. To this end, the Act created USARC, which develops and recommends to Congress and the President an integrated national Arctic research policy, and biennially publishes a *Report on Goals and Objectives*. IARPC responds to the report by formulating a five-year *US Arctic Research Program Plan* and by revising it biennially.

Growing interagency relationships are reinvigorating IARPC under the leadership of the NSF Director. In light of evolving national priorities, this interagency effort is transforming. Participants are becoming actively engaged, and IARPC is strengthening its internal partnerships. We encourage regular meetings of IARPC, and active involvement with USARC and representatives from the Executive Office of the President (specifically, the Office of Management and Budget, the Office of Science and Technology Policy, the Council for Environmental Quality, and the Natural Security Council). In its efforts, IARPC should engage the public and endeavor to improve its strategic planning and integration of Arctic research across federal agencies. We also encourage IARPC to work closely with the National Science and Technology Council that plans and oversees other interagency research initiatives.

RECOMMENDATIONS

First, the Commission recommends that IARPC expand its membership and planning activities to include independent, federally created entities that can play a major role in Arctic research. The North Pacific Research Board, the North Slope Science Initiative, Alaska Ocean Observing System, and the Prince William Sound Oil Spill Recovery Institute—all created by Congress—are essential to making the goals of this report happen. The Denali Commission, also created by Congress, has the capability to support "pilot projects" that can advance research goals. Further, there is an increasing contribution to research by "community development quota" groups in western Alaska that exist as the result of federal fishing quota allocations.

Second, the Commission recommends that IARPC, under NSF's leadership, meet its statutory obligations and "provide the necessary coordination, data, and assistance for the preparation of a single integrated, coherent, and multi-agency budget request for Arctic research" as per Section 108 (a) 5 of the Arctic Research and Policy Act. This budget will be produced annually, in conjunction with the release of the President's budget. As per Section 105(c), IARPC agencies "shall consult with the commission before undertaking major Federal actions relating to Arctic research." The Commission supports bringing both IARPC and the Interagency Coordinating Committee on Oil Pollution Research under the umbrella of the White House NSTC.

Third, consistent with the two prior recommendations, the Commission asks that the White House Office of Science and Technology Policy and the Office of Management and Budget actively participate in integrating Arctic research plans and budgeting and budget reporting as explicitly called for in the Arctic Research and Policy Act of 1984.

REVIEW AND REVISE US ARCTIC POLICY AND INTERNATIONAL COMMITMENTS

President Bush released a new Arctic Region Policy in January 2009 following a comprehensive two-year review and assessment that was recommended in USARC's 2007 goals report. This policy, designated National Security Presidential Directive 66 and Homeland Security Presidential Directive 25, builds upon the previous review, completed in 1994 (Presidential Decision Directive 26) during the Clinton administration. At that time, circumpolar cooperation was just getting started. The Arctic Council was established in 1996 as a high-level intergovernmental forum to foster and promote cooperation, coordination, and interaction among the Arctic States, including the United States, with the involvement of Arctic indigenous communities and other Arctic inhabitants on common Arctic issues.

We commend the Obama Administration for the initiatives it has taken to implement this policy. Some examples: The Ocean Policy Task Force has paid close attention to the imperatives of an increasingly accessible Arctic Ocean and the need to establish a baseline integrated ecosystem science program that can bring together and build upon significant work done to date. The US Navy completed an "Arctic Roadmap" that will provide a basis for Arctic research and operational investments in the decade to come. USCG has conducted a "High Latitude Study" and continues to advance its operations in the Arctic region. DOS has commenced negotiations on search and rescue cooperation in the Arctic and has announced an initiative with EPA to address black carbon and other short-term forcers of Arctic climate change.

We now know that climate change in the Arctic will impact research, civil infrastructure, energy supplies, indigenous cultures, fisheries, national security, and global transportation—to name a few. The policy in place mandates an integrated US strategy that will allow us to better adapt our goals and international commitments in the areas of research, safety, search and rescue, environmental protection, economic development, health and ecological risks, biodiversity, offshore oil and gas development, shipping activities, marine pollution, and cultural tourism.

ENGAGE THE NEXT GENERATION OF ARCTIC RESEARCHERS AND RESIDENTS

Many Arctic residents, and particularly indigenous peoples, contribute significantly to the success of scientific research efforts. Highly successful co-management agreements, such the Alaska Sea Otter and Sea Lion Commission, the Alaska Nanuuq (polar bear) Commission, and the Eskimo Walrus Commission, have been established with USFWS. These entities biosample subsistence-harvested marine mammals, thus providing researchers with valuable materials and data on animal populations and behaviors. Other forms of traditional and TEK provided by Alaska Natives have also been critical to success. Likewise, NOAA has a cooperative agreement with the Alaska Eskimo Whaling Commission to co-manage the subsistence harvest of bowhead whales. Similarly, this agreement provides researchers with valuable samples and data. Despite the importance of these research relationships, funding for co-management agreements, like extramural research funding, are often cut off when agency budgets tighten.

Communication and collaborative efforts need to be improved between researchers unfamiliar with Arctic people and local communities of indigenous Alaskans. Constructive and culturally sensitive engagement with the communities that provide logistical and other research support are critically needed, and will go a long way toward better communication and collaboration in future scientific research and policy efforts. Higher priority must be placed on incorporating and translating local traditional knowledge into scientific research issues that impact Arctic residents. Scientific progress is not a one-way street, from the Arctic outward. Instead, research results from studies of Arctic climate change, ecosystems, oceanography, human health, resource assessment, polar technology, and infrastructure must be communicated and disseminated back to Arctic residents in manners that best serve their needs.

USARC recommends renewed federal support for the Alaska Native Science Commission, which was established to bring together research and science in partnership with indigenous communities. The Commission recommends that IARPC agencies develop new mechanisms to create stronger collaboration with Arctic residents and the public at large. Too often federal agencies hold stakeholder meetings in Washington, DC, or other urban centers at times that conflict with local subsistence activities essential for Arctic communities. In addition, because travel from Arctic communities to Alaska urban hubs and beyond is costly, researchers and federal managers should seek out opportunities, such as the annual Alaska Federation of Natives meetings, to acquire input on research concerns of Arctic communities and user groups.

Communication among researchers, resource managers, and communities will lead to valuable collaborations that will assist in future research and in dealing with emergency situations. For example, in examining the response to the *Selendang Ayu* oil spill off Unalaska Island in the Aleutians, the key lessons learned were the need for more input from local organizations and individual community members, and better communication between the Unified Command and the local entities (Brewer, 2006).

NOAA's Arctic Vision & Strategy

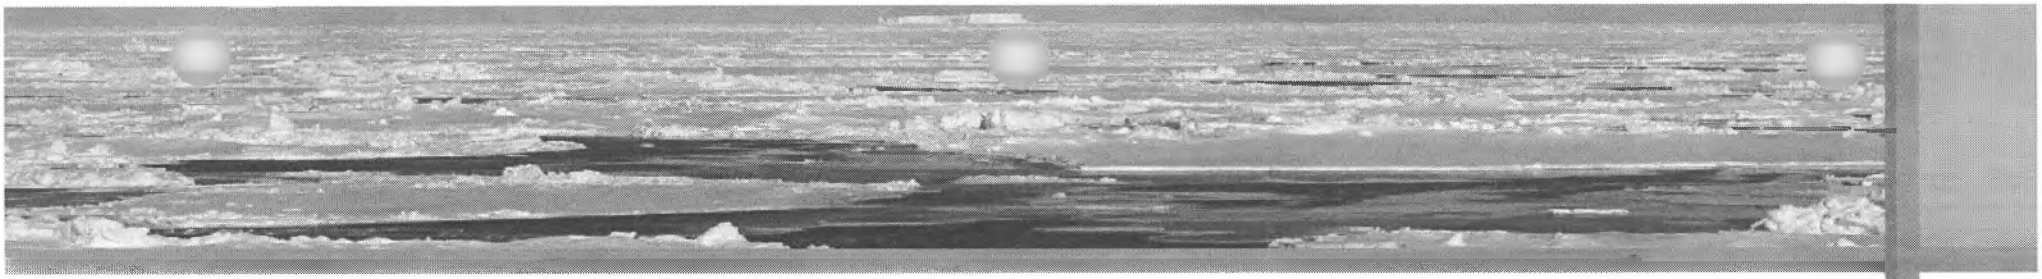
Executive Summary

"For centuries annual sea ice has protected the Arctic and its inhabitants. Now the Arctic, both on land and sea, is being transformed by significant warming. The melting of sea ice in the Arctic Ocean is happening at a faster pace than we had predicted, and an ice-diminished Arctic Ocean is creating many new opportunities. These opportunities must be pursued in ways that will ensure our precious ecosystems and Arctic communities remain healthy and resilient, now and for future generations."

The Honorable Dr. Jane Lubchenco,
NOAA Administrator and Under Secretary of
Commerce for Oceans and Atmosphere

The Arctic (Figure 1) has profound significance for climate and functioning of ecosystems around the globe. The region is particularly vulnerable and prone to rapid change. Increasing air and ocean temperatures, thawing permafrost, loss of sea ice, and shifts in ecosystems are evidence of widespread and dramatic ongoing change. As a result, critical environmental, economic, and national security issues are emerging, many of which have significant impacts for human lives, livelihoods, and coastal communities. Though NOAA has numerous and diverse capabilities that support these emerging issues, a strategic approach that leverages NOAA's existing priorities and strengths, as well as those of our national and international partners, is needed. This document provides a high-level framework and six strategic goals to address NOAA's highest priorities in the region. It is based upon assumptions that the region will: 1) continue to experience dramatic change, 2) become more accessible to human activities, and 3) be a focus of increasing global strategic interest.

NOAA envisions an Arctic where decisions and actions related to conservation, management, and use are based on sound science and support healthy, productive, and resilient communities and ecosystems. The agency seeks a future where the global implications of Arctic change are better understood and predicted.



NOAA will focus its efforts on the following six priority goals needed to realize this vision:

1) Forecast Sea Ice
2) Strengthen Foundational Science to Understand and Detect Arctic Climate and Ecosystem Changes
3) Improve Weather and Water Forecasts and Warnings
4) Enhance International and National Partnerships
5) Improve Stewardship and Management of Ocean and Coastal Resources in the Arctic
6) Advance Resilient and Healthy Arctic Communities and Economies

These goals were selected because they represent areas where NOAA can address urgent and timely issues that meet two key criteria: providing the information, knowledge, and policies to meet NOAA mandates and stewardship responsibilities, and providing the information, knowledge, and services to enable others to live and operate safely in the Arctic. Each goal also fulfills international goals and establishes, enhances, or leverages partnerships with other Arctic nations, international organizations, government agencies, and non-governmental organizations, academia, and local communities. The goals are also geared towards generating large societal benefits relative to the resources required and strengthening NOAA's engagement, politically, scientifically, internationally, and publicly.

NOAA will next develop and execute a five-year Arctic Action Plan to achieve these goals. Development and execution of the plan will require coordination across all NOAA Line and Staff Offices and collaboration with local, regional, federal, non-governmental, and academic partners. As a starting point, NOAA will establish a single point of contact within NOAA Senior Executive Leadership who will be accountable for achieving the Arctic goals. The Arctic Action Plan will also include an engagement strategy for reaching internal and external employees, partners, and stakeholders, as well as a detailed budget strategy. NOAA is committed to enhancing its current involvement in research and management programs in the Arctic, and anticipates an initial investment of $10 million towards the implementation of this strategy, recognizing that additional funds will be needed to achieve the goals.

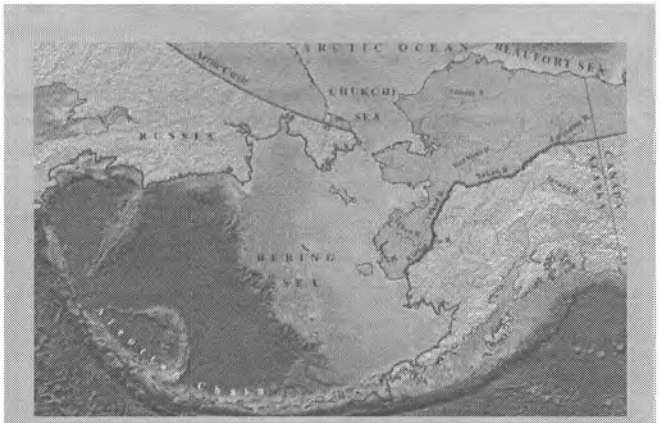


Figure 1. The Arctic: As used in this document, the term "Arctic" means all United States and foreign territory north of the Arctic Circle and all United States territory north and west of the boundary formed by the Porcupine, Yukon, and Kuskokwim Rivers; all contiguous seas, including the Arctic Ocean and the Beaufort, Bering and Chukchi Seas; and the Aleutian chain. For purposes of this document only, this map illustrates the Arctic as defined under the Arctic Research and Policy Act and does not represent or reflect the position of NOAA with respect to the international boundaries and limits depicted therein. Map courtesy of the Interagency Arctic Research Policy Committee.

Introduction

Evidence of a Changing Arctic

There is now widespread and dramatic evidence of overall change in the Arctic region. Many of these observations are highlighted in the annual NOAA Arctic Report Card (www.arctic.noaa.gov):

- **Atmosphere** – Recent Arctic temperature increases are more than double those found at more southerly latitudes. The Arctic's 2008 annual mean air temperature over land was the fourth warmest on record, which continues a long-term upward trend.
- **Sea Ice** – Four of the last five years represent the lowest sea ice extents on record, with open water extending later into the fall prior to freeze-up. Thick multi-year sea ice has decreased 35 percent in the last five years.
- **Ocean** – From the Aleutian Islands to Barrow, Alaska, ocean ecosystems are shifting due to a combination of Arctic warming, large natural variability, and sensitivity to changing sea ice conditions.

These changes in Arctic climate have local to global implications. The Polar Regions, though physically remote from the population centers of the globe, have profound significance for the planet as a thermostat to stabilize the Earth's climate. They act not only as regulators of global temperature, but also as barometers of change. National security concerns are increasing as reductions in sea ice and other climate-induced changes bring increased opportunities for economic development and increased access to Arctic resources. These economic drivers, in turn, can further threaten ecosystems and Arctic inhabitants already impacted by the rapidly changing climate. The risks to national security and sound Arctic stewardship are further intensified because the science that underpins many of the decision-making processes and support services is largely inadequate.

International and domestic interest in the Arctic is increasing in concert with broader discussions regarding climate change, national security, and stewardship. Some examples include:

- The U.S. Government's issuance in January 2009 of a National Arctic Policy (National Security Presidential Directive (NSPD 66)/ Homeland Security Presidential Directive (HSPD 25),
- The November 2009 issuance of the Navy Arctic Road Map, developed by the Navy Task Force Climate Change,
- The Secretary of Commerce's February 2009 approval of the North Pacific Fishery Management Council's Arctic Fishery Management Plan, which prohibits expansion of commercial fishing in U.S. federal waters in the Beaufort and Chukchi Seas,
- Recent decisions on listings of Arctic marine mammals under the Endangered Species Act and Marine Mammal Protection Act,
- Establishment of the Extended Continental Shelf Interagency Task Force to support a potential claim as allowed under United Nations Convention on the Law of the Sea (2007),
- The State of Alaska's move to take immediate actions and plan longer-term research and operations addressing a broad range of impacts (Governor's Climate Change Sub-Cabinet 2007, Joint Alaska Climate Impact Assessment Commission 2007), and
- The Interagency Ocean Policy Task Force's recognition of the Arctic as an area of special emphasis in its interim report (see sidebar).

The *Interim Report of the Interagency Ocean Policy Task Force* (September 2009) identified "Changing Conditions in the Arctic" as an area of special emphasis, calling for the National Ocean Policy to "address environmental stewardship needs in the Arctic Ocean and adjacent coastal areas in the face of climate-induced and other environmental changes." The interim report calls for "better ways to conserve, protect, and sustainably manage Arctic coastal and ocean resources... new collaborations and partnerships to better monitor and assess environmental conditions... improvement of the scientific understanding of the Arctic system and how it is changing in response to climate-induced and other changes." NOAA's strategic Arctic goals were developed to directly support the recommendations identified by the Task Force.

NOAA's Evolving Role in the Arctic:
Providing Critical Science, Services, & Stewardship to the Arctic & Partners

No single region better demonstrates the complex interdependence of communities and changing ecosystem conditions than the Arctic. The breadth and complexity of the cultural, societal, economic, and environmental impacts requires a concerted, systematic, and rapid effort with partners from local to international levels. NOAA provides vital Arctic science, services, and stewardship, including information and products that form a critical foundation for science and management of our trust resources in Arctic oceans and on the coasts–products that are essential for other agencies to succeed in their Arctic missions. However, achieving the Nation's Arctic goals requires strong integrated partnerships at all levels of governance. NOAA is building and continues to advance partnerships with several international, federal, state, and local partners and stakeholders focused on Arctic issues. Interagency and international cooperation should be an element of most of NOAA's Arctic activities and should be included in relevant project plans. Some elements of collaboration have general applications and need to be organized and conducted for the benefit of NOAA as a whole. In this category are participation in interagency working groups such as the Interagency Arctic Research Policy Committee, implementation and development of international agreements, and participation in policy-relevant activities focused on the Arctic.

Given our science, service, and stewardship responsibilities to Arctic residents and to the Nation, NOAA must engage its diverse and unique capabilities to rapidly address the emerging environmental, social, economic, and national security issues in the Arctic. NOAA's scientific capabilities can be deployed to increase our understanding of climate and assess key environmental trends; to predict the ecosystem response to those trends; and to offer the technical expertise needed to develop policy options and planning and management strategies for mitigation and adaptation to the environmental challenges in the Arctic region. NOAA's service capabilities are needed to support safety and security needs for fishing, marine mammal protection, transportation, energy, infrastructure, and mineral exploration in the unique Arctic environment. NOAA's legal and regulatory authorities and operational and international cooperation requirements will set the framework for delivery of our science, services, and stewardship.

Strategic Alignment of NOAA's Priorities

NOAA's Annual Guidance Memorandum, signed August 5, 2009, identified the need to "strengthen Arctic science and service" as one of the agency's five strategic priorities. The other four priorities include: 1) enhance NOAA's climate services and support the establishment of a National Climate Service, 2) support Coastal and Marine Spatial Planning, 3) ensure sustainability of marine fisheries, and 4) sustain satellite-based Earth observations. This Arctic strategy integrates the enhanced capacity provided by implementing NOAA's strategic priorities and positions NOAA to move forward in these areas. Concurrently, it aligns NOAA's Arctic goals to directly support priorities of our federal partners.

NOAA's Arctic Vision

NOAA envisions an Arctic where:

- Conservation, management, and use are based on sound science and support healthy, productive, and resilient communities and ecosystems; and
- The global implications of Arctic change are better understood and predicted.

Guiding Principles

The U.S. and its partners will greatly benefit from enhanced and better coordinated NOAA efforts in the Arctic region. Though NOAA's scientific interests in the Arctic are broad, this strategic framework establishes a limited set of guiding principles that emerged from the strategic planning process. NOAA Arctic activities in the next one to five years will:

1) Provide outcomes critical for other agencies to succeed in fulfilling their responsibilities and support the implementation of the National Ocean Policy,
2) Strive to better understand the linkages between oceans and climate,
3) Advance the implementation of ecosystem-based management and Coastal and Marine Spatial Planning,
4) Concentrate action in the Bering, Chukchi, and Beaufort areas, but be global in scope,
5) Enable, inspire, and engage our partners and stakeholders, both domestic and international,
6) Incorporate the value of traditional and local knowledge,
7) Integrate a coordinated education and outreach program that encompasses formal and informal education and the general public,
8) Incorporate new developments in science and technology, and
9) Anticipate, respond, and adapt to new and emerging issues of importance.

Arctic Goals & Strategy

NOAA's six Arctic goals are both integrated and crosscutting, and are designed to achieve NOAA's Arctic vision. The goals, and initial priorities described within them, were developed based on a set of criteria vetted across NOAA's Line Offices, Staff Offices, and Goal Teams; and derived from the Draft NOAA Strategic Plan for the Arctic. They are intended to support the goals and priorities of our federal and intergovernmental partners and stakeholders.

The goals first provide a foundation for improved research and understanding of the scientific underpinnings, climate changes, and dynamic feedback loops that are needed to support effective stewardship and address national security concerns. Increased scientific understanding and improved service delivery of predictions and forecasts, in concert with increased cooperation and collaboration with national and international partners, will result in more effective management of coastal and ocean resources and resilient and vibrant Arctic communities and economies (Figure 2).

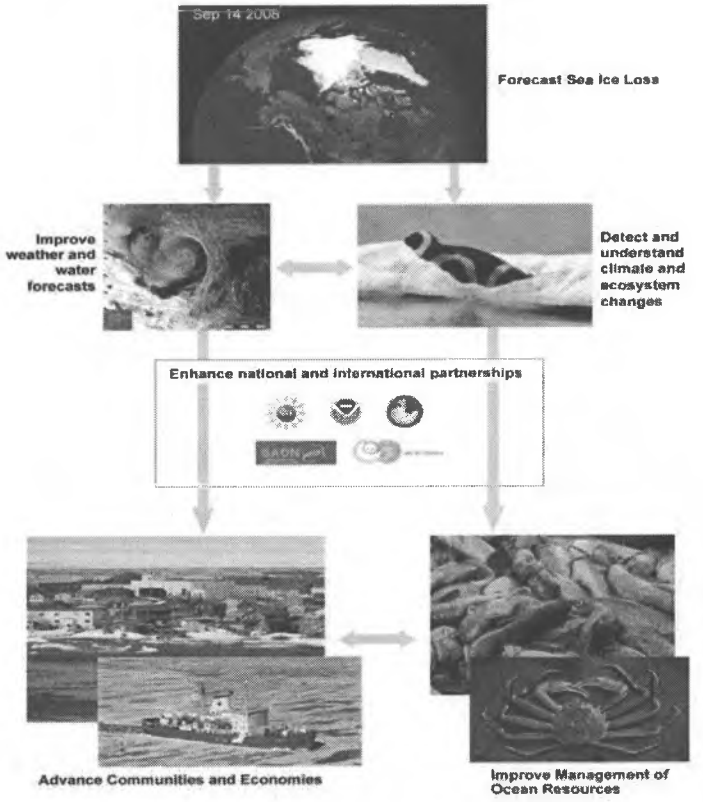

Figure 2. NOAA's Strategic Arctic Goals. This diagram illustrates the alignment and integration of NOAA's Arctic goals.

Goal 1: Forecast Sea Ice

Goal Statement – Accurate, quantitative, daily forecasts to decadal predictions of sea ice are provided to support safe operations and ecosystem stewardship.

Importance: Continued rapid loss of sea ice will be a major driver of large changes across the Arctic (Figure 3). The loss of sea ice affects marine access, regional weather, ecosystem changes, and coastal communities. Food webs are expected to dramatically shift between benthic-focused food webs and pelagic webs as ice cover diminishes. The understanding of ice as a habitat also has implications for oil spill response and damage assessment. As the Arctic Ocean becomes seasonally passable and tourism, oil and gas exploration, and shipping increase, floating sea ice will present a major threat to maritime safety and increase the potential for oil spills in the region.

Projections of a nearly sea ice-free summer by the end of the century, made just three years ago, have been revised recently and now indicate that ice-free summers may occur before mid-century (Figure 4). Arctic change is accelerated by the unique physical properties associated with sea ice loss, which acts to accelerate warming of the Arctic, driven by increasing greenhouse gases in the global atmosphere. Reduction in summer sea ice diminishes reflection

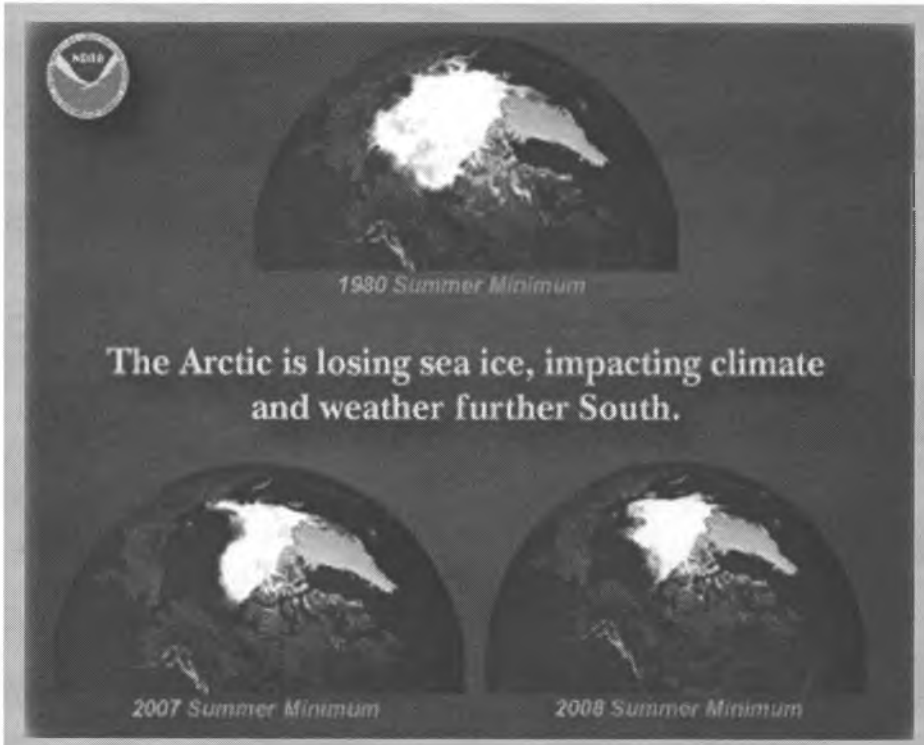

Figure 3. Arctic summer sea-ice cover has decreased over 35 percent over the last 30 years, and the amount of stable long-term multi-year sea ice has decreased by the same amount.

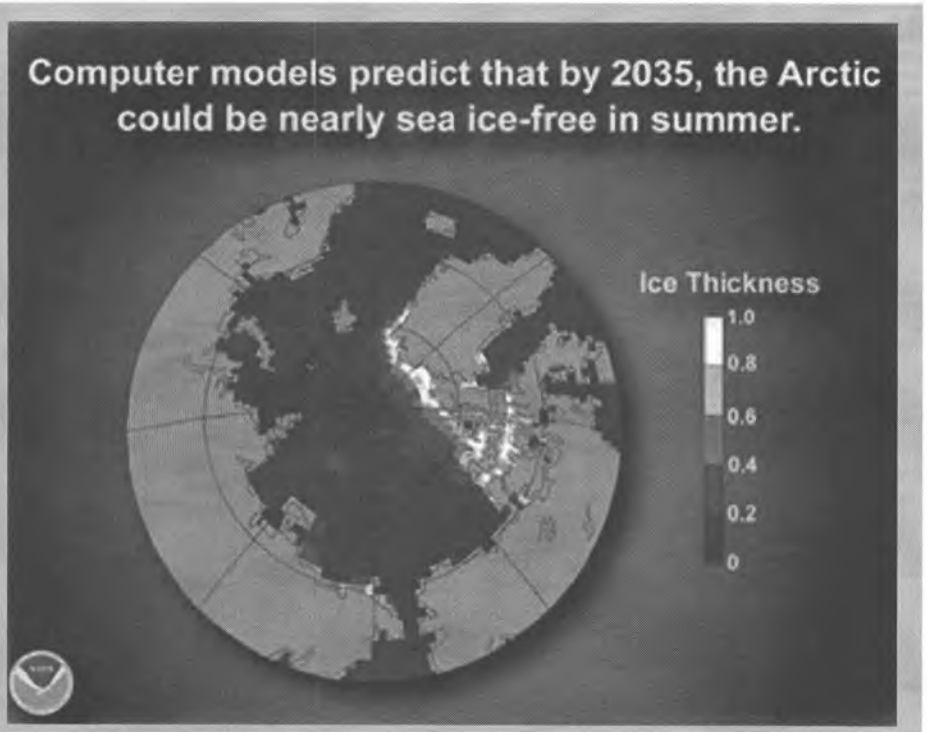

Figure 4. Model projections of sea ice thickness when the Arctic is nearly ice free, in September, within 30 years. Units for sea ice thickness are meters. Figure from Wang and Overland (2009).

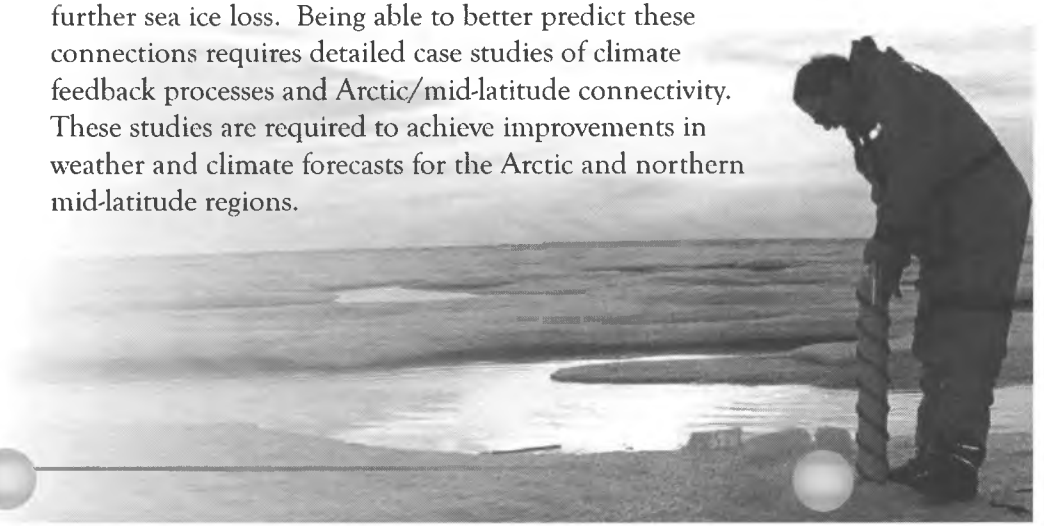
of solar energy and creates additional ocean heat storage in newly formed sea ice-free areas. Further, the additional heat stored in the ocean during summer is given back to the atmosphere the following autumn, causing changes in normal patterns of weather and climate variability with global consequences. The ability to quantitatively forecast Arctic sea ice over varied time scales requires regular observation of Arctic atmospheric and ocean states, circulation, and sea ice characteristics; understanding of the interactions among clouds, radiation, and aerosols; and development of coupled atmosphere-ice-ocean models.

NOAA's current activities: NOAA is currently conducting sea ice analysis and forecasts, evaluation of sea ice projections in Intergovernmental Panel on Climate Change (IPCC) climate models, conducting and analyzing satellite and airborne observations of sea ice freeboard or thickness, improving satellite image analyses, and contributions toward the Arctic buoy program.

Five-year strategy: *Improving daily to weekly sea ice models and forecasts and new seasonal prediction* services will fill a critical gap in marine weather and climate services that will benefit community activities, support the management of protected marine resources, and improve safe operation and navigation through these waters as marine transportation and industry use expands. There is currently no up-to-date sea ice atlas for Alaskan waters, necessary for operational planning. Native communities have noted that not only is the extent and timing of sea ice changing, but its character (floe size, thickness, ridging) is also changing. *Forecast improvements* can be made by enhancing and integrating different types of observations of the atmosphere, sea ice, and ocean, including use of local knowledge, classifying sea ice characteristics, and directly combining data-assimilating sea ice models and climatological information with forecast models. *Seasonal predictions*, particularly the period of open water that defines an extended operations and shipping season, are increasingly in demand. An exploratory Sea Ice Outlook, led by NOAA and the National Science Foundation, in coordination with 20 international contributors, suggests that it is possible to develop seasonal predictions constrained by late spring sea ice conditions and driven by projected weather conditions.

Multi-decadal sea ice projections are required for infrastructure planning, ecosystem stewardship under rapidly changing conditions, and projection of global climate impacts forced by changes first occurring in the Arctic. The most important requirement is to reduce the uncertainty in climate projections forced by anthropogenic gas increases relative to the large natural variability in the Arctic. Current multi-decadal sea ice projections are based on a judicious evaluation of the 24 climate models provided through the IPCC Fourth Assessment Report. NOAA must anticipate a major evaluation of the new model results for application in the Arctic using information that will soon be made available by the IPCC Fifth Assessment Report. Further, special studies using climate and Earth system models need to target Arctic processes. Global models are necessary but not sufficient for regional applications, meaning that development of regional models is also needed.

Retrospective and prospective studies of the linkages between changes in Arctic sea ice and hemispheric weather and climate will lead to new understanding of how these changes affect larger areas. The cold conditions in eastern Asia and the eastern U.S. during winter 2009-2010 highlight the importance of shifts in hemispheric climate patterns to regional weather events, specifically the combination of the two major northern hemisphere patterns of variability—El Nino and the Arctic wind vortex, also known as the Arctic Oscillation. Recent studies support an increased connection between shifts in Arctic climate and increased climate variability in mid-latitudes. Such Arctic/mid-latitude connections can be expected to strengthen over the next decades as the planet experiences further sea ice loss. Being able to better predict these connections requires detailed case studies of climate feedback processes and Arctic/mid-latitude connectivity. These studies are required to achieve improvements in weather and climate forecasts for the Arctic and northern mid-latitude regions.

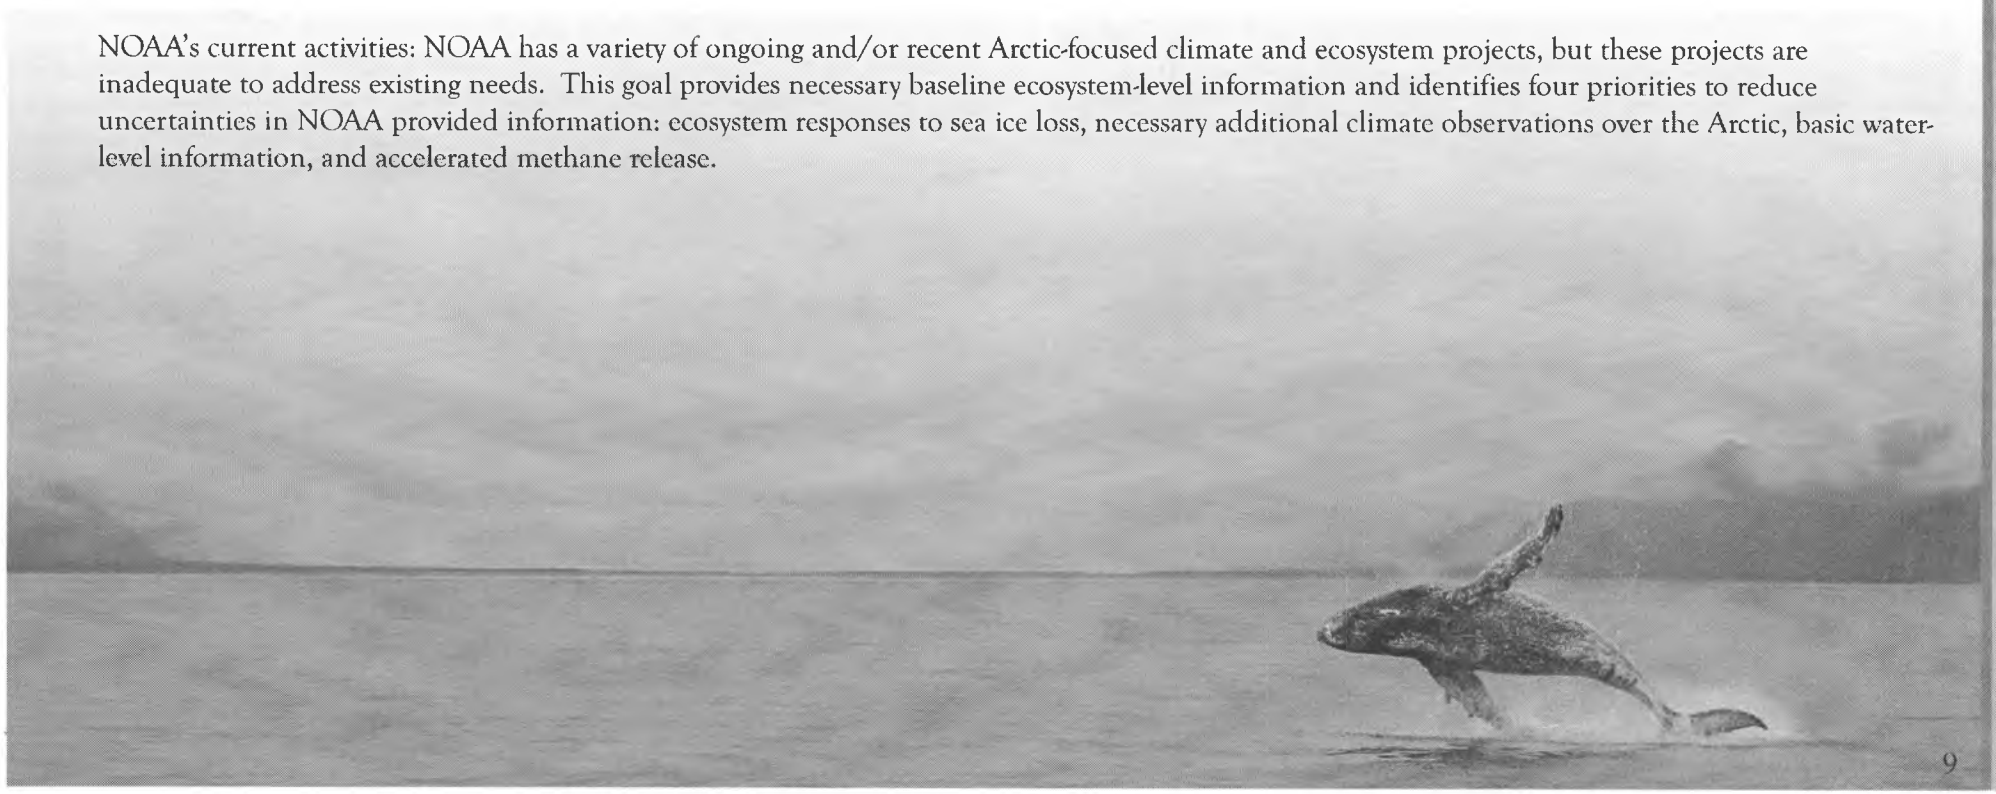


Goal 2: Strengthen Foundational Science to Understand & Detect Arctic Climate & Ecosystem Changes

Goal Statement – Improved baseline observations and understanding of Arctic climate and ecosystems reduces the uncertainty in assessing and predicting impacts caused by a changing Arctic.

Importance: While sea ice extent can be tracked by satellite sensors from year to year, there is much greater uncertainty in tracking the types and magnitudes of social and ecological impacts caused by Arctic climate changes and economic development. The Arctic will continue to provide short-term surprises as ecosystems move toward new and generally unknown states. Previous data and understanding can provide only minor guidance. For example, the response of marine primary production and the impacts on higher levels of the food chain from additional loss of sea ice are basically unknown. Recent data show that a simple conceptual model of a uniform northward shift of ecosystems as the Arctic warms is too simplistic. Other examples of changes in the Arctic are the warming of permafrost, increased coastal erosion, sea level changes, shifts in land and marine transportation patterns, the recent decrease in the pollock stock of the Bering Sea, and changes in land-based human subsistence resources. Monitoring and understanding climate change in the Arctic is important for other socioeconomic applications as well, including sea level and infrastructure protection, transportation, and community resilience. While the International Polar Year initiated a single intensive observational period in the Arctic, most NOAA missions require an enhanced effort to achieve sustained observations.

NOAA's current activities: NOAA has a variety of ongoing and/or recent Arctic-focused climate and ecosystem projects, but these projects are inadequate to address existing needs. This goal provides necessary baseline ecosystem-level information and identifies four priorities to reduce uncertainties in NOAA provided information: ecosystem responses to sea ice loss, necessary additional climate observations over the Arctic, basic water-level information, and accelerated methane release.



High Arctic Biodiversity

In June/July 2005, NOAA organized an international team of 45 scientists from the United States, Canada, Japan, China, and Russia in a collaborative effort to explore the frigid depths of the Canada Basin, one of the deepest parts of the Arctic Ocean. The expedition focused on assessing the diversity of life and the environment in all three major realms of the Arctic—the sea ice, the water column, and the sea floor. For one month, 35 members of the science party and 75 U.S. Coast Guard crewmembers worked together on board the U.S. Coast Guard Cutter Healy to conduct round-the-clock science operations. Scientists examined the hidden world of life in these extreme conditions with the aid of divers, photographic platforms, and a remotely operated vehicle specially designed to operate under ice and at great depth. More traditional techniques like ice coring, plankton nets, and bottom trawls supported these efforts. Expedition results form much of the basis of the January 2010 special issue of the journal Deep Sea Research.

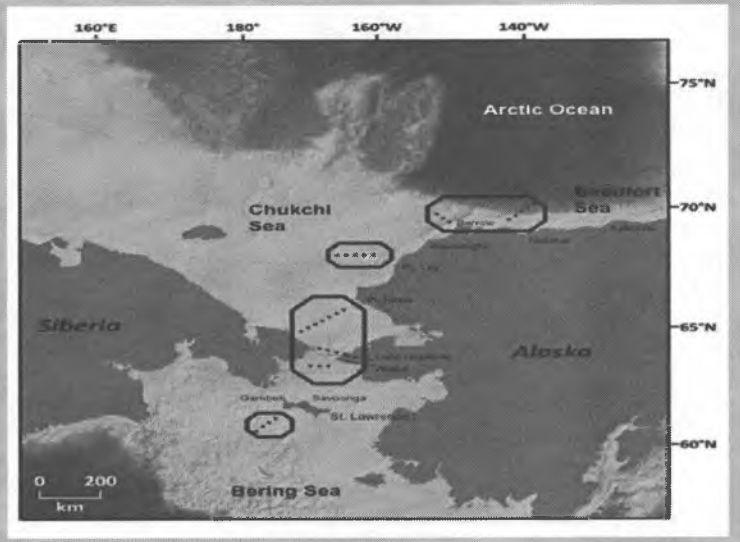


Figure 5. Four possible regional locations of Distributed Biological Observatory transect lines and stations for standard hydrological and biological measurements in the Pacific Arctic sector, including acoustics for marine mammal detection. These stations would include Canadian, Chinese, Japanese, Korean, Russian, and U.S. research vessels, coordinated through the international Pacific Arctic Group, and land-based research from coastal communities using helicopters, small ships, and long-term moorings.

Five-year strategy: An enhanced and integrated set of environmental observations is required to track the new trajectory of Arctic change across land, in the atmosphere, and in the ocean, including physical indicators, biological responses, and social and economic impacts. Rapid organization, interpretation, and dissemination of this information in near real-time is also a necessity, placing it in context with past conditions, natural variability, and model studies. Increased knowledge gained through this process, combined with model forecasts, will further enhance NOAA's capability to project and respond to future change. These enhancements would form the basis for a NOAA Arctic Change Detection System.

Such a system also includes a *marine Distributed Biological Observatory* (DBO) in the U.S. Arctic for consistent monitoring of biophysical responses in four pivotal oceanographic areas along a north-south latitudinal gradient (Figure 5). Each area exhibits high biological productivity, biodiversity, and gradients in ecosystem properties and direct linkages to subsistence-based coastal communities. All areas are projected to experience increased commercial use with the loss of sea ice. The Bering Strait region represents potential conflicts between commercial shipping and resource exploration, subsistence hunting, and management of biological resources. As sea ice retreats, the DBO will track the rate of ecosystem change and sample currently unknown impacts. The DBO was the central recommendation from a NOAA-sponsored workshop in May 2009 on the biological impacts of loss of sea ice. The DBO integrates biological and physical sampling, including both mooring and dedicated repeat ship occupations using a collaborative international network of logistical support. Efforts such as the Russian-American Long-term Census of the Arctic (RUSALCA) should be expanded to improve the exchange of information about near and far-field changes in the Arctic.

The science community was surprised by the rate of loss of summer Arctic sea ice from 2007 through 2009, as well as the magnitude of its impact on the regional and potentially hemispheric ocean and atmosphere. Current observing systems are inadequate to track and understand such changes. New in-situ, airborne, and satellite observing technologies are needed to fill gaps in meteorological and oceanographic fields. While satellites provide vertical profiles of air temperatures, they are less reliable in the lower layers of the Arctic atmosphere. For example, three areas of enhancement can improve analysis products, which in turn are the basis for understanding current Arctic change and improving forecasts. First, *in situ atmospheric profiles* across the Arctic Ocean are needed to stabilize the satellite data in reanalysis products and initial conditions. Second, *increase the number of drifting buoys and long-term moorings*. It is imperative to know upper ocean temperatures at the beginning of the summer melt and fall sea-ice freeze-up seasons to project future sea ice conditions. Long-term biophysical moorings at key locations in the Arctic are essential for tracking influx of heat to the Arctic. Third, NOAA should work to *maintain real-time access to NOAA and other national and international satellites* to fill critical gaps in observations, including the European CryoSat, the Canadian RadarSat, and Indian satellites. In addition, NOAA needs to continue and enhance research on integration of satellite data into regional products and scientific analyses to make the best use of these expensive systems.

Water-level information and forecasts are necessary for coastal community hazard resilience. NOAA is limited in its ability to meet this goal due to insufficient resources and outdated historical data sets. Increased sea-ice-free areas in fall allow a completely new wave and storm surge regime to develop. Deficiencies in information include accurate elevations based on new and updated gravity data and a geodetic framework tied to a new Arctic tide gauge network. Traditional tide gauges have difficulties in freezing and sea ice areas, but these difficulties can be overcome. More effort is needed to conduct circum-Arctic sea level analyses using all in situ and satellite data available from national and international sources.

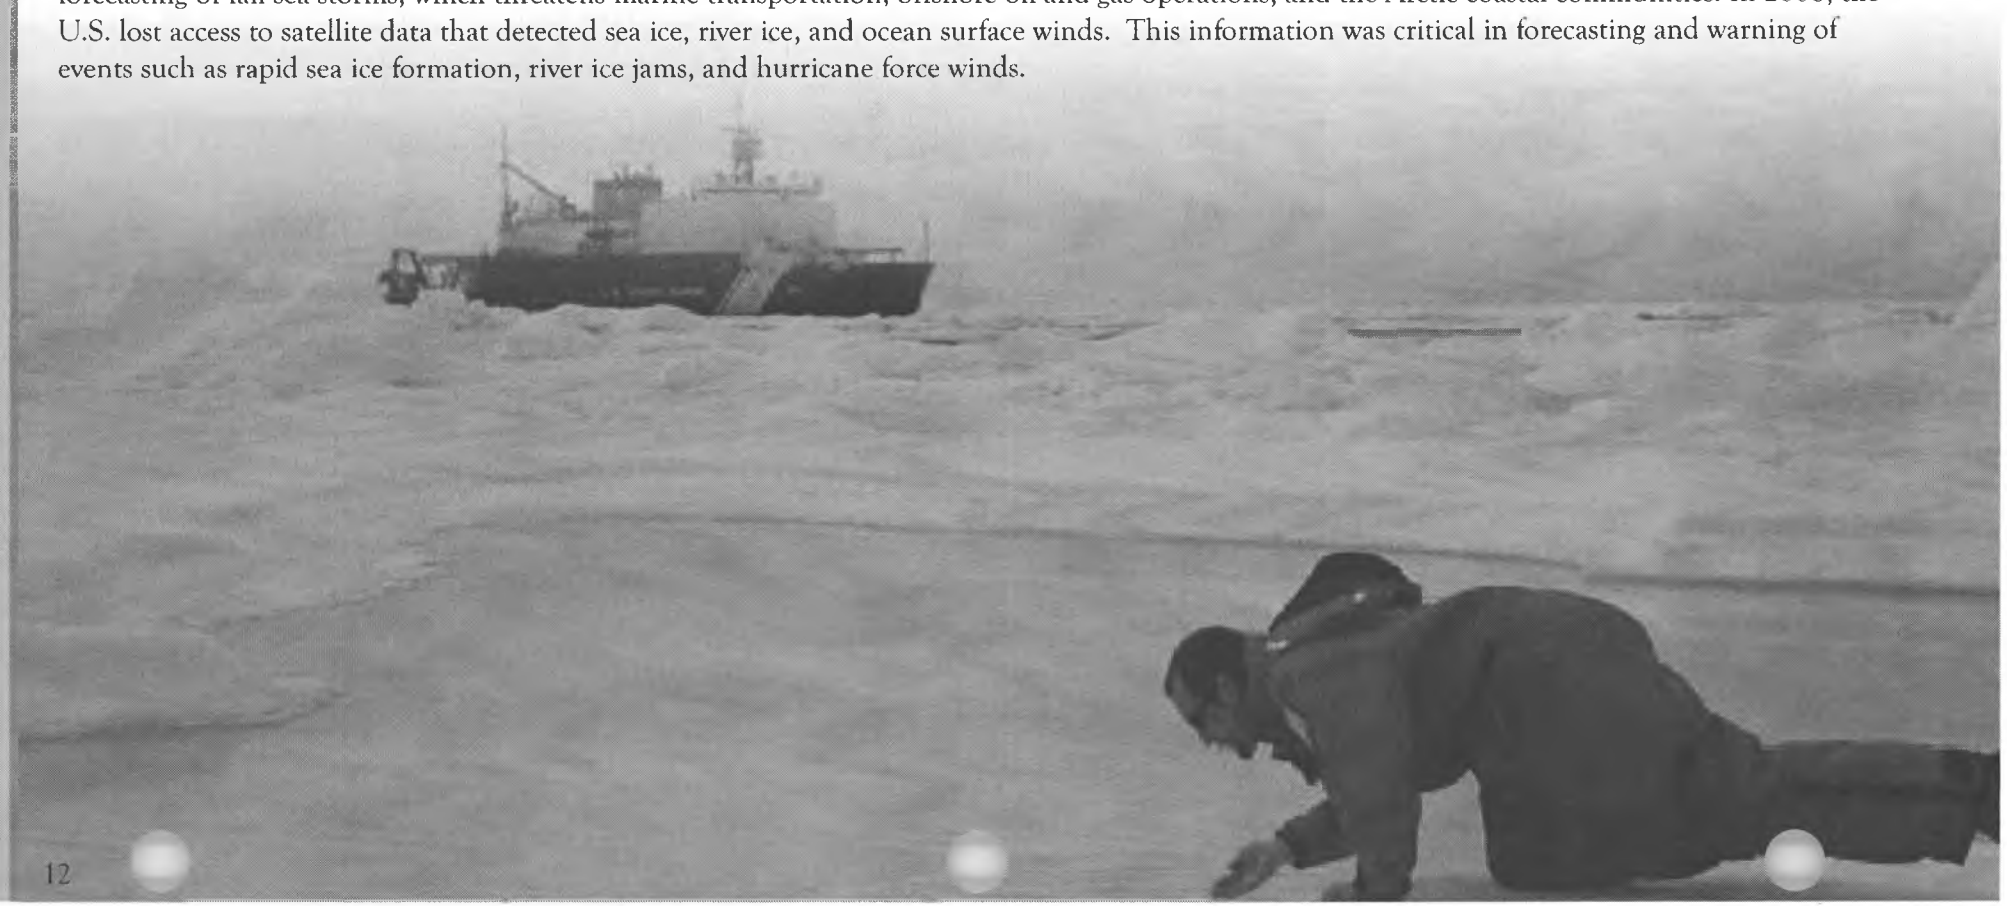
Recent research has shown that methane is being released from thawing permafrost on land and in shallow coastal seas. The amount of methane potentially available for release is very large, but there are no data sets that allow an estimate of the current rate of methane release throughout the Arctic and how this rate may be changing over time. *New synoptic observations over large regions of the Arctic, coupled with modeling and process research* are needed to determine if methane release from Arctic permafrost will be another positive, and powerful, feedback to the global climate system.

Goal 3: Improve Weather and Water Forecasts and Warnings

Goal Statement – Advanced, accurate forecasts and warnings are provided to ensure society can prepare for and respond appropriately to weather-related routine and extreme events.

Importance: Major stakeholders and partners, including the U.S. Coast Guard and the State of Alaska Division of Homeland Security and Emergency Management, require more useful weather and water information for planning and decision making to protect lives, property, and manage the region's many resources. Arctic weather also plays an important role in global weather; understanding this role is essential to improving global forecasts as well.

Arctic populations rely on aviation and marine systems for transportation and access to goods and services. A 2006 study by the National Institute of Occupational Safety and Health reported that the accident rate for commercial pilots in Alaska was five times higher than the national average. Additionally, Alaska's $4 billion fishing industry is one of the most dangerous in the Nation. Improvements in weather and water information will lead to increased safety and efficiency in these important sectors. Environmental observations and studies supporting weather and ice forecasts are highly limited in both geographic scope and frequency. For example, there is inadequate real-time meteorological data in U.S. Arctic waters to support accurate forecasting of fall sea storms, which threatens marine transportation, offshore oil and gas operations, and the Arctic coastal communities. In 2008, the U.S. lost access to satellite data that detected sea ice, river ice, and ocean surface winds. This information was critical in forecasting and warning of events such as rapid sea ice formation, river ice jams, and hurricane force winds.



Climate change is also affecting the Arctic environment, as evidenced by changing precipitation patterns, later freezing and earlier thawing of snow and ice, and changing sea level. People living along rivers and inland waterways face increasing disruption due to more frequent and devastating flooding. Still others face drought, straining municipal water supplies and putting the sustainability of entire businesses and communities at risk. Alaska's strategic location and waterways present both challenges and opportunities in terms of marine transportation, homeland security, and economic development.

NOAA's current activities: NOAA provides forecasts, warnings, and information for surface, marine, and aviation weather interests, with emphasis, when possible, on high-impact events such as extra-tropical storms and polar lows, storm surge and other coastal hazards such as tsunamis, heavy precipitation, floods, droughts, volcanic ash, and space weather. Services are delivered through a number of media from Internet to high frequency radio broadcasts.

Updating Alaska's Precipitation Frequency Estimates

NOAA is using a team of experts, and a set of global best practices, to update the 40-year-old Precipitation Frequency Estimates (PFE) for the State of Alaska. The PFE data are commonly used to reduce the risk of runoff-related loss of life and property and to prevent pollution. The data provide rainfall-related criteria used extensively by the engineering and environmental communities for the design of structures such as sewers and drainage systems, for environmental studies and design, and for sediment control. The criteria are used by the Federal Emergency Management Agency to update National Flood Insurance rate maps and by the Environmental Protection Agency's National Pollution Discharge Elimination System Program to regulate pollution control in streams. Results from climate change investigations in Alaska suggest the seasonality, amount, and type of precipitation are changing in many locations. NOAA uses these criteria for comparison during rainstorms that could produce flash flooding. NOAA expects to complete this task in September 2010.

Five-year strategy: Predictive services are generally not of the same accuracy, resolution (temporal and spatial), and reliability as similar products in mid-latitude regions. Forecasts of weather and water conditions lack detail beyond 60-72 hours and lose reliability considerably thereafter. A primary reason for this discrepancy is the relative coarseness of the observational fields to support meteorological and oceanographic modeling. New in-situ, airborne, and satellite observing technologies are needed to fill gaps in meteorological and oceanographic datasets, with then intent of improving both local and global weather forecasts. NOAA must expand services by addressing greater needs for observations, modeling, and forecasts while incorporating new techniques for ensuring this information leads to the best possible decisions and associated response. Science and technology will need to be leveraged based on advanced numerical models, including ranges of uncertainty. Improved Earth system models will include coupling of atmosphere, ocean, land and ice at local, regional, and global scales.

NOAA *must improve Arctic marine weather, sea ice, and storm surge forecast services* by addressing greater needs for observations, modeling, and forecasts while incorporating new techniques for ensuring this information leads to the best possible decisions and associated response. Improved forecast services will ensure the safety and security of marine transportation, mineral (oil and gas) exploration, and tourism activities, and *protect northern and western Alaska coastal communities from storm surge, inundation, and erosion hazards.* The operational marine weather service infrastructure in the National Weather Service will enable NOAA to provide regular forecasts and on-demand support for the Arctic Ocean to meet the NOAA mandate to protect life and property as well as enhance the economy and fulfill NOAA's obligations under international treaties.

Goal 4: Enhance International & National Partnerships

Goal Statement – National and international partners are engaged to promote cooperation and sharing of data, observational platforms, and intellectual resources to enable more rapid and comprehensive attainment of NOAA's Arctic science and ecosystem-based management goals.

Importance: The Arctic is comprised of the northern regions of eight countries and adjacent marine areas. As the Arctic climate continues its warming trend, sea ice in the Arctic continues to recede and freshwater entering the Arctic from rivers is increasing. These changes in the Arctic environment are likely to impact the globe, making it urgent that NOAA builds on its abilities to observe, understand, predict, and respond to these Arctic changes. Both national and international partnerships are needed to help fill data gaps; improve analyses, models, and forecasts; and apply ecosystem-based management.

NOAA's current activities: NOAA currently cooperates with other governments through broad Science and Technology (S&T) Agreements and NOAA-specific agreements, as well as through international institutions and organizations. S&T Agreements and Memorandums of Understanding with Russia, Norway, Sweden, Finland, Canada, and Denmark support NOAA's work with these Arctic countries in areas such as weather, climate, aviation, and marine observations, forecasts, and services; ecosystem management; fisheries; and ice monitoring. . These agreements allow us to cooperate on sea ice forecasts, as well as better understand and predict changes in the Earth's environment by observing the Arctic atmosphere and cryosphere from manned observatories in places such as Summit, Greenland and Tiksi, Russia.

NOAA is also an active participant in numerous international organizations such as the World Meteorological Organization, International Maritime Organization, International Hydrographic Organization,

Enhance International and National Partnerships: Arctic Council

NOAA has played a key role in major products of the Arctic Council and is now providing leadership on future products. By enhancing and institutionalizing its support for the Council, NOAA can exert stronger leadership on the Council's science-based activities and offer greater support to U.S. Arctic policy goals. The Arctic Council is the only intergovernmental group that focuses solely on the Arctic. By engaging through the Council with the other seven Arctic countries, permanent participants, and the several observer countries, the goals outlined in this plan can be more readily achieved.

and the Arctic Council. NOAA serves in leadership roles in two Arctic Council working groups (Protection of the Arctic Marine Environment and Arctic Monitoring and Assessment Program), while providing expertise to others. Current Arctic Council work includes assessing the effects of pollutants in the Arctic, reviewing the comprehensiveness of governance mechanisms for the Arctic, and understanding the status of biodiversity in Arctic ecosystems.

Five-year strategy: Modeling climate change at the regional and global levels is an enormous task, best accomplished by *sharing data at multiple levels* – with universities and researchers, with other Arctic countries, and with non-Arctic countries possessing satellite and observation capabilities in the Arctic. NOAA must continue and expand these relationships through partnerships and formal bilateral arrangements. Understanding and predicting how ice cover and consistency will change in the Arctic will necessitate cooperation. NOAA should increase both its interagency and international partnerships to increase the accuracy, timeliness, and coverage of its sea ice forecasts – ensuring seamless transitions across jurisdictional boundaries and enhancing safe navigation.

With reduced sea ice comes opportunities for trans-Arctic shipping, increased oil and gas exploration and extraction, tourism, and other uses that increase regional vessel traffic, as well as associated threats such as oil spills, transport of invasive species, and collisions with species or small craft. NOAA, working through the interagency process, should *expand Arctic protection mechanisms* at the international level (e.g., the International Maritime Organization), including developing a mandatory Polar Code, Particularly Sensitive Sea Areas, vessel routing measures and sea lanes (in particular for choke points such as the Bering Strait). NOAA also should increase hydrographic charting and cooperation in the region (e.g., via the International Hydrographic Organization).

These changes in climate and sea ice are also driving changes in marine ecosystems, species abundance, and composition, in ways not yet fully understood. NOAA should *provide leadership and additional resources to support Arctic governance and science organizations*. Specifically, NOAA should support the Arctic Council and its working groups, which monitor and assess biodiversity, climate, and the health of humans and ecosystems and contribute to international approaches to ecosystem and protected area management, and management of shipping. The International Arctic Science Committee and the Pacific Arctic Group identify science priorities across countries and build trusted and lasting relationships among scientists.

The Sustaining Arctic Observing Networks (SAON) activity co-sponsored by the Arctic Council and the International Arctic Science Committee aims to become an effective mechanism for sharing data among the Arctic countries and for identifying critical observing systems that should be maintained for long periods. The success of SAON will make achievement of NOAA Arctic science goals more likely and NOAA should *support development of an effective international SAON process*.

Continued coordination across federal entities, such as that provided by the Interagency Arctic Research Policy Committee, will be needed to implement overarching U.S. Arctic Policy goals, particularly those identified by the U.S. Arctic Policy (NSPD 66/HSPD 25) and the Interagency Ocean Policy Task Force. Scientific research and discovery will proceed in collaboration with the National Science Foundation, and other federal, state and local partners, academia, non-governmental organizations, and private entities. Due to the interconnected nature of Arctic ecosystems, the U.S. will also need to continue to improve collaboration and engagement with other Arctic nations through international mechanisms, such as the Arctic Council and our bilateral relationships, to better understand, observe, research, and manage Arctic resources.

Goal 5: Improve Stewardship & Management of Ocean & Coastal Resources in the Arctic

Goal Statement – Conservation, management, and use of ocean and coastal resources are based on sound science and support healthy, productive, and resilient ecosystems and communities.

Importance: As the Arctic Ocean becomes more accessible with the retreat of sea ice in summer months, cascading consequences must be anticipated. Biophysical and chemical changes in the ocean, combined with increasing human uses will impact the Bering, Chukchi, and Beaufort Seas. Currently commercial harvest of groundfish, shellfish, salmon and other resources, primarily in the Bering Sea, constitute almost 50 percent of marine fish landings in the U.S. Further, these same resources, plus various species of marine mammals, seabirds, and other marine life are critical to the maintenance of the subsistence lifestyle of over 40,000 indigenous people who inhabit small towns and villages on Alaska's Arctic coastline. It is therefore critical to both the U.S. economy and the coastal inhabitants of the U.S. Arctic that NOAA, in cooperation with Federal, state, and local partners and stakeholders, expand its capabilities to understand and predict the full spectrum of changes associated with climate change in the Arctic, with the intended outcome of improving the stewardship of Arctic marine resources.

NOAA's current activities: NOAA currently conducts population assessments and ecological process studies to meet its living marine resource management mandates. However, data in the Arctic are insufficient to make adequate assessments, and it is currently beyond the scope of existing ecosystem models to provide reliable indications of how loss of sea ice, increased ocean acidity, and increasing ocean temperatures will impact key fish and mammal species. NOAA will need to expand aspects of its current Arctic ecosystem research program and the regional Alaska Ocean Observing System, as well as implement better data collection, analyses, and models to provide reliable predictions of the changes coming to marine ecosystems in the U.S. Arctic.

Extended Continental Shelf Mapping
Since 2001, NOAA activities have been critical to U.S. efforts to gather and analyze data to determine the outer limits of its extended continental shelf (ECS) including the Arctic region. The primary goal these efforts is to establish the limits of the areas of seabed beyond 200 miles where the United States can exercise sovereign rights over seabed and sub-seafloor continental shelf natural resources. NOAA is a co-vice chair on the State Department-led interagency task force established in 2007. To date, U.S. data collection efforts have provided a wealth of bathymetric and seismic information. Though beyond the scope of ECS, collecting the baseline ecosystem-level data would enhance the existing information and provide the U.S. with a better understanding of the nature, extent, and economic value of these resources, as well as insights into issues such as climate variability; marine ecosystems; and undiscovered or unconventional energy, biological, and mineral resources.

Five-year strategy: At present, the biggest limiting factor in providing managers with the information they need regarding the impact of climate change on Arctic living marine resources off Alaska is access to survey vessels and aircraft during the ice-free summer months and support for over-wintering sampling tools including autonomous sea gliders, passive acoustic recorders, and satellite-linked tags. Specifically, very few surveys have been conducted to assess the status of living marine resources in the northern Bering, Chukchi, and Beaufort Seas. Additional Arctic surveying capability is proposed in NOAA's Fleet and Aircraft Recapitalization plans, which include state-of-the-art replacements of aging NOAA survey vessels and planes. Additional charters are required to meet capacity shortfalls. Also, resources are needed to conduct ecological process studies on how loss of sea ice, increased acidity, and sea surface temperature warming will change the productivity and composition of Arctic marine resources in waters off Alaska.

Because of fiscal limitations, it is beyond the capability of NOAA to address all of these deficiencies in the next five years. Therefore, in this strategy, NOAA is proposing to expand two existing programs, while *continuing on-going assessment programs on marine mammals, fish, and shellfish*: 1) the Bering-Aleutian Salmon International Survey (BASIS) and the RUSALCA (Figure 6), which are cooperative international research programs in the northern Bering and Chukchi Seas, and 2) NOAA's *ocean acidification* program. The former will provide critical information on the biodiversity of this region and a baseline for assessing how biodiversity will respond to climate change and loss of sea ice. The latter activity will result in greater attention given to the *impact of more corrosive waters on the ecology and life history of key Arctic species* such as king crab. The geographic scope of this proposal is therefore limited to the northern Bering and Chukchi Seas. This is a critical region because of the connectivity of the high Arctic marine ecosystems with the Bering Sea through the Bering Strait. Further, the expansion of existing research programs in this area is a cost-effective way to address critical information needs. Expansion of the existing research program in the Beaufort Sea will be dependent on the availability of funding between 2015 and 2020.

The data produced by the continuation and expansion of these two on-going research programs will provide a subset of the information needed to develop models that will allow resource managers to better assess the risk of action or inaction, as well as the relative benefit of specific actions. Integrated ecosystem assessments and operational ecosystem modeling will ultimately require further investments in human and facility infrastructure in the Arctic (e.g., real-time sea-ice monitoring at the appropriate scale for safe maritime operations). Through conservation, research, and response to environmental threats, NOAA will assist the part of the U.S. that is already impacted by climate change in developing risk-averse strategies to maximize the resilience of marine ecosystems in the Arctic, and develop strategies to mitigate and adapt to adverse impacts.

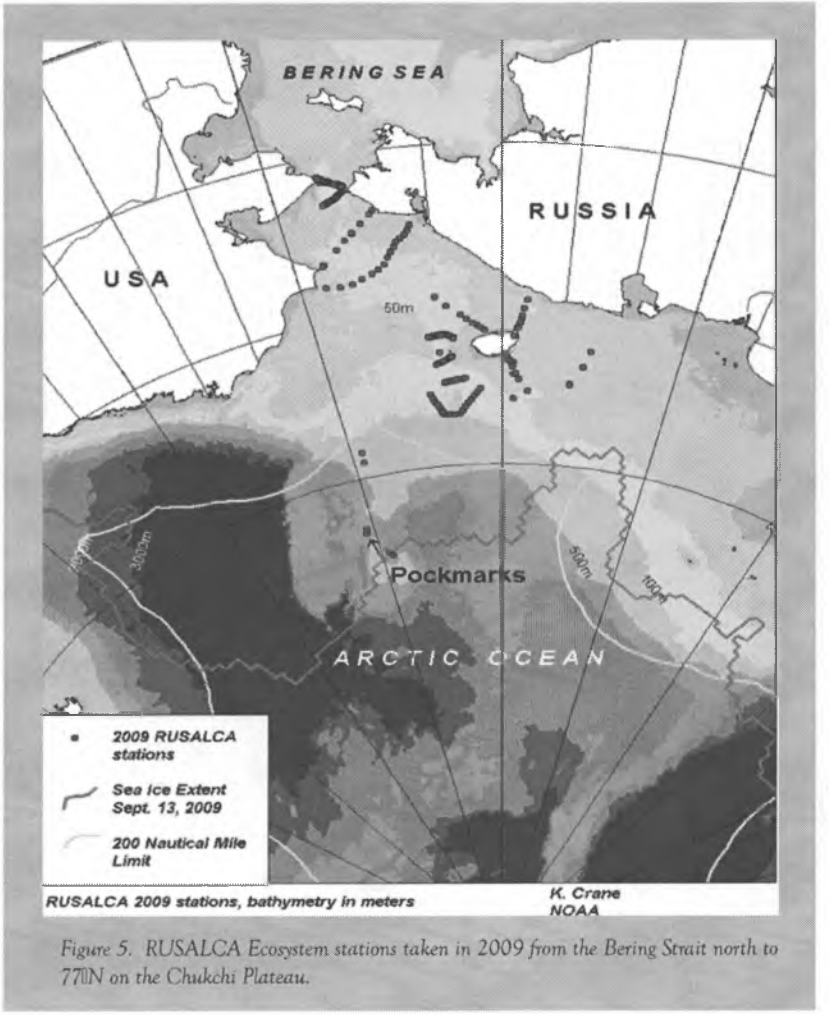


Figure 5. RUSALCA Ecosystem stations taken in 2009 from the Bering Strait north to 77ºN on the Chukchi Plateau.

Goal 6: Advance Resilient & Healthy Arctic Communities & Economies

Goal Statement - Resilient and healthy Arctic communities and economies through improved geospatial infrastructure, safe navigation, oil spill response readiness, and climate change adaption strategies.

Importance: We measure the well-being of our Nation through the health of our communities and economies. The condition of the Arctic can be gauged by the health of the people living and working in this unique environment, and by the impact of increased economic activity on it. Indigenous people have long depended upon the unique characteristics of the Arctic for food, livelihoods, cultural heritage, and protection. However, climate change in the Arctic is altering the foundations of their communities and challenging indigenous ways of life. At the same time, the loss of sea ice creates opportunities for commercial enterprises such as oil and gas development, cruise and cargo shipping, fishing, and other economic sectors. This creates tension between the traditional and the new, and argues for a measured approach to Arctic resource utilization.

As the ice barriers that protect Arctic coastal communities diminish, the State of Alaska and its people must make critical decisions based on threats from stronger storms, increasing erosion, thawing permafrost, changing animal migration patterns, and sea level changes. Shorter freeze periods and weak ice impact transportation and can result in loss of life. The potential economic effects of these changes in the Arctic are also enormous, as retreating sea ice opens access to economic development. Oil companies are investing in exploration, private interests are anticipating an open Arctic trade route, and pressure is increasing on our defense and security assets to maintain a presence in the region in a "response-ready state" because of the increased risks.

NOAA's current activities: NOAA has a variety of mandates relating to resilient communities and economies. The agency has the U.S. government lead for hydrographic surveys, nautical charts, and the National Spatial Reference System. NOAA is also responsible for administering the Coastal Zone Management Program. During oil spills, NOAA is legally responsible for providing scientific support to the U.S. Coast Guard and conducting natural resource damage assessments following those incidents. In addition, people who live in, work in, and visit the Arctic rely on NOAA and the Search and Rescue Satellite System to rescue them in an emergency.

Environmental preparedness, response, and recovery: NOAA and the University of New Hampshire's Coastal Response Research Center are partnering to expand Environmental Response Management Application (ERMA) coverage to one or two key areas of concern in the Chukchi and Beaufort Seas. The demonstration will show how the ERMA tool can benefit Arctic stakeholders, including coastal communities, Alaska Native villages, the State of Alaska, NOAA, Federal agencies, and industry. ERMA is a web-based map tool designed to assist both emergency responders and environmental resource managers who deal with incidents that may adversely impact the environment. The data within ERMA also assist in resource management decisions regarding hazardous waste site evaluations and restoration planning. ERMA includes human use and human dimension data components and, for the Arctic, will include sea-ice conditions. Federal, State and Tribal governments would be able to use this information and the ERMA interface to address not only oil spill planning and response, but also to access sea-ice/shoreline erosion information.

The Arctic is severely deficient in many of the capabilities that NOAA extends to the rest of the Nation. The region currently has virtually no geospatial infrastructure for accurate positioning and elevations; sparse tide, current, and water-level prediction coverage; obsolete shoreline and hydrographic data; poor nautical charts; insufficient weather and ice forecast coverage; inadequate oil spill response capacity; and poor understanding of baseline conditions for existing ecosystems. There are large gaps in the information that NOAA does have, illustrated by empty white space on nautical charts of the region and limited capabilities for modeling spills in ice conditions. Most Arctic waters that are charted were surveyed with obsolete technology, some dating back to the 1800s, before the region was part of the United States. Most of the shoreline along Alaska's northern and western coasts has not been mapped since 1960, if ever, and confidence in the nautical charts of the region is extremely low.

Five-year strategy: NOAA can make the highest positive impact to Arctic communities and sustainable economic growth by providing products and services for safe navigation and security, oil spill response readiness, post-incident resource restoration efforts, and climate change adaptation strategies.

The Arctic region needs accurate land and tidal elevations to build flood protections, harden infrastructure, ensure safe and efficient marine transportation, model storm surge, and monitor sea levels. Good weather and navigation tools, building the capacity to respond to spills when they occur, and research to improve Arctic spill response and restoration capabilities are essential. Arctic communities also need a reliable source for information on climate in Alaska to support decisions on moving communities and other adaptive strategies. By building on the capabilities noted in other strategic priorities such as marine weather, sea ice forecasts, and increased observing capacity, NOAA can act to support navigation safety, maritime security, and environmental protection from oil spills and other hazardous events. NOAA's geospatial framework, products, and services will also provide the foundation for all other NOAA activities in the Arctic, including effective climate adaptation, community resilience, coastal resource, and marine spatial planning strategies in the region.

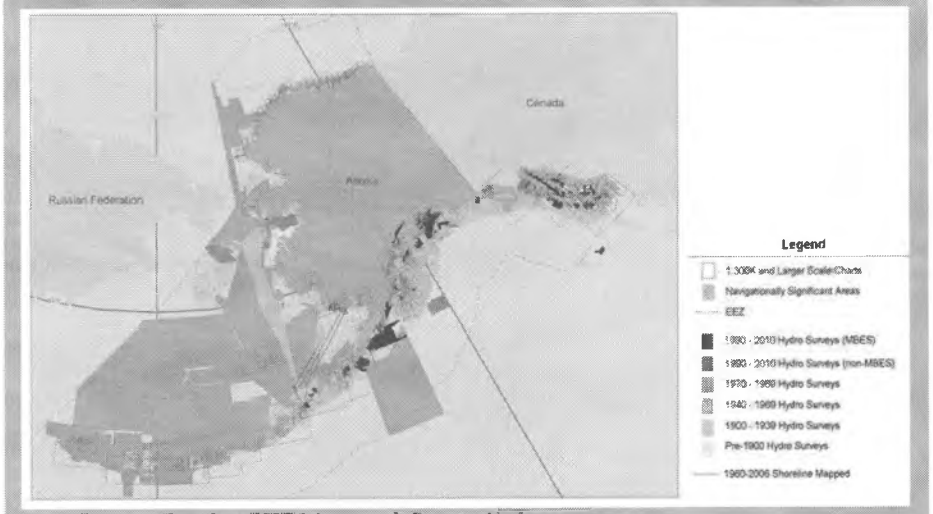

Figure 7. **Age and quality of NOAA nautical charts** *in Alaska.*

Figure 8. NOAA Arctic hydrographic survey priorities (2010 – 2014)

Overhauling the Arctic Geospatial Framework of geodetic control and water levels will correct meters-level positioning errors and enable centimeter-level measurements to support such critical needs as marine transportation, sea level rise monitoring, understanding of erosion and permafrost thaw impacts to infrastructure, oil/gas resource exploration, and storm surge modeling. *Delivering scientific support for Arctic pollution response* such as contingency plans, place-based drills and community workshops, and spill trajectory modeling to decision makers will help to reduce risk of accident and injury to protected resources and ecosystems as commercial vessel traffic in and through the Arctic increases. *Surveying and mapping Arctic waters and shoreline* for accurate coastal maps and nautical charts will benefit navigation and national security, sea level change impact assessments, and habitat characterizations (Figure 8). NOAA will work with partners to prioritize and survey likely shipping lanes in the North Bering and Chukchi Seas and around coastal communities. This effort will help address the Bering Strait chokepoint in particular, and reduce the risk of accidents and environmental impacts in Arctic waters more broadly.

Finally, by working with local, State and Federal health agencies such as the Alaska Native Tribal Health Consortium and the Centers for Disease Control, NOAA will *support coastal communities with adaptive strategies and planning tools* and contribute to the understanding of how the changing climate is affecting health and welfare. NOAA will assist Arctic communities on this issue by leading the development of a regional climate service partnership. This climate center will serve as a one-stop shop for information on climate in Alaska. NOAA will also work with other agencies, the State, and tribal entities to implement coastal and marine spatial planning to improve the management and coordination of human activities in the coastal zone and U.S. Exclusive Economic Zone.

Conclusion & Next Steps

As the Nation's only Arctic state, Alaska and its communities are the first to be impacted by climate change. Observations have shown that Alaska has warmed at over twice the rate of the rest of the Nation. The average annual temperatures in Alaska have increased by 3.4 degrees Fahrenheit and the winter time average temperatures have increased by 6.3 degrees. This means Alaska is already experiencing early snow melt, changes in sea ice, wide-spread glacial retreat, and permafrost thawing.

The Arctic is a particularly vulnerable system, which is prone to rapid change. It is also a primary driver for global weather patterns. Initial predictions from global climate change models underestimated the rate at which the Arctic would lose sea ice. This has led to an underestimate of global warming. Understanding global climate change and providing reliable predictions regarding changes in worldwide weather patterns will require an improved understanding of the impacts of Arctic climate change.

NOAA has diverse capabilities that can and should be brought to bear on the emerging environmental, economic, and national security issues in the Arctic. NOAA envisions an Arctic where:

- Conservation, management, and use are based on sound science and support healthy, productive, and resilient communities and ecosystems; and
- The global implications of Arctic change are understood and predicted.

In support of this vision and in order to fulfill NOAA's missions and responsibilities that are critical for other agencies to succeed in fulfilling their responsibilities, NOAA intends to undertake the following four steps:

Step 1 – In the next five years, implement, through a NOAA five-year Arctic Action Plan, actions to achieve the six primary goals that are identified and described in this document in support of the Arctic vision.

1) Accurate, quantitative, daily forecasts to decadal predictions of sea ice are provided to support safe operations and ecosystem stewardship,
2) Improved baseline observations and understanding of Arctic climate and ecosystems reduces the uncertainty in assessing and predicting impacts caused by a changing Arctic,
3) Advanced, accurate forecasts and warnings are provided to ensure society can prepare for and respond appropriately to weather-related routine and extreme events,
4) National and international partners are engaged to promote cooperation and sharing of data, observational platforms, and intellectual resources to enable more rapid and comprehensive attainment

of NOAA's Arctic science and ecosystem-based management goals,

5) Conservation, management, and use of ocean and coastal resources are based on sound science and support healthy, productive, and resilient ecosystems and communities, and
6) Resilient and viable Arctic communities and economies through improved geospatial infrastructure, safe navigation, oil spill response readiness, and climate change adaption strategies.

Step 2 – In order to accomplish these goals, coordination across all NOAA Line and Staff Offices and collaboration with local, regional, federal, academic, and non-governmental organizational partnerships will be required.

Step 3 – Develop an engagement strategy to reach internal and external employees, partners, and stakeholders. As a starting point, establish a single point of contact within NOAA Senior Executive Leadership that is accountable for implementation of this strategy.

Step 4 – Include the formalization of a detailed budget strategy as part of the NOAA Arctic Action Plan. NOAA is committed to enhancing its current involvement in research and management programs in the Arctic, and anticipates initial investment of $10 million towards the implementation of this strategic plan, recognizing that additional funds will be needed to achieve these goals.

No single region better exemplifies the complex interdependence of communities and changing ecosystem conditions than the Arctic. The breadth and complexity of the cultural, societal, economic, and environmental impacts requires a concerted, systematic and rapid effort with partners from international to local levels. NOAA's scientific capabilities can be deployed to increase understanding of climate and other key environmental trends, to predict the ecosystem response to those trends, and to offer the technical expertise needed to develop policy options and management strategies for mitigation and adaptation to the environmental challenges in the Arctic region. NOAA's service capabilities are needed to support safety and security needs for fishing, marine mammal protection, transportation, energy, infrastructure, and mineral exploration in the unique Arctic environment. The choices we make today can have pivotal impacts on the future state of the Arctic.

UNDER SECRETARY OF COMMERCE FOR OCEANS AND ATMOSPHERE AND ADMINISTRATOR, NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION - NOAA

Arctic Report Card

Arctic Report Card: *Update for 2009*

Tracking recent environmental changes

Warming of the Arctic continues to be widespread, and in some cases, dramatic. Linkages between air, land, sea, and biology are evident.

Sea Ice: Multi-year ice is going away

Melting multi-year sea ice in the Arctic Ocean
Credit: Kitty Mecklenburg

Atmosphere	Ocean
Sea Ice	Greenland
Biology	Land

Red boxes: Consistent evidence of warming.
Yellow boxes: Many indications of warming.

Atmosphere
Large scale wind patterns impacted by loss of summer sea ice

Sea Ice
Multi-year sea ice is being replaced by first year sea ice

Ocean
Upper ocean remains warm and less salty

Land
Increased runoff in Siberia, less snow in North America

Greenland
Ice sheet loss continues

Biology
High Arctic species impacted by loss of sea ice

October 9, 2009

Summary

It is apparent that the heating of the ocean in areas of extreme summer sea ice loss is directly impacting surface air temperatures over the Arctic Ocean, where surface air temperature anomalies reached an unprecedented +4°C during October through December 2008. There is evidence that the effect of higher air temperatures in the lower Arctic atmosphere is contributing to changes in the atmospheric circulation in both the Arctic and northern mid-latitudes.

The annual mean Arctic temperature for the year 2008 was the fourth warmest year for land areas since 1990 (Figure A1). This continued the 21st century positive Arctic-wide surface air temperature (SAT) anomalies of greater than 1.0° C, relative to the 1961–1990 reference period. The mean annual temperature for 2008 was cooler than 2007, coinciding with cooler global and Pacific temperatures (Hansen, 2009). The outlook is for increased temperatures, because there are currently (October 2009) El Nino conditions which are expected to continue through winter 2009–2010.

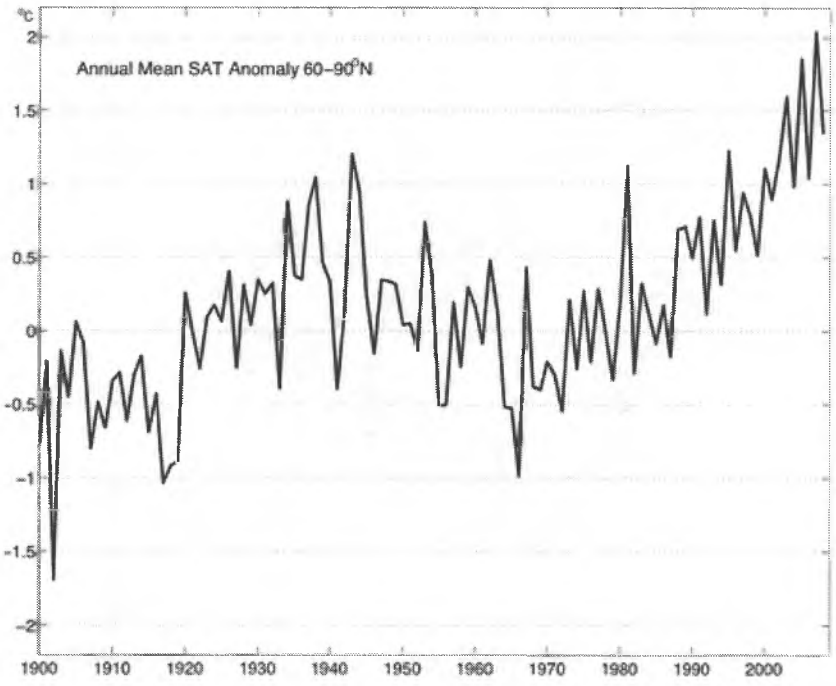

Figure A.1. Arctic-wide annual averaged surface air temperature anomalies (60°–90°N) based on land stations north of 60°N relative to the 1961–90 mean. From the CRUTEM 3v dataset, (available online at www.cru.uea.ac.uk/cru/data/temperature/ . Note this curve does not include marine observations.

During October through December 2008 SAT anomalies remained above an unprecedented +4° C across the central Arctic (Fig. A2(A)). This is linked to summer sea ice conditions. The summer of 2008 ended with nearly the same extreme minimum sea ice extent as in 2007, characterized by extensive areas of open water (see sea ice section). This condition allows extra heat to be absorbed by the ocean from longwave and solar radiation throughout the summer season, which is then released back to the atmosphere in the following autumn (Serreze et al., 2009). We expect similar warm fall temperatures over the Arctic in 2009, as in 2007 and 2008.

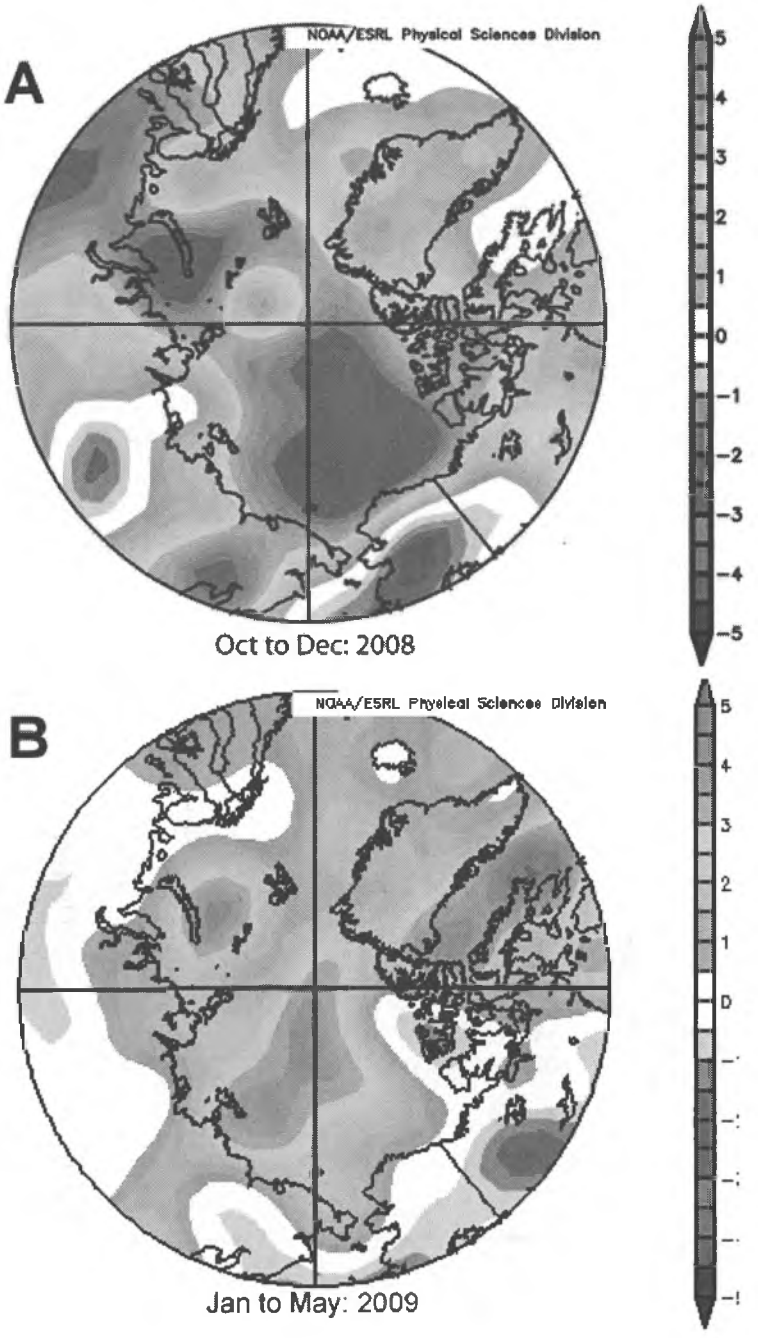

Figure A.2. Near surface air temperature anomalies for (A, top) October through December 2008 and (B, bottom) January–May 2009. Anomalies are relative to 1968–1996 mean. Data are from the NCEP – NCAR reanalysis through the NOAA /Earth Systems Research Laboratory, generated online at www.cdc.noaa.gov .

Similar to the previous years of the 21st century, in 2009 the spatial extent of positive SAT anomalies in winter and spring of greater than +1°C was nearly Arctic-wide (Figure A2 (B)), in contrast with more regional patterns in the 20th century (Chapman and Walsh, 2007). The exception was the Bering Sea/southwestern Alaska which experienced a fourth consecutive cold or average winter associated with weaker winds and colder temperatures in the North Pacific.

There is evidence that, by creating a new major surface heat source, the recent extreme loss of summer sea ice extent is having a direct feedback effect on the general atmospheric circulation into the winter season (Francis et al., 2009). Fall air temperature anomalies of greater than +1.0° C were observed well up into the atmosphere (Figure 3A), when averaged over 2003–2008 relative to a 1968–1996 base period. The higher temperatures in the lower troposphere decrease the atmospheric air density and raise the height of upper-air-constant-pressure levels over the Arctic Ocean (Figure 3B). These increased heights north of 75 °N weaken the normal north-to-south pressure gradient that drives the normal west-to-east airflow in the upper troposphere. In this sense, the effect of higher air temperatures in the lower Arctic atmosphere is contributing to changes in the atmospheric circulation in both the Arctic and northern mid-latitudes. For example, Honda et al. (2009) suggest a remote connection between loss of Arctic sea ice and colder temperatures over eastern Asia.

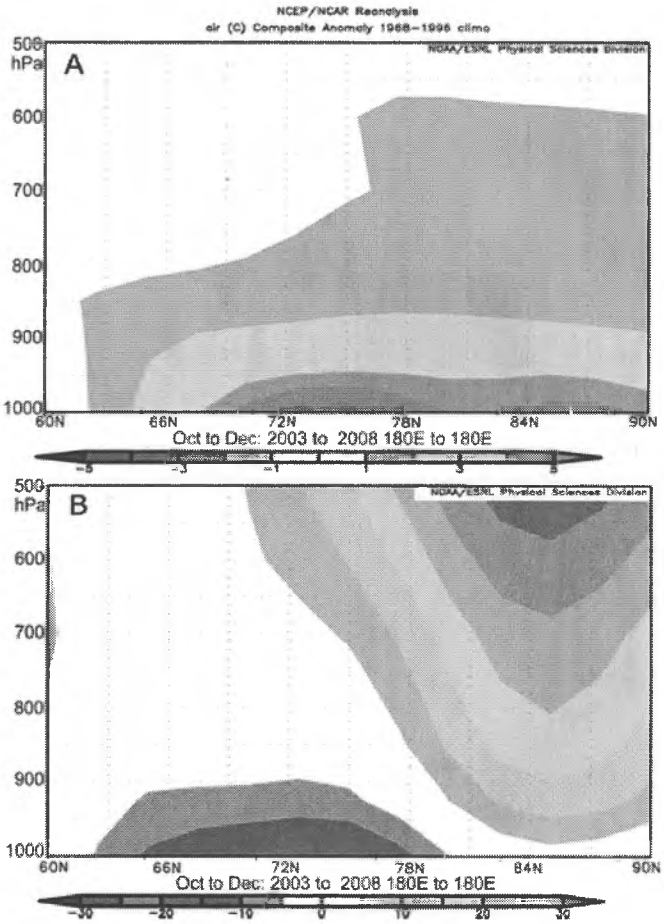

Figure A.3. Vertical cross section from 60° to 90° N along 180° longitude averaged for October–December 2003 through 2008 (years for which summertime sea ice extent fell to extremely low values) for (A) air temperature, and (B) geopotential height. Data are from the NCEP – NCAR reanalysis available online at www.cdc.noaa.gov.

The climate of the Arctic is influenced by repeating patterns of sea level pressure that can either dominate during individual months or represent the overall atmospheric circulation flow for an entire season. The main climate pattern for the Arctic is known as the Arctic Oscillation (AO) with anomalous winds that blow counter-clockwise around the pole when the pattern is in its positive phase. A second wind pattern has been more prevalent in the 21st century and is known as the Arctic Dipole (AD) pattern (Wu et al., 2006; Overland et al., 2008). The AD pattern has anomalous high pressure on the North American side of the Arctic and low SLP on the Eurasian side. This implies winds blowing more from south to north, compared to the AO, and increasing transport of heat into the central Arctic Ocean. The AD pattern occurred in all summer months of 2007 and helped support the major 2007 summer reduction in sea ice extent (Overland et al., 2008). Fall 2008 and winter/spring 2009 showed a return of the AO pattern, but also considerable month to month variability in the presence of these various climate patterns.

New! Monthly Sea Ice Outlook from SEARCH/Arcus

Summary

One of the most dramatic signals of the general Arctic-wide warming trend in recent years is the continued significant reduction in the extent of the summer sea ice cover and the decrease in the amount of relatively older, thicker ice. The extent of the 2009 summer sea ice cover was the third lowest value of the satellite record (beginning in 1979) and >25% below the 1979–2000 average.

Sea ice extent

Sea ice extent is the primary parameter for summarizing the state of the Arctic sea ice cover. Microwave satellites have routinely and accurately monitored the extent since 1979. There are two periods that define the annual cycle and thus are of particular interest: March, at the end of winter when the ice is at its maximum extent, and September, when it reaches its annual minimum. Maps of ice coverage in March 2009 and September 2009 are presented in Figure S1, with the magenta line denoting the median ice extent for the period 1979–2000.

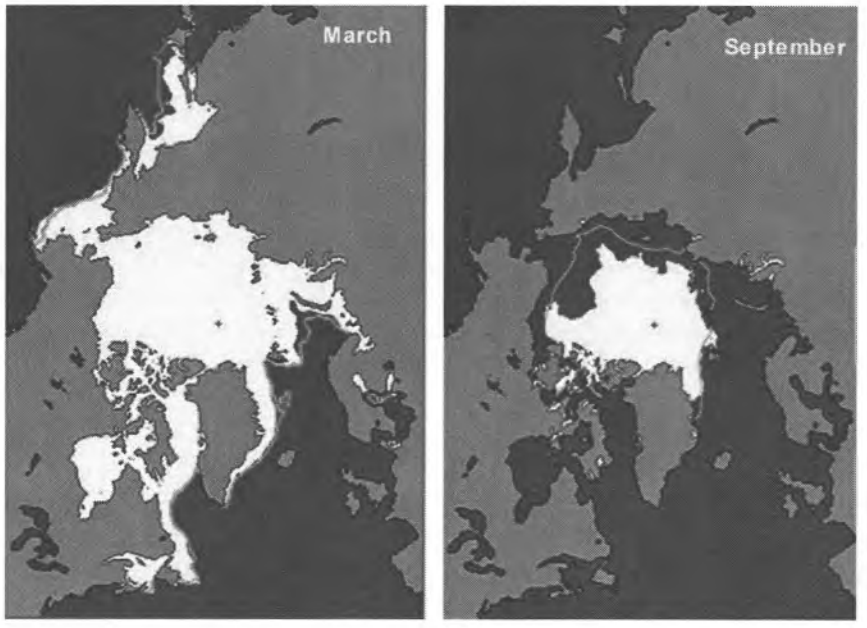

Figure S1. Sea ice extent in March 2009 (left) and September 2009 (right), illustrating the respective winter maximum and summer minimum extents. The magenta line indicates the median maximum and minimum extent of the ice cover, for the period 1979–2000. [Figures from the National Snow and Ice Data Center Sea Ice Index: nsidc.org/data/ seaice_index.]

On September 12, 2009 sea ice extent reached a 2009 minimum of 5.1 million km^2. The 2009 summer minimum is the third-lowest recorded since 1979. It was 0.6 million km^2 greater than 2008 and 1.0 million km^2 above the record low in 2007. Surface air temperatures through the 2009 summer were relatively cooler, particularly in the Chukchi and Beaufort seas. Winds in 2009 also tended to disperse the ice pack over a larger region. While the 2009 minimum was an increase over the two previous years, it was still 1.6 million km^2 below the 1979 to 2000 average minimum. The March 2009 ice extent was 15.2 million km^2, the same as in 2008 and only 4% less that the 1979–2000 average of 15.8 million km^2.

The time series of the anomalies in sea ice extent in March and September for the period 1979–2009 are plotted in Figure S2. The anomalies are computed with respect to the average from 1979 to 2000. The large interannual variability in September ice extent is evident. Both winter and summer ice extent exhibit a negative trend, with values of -2.5 % per decade for March and -8.9 % per decade for September over the period 1979–2009.

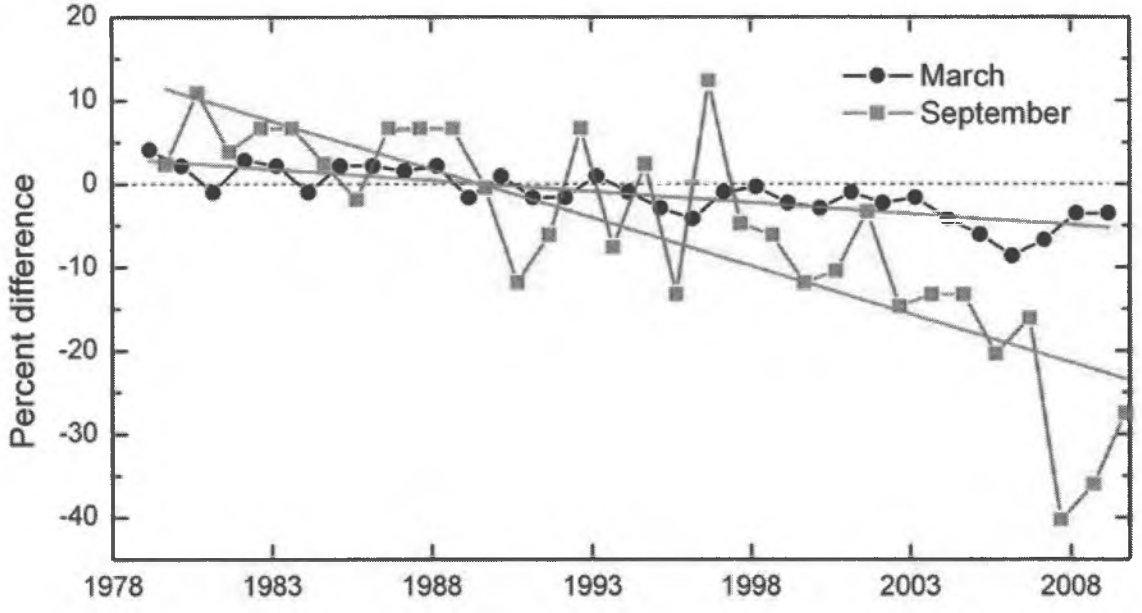

Figure S2. Time series of the percent difference in ice extent in March (the month of ice extent maximum) and September (the month of ice extent minimum) relative to the mean values for the period 1979–2000. Based on a least squares linear regression for the period 1979-2009, the rate of decrease for the March and September ice extents is –2.5% and –8.9% per decade, respectively.

Sea ice age and thickness

The age of the ice is another key descriptor of the state of the sea ice cover, since older ice tends to be thicker and more resilient than younger ice. A simple two-stage approach classifies sea ice into first year and multiyear ice. First-year is ice that has not yet survived a summer melt season, while multi-year ice has survived at least one summer and can be several years old. Satellite derived maps of ice age for March of 2007, 2008, and 2009 are presented in Figure S3.

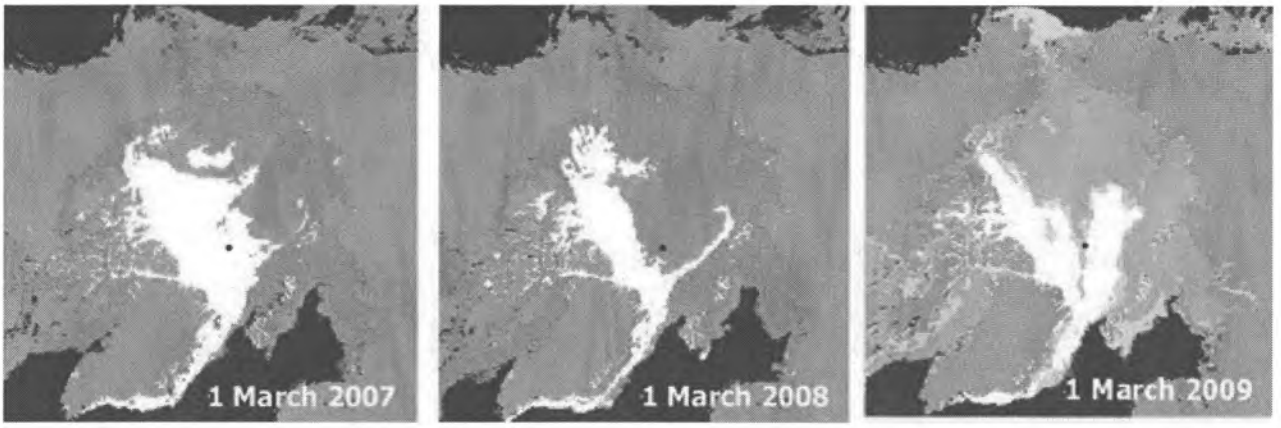

Figure S3. Arctic sea ice distribution in March of 2007, 2008, and 2009. Multiyear ice is in white, mixed ice aqua, first-year ice teal, and ice with melting surface red. Dark blue is for open water and brown for land. From a combination of AVHRR and SSM/I satellite observations and results from drifting ice buoys. (courtesy of Son Nghiem)

In the past decade, the extent of multiyear sea ice rapidly reduced at a rate of 1.5×10^6 km^2 per decade, triple the reduction rate during the three previous decades (1970–2000). Springtime multiyear ice extent was the lowest in 2008 in the QuikSCAT data record since 2000. QuikSCAT results in March 2009 showed a multiyear ice extent of 3.0 ± 0.2 million km^2. This was 0.3 million km^2 larger than the multiyear ice extent on the same date in 2008, even though the total sea ice extent was similar in the spring of 2008 and 2009. While the multiyear ice extent was similar in March 2008 and 2009, its distribution was quite different. More specifically, in 2008 there was a significant amount of multiyear ice the Beaufort Sea and in 2009 there was a large amount of multiyear ice the central Arctic Ocean.

Recent estimates of Arctic Ocean sea ice thickness from satellite altimetry show a remarkable overall thinning of ~0.6 m in ice thickness between 2004 and 2008 (Figure. S4a). In contrast, the average thickness of the thinner first-year ice in mid-winter (~2 m), did not exhibit a downward trend. Seasonal ice is an important component covered more than two-thirds of the Arctic Ocean in 2008. The total multiyear ice volume in the winter experienced a net loss of more than 40% in the four years since 2005 while the first year ice cover gained volume due to increased overall coverage of the Arctic Ocean. The declines in total volume and average thickness (black line in Figure S4a) are explained almost entirely by thinning and loss of multiyear sea ice due to melting and ice export. These changes have resulted in seasonal ice becoming the dominant Arctic sea ice type, both in terms of area coverage and of volume.

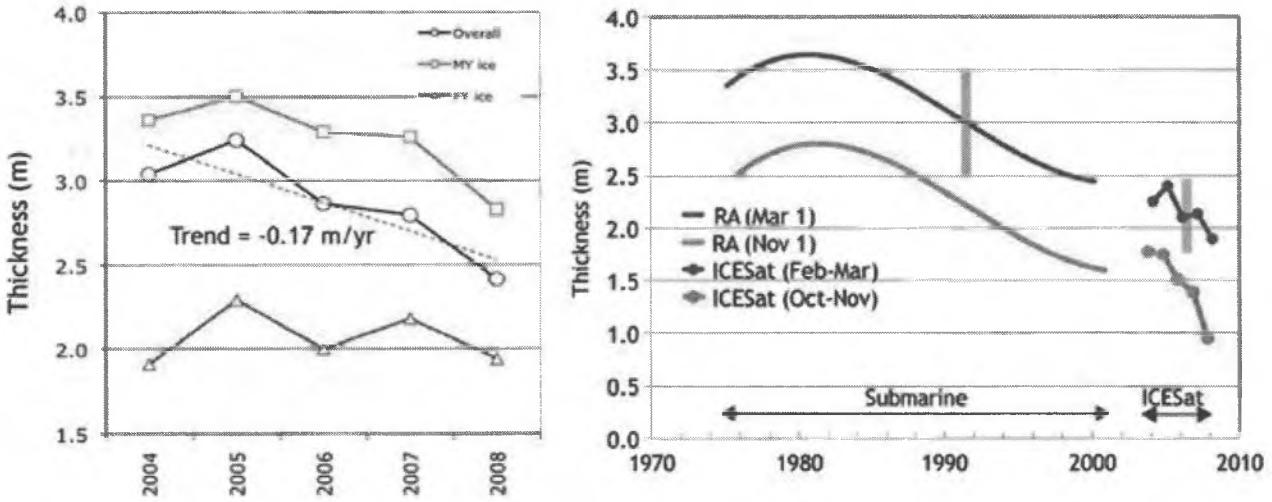

Figure S4. (a) Winter Arctic Ocean sea ice thickness from ICESat (2004–2008). The black line shows the average thickness of the ice cover while the red and blue lines show the average thickness in regions with predominantly multiyear and first-year ice, respectively. b) Interannual changes in winter and summer ice thickness from the submarine and ICESat campaigns within the data release area spanning a period of more than 30 years. The data release area covers approximately 38% of the Arctic Ocean. Blue error bars show the uncertainties in the submarine and ICESat data sets. (after Kwok et al., 2009 and Kwok and Rothrock, 2009)

The recent satellite estimates were compared with the longer historical record of declassified sonar measurements from US Navy submarines (Figure S4b). Within the submarine data release area (covering ~38% of the Arctic Ocean), the overall mean winter thickness of 3.6 m in 1980 can be compared to a 1.9 m mean during the last winter of the ICESat record—a decrease of 1.7 m in thickness. This combined submarine and satellite record shows a long-term trend of sea ice thinning over submarine and ICESat records that span three decades. The contribution of the increasing fraction of first year ice to the long term thickness trend remains to be determined.

August 26, 2009

Summary

In 2008, there was an unprecedented amount of fresh water in the surface layer of the Arctic Ocean. The source of the fresh water was melting sea ice. The heating of the ocean in areas of extreme summer sea ice loss (for instance, summer surface water temperatures in the Beaufort Sea were more than 3°C above average) was contributing to record high surface air temperatures in the fall (October through December) over the Arctic Ocean.

Circulation

In 2008, the ocean surface circulation regime in the central Arctic was anticyclonic (clockwise) in winter and summer (Fig. O.1). The intensity of motion was weaker than observed in 2007, consistent with changes in the observed sea level atmospheric pressure patterns (see section 5b). In winter the major flow stream removed sea ice from the Kara and Laptev Seas, while in the summer sea ice from the Canada Basin was transported toward the Fram Strait. Data from satellites and drifting buoys (Proshutinsky et al. 2009) indicate that the entire period of 1997–2008 has been characterized by a relatively stable anticyclonic ocean surface circulation regime. This circulation pattern was the result of a higher sea level atmospheric pressure over the Arctic Ocean, relative to the 1948–2008 mean, and the prevalence of anticyclonic winds. These conditions have significantly influenced the sea ice cover, oceanic currents, and ocean freshwater and heat content.

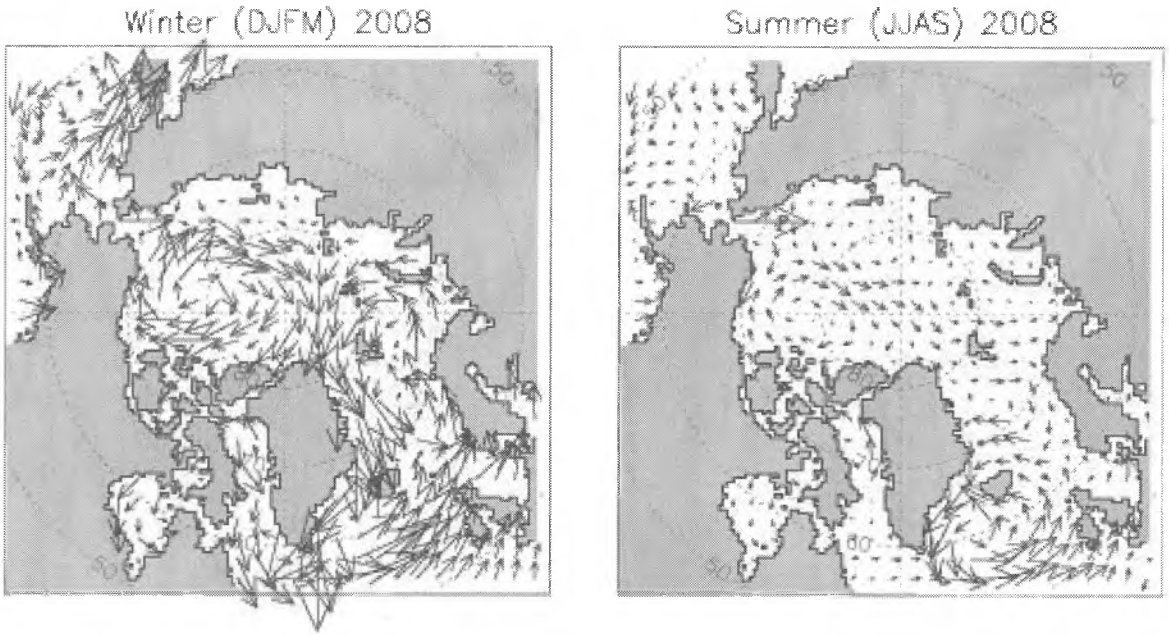

Figure O.1. Simulated circulation patterns of the upper-ocean wind-driven circulation in (left) winter and (right) summer in 2008. Both patterns are identified as anticyclonic (clockwise). The intensity of anticyclonic circulation in summer 2008 has reduced relative to 2007 (see Proshutinsky and Johnson 1997 for details).

Water temperature and salinity

Upper-ocean temperatures in summer 2008 were not quite as high as in the record-breaking summer of 2007. Although the position of the September ice edge did not change significantly in 2008 relative to 2007, the timing of ice retreat was different. Early ice retreat from the Beaufort Sea in 2008 led to anomalously high sea surface temperatures that exceeded even those in 2007 in this region (Fig. O.2). However, ice retreat in the Chukchi and east Siberian Seas occurred relatively late in the summer, leading to near-normal or only slightly above-normal ocean warming (Fig. O.2). This difference illustrates that the warming of the upper ocean is dependent not only on the position of the September ice edge but also on the time history of the ice cover over the summer. More specifically, ocean surface warming depends on the time history of atmospheric heat input to the sea surface, which depends both on atmospheric conditions (winds, clouds) and on the presence of the ice cover that acts to block this heat input (Steele et al. 2009).

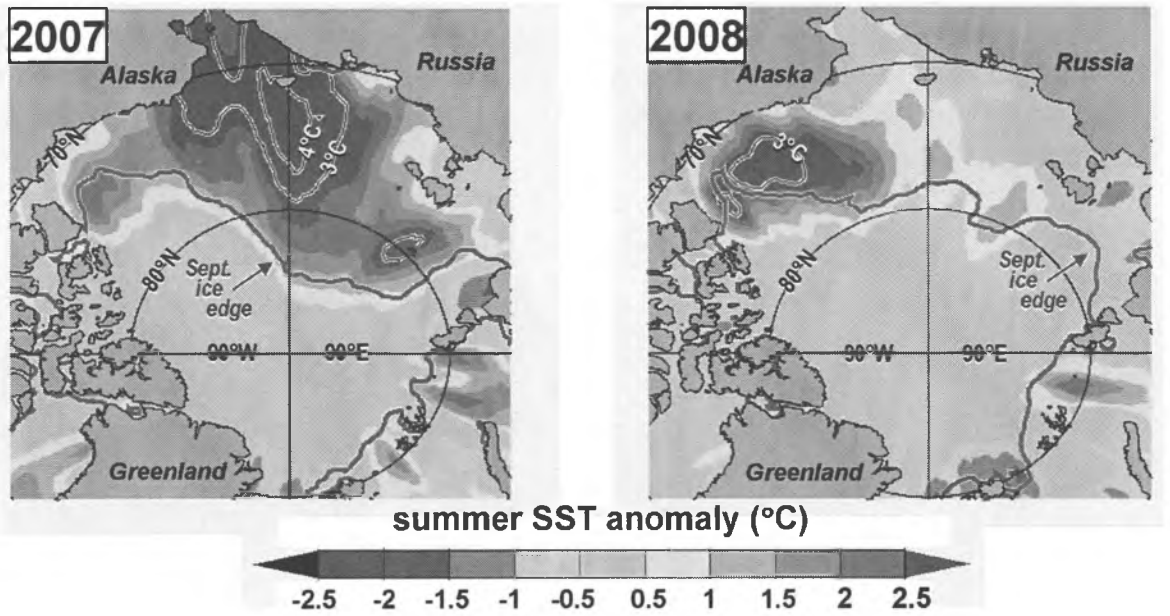

Figure O.2. Satellite-derived summer (JAS) SST anomalies (Reynolds et al. 2002) in (left) 2007 and (right) 2008, relative to the summer mean over 1982–2006. Also shown is the Sep mean ice edge (thick blue line).

Changes in the AWCT varied regionally in 2008, reflecting temporal pulses in the Atlantic water flow volume, temperature, and salinity in the Fram Strait. The Atlantic water propagates cyclonically (counterclockwise) along the Arctic Ocean continental slope, entering the Arctic Ocean via the Fram Strait west of Spitsbergen and leaving the Arctic via the Fram Strait east of Greenland. Observations at a NABOS (http://nabos.iarc.uaf.edu/) mooring in the vicinity of Spitsbergen (Fig. O.3) along the entry point of the AWCT showed that the monthly mean AWCT at 260 m reached a maximum of ~3.8°C in November–December 2006. Subsequently, the temperature at this location has declined or cooled, reaching ~2.8°C in 2008. Observations at sections crossing the continental slope in the vicinity of Severnaya Zemlya also revealed cooling of AWCT by approximately 0.5°C (Fig. O.3). This cooling signal has not reached central parts of the Arctic Ocean and the Beaufort Gyre of the Canada Basin (Proshutinsky et al. 2009). In the Beaufort Gyre region, the AWCT in 2008 was 0.80°–0.90°C, which is 0.10°C above AWCT observed in 2007 and 0.50°C above AWCT from pre-1990s climatology. In spring of 2008, data collected at the NPEO (http:// psc.apl.washington.edu/northpole/index.html) indicate that the AWCT increased to nearly 1.4°C, which is about 0.1°C higher than observed in a 2007 survey and about 0.7°C higher than pre-1990s climatology.

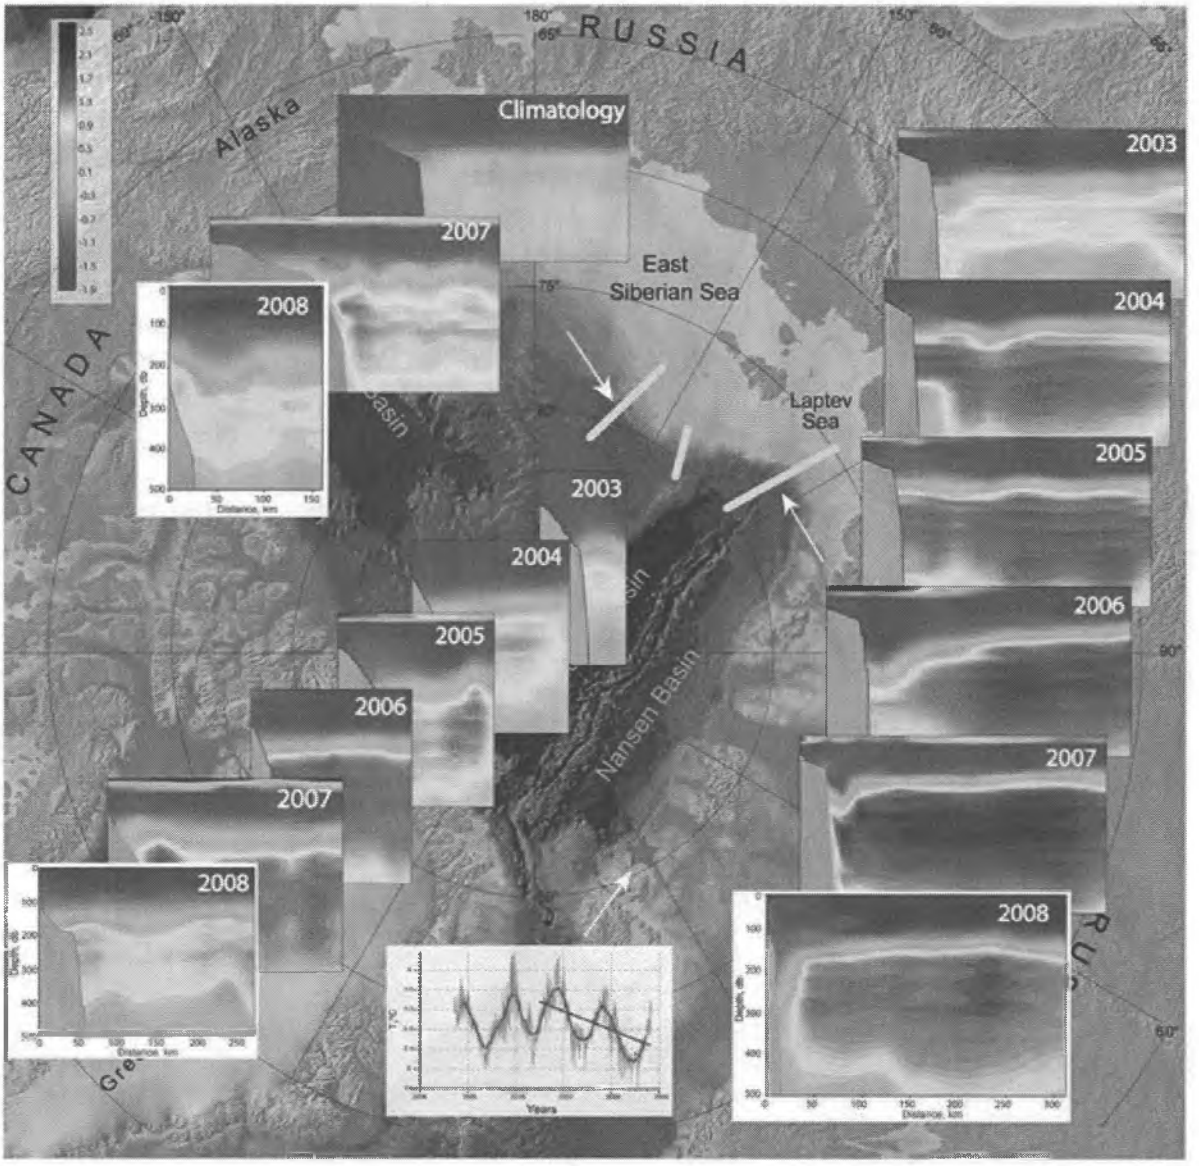

Figure O.3. Temporal (°C) and spatial variability of the AWCT. Locations of sections are depicted by yellow thick lines. Mooring location north of Spitsbergen is shown by a red star. There is a decline of Atlantic water temperature at 260 m at mooring locations with a rate of 0.5°C per year starting at the end of 2006. Some cooling in 2008 is also observed at the sections crossing the continental slope in the vicinity of Severnaya Zemlya and in the east Siberian Sea (Polyakov et al. 2009, manuscript submitted to Geophys. Res. Lett.).

Summer 2008 ship-based hydrographic surveys (Ashik, Sokolov, Frolov, and Polyakov 2008, personal communications) in different regions of the Arctic Ocean showed a continued freshening of the upper 20-m ocean layer, similar to 2007. In the 25–75-m layer, some salinification was observed in the central regions of Amundsen and Makarov Basins, while along the continental slope the water salinity remained unchanged relative to salinities observed in 2007. There was also some freshening of the deeper water layers in the Beaufort Gyre in 2008, as the surface freshening in this region was accompanied by Ekman pumping (Proshutinsky et al. 2009).

Data collected as part of the BGOS (www.whoi.edu/beaufortgyre/index.html) show that in 2000–08 the total freshwater summer content in the Beaufort Gyre has significantly increased relative to

climatology of the 1970s (Arctic Climatology Project 1997, 1998; Fig. O.4). In 2008, the center of the freshwater maximum remained shifted toward Canada as in 2007 but significantly intensified relative to 2007 (Fig. O.4). As a result, the northwest part of the region is much saltier and the southeast region of the Beaufort Gyre is much fresher than in 2006–07 and, also, compared to 30 years ago. At some stations in the southeast of the Canada Basin the FWC reached the maximum observed value, increasing by as much as 11 m, which is 60% above climatology values. The freshening extends northward through the Canada and Makarov Basins to the Lomonosov Ridge (not shown). On the Eurasian side of the Lomonosov Ridge, the FWC anomaly is negative (water salinity was increased relative to climatology) with minimum FWC values of about -4 m (McPhee et al. 2009). The Beaufort Gyre heat content is significantly elevated relative to 1970s climatology (Arctic Climatology Project 1997, 1998; Fig. O.4), but no significant changes relative to 2007 heat content were registered by the BGOS in 2008.

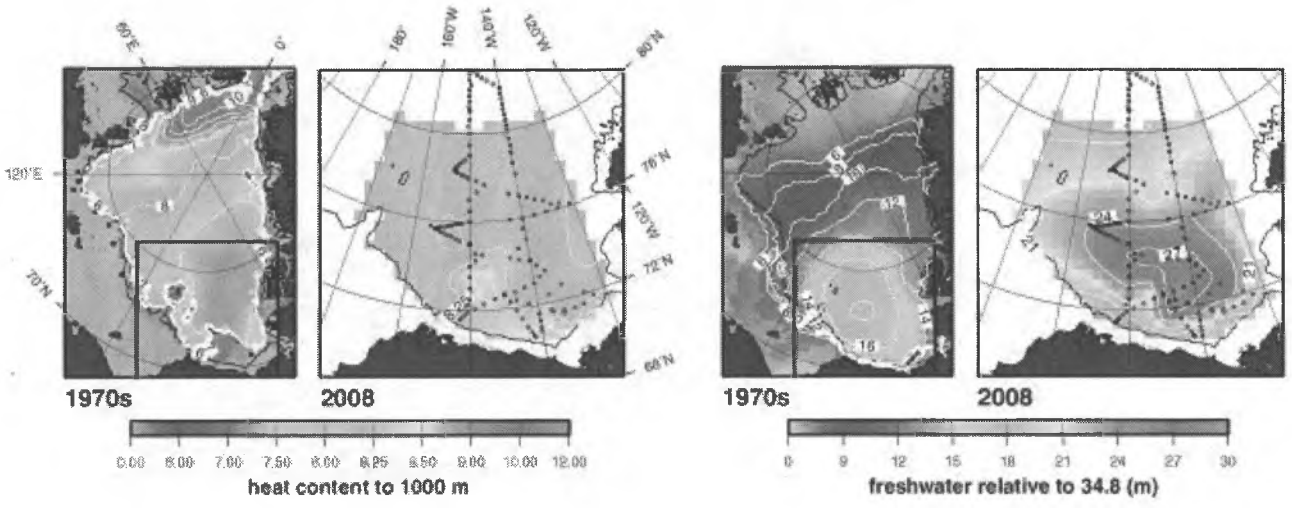

Figure O.4. (left) Summer heat (1×10^{10} J m^{-2}) and (right) freshwater (m) content. Panels 1 and 3 show heat and freshwater content in the Arctic Ocean based on 1970s climatology (Arctic Climatology Project 1997, 1998). Panels 2 and 4 show heat and freshwater content in the Beaufort Gyre in 2008 based on hydrographic survey (black dots depict locations of hydrographic stations). For reference, this region is outlined in black in panels 1 and 3. The heat content is calculated relatively to water temperature freezing point in the upper 1000-m ocean layer. The freshwater content is calculated relative to a reference salinity of 34.8.

The Bering Strait is an important gateway to the Arctic Ocean. Preliminary observations from a mooring site, established and maintained since 1990 (Woodgate et al. 2006), suggest the 2007 annual mean transport through the Bering Strait is around 1 Sv (1 Sv = 10^6 m^3 s^{-1}), greater than 2006 but comparable with previous high years, such as 2004. The same is true of the freshwater flux through the strait. The heat flux, being largely determined by the total volume flux, is also high, but in this case it appears to be somewhat higher than the 2004 values.

Sea Level

Figure O5 shows SL time series from nine coastal stations in the Siberian Seas, having representative records for the period of 1954–2008 (Arctic and Antarctic Research Institute data archives). For the nine stations, the rate for 1954–89, after the GIA, was 1.94 ± 0.47 mm yr^{-1}. This compares to an estimated rate of 1.85 ± 0.43 mm yr^{-1} along the Arctic coastlines over the same period, based on 40 arctic coastal stations (Proshutinsky et al. 2004). Addition of 1990–2008 data

increases the estimated rate of SL rise for the nine stations in the Siberian seas, beginning in 1954, to 2.68 ± 0.45 mm yr^{-1} (after correction for GIA).

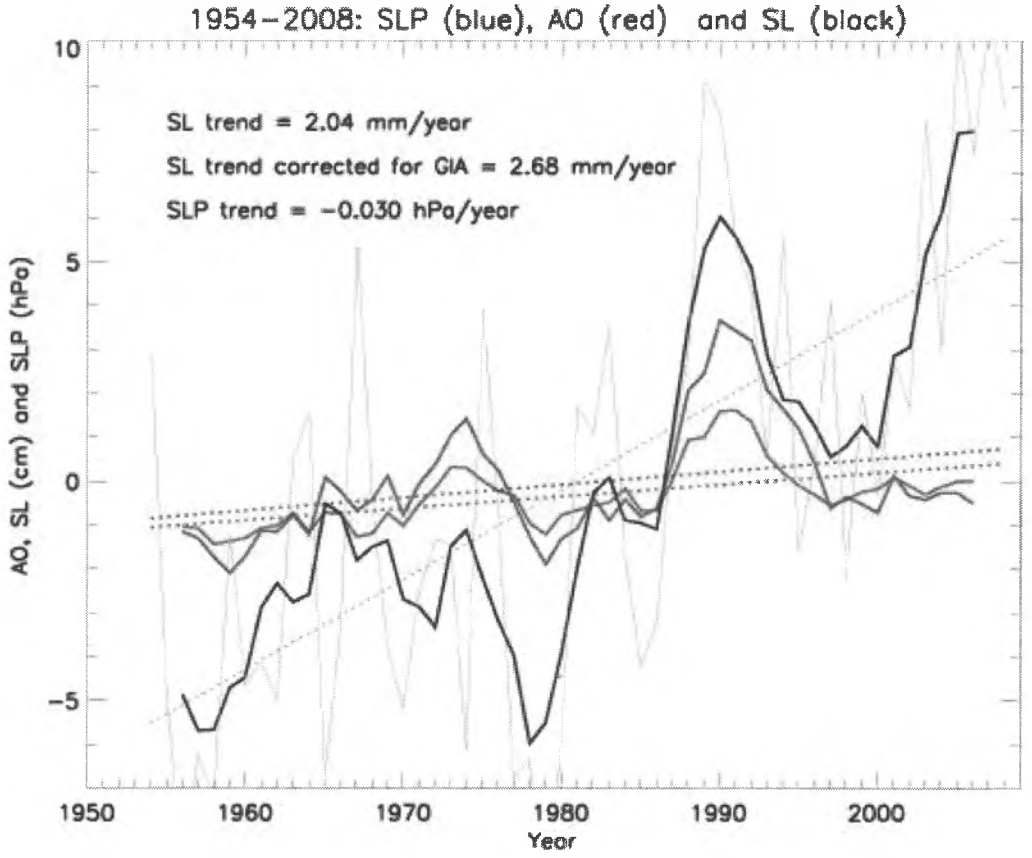

Figure O.5. The 5-yr running mean time series: annual mean sea level at nine tide gauge stations located along the Kara, Laptev, east Siberian, and Chukchi Seas' coastlines (black line). The red line is the anomalies of the annual mean AO Index multiplied by 3. The dark blue line is the sea surface atmospheric pressure at the North Pole (from NCAR–NCECEP reanalysis data) multiplied by -1. Light blue line depicts annual sea level variability.

Until 1996, SL correlates relatively well with the times series of the AO Index and sea level atmospheric pressure at the North Pole (Fig. O5). In contrast, from 1997 to 2008 the SL has generally increased, despite the more or less stable behavior of AO and SLP. Possible reasons for the rapidly rising sea level are ocean expansion, due to heating and freshening of the Arctic Ocean, and increased rates of the Greenland ice sheet melt (see Greenland essay).

Land

J. Richter-Menge, Topic Editor

ERDC-Cold Regions Research and Engineering Laboratory, Hanover, NH

September 3, 2009

Summary

Observations of land-based changes in the Arctic cover a wide spectrum, including variations and trends in vegetation, permafrost, river discharge, snow cover, and mountain glaciers and ice caps. In general, these observations present further evidence of the impact of a general, Arctic-wide warming trend that is accompanied by high variability from year to year and region to region. For instance, the 2007/08 and 2008/09 snow cover seasons marked a continuation of the trend towards shorter snow seasons due to earlier spring melt, which has been observed during the last two decades following a rapid reduction in snow cover duration that occurred in the 1980's. Despite this overall trend, there was evidence of considerable annual and regional variability. The Arctic 2008 spring melt exhibited close to normal conditions over Eurasia, but the earliest snow cover disappearance in the period of record (1966–present) over North America. In 2008/09, the Arctic snow cover was slightly deeper than average in many areas, and the onset of snow melt was near normal or slightly later than normal across large regions of the Arctic, yet the melt intensity was sufficient to again produce an earlier than usual disappearance of snow.

Other observations reveal that there has been a general increase in land-surface temperatures and in permafrost temperatures during the last several decades throughout the Arctic region. New permafrost data from Russia show striking similarity to observations made in Alaska, with permafrost temperature typically increased by 1 to 2°C in the last 30 to 35 years. Significant losses in the mass of ice sheets and the area of ice shelves continued, with several fjords on the northern coast of Ellesmere Island being ice-free for the first time in 3000–5500 years. There continues to be a general increase of freshwater input to the Arctic Ocean from major rivers in Eurasia and North America.

Illustrating the connectivity between various elements of the Arctic system, direct observations confirm model predictions that the affects of the retreating sea ice influence the temperature and vegetation of adjacent lands. Temporal analyses generally show that, within a specific region, periods of lower sea-ice concentration are correlated with warmer land-surface temperatures and an increase in the amount of live green vegetation in the summer.

Vegetation

October 19, 2009

There continues to be evidence of widespread changes in vegetation in northern latitudes, primarily determined from trends in terrestrial greenness as detected by the Normalized Difference Vegetation Index (NDVI) derived from the NOAA AVHRR satellites (Myneni et al. 1997; Zhou et al. 2001; Lucht et al. 2002; Jia et al. 2003; Goetz et al. 2005; Bunn et al. 2007). Changes in land cover, vegetation density, and other factors are reflected in NDVI. Overall, increasing NDVI is consistent with warming soil and air temperatures, earlier snow melt, and the expansion of shrubs and tree line to the north.

In coastal regions, models have predicted that the retreating sea ice should affect the temperature and ecosystems of adjacent lands (e.g., Lawrence et al., 2008). Time series of sea-ice area, land temperatures, and an index of photosynthetic activity (the annual maximum NDVI or MaxNDVI) were investigated for trends and variability during the period 1982–2008 along the coastlines of 14 Arctic seas. Temporal analyses of these regional time series (not shown) consistently indicate that higher land-surface temperatures and higher NDVI values correspond to below-average sea-ice concentration (Bhatt et al., 2008, 2009).

The trend analysis shows that summer sea ice within 50 km of the coast declined in all regions, with a decrease of 25% for the northern hemisphere as a whole (Fig. 1, blue bars). The largest declines were along the northern Beringia region, including the E. Siberia (-47%), W. Chukchi (-46%), and E. Chukchi (-44%) seas. This portion of the Arctic saw large areas of summer ice retreat in 2005, 2007, and 2008.

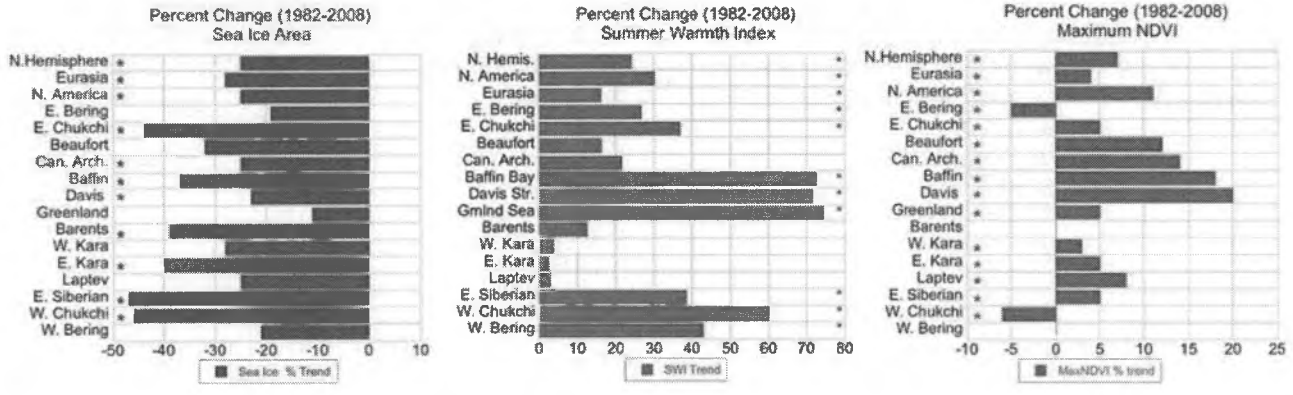

Figure 1. Blue bars: Percentage change in sea-ice area in late spring (when the long-term mean 50% concentration is reached) during 1982–2008 along the 50-km-seaward coastal margin in each of the major seas of the Arctic using 25-km resolution SSMI passive microwave Bootstrap sea-ice concentration data (Comiso and Nishio, 2008). Red bars: Percentage change in the summer land-

surface temperature landward of each sea for the entire tundra domain as measured by the summer warmth index (SWI = sum of the monthly mean temperatures above freezing, °C mo) based on AVHRR surface-temperature data (Comiso, 2003). Green bars: Percentage change in greenness for the full tundra area in the vicinity of each Arctic sea as measured by the annual maximum Normalized Difference Vegetation Index (MaxNDVI) based on revised biweekly GIMMS NDVI (Tucker et al., 2001). Asterisks denote significant trends at $p < 0.05$.

Summer tundra land temperatures as measured by the summer warmth index (sum of the monthly mean temperatures that are above freezing) increased 24% for the northern hemisphere as a whole (Fig. 1, red bars). The North America Arctic tundra experienced a 30% increase in summer land temperatures while Eurasia experienced a 16% increase. Large increases in summer warmth occurred in the vicinity of the W. Chukchi (60%) and W. Bering (43%) seas and near Davis Strait (72%), Greenland Sea (75%) and Baffin Bay (73%). Weak warming occurred along the northern coast of Russia (Laptev Sea, E. Kara Sea and W. Kara Sea).

Photosynthetic activity was determined using the MaxNDVI derived from Global Inventory Modeling and Mapping Studies (GIMMS) data set. The NDVI is an index of the photosynthetic activity that is derived from earth's reflectance in the visible and near infrared portions of the spectrum. MaxNDVI over the tundra region increased 7% for the Arctic as a whole (Fig. 1, green bars), but was variable. Larger percentage increases occurred in North America (11%) than in Eurasia (4%). The largest percentage increases were in the North American High Arctic in the vicinity of Davis Strait (20%), Baffin Bay (18%), and the Canadian Archipelago (14%) and in the Beaufort Sea (12%). Declines or no trend occurred in the Bering-Chukchi region (W. Chukchi -6%, E. Bering -5% and W. Bering 0%). The NDVI changes observed in coastal regions are in general agreement with strong increases in NDVI noted previously in the North American Arctic (Jia et al., 2003; Goetz et al., 2005; Verbyla, 2008; Raynolds et al., 2008) and with ground observations from the same regions (Tape et al., 2006; Walker et al., 2008; Epstein et al., 2008), but the new information from the High Arctic of Canada and Greenland points to previously overlooked major changes to plant productivity occurring in this region. Because of the currently low productivity in these coldest areas of the Arctic, small increases in photosynthetic activity are likely to lead to major changes in biodiversity and total plant biomass.

Permafrost

V. Romanovsky[1], N. Oberman[2], D. Drozdov [3], G. Malkova [3], A. Kholodov[1], and S. Marchenko[1]

[1]Geophyiscal Institute, University of Alaska Fairbanks, Fairbanks, AK
[2] MIREKO, Syktivkar, Russia
[3] Earth Cryosphere Institute, Tumen, Russia

October 7, 2009

Observations show a general increase in permafrost temperatures during the last several decades in Alaska (Romanovsky et al., 2002; Romanovsky et al., 2007; Osterkamp, 2008), northwest Canada (Couture et al., 2003; Smith et al., 2005), Siberia (Oberman and Mazhitova, 2001; Oberman, 2008; Drozdov et al., 2008; Romanovsky et al., 2008), and Northern Europe (Isaksen et al., 2000; Harris and Haeberli, 2003). Most of the permafrost observatories in Alaska show a substantial warming during the last 20 years. The detailed characteristic of the warming varies between locations, but is typically from 0.5 to 2°C at the depth of zero seasonal temperature variations in permafrost (Osterkamp, 2008). It is worth noting that permafrost temperature has been relatively stable on the North Slope of Alaska during 2000–2008.

Permafrost temperature has increased by 1 to 2°C in northern Russia during the last 30 to 35 years (Figure P1). This observed increase is very similar in magnitude and timing to what has been observed in Alaska. Also, a common feature for Alaskan and Russian sites is more significant warming in relatively cold permafrost than in warm permafrost. This fact may be explained by a partial melting of constituent ice within a substantial portion of warm permafrost (upper 20–25 meters) with temperatures in this portion still below 0°C. This partial ice melting slows down the rate of permafrost warming as the temperature of permafrost approaches 0°C (Romanovsky, 2007). An especially noticeable permafrost temperature increase in the Russian Arctic was observed during the last two years. The mean annual permafrost temperature at 15-m depth increased by more than 0.3°C in the Tiksi area and by 0.25°C at 10-m depth in the European North of Russia.

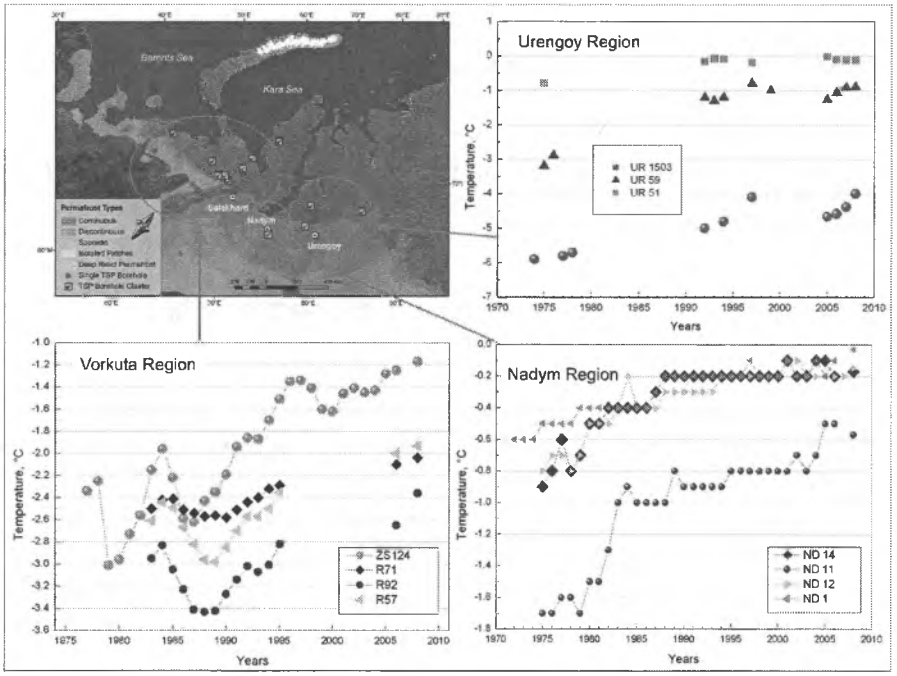

Figure P1. Left above: Location of the long-term MIREKO and the Earth Cryosphere Institute permafrost observatories in northern Russia. Left below: Changes in permafrost temperatures at 15-m depth during the last 20 to 25 years at selected stations in the Vorkuta region (updated from Oberman, 2008). Right: Changes in permafrost temperatures at 10-m depth during the last 35 years at selected stations in the Urengoy (above) and Nadym (below) regions (updated from Romanovsky et al., 2008).

The last 30-years warming in permafrost temperatures have resulted in thawing of permafrost in areas of discontinuous permafrost in Russia. Most of observed long-term thawing has occurred in the Vorkuta and Nadym research areas (Oberman, 2008). At one of the locations, the upper boundary of permafrost lowered to 8.6 m in 30 years. It lowered even more, to almost 16 m, in an area where a newly developed talik (a volume or layer of all-year-round unfrozen soil above or within the permafrost) coalesced with an already-existing lateral talik. The average increase in depth of the permafrost table in the Vorkuta and Nadym regions in Russia ranged from 0.6 to 6.7 m depending on the geographical location, ice content, lithological characteristics of sediments, hydrological, hydrogeological, and other factors.

River Discharge

A. Shiklomanov

University of New Hampshire, Durham, NH

August 27, 2009

A general increase of river discharge to the Arctic Ocean from Eurasia was observed over the period 1936–2007, with a rate of annual change (defined from the linear trend) of 2.7 ± 0.5 km^3/year (Fig. R1). The most pronounced positive (increasing) trend for the six largest Eurasian rivers is observed during the last 21 years (1987–2007), at a rate of 11.8 km^3/year. The rate of discharge has continued to increase in the 21st century. The mean 2000–2007 discharge was 171 km^3 higher (10%) than the long-term average over the period 1936–1999. A new historical maximum for Eurasian river discharge to the Arctic Ocean was observed in 2007, reaching 2250 km^3/year or 30% higher than the long-term mean discharge from 1936–1999, reported in Peterson et al. (2002).

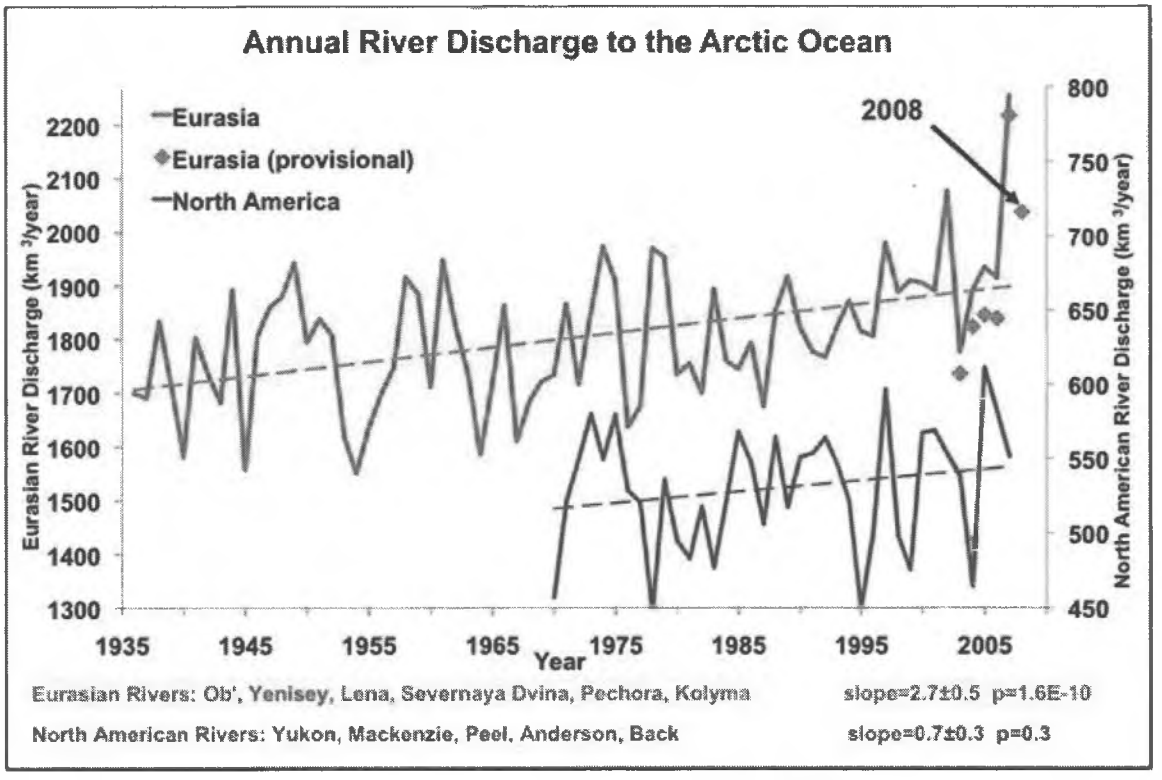

Figure R1. Total annual river discharge to the Arctic Ocean from the six largest rivers in the Eurasian Arctic for the observational period 1936–2007 (updated from Peterson et al., 2002) (red line) and from the five large North American pan-Arctic rivers over 1973–2006 (blue line). The least squares linear trend lines are shown as dashed lines. Provisional estimates of annual discharge for the six major Eurasian Arctic rivers based on near real time data from http://RIMS.unh.edu are shown as red diamonds.

The mean annual discharge to the ocean over 2000–2007 from the 5 large North American Arctic rivers based on data from the Environment Canada and USGS was about 6% (31 km^3) greater than the long-term mean from 1973–1999. The river discharge during 2007 was higher than the

long-term mean and, taking into account that this year had extremely high fresh water discharge from Greenland (Mernild et al., 2009), we can estimate that 2007 showed record high total freshwater input to the Arctic Ocean from the terrestrial land surface.

Official river discharge data are usually processed and published with some delay, the longest delay often being associated with rivers in cold regions that are ice covered for extended periods (Shiklomanov et al. 2006). To provide for more timely detection and diagnosis of changing conditions, a method to estimate near-real time river discharge from the most important Russian monitoring sites, based on provisional stage measurements and river ice data, has been developed in cooperation with the Arctic and Antarctic Research Institute (AARI) (http://RIMS.unh.edu). The provisional estimates over 2003–2007 show a tendency to underestimate the annual observed values within an error of 5% of the officially released data (Figure R1). The preliminary estimate of annual river discharge to the Arctic Ocean from the major Russian rivers in 2008 was significantly greater than the long-term mean but lower than the historical maximum observed in 2007. The North American annual river discharge to the Arctic Ocean in 2008 was probably close to or slightly higher than the long-term mean. However, this estimate is much less reliable due to gaps in near real time discharge data for major North American rivers.

Terrestrial Snow

C. Derksen, R. Brown, and L. Wang

Climate Research Division, Environment Canada

October 7, 2009

Overview

Northern hemisphere terrestrial snow cover exhibits a high degree of intra- and inter-seasonal variability in spatial extent, covering up to 47 million km^2 in winter, and receding to as low as 4 million km^2 in summer. Across the Arctic and sub-Arctic, snow cover is a defining characteristic of the environment, covering the landscape for up to 9 months of the year. Unlike liquid precipitation, snowfall is stored on the land surface, redistributed by wind, and metamorphosed by various physical processes before the spring melt period. For a comprehensive perspective on terrestrial snow it is necessary to consider snow cover extent (SCE: the area covered by snow), snow cover duration (SCD: how long snow is on the ground), snow water equivalent (SWE: the amount of liquid water stored in the form of snow), and snow melt timing/duration (when and for how long the snow melts).

Various satellite and ground-based measurements are available to characterize these parameters across the northern hemisphere, and assess the 2007/08 and 2008/09 snow seasons relative to the historical record. Seasonal SCD departures (difference from the 1988–2007average) were computed from the NOAA snow extent data record maintained at Rutgers University (http://climate.rutgers.edu/snowcover/). SWE is more difficult to monitor than SCD due to high spatial variability, a sparse surface observation network across the Arctic, and uncertainties in satellite datasets. The Canadian Meteorological Centre (CMC) has produced a daily global snow depth analysis (~35 km resolution) since 1998 by combining the available ground observations with a snow model (Brasnett, 1999). The main snow melt onset date across the pan-Arctic land mass was derived from satellite scatterometer measurements via QuikSCAT, using the algorithm of Wang et al. (2008).

2007/08

The 2007/08 snow season was characterized by a shorter than average snow cover season over the central Canadian Arctic, most of Europe, and eastern Siberia, with a longer than average snow season in central China and the mid-latitudes of North America (Figure S1a). Time series of fall and spring SCD anomalies (departures divided by the standard deviation over the 1988–2007 period to give an indication of relative magnitude) across the North American and Eurasian sectors of the Arctic (north of 60N) are illustrated in Figure S1b. In fall, the 2007/08 snow cover season was close to the 1988–2007 average in both regions while in spring, the North American Arctic had the earliest disappearance of snow since the start of the NOAA record which dates to 1966.

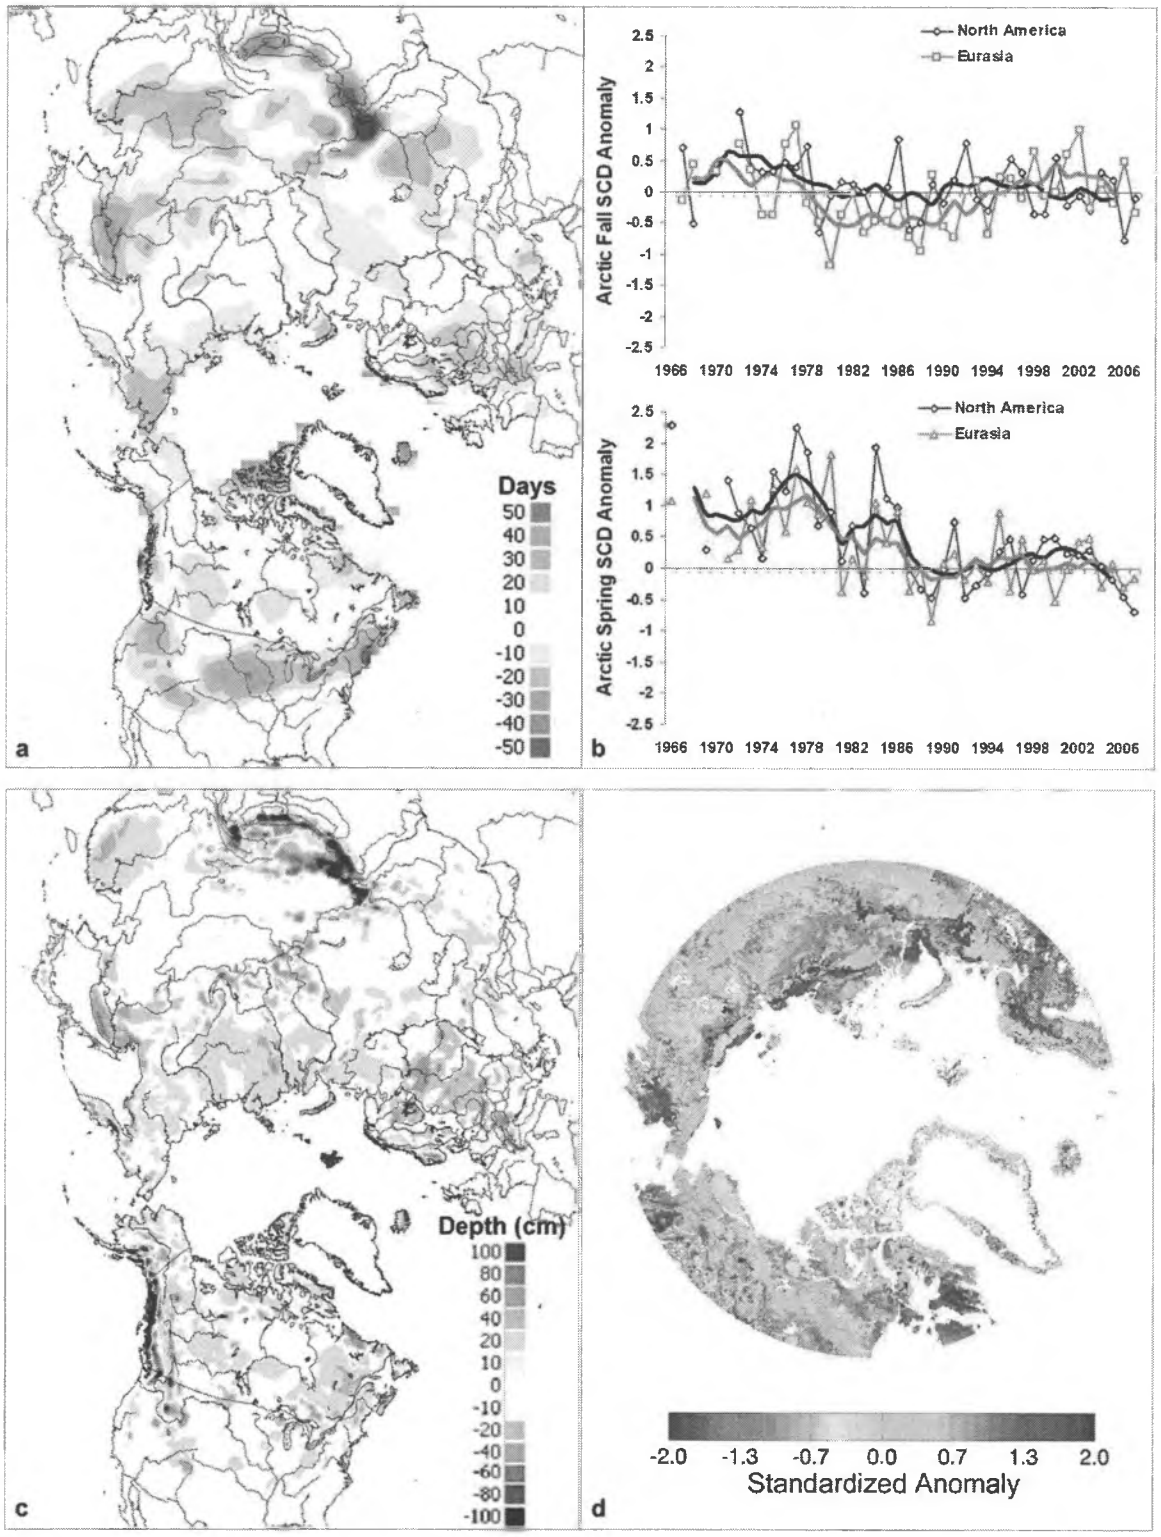

Figure S1. (a) Snow cover duration (SCD) departures (with respect to 1988–2007) for the 2007/08 snow year and (b) Arctic seasonal SCD anomaly time series (with respect to 1988–2007) from the NOAA record for the first (fall) and second (spring) halves of the snow season. Solid lines denote 5-yr moving average. (c) Maximum seasonal snow depth anomaly for 2007/08 (with respect to 1998/99–2007/08) from the CMC snow depth analysis. (d) Terrestrial snow melt onset anomalies (with respect to 2000–2008) from QuikSCAT data derived using the algorithm of Wang et al. (2008).

Maximum seasonal snow depth anomalies for 2007/08 determined from the CMC analysis are shown in Figure S1c. Below-average snow accumulation occurred across the Himalayas, Europe and northern China; above-average snow depth occurred across central North America and Siberia.

The main snow melt onset date for 2008, relative to the 9-year QuikSCAT record (2000 to 2008), confirms regional early melt onset over the North American Arctic that matches the unusually early dates of snow disappearance identified in the NOAA record (Figure S1d).

2008/09

As for the 2008/09 snow season, there was a shorter than normal snow cover season across a large portion of eastern Siberia, with strong negative anomalies in the North American sector confined to the Canadian Arctic Islands (Figure S2a). When separated for fall and spring, and averaged regionally, negative SCD anomalies were evident across Eurasia in the fall, and the entire Arctic in spring (Figure S2b). The 2009 spring Arctic snow season can therefore be characterized as shorter than normal due primarily to an early disappearance of snow cover in spring.

The shorter than average snow season in 2008/09 occurred in spite of slightly deeper than average snow depth in many parts of the Arctic (Figure S2c). Snow melt onset anomalies from QuikSCAT observations show that the initial timing of snow melt was near normal, or slightly later than normal across large regions of western Siberia, northern Europe, and the Canadian tundra (Figure S2d). Collectively, these datasets suggest that although melt was initiated near the average time, it was of sufficient intensity to rapidly remove the snowpack across large regions of the Arctic.

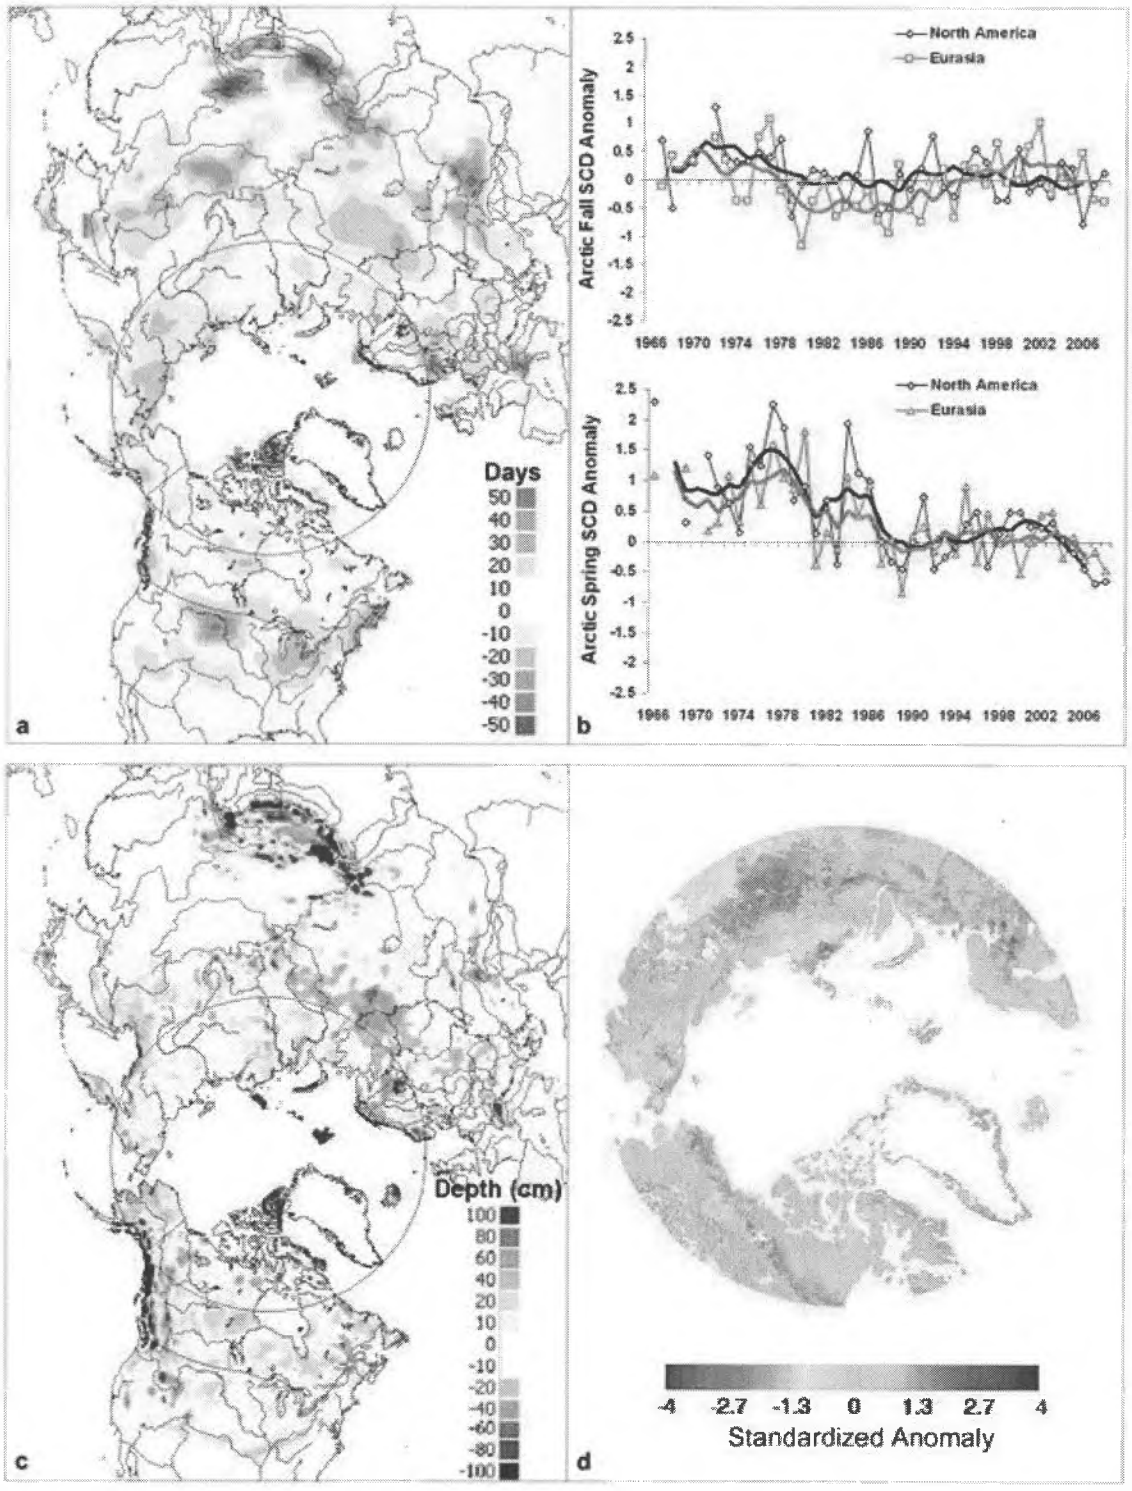

Figure S2. (a) Snow cover duration (SCD) departures (with respect to 1988–2007) for the 2008/09 snow year and (b) Arctic seasonal SCD anomaly time series (with respect to 1988–2007) from the NOAA record for the first (fall) and second (spring) halves of the snow season. Solid lines denote 5-yr moving average. (c) Maximum seasonal snow depth anomaly for 2008/09 (with respect to 1998/99–2007/08) from the CMC snow depth analysis. (d) Terrestrial snow melt onset anomalies (with respect to 2000–2009) from QuikSCAT data derived using the algorithm of Wang et al. (2008).

Glaciers outside Greenland

M. Sharp and G. Wolken

Department of Earth and Atmospheric Sciences, University of Alberta

August 26, 2009

Glacier shrinkage is a major contributor to global sea level change, and mountain glaciers and ice caps may account for up to 60% of the total glacier contribution to sea level rise since the 1990's (Meier et al., 2007; Cazenave et al., 2009). Since the Arctic (including Alaska) contains nearly 50% of the total global mountain glacier and ice cap area, it has accounted for a large fraction of this contribution (50–60% in the 1961–2004 period) (Kaser et al., 2006).

Surface mass balance (annual net balance and its summer/winter components) measures how climate affects the health of Arctic glaciers. Measurements of this quantity on Arctic glaciers and ice caps suggest accelerating rates of mass loss since the early 1990's (Kaser et al., 2006). As most 2007–8 measurements are not yet available, we report results for the 2006–2007 balance year (Svalbard: 4 glaciers, Iceland: 6, Alaska:3, Arctic Canada:4). Annual surface balances were negative for 14 glaciers, positive for 2 (1 each in Iceland and Alaska) and zero for one (in Svalbard) (WGMS, 2009). The 2006–2007 annual surface balances were among the five most negative balances in the > 40-year long records from the four Canadian Arctic sites. These results suggest a continuation of the longer term trend of overall mass loss.

Summer (JJA 2008) 700 hPa air temperature and winter (September 2007–May 2008) precipitation data from the NCEP/NCAR Reanalysis serve as climatic indices for regions centered over each of the Arctic's major glaciated regions (excluding Greenland). Correlations between the 1948–2008 NCEP summer temperature series from 16 discrete regions form 4 groups (Alaska, Arctic Canada, Iceland, and the Eurasian Arctic). Measurements from glaciers in these regions suggest that inter-annual variability in the annual net balance arises primarily from variability in the summer balance (Arctic Canada), the winter balance (southern Alaska, Iceland) or both (Eurasian Arctic, with greater influence from the summer balance). The climatic indices therefore suggest that the annual mass balance was likely extremely negative in Arctic Canada, due to unusually warm summer air temperatures, and positive in Alaska due to strong positive winter precipitation anomalies (confirmed by GRACE satellite gravimetry; pers. comm. from S. Luthcke, 2009). Annual balance was likely near zero or slightly positive in the Eurasian Arctic (relatively cool summers and generally high winter precipitation) and negative in Iceland (warmer than average summer temperatures and below average winter precipitation).

Melt onset and freeze-up dates and 2008 melt season duration were determined from temporal backscatter variations measured by QuikScat's SeaWinds scatterometer (Table G1; Figure G1). In Arctic Canada, melt duration anomalies (relative to 2000–2004 climatology) on the N Ellesmere, Agassiz, and Axel Heiberg ice caps ranged from +17.6 to +22.5 days, largely due to late freeze-up (Table 1). Here, summer 2008 was the longest melt season in the 2000–2008 record. Melt duration anomalies were also strongly positive on northern Prince of Wales Icefield and Severnaya Zemlya, and positive in the southern Queen Elizabeth Islands and Baffin Island (Arctic Canada), Franz Josef Land, and Iceland. The melt season in southwest Alaska was the shortest in the nine-year record, with strongly negative melt duration anomalies, mostly due to early freeze-up.

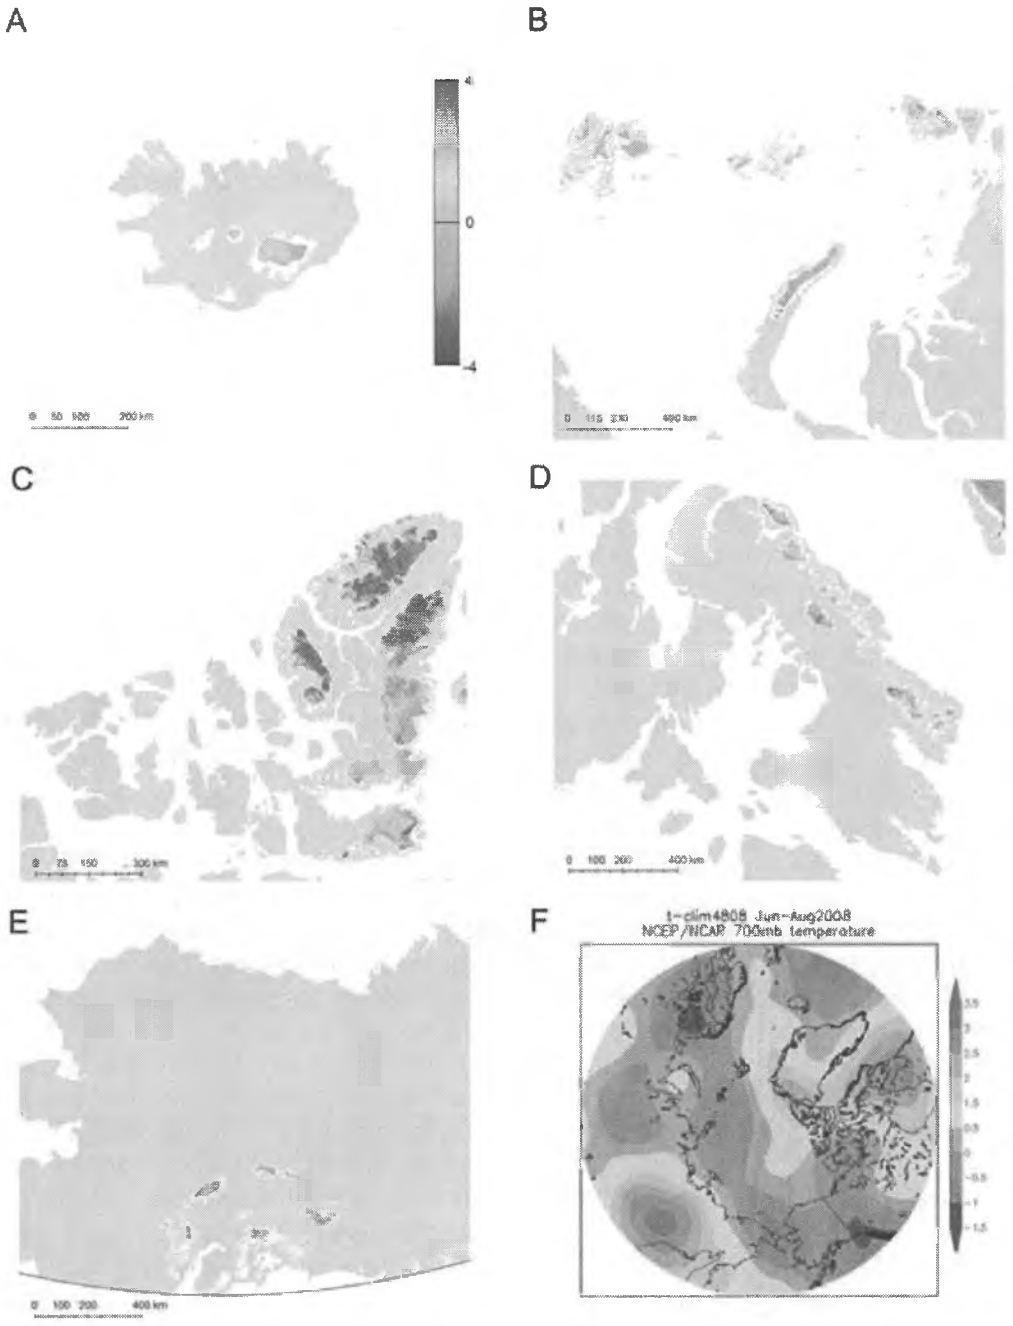

Figure G1. 2008 standardised melt duration anomalies derived from QuikScat for glaciers and ice caps in (a) Iceland, (b) the Eurasian Arctic, (c) the Queen Elizabeth Islands, (d) Baffin and Bylot Islands, and (e) Alaska. (f) Anomalies in JJA 2008 mean air temperature (degrees Celsius) at 700 hPa relative to 1948–2008 climatology from the NCEP/NCAR Reanalysis.

The total ice shelf area in Arctic Canada decreased by 23% in summer 2008 (Mueller et al., 2008). The Markham ice shelf disappeared completely and the Serson ice shelf lost 60% of its area. 90% of Arctic ice shelf area has been lost in the past century. Several fjords on the north coast of Ellesmere Island are now ice-free for the first time in 3000–5500 years (England et al., 2008).

October 19, 2009

Summary

An abnormally cold winter across the southern half of Greenland led to substantially higher west coast sea ice thickness and concentration. Even so, record-setting summer temperatures around Greenland, combined with an intense melt season (particularly across the northern ice sheet), led the 2008 Greenland climate to be marked by continued ice sheet mass deficit and marine-terminating ice disintegration.

Regional surface temperatures

Temperature anomalies were mixed and exhibited seasonal variability (Fig. 5.17). Annual mean temperatures for the whole ice sheet were +0.9°C, but were not abnormal, given a rank of 23 of 51 years over the 1958–2008 period (Box et al. 2006). Persistent warm anomalies were evident over the northern ice sheet in all seasons. Temperatures were abnormally cold over the southern ice sheet in winter. Coastal meteorological stations around Greenland with a consistent 51-yr period (1958–2008) (Cappelen 2009) indicate a record-setting warm summer in 2008. The Upernavik (Nuuk) summer temperature was the warmest (second warmest) on record since 1873, respectively.

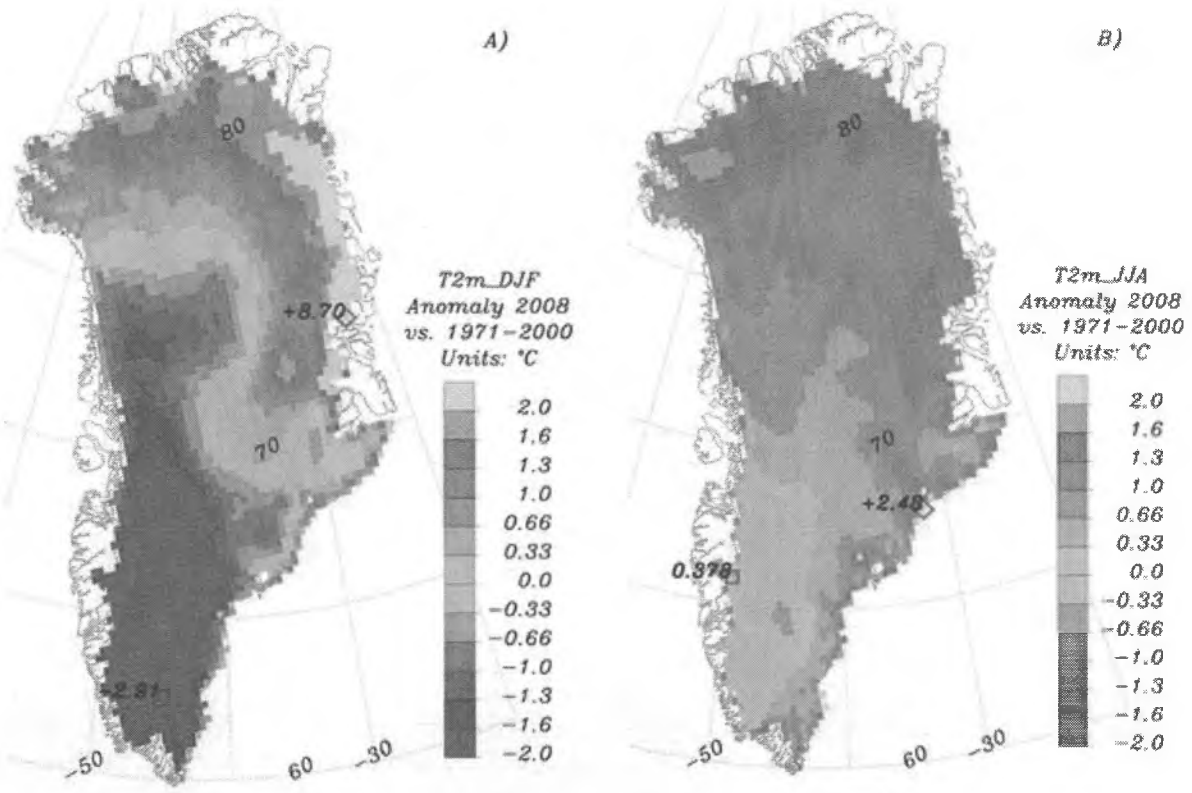

Figure G1. (a) winter and (b) summer near-surface (2 m) air temperature anomalies with respect to the 1971–2000 base period, simulated by Polar MM5 after Box et al. (2006).

Table G1. 2008 Summer 700-hPa temperature and winter precipitation anomalies (relative to 1948–2008 NCEP reanalysis means) for glaciated regions of the Arctic (excluding Greenland). Inferred sign of surface mass balance is based on comparison of historical mass balance records for each region with NCECEP reanalysis temperature and precipitation anomalies. Anomalies in melt duration and the timing of melt onset and freeze-up (relative to 2000–04 climatology) derived from QuikSCAT data. For timing, negative anomalies indicate an earlier-than-normal date.

Upper-air temperatures

Upper-air sounding data available from the Integrated Global Radiosonde Archive (Durre et al. 2006) indicate a continued pattern of lower tropospheric warming and lower stratospheric cooling

1964-onward (Box and Cohen 2006). Lower tropospheric warm anomalies in all seasons, particularly in spring along western Greenland, were accompanied by relatively small midtropospheric cool anomalies. Winter tropopause temperatures (200 hPa) were above normal. Lower stratospheric (above 100 hPa) temperatures were lower than normal.

Surface melt extent and duration

Passive (SMMR and SSM/I, 1979–2008) and active (QuikSCAT, 2000–08) microwave remote sensing (Bhattacharya et al. 2009, submitted to Geophys. Res. Lett.; Liu et al. 2005) indicate abnormally high melt duration over the north and northeast ice sheet and along the east and west coasts above Greenland's most productive three outlet glaciers in terms of ice discharge into the sea: Kangerlussuaq; Helheim; and Jakobshavn (Fig.G2). Lower-than-normal melt duration is evident over much of the upper elevations of the ice sheet. New records of the number of melting days were observed over the northern ice sheet, where melting lasted up to 18 days longer than previous maximum values. Anomalies near the west coast are characterized by melting up to 5–10 days longer than the average (Tedesco et al. 2008).

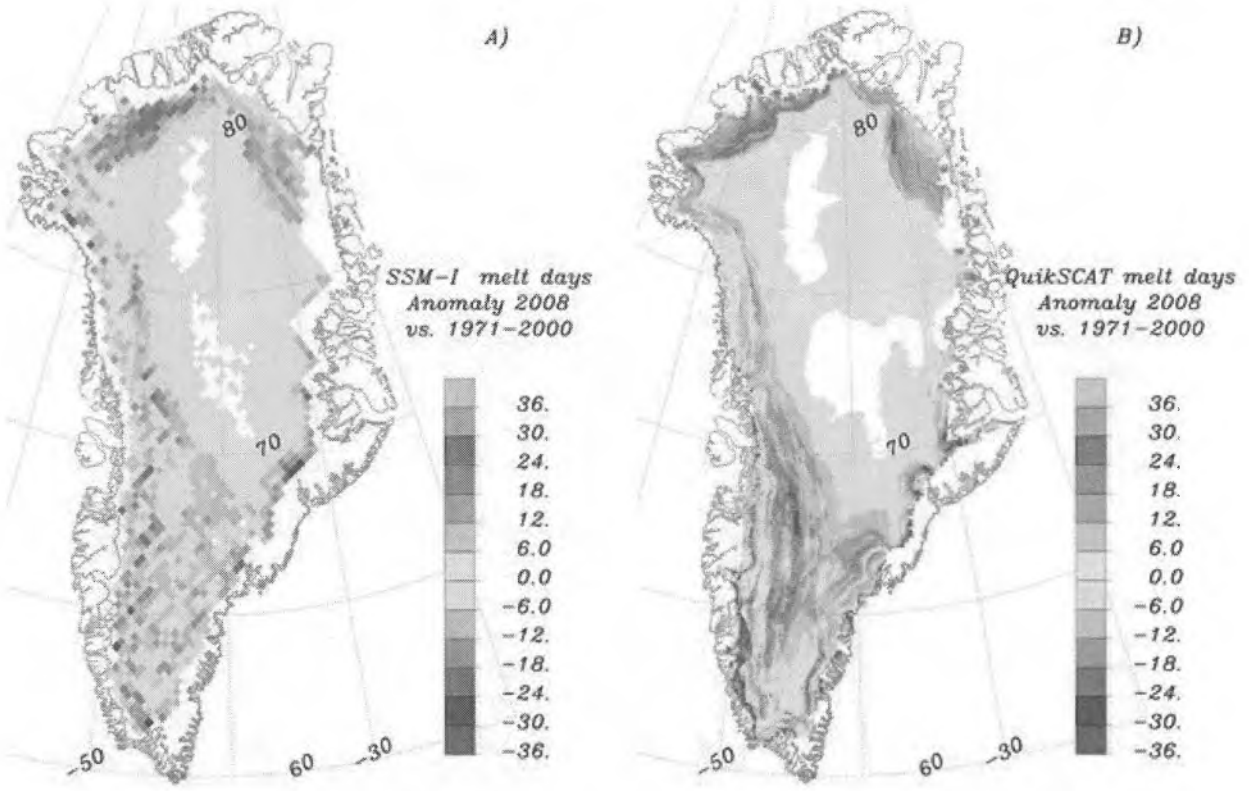

Figure G2. 2008 Greenland ice sheet surface melt duration anomalies relative to the 1989–2008 base period based on (a) SSM/I and (b) QuikSCAT (2000–08 base period), after Bhattacharya et al. (2009, submitted to Geophys. Res. Lett.).

The average daily melt extent, after Mote and Anderson (1995) and Mote (2007), for 2008 was 424,000 km^2, about 2.4% greater than the 1989–2008 average of 414,000 km^2, representing the lowest average melt extent since 2001. Significantly more melt occurred in 2008 in the northeast (45.6% greater than the 1989–2008 average) and northwest (29.7%), but less occurred in the two east-central regions (−16.8% and −25.4%) and in the southeast (−21.1%). Melt extent in 2008 was also above the 1979–2007 average. The trend in the total area of melt during 1979–2008 is approximately +15,900 km^2 yr^{-1} and is significant at the 95% confidence interval ($p < 0.01$).

Precipitation anomalies

Annual PT anomalies in 2008, determined using Polar MM5 data assimilation modeling (Bromwich et al. 2001; Cassano et al. 2001; Box et al. 2006), were positive (negative) up to 750 mm (−250 mm) over the eastern (western) ice sheet, respectively. More PT than normal occurred in isolated areas in extreme southeast, east, north, and northwestern Greenland. The overall anomaly indicated approximately 41 Gt more PT than normal for the 1971–2000 standard normal period.

Surface albedo

Melt season (day 92–274) surface albedo anomalies, derived using the Liang et al. (2005) algorithm applied to daily cloud-free MODIS imagery, indicate a lower surface albedo around the ablation zone (except the east ice sheet) (Fig. G3) resulting from the combined effect of the positive summer surface melt intensity anomaly and, in most areas, less winter snow coverage. A positive albedo anomaly is evident for the ice sheet accumulation zone and is consistent with above-average solid precipitation and/or less-than-normal melting/snow grain metamorphism.

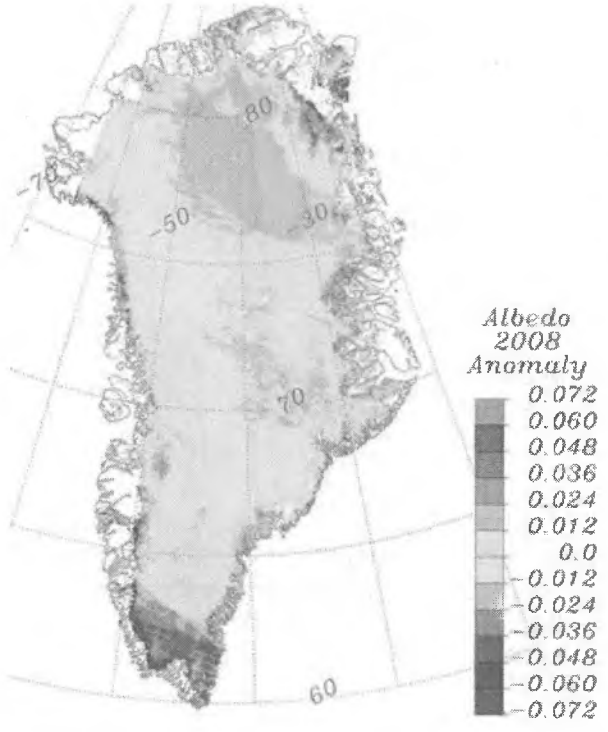

Figure G3. Surface albedo anomaly Jun–Jul 2008 relative to a Jun–Jul 2000–08 base period.

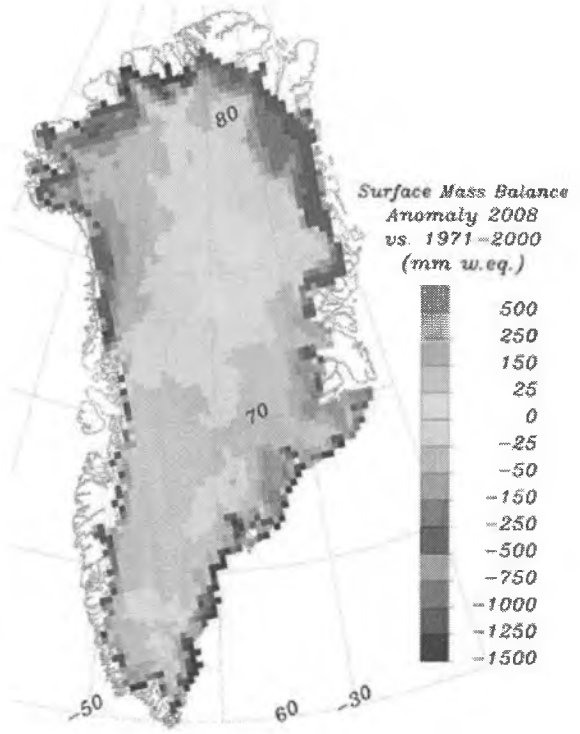

Figure G4. 2008 surface mass balance anomalies with respect to the 1971–2000 base period, simulated by Polar MM5 after Box et al. (2006).

Surface mass balance

Polar MM5 climate data assimilation model runs spanning 51 years (1958–2008), calibrated by independent in situ ice-core observations (Bales et al. 2001; Mosley-Thompson et al. 2001; Hanna et al. 2006) and ablation stakes (van de Wal et al. 2006), indicate that 2008 total precipitation and net snow accumulation was slightly (6%–8%) above normal (Table G2). In accordance with a +0.9°C 2008 annual mean surface temperature anomaly, the fraction of precipitation that fell as

rain instead of snow, surface meltwater production, and meltwater runoff were 142%–186% of the 1971–2000 mean. Consequently, and despite 6%–9% (39–50 Gt) more snow accumulation than normal, the surface net mass balance was substantially (145 Gt) below normal. 2008 surface mass balance ranked ninth-least positive out of 51 years (1958–2008).

Table G2. Greenland ice sheet surface mass balance parameters: 2008 departures from 1971–2000 average (adapted from Box et al. 2006). Estimates by Hanna et al. (2008) are included for comparison.

	Box			Hanna		
	Mean (1971–2000)	% of normal	2008 Anomaly (Gt)	Mean (1971–2000)	% of normal	2008 Anomaly (Gt)
Total Precipitation	710.7	105%	38.5	624.16	108%	52
Liquid Precipitation	16.8	142%	7.1	27.01	147%	13
Surface Water Vapor Flux	66.7	100%	−0.2	40.59	74%	−11

Meltwater Runoff	214.9	186%	184.3	277.91	142%	116
Surface Mass Balance	389.6	63%	−145.3	305.66	83%	−53
Mean T	−19.0		0.9	−21.4		1.1
AAR	0.920	0.905%	−0.087	0.859	0.933%	−0.007

Surface mass balance anomalies indicate a pattern of increased marginal melting with noteworthy departures in excess of 1-m water equivalence per year from normal across the northern ice sheet (Fig.G4). The pattern of steepening mass balance profile is consistent with observations from satellite altimetry (Zwally et al. 2005) and airborne altimetry (Krabill et al. 2000); satellite gravity retrievals (e.g., Luthcke et al. 2006); and climate projections (Solomon et al. 2007).

Marine-terminating glacier area changes

Daily surveys of Greenland ice sheet marine terminating outlet glaciers from cloud-free MODIS imagery (http://bprc.osu.edu/MODIS/) indicate that the 34 widest glaciers collectively lost 106.4 km^2 of marine-terminating ice between the end of summer 2008 and the end of summer 2009 (Figure G4). This is equivalent to an area 20% larger than Manhattan Island (87.5 km^2), New York. The largest individual glacier losses are observed at: Humboldt (-37 km^2); Zachariae Isstrom (-31 km^2); and Midgard (-16 km^2). The 2000–2009 rate (106 km^2) has been linear (R = −0.98) despite the fact that a few individual glaciers exhibit erratic annual net ice area changes. The cumulative area change from end-of-summer 2000 to 2009 is −990 km^2, an area 11.3 times that of Manhattan Island.

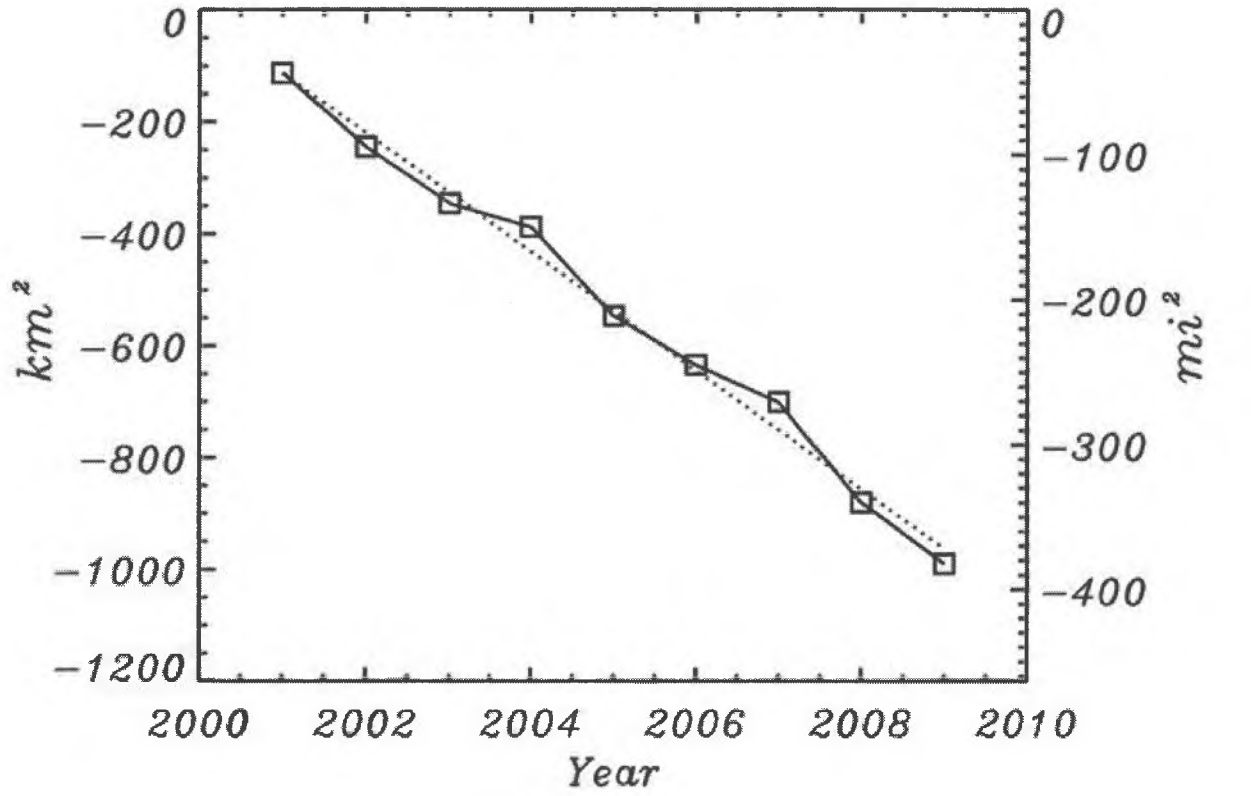

Figure G4. Cumulative annual area changes for 34 of the widest Greenland ice sheet marine-terminating outlets.

Biology

Michael J. Gill, Topic Editor

Chair, Circumpolar Biodiversity Monitoring Program, Environment Canada, Whitehorse, Yukon CA

October 16, 2009

Summary

Broad-scale changes to Arctic wildlife populations and ecosystems illustrate the sensitivity of these systems to changing conditions, both natural and human-induced. Recent research and monitoring has shown close correlations between ocean temperatures and ecosystem states (e.g. Bering Sea fisheries) and population abundance (e.g. Murres). Also, in some instances, largely synchronous, pan-Arctic periods of abundance and scarcity suggest large-scale mechanisms (e.g. continental climate oscillations) are important determinants of population trajectories for some species. Recent examples of these close connections are the declines in wild caribou and reindeer herds across the Arctic, which are thought to be part of a long-term natural cycle. The strong linkages between arctic ecosystems and physical conditions are cause for concern as the Arctic is experiencing and expected to continue to experience rapid and wide-scale changes in temperatures and associated conditions (e.g. sea ice extent, permafrost). Broad changes in wildlife abundance and distributions are expected, with some early evidence of these changes already emerging (e.g. sea-ice dependent marine mammals such as walrus and polar bears). However, our current understanding of the response of arctic wildlife and ecosystems to both natural and human-induced change is limited. More coordinated research and monitoring is required to provide an accurate picture as to how these systems may be responding to a changing Arctic.

State of Wild Reindeer Herds

D. Russell

Scientist Emeritus, Canadian Wildlife Service, Environment Canada, Yukon, Canada

October 19, 2009

Summary

Rangifer (wild reindeer and caribou) herds across the circumpolar north have long been characterized by periods of abundance and periods of scarcity. Recent population estimates indicate we may be entering a period of declining numbers. Populations that have been increasing at a steady rate since the early to mid 1970's are either showing signs of peaking or beginning to decline. Figure R1 shows the current status of selected *Rangifer,* the major migratory herds and herds being monitored as part of the CARMA Network (see note on CARMA at bottom of this article). In 2009, a number of population counts were made available, which illustrates the diversity of trends across the arctic.

- On the Alaskan coastal plain the Teshekpuk Lake Herd (TLH) and the Central Arctic Herd (CAH) continued to increase by 5–7% per year. Counted in 2008 the TLH numbered 64,000 up from 45,000 in 2002. The CAH in 2008 were estimated at 67,000 up from 32,000 in 2002.
- In the Central barrens attempts to count the Beverly herd failed because only a few hundred breeding females could be found on the traditional calving grounds. The Beverly herd was last counted in 1994 when the population was estimated at 276,000 animals.
- The Bathurst Caribou herd was counted in 2009 and, although an estimate is not finalized, biologists believe the count will be less than 50,000 animals down from a population peak of over 470,000 in 1986.
- Across the north a number of herds were counted in 2009 or are scheduled to be counted in 2010 in an effort to more closely monitor the apparent declines that are occurring.

Most feel the general declines that the north is experiencing are part of a natural cycle. However during this population scarcity many are concerned that the increased threats of climate change, increased industrial expansion in the north and the increased sophistication and mobility of harvesters will require more careful monitoring and analysis of population response. The CircumArctic *Rangifer* Monitoring and Assessment (CARMA) Network (http://www.rangifer.net/carma/) was formed in response for a need to cooperate and coordinate monitoring efforts across the north. The Network is taking advantage of the International Polar Year initiative to increase its monitoring and assessment activities.

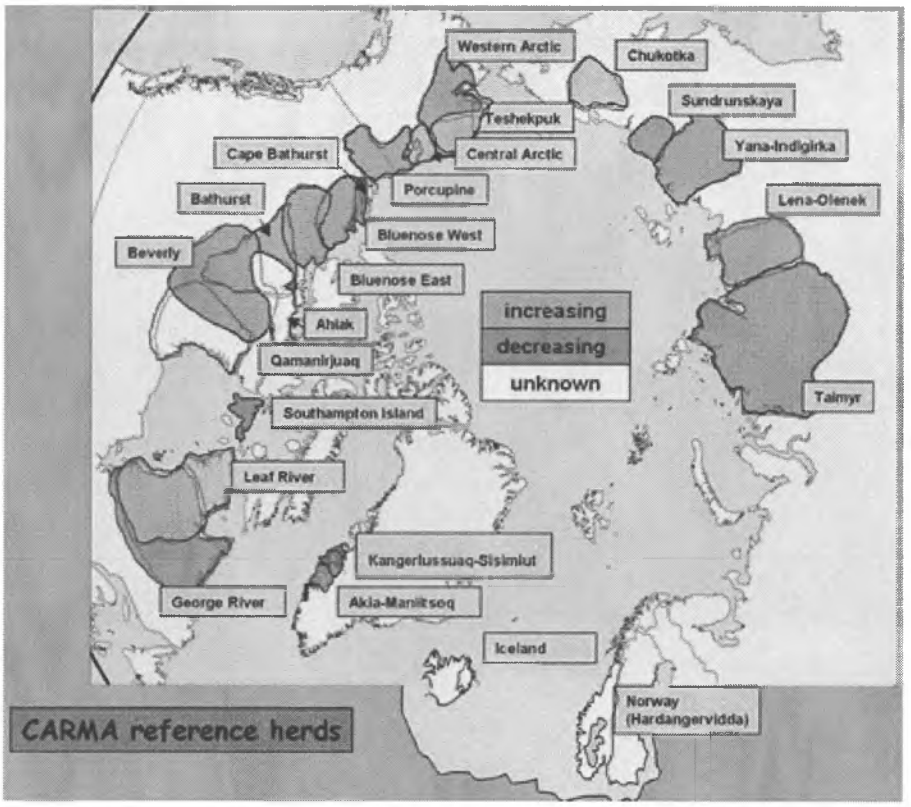

Figure R1. Current status of the main migratory herds across the circumpolar north.

Marine Mammals

M. Simpkins

NOAA Fisheries Service

October 19, 2009

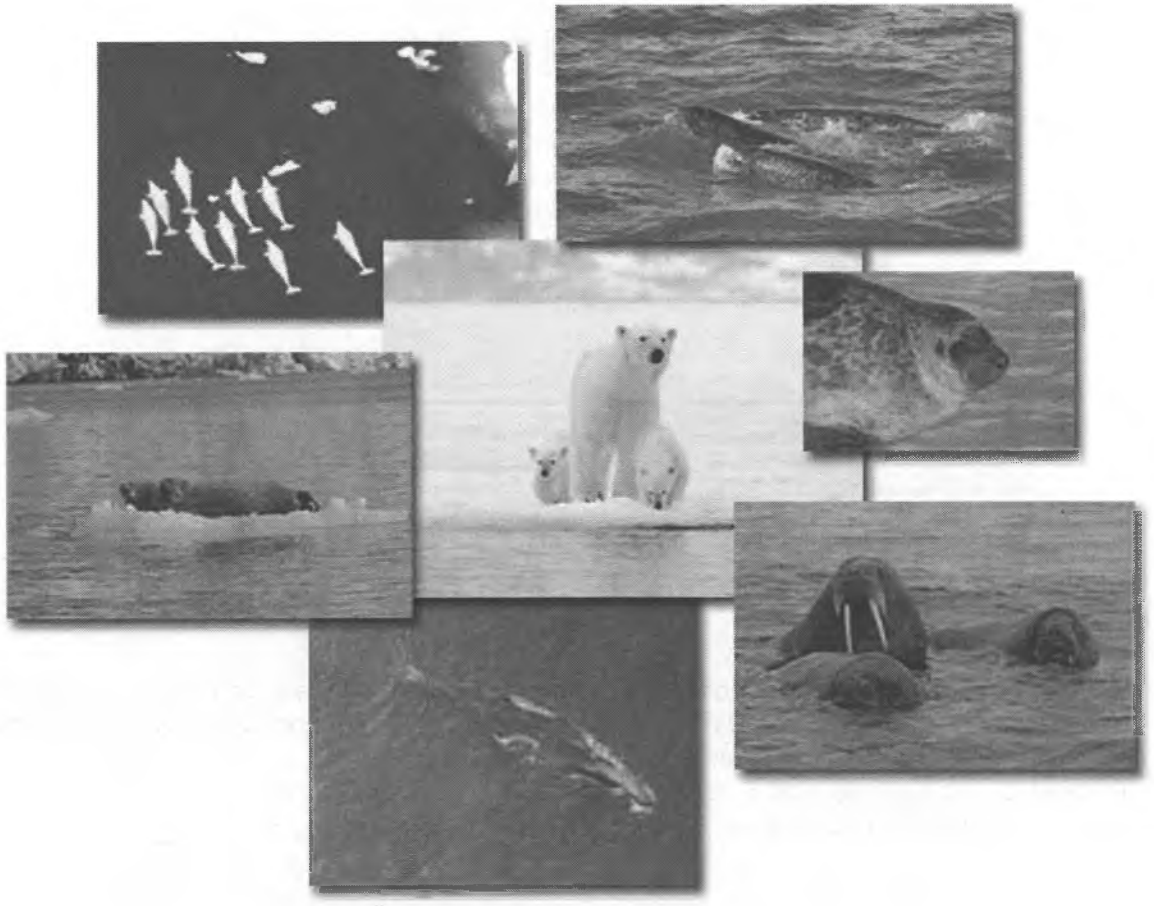

Figure M1. Marine mammals found in the Arctic. Clockwise from the upper left: Beluga whales, Narwhal, Ringed seal, Walrus, Bowhead whale, Bearded Seal, and center, Polar Bear.

A variety of marine mammals can be found in the Arctic at least seasonally. Seven species are present in the Arctic year-round and are often associated with sea ice—bowhead whale, beluga whale, narwhal, ringed seal, bearded seal, walrus, and polar bear. All seven of these species are important top predators within Arctic marine ecosystems. As such they may serve as sentinels of Arctic climate change, with changes in their status reflecting ecosystem-wide perturbations[1]. Table M1 summarizes current knowledge regarding the abundance and trends of these species. Unfortunately, abundance estimates are not available for one or more populations of most species, and trends are unknown for even more populations. Further, some of the available estimates are based on data from the 1990s or earlier and, therefore, are out of date. It is clear, even from this limited information, that several populations of Arctic marine mammals are quite small (e.g., Ungava Bay and Cook Inlet belugas, Lake Saimaa ringed seals, and several stocks of polar bears each have 400 or fewer animals), and this raises concerns about the potential impact of

catastrophes such as oil spills or disease outbreaks. Also, all species with sufficient data exhibit mixed population trends, with some populations of each species increasing while others are stable or declining. The available data are not sufficient for an analysis of trends by region (e.g., to highlight regions within which populations of several species are all increasing or all declining). However, it is likely that species within a region will exhibit different trends because they occupy very different ecological niches, ranging from the bowhead whale that filters zooplankton out of the water to the polar bear that hunts seals on the sea ice (Table M2).

A comprehensive assessment of the status of Arctic marine mammals must consider current population demography and dynamics as well as the resistance or resilience of each species to current and projected threats. Arctic marine mammals appear to be in a tenuous position—they are adapted to life in seas that are at least seasonally ice-covered, and the extent of summer ice cover is rapidly diminishing[41]. These species are long-lived and reproduce slowly and, although they have persisted through ice ages and interglacial periods in the past, it is unclear how quickly they can adapt to rapid changes in habitat. The impacts of reduced sea ice vary depending on the ecological relationship between each species and sea ice[41] (Table M2). A recent special publication of Ecological Applications provides a comprehensive review of the likely impacts of climate change on Arctic marine mammals[42], and other reviews discuss impacts of climate change on marine mammals broadly at a global scale[43] and in more detail for the North Atlantic Arctic[44].

Although assessment of future impacts is by its very nature speculative, currently observed impacts on polar bears and walruses indicate that Arctic marine mammals will almost certainly be affected by the predicted changes in Arctic marine ecosystems [45]. Reduced sea ice has already been implicated in lower body condition and reduced survival of polar bears in western Hudson Bay, and similar impacts are likely elsewhere as sea ice breaks up earlier and bears are forced to fast on shore longer [46,47]. The record sea ice retreat of 2007 caused Pacific walruses to haul out along the shores of Alaska and Russia in unusually large numbers and in new locations [48]. The immediate impact of this redistribution was an increase in trampling deaths as walruses on shore stampeded in response to terrestrial disturbances [48]. Over the long-term, walruses could deplete nearshore benthic resources if they are forced to use land haul-out sites exclusively in the future. Similar shifts in the seasonal distribution of all Arctic marine mammals are likely. For example, species that are strongly tied to sea ice habitats, such as the polar bear and ringed seal, may be limited in the future to areas with sea ice refugia (e.g., summer sea ice is predicted to persist longer in the Canadian Arctic Archipelago than elsewhere), whereas sub-Arctic or migratory species may be able to access areas where sea ice had previously excluded them[41]. Further, species or populations that either migrate with the sea ice edge or make forays to the ice edge from coastal areas may have to travel farther and expend more energy as the summer sea ice edge retreats farther from the coast and from the location of the winter ice edge [49,50].

In addition to the more obvious impacts that changes in the distribution and quality of habitat will have on the distribution of Arctic marine mammals, early spring rains could cause ringed seal lairs to collapse, exposing their pups to hypothermia and increased predation by polar bears and arctic foxes [51], and it has been suggested that increased variability in sea ice and weather conditions could result in more frequent ice entrapments of narwhals and belugas [52,53]. Further, changes in the seasonality of ice retreat could result in changes in the timing and location of phytoplankton blooms (e.g., associated with the melting ice edge or in open water following ice retreat), which in turn could influence both the total amount of primary production and the allocation of that production among pelagic and benthic food webs [39]. Of course, in addition to environmental impacts, reduced sea ice will make the Arctic more accessible for some species (e.g., gray whales[1]) and for human activities, some of which could impact marine mammals (e.g., oil spills, habitat alteration, prey removals, contaminants, and ship strikes). Also, all of these species are harvested for subsistence, with varying degrees of regulation among populations and regions.

Given the threats (both observed and predicted) facing marine mammals, there is justifiable cause for concern regarding populations that are small or declining, as well as those for which information is insufficient. Expanded and accelerated research and monitoring efforts will be necessary to detect changes in the status of Arctic marine mammal populations and to identify the causes of those changes in time to allow developing problems to be addressed [54,55,56].

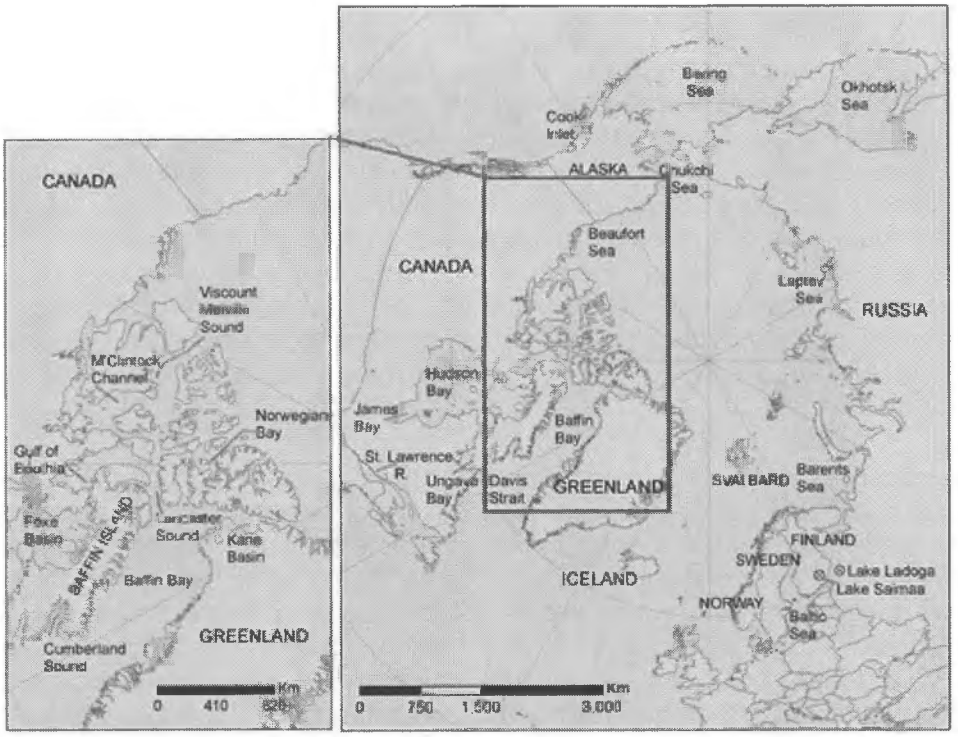

Figure M2. Map of the Arctic with place names referred to in the text or in Table M1.

Table M1. Current abundance and trends of Arctic marine mammal species. Information on abundance, trends, and most recent data (year) are summarized by biological stock, except for ringed seals, bearded seals, and walruses, whose stock structure is unknown (see table footnotes). Figure M2 indicates the locations of place names referred to here. Citation numbers refer to literature cited.

[b] Bearded seal stock structure unknown; information summarized for geographic regions.
[c] Walrus stock structure unknown; information summarized for Atlantic subspecies and geographic regions for Pacific subspecies.
[d] Recent analysis of genetic, ecological and life history data from Canadian polar bears suggests that their stock structure may need to be revised [38].

Table M2. Key Arctic marine mammal species ecology		
Species	**Primary Diet** [39]	**Relationship with Sea Ice Habitat** [40]
Bowhead whale	Zooplankton (filter feeder)	Forage in productive marginal ice zone
Beluga whale	Diverse fishes and invertebrates	Refuge from predation? Access ice-associated prey
Narwhal	Ice-associated and benthic fishes (deep diver)	Forage in areas of very dense ice
Ringed seal	Diverse fishes and invertebrates	Resting and nursing platform Access ice-associated prey
Bearded seal	Benthic invertebrates	Resting and nursing platform Access to benthic foraging grounds
Walrus	Benthic invertebrates	Resting and nursing platform Access to benthic foraging grounds
Polar bear	Seals (primarily ringed) and other marine mammals	Hunting platform

Acknowledgments

The information summarized here was collected through the hard work of countless Arctic researchers whose contributions to this report far outweigh the author's own. Kit Kovacs, Randy Reeves, and their colleagues in the Pinniped and Cetacean Specialist Groups of the International Union for Conservation of Nature (IUCN) provided invaluable help by identifying key sources of information for Arctic marine mammal stocks. Joselyd Garcia compiled the information presented in Table M1, and Mina Innes produced Figure M1. This report was improved by comments on earlier versions by Mike Cameron, Mike Gill, Bob Gisiner, Kit Kovacs, Kristin Laidre, Sue Moore, Jim Overland, Tim Ragen, Jackie Richter-Menge, Randy Reeves, Dave Rugh, Michael Svoboda, and anonymous reviewers.

Murres

T. Gaston, G. Gilchrist

Environment Canada, National Wildlife Research Centre, Carleton University, Ottawa, Canada K1A 0H3

September 9 , 2009

Introduction

The two species of murres (N. America)/guillemots (Europe), *Uria lomvia* (Thick-billed Murre) and *U. aalge* (Common Murre), both have circumpolar distributions, the former breeding in Arctic and Subarctic regions, from northern Norway, Iceland, Newfoundland and the Aleutian Islands to the High Arctic, while the latter is predominantly a Subarctic and Boreal species breeding from California, the Gulf of St. Lawrence and northern Spain to the northern Bering Sea, Labrador and Bjornoya (Bear Island). In winter, *U. lomvia* occurs mostly in Arctic waters, while *U. aalge*, although overlapping extensively with *U. lomvia*, is found predominantly in subarctic and temperate waters (Figs 1 and 2). They are among the most abundant seabirds in the northern hemisphere, with both species exceeding 10 million adults (Gaston and Jones 1998).

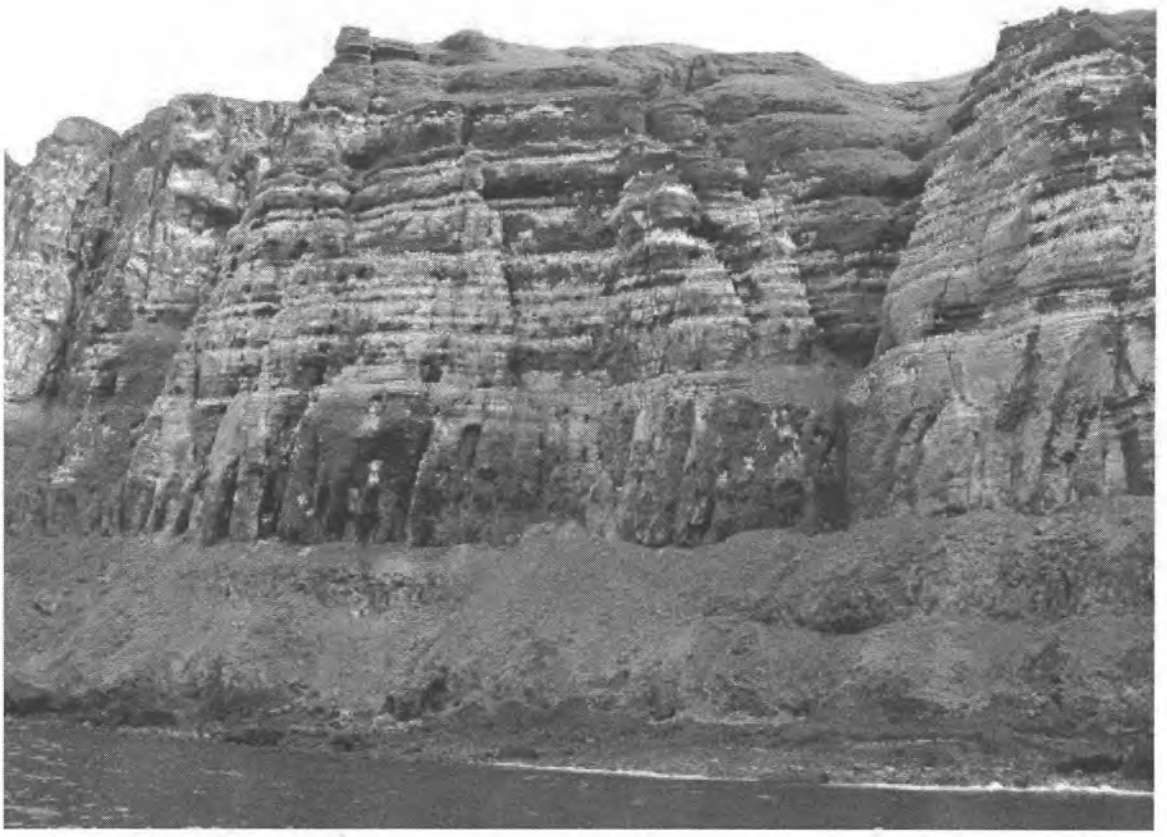

Figure 1. St. Lawrence Island, Bering Sea, Alaska (Lisa Sheffield).

Figure 2. Murres on St. Lawrence Island, Bering Sea, Alaska (Lisa Sheffield).

Murres feed from coastal to pelagic waters, taking a wide range of small fish (<50 g) and invertebrates, including annelids, pteropod and cephalopod molluscs, and mysid, euphausiid, amphipod and decapod crustacea. Common Murres generally feed more on fish than Thick-billed Murres (Gaston and Jones 1998, Anker-Nilssen et al. 2000). Adults of both species weigh about 1 kg, can remain under water for up to 4 min and dive regularly to depths >100 m, reaching a maximum depth of ~150 m. Their diving capacity, when combined to their typical foraging radius of up to100 km from the colony, means that murres sample a relatively large volume of the marine environment around their colonies (Falk et al. 2000, Elliott et al. 2008).

Murres have proven useful indicators of environmental change in studies of population trends (Gaston et al. 2009), nestling growth (Barrett 2002, Gaston et al. 2005) and nestling diet (Osterblom et al. 2001). They breed in very large colonies of up to 1 million birds on mainland cliffs or offshore islands. In most places, they lay their eggs in the open, making breeding adults simple to count. Consequently, their population trends are relatively easy to assess and this, allied to their abundance and widespread distribution, makes them ideal subjects for circumpolar environmental monitoring. In addition, being robust birds and returning annually to the same breeding sites, they are useful platforms on which to deploy depth and temperature recorders, GPS and geolocator tags. These devices have greatly amplified the value of the birds for environmental monitoring.

Status and Trends

The sensitivity of murre populations to changes in environmental conditions has been demonstrated on a hemispheric scale in recent studies by the Seabird Working Group of CAFF

(C-Bird). Irons et al. (2008) combined population trend data from around the Arctic with information on surface sea temperature (SST) and decadal-scale oscillations, to show that both species of murre showed negative population trends where there was a large change in SST, either warmer or cooler. Colony growth was most often positive where conditions remained relatively stable (Fig. 3). More specifically, the northern species, *U. lomvia*, exhibited highest population growth where conditions warmed moderately. *U. aalge* showed highest rates of increase where things cooled moderately. In the context of global warming, this result suggests that not only the direction but the magnitude of change may be important in determining outcomes and that Common and Thick-billed Murres may not necessarily react in the same way to a given temperature change.

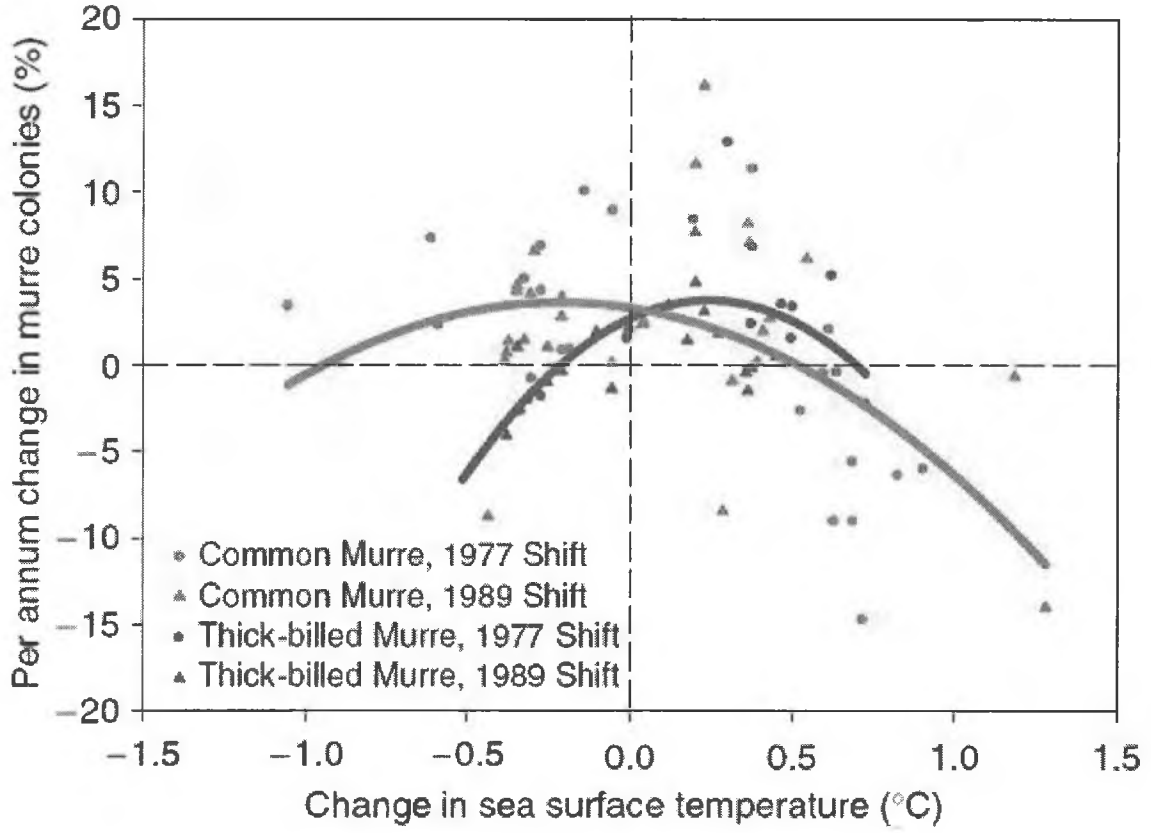

Figure 3. Relationship between per annum change in the size of murre colonies during the 12 years after the1977 climatic regime shift and during 9 years after the 1989 shift, and changes in sea surface temperatures around the colonies from one decadal regime to the next. Population data are from 32 Common and 21 Thick-billed Murre colonies, encompassing the entire circumpolar region. As 10 sites supported both species, 43 different study areas were represented. Quadratic functions were fitted to the data (Thick-billed Murres $P=0.002$, $df=27$, $r2=0.370$; Common Murres $P<0.001$, $df=48$, $r2=0.280$). Reprinted from Irons et al. 2008.

Both species have shown substantial variation in regional population trends since the 1970s. A comparison of the period from 1977–1989, when Sea Surface Temperatures (SST) in the North Pacific were generally above normal and those in the North East Atlantic generally below normal, with the period from 1989–1999 when the situation reversed, showed that populations in the North Pacific were generally decreasing during the earlier decade and increasing subsequently (Fig. 4, Irons et al. 2008). Conversely, those in the eastern Atlantic showed more variable trends. However, several European colonies were affected by widespread collapse of fish stocks in the 1980s (Vader et al. 1990). Those European colonies not affected by fish-stock collapses mostly increased up to 1989, but increases were less general between 1989–1999. Only a few colonies,

principally those in the eastern Canadian Arctic, have shown consistent increases in population and no colonies have shown persistent downward trends (C-bird unpubl. data). Subsequent to 1999, regional trends have been less clear. Populations of both species in the Barents Sea have begun to recover from earlier declines related to fish stock collapse (Barrett et al. 2006). Those in Alaska and in the Canadian Arctic have been stable overall since the 1990s (Dragoo et al. 2008, Gaston et al. in press).

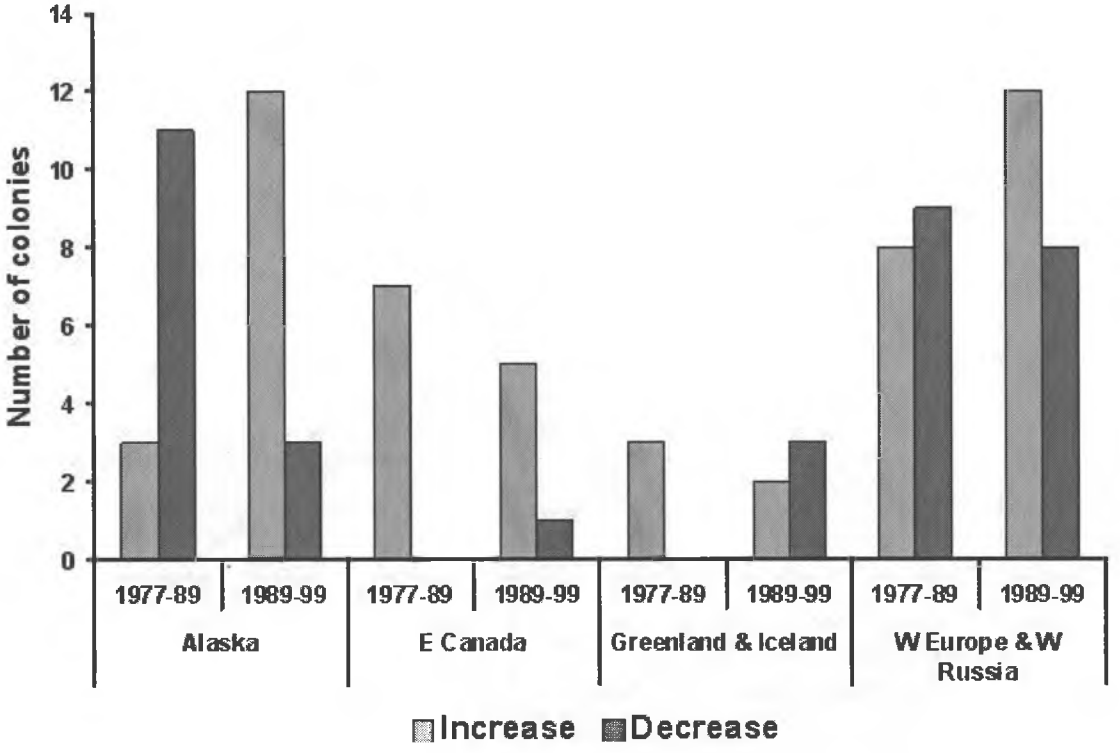

Figure 4. Number of Common and Thick-billed Murre colonies increasing or decreasing during 1977–1989 and 1989–1999.

Threats

Murres, both adults and eggs (especially lomvia), are harvested by aboriginal people and by local communities in many Arctic jurisdictions. These activities are not thought to have much impact on populations except in West Greenland, where some colonies have been substantially reduced by harvesting of adults while breeding (CAFF). Both species are highly susceptible to oiling and they are often the most numerous species killed by oil spills. They are frequently drowned in gill-nets, especially when these are set overnight (Melvin et al. 1999): hundreds of thousands were killed in salmon gill-nets off West Greenland in the 1960s (Tull et al. 1972). Although currently abundant, with few populations showing cause for alarm, climate change will pose a future problem and range contraction appears likely in the longer-term.

Knowledge Gaps

Despite substantial research and monitoring on the two species, information is generally inadequate to quantify changes in murre feeding ecology and food availability, or changes in mortality due to oil pollution, commercial fisheries, and hunting. In 1996, the Circumpolar Seabird Group reviewed conservation issues affecting murres, and produced an *International Murre*

Conservation Strategy and Action Plan to guide future international conservation efforts. The plan proposed action to assess the threats to murres from harvests, and commercial and industrial activities. The Plan also recommended further research to address the potential effects of global climate change on murre populations.

* **Note:** On "murres" vs "guillemots". We think the use of murres is preferable because guillemot does not exclude *Cepphus* spp. when used as a collective noun.

Fisheries in the Bering Sea

J. Overland

NOAA, Pacific Marine Environmental Laboratory, Seattle, WA

October 5, 2009

With warm sea temperatures during 2000 to 2005, the Bering Sea was showing indications that Arctic species that require the presence of sea ice were being replaced by sub-Arctic species that don't require sea ice. This is shown schematically in the Figure F1 as a shift of the biological energy pathway that favors bottom animals (Benthic) to one favoring species that live closer to the ocean surface (Pelagic).

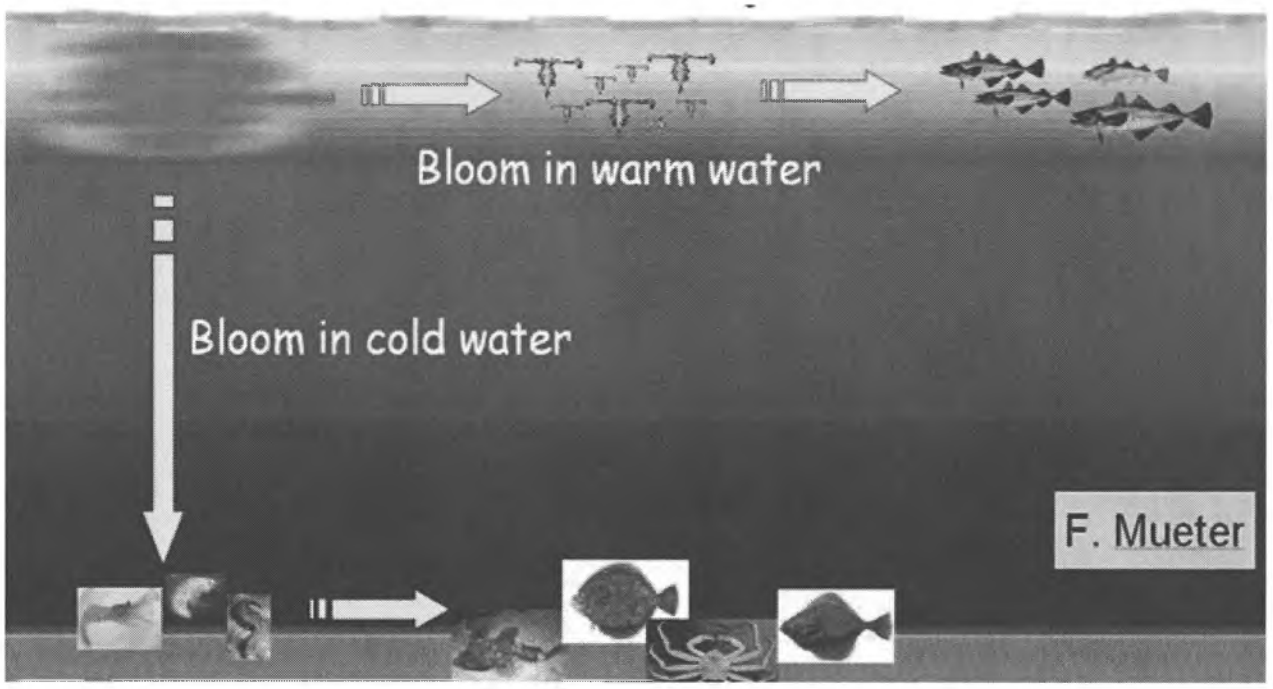

Figure F1. Bering Sea Ice shifting from Benthic to Pelagic Pathway.

However since 2005, the Bering Sea has been relatively cold with more sea ice in the winter and spring than normal. In 2008 and 2009, the winter sea ice extent in the Bering Sea was at a near record maximum, not seen since the early 1970s, and ocean temperatures were at a near record minimum (Figure F2). Under these conditions, cold water species, such as Arctic cod, have returned toward the south. At present Bering Sea climate change and ecosystem response are more effectively characterized by natural variability with multiple years of warm and cold temperatures, than by an emerging global warming trend or by an influence from the major summer sea ice losses in the Arctic Ocean proper.

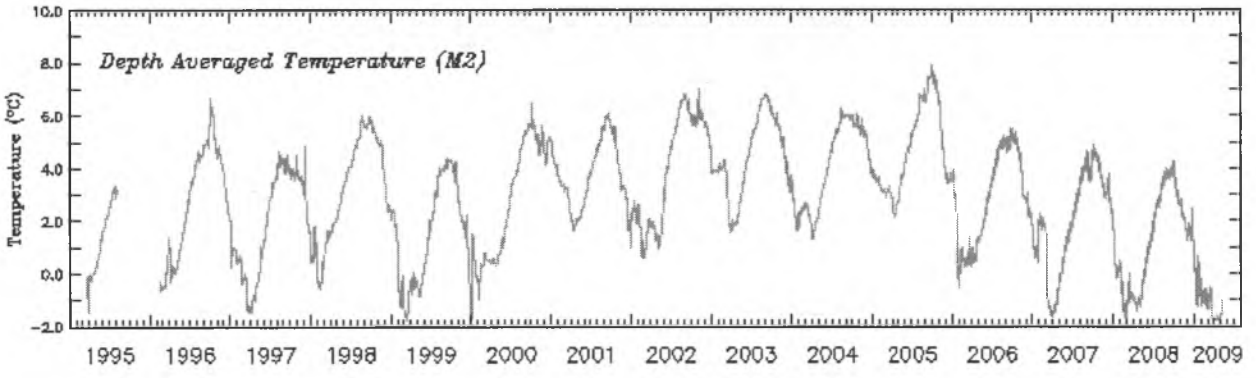

Figure F2. Southeast Bering Sea summer ocean bottom temperatures. From NOAA, P. Stabeno.

Pollock are a major economic resource from the Bering Sea. Warm temperatures and lack of sea ice have tended to favor pollock in the recent past, creating one of highest biomass for any large marine ecosystem throughout the world. The biomass for pollock in the Bering Sea and the number of new fish added each year (called recruitment) are shown in Figure F3. In recent years pollock recruitment has been low, with the decrease beginning before the return of the cold temperatures (Figure F2). The Bering Sea pollock population is now in collapse. It is suggested that during the end of the warm period (2003–2005), the normal food supply for pollock shifted to less favorable species and that pollock predators, such as arrowtooth flounder, became well established. With the recent shift to a cold period, the favorable food supply for pollock returned to the Bering Sea, but it was less available due to the presence of sea ice. Further, the continued presence of arrowtooth flounder as a predator on pollock remained a negative factor.

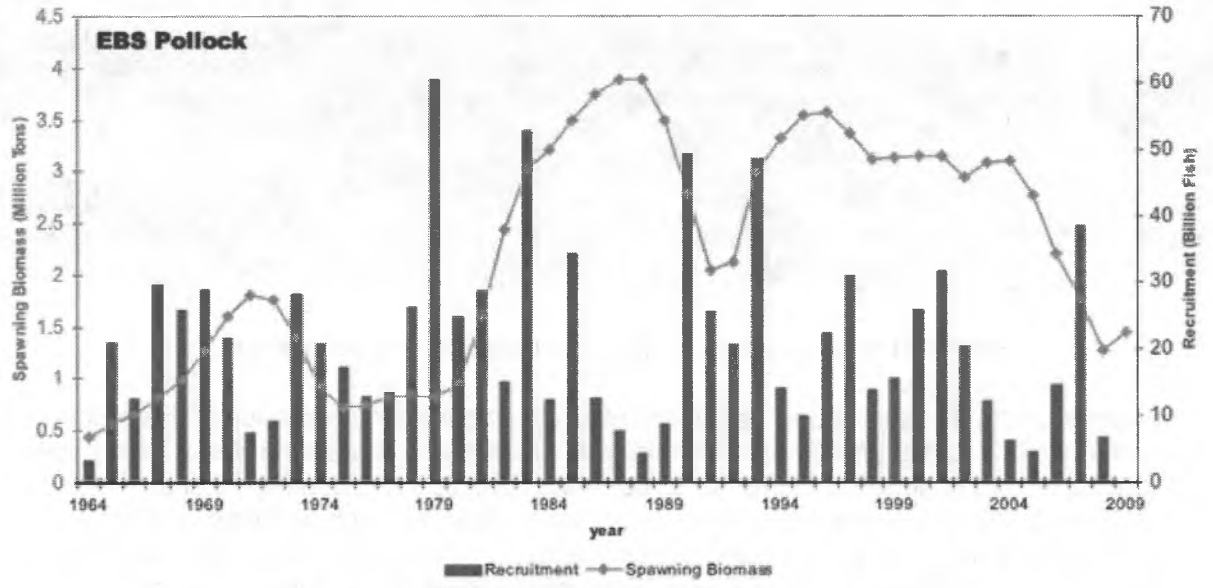

Figure F3. Bering Sea Pollock. Diamonds indicate biomass, and vertical bars indicate recruits to the population each year. From the NOAA/NMFS SAFE report.

Bering Sea temperatures respond both to global warming and large natural variability. While the Bering is cold at present we anticipate a swing back to average temperatures in the coming winter due to El Nino conditions. By 2020 or before, we anticipate a swing back to prolonged warm temperatures. This scenario would continue the negative impact on Arctic and bottom species, such as crab, while favoring sub-Arctic species such as salmon.

Status of the Barents Sea Ecosystem

Norwegian Institute of Marine Research
http://www.imr.no/filarkiv/havets_ressurser_og_miljo_2009/tilstand_okosyst_BH2sammendrag.pdf/en

September 23, 2009

Summary

The commercial fish stocks in the Barents Sea are, with a few exceptions, in a healthy condition. Positive trends are a growing capelin stock and an increasing spawning stock of Northeast Arctic cod. In a long-term perspective, the water masses are warm, although on average, not as warm as in 2006 (Figure B1). The stock level of blue whiting, a more southern species, has decreased in 2008.

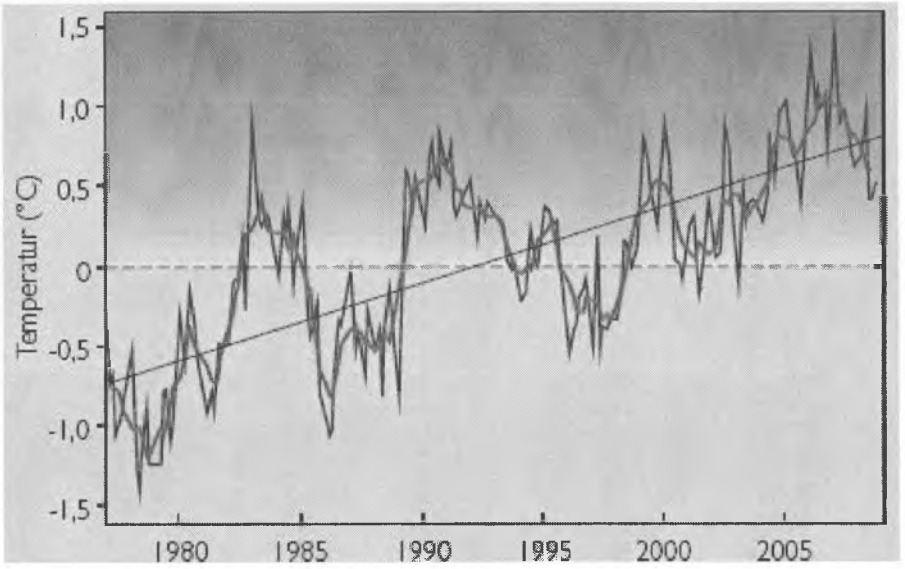

Figure B1. Temperature anomaly in the core of the Atlantic Water flowing into the Barents Sea between Norway and Bear Island (the Fugløya–Bear Island transect). The series are deviations from the long-term mean temperature between 50 and 200 m. Observed values (blue line) and 1 year moving average (red line) are shown. The straight line represents a linear trend over the period.

A clean ocean

Although wind and ocean currents transport various contaminants into the Barents Sea, the level observed in organisms is generally low. The main exception is top predators such as the polar bear, where persistent organic contaminants aggregate.

High temperatures

The water masses in the Barents Sea have been extraordinarily warm since 2000 (Figure B1). However, 2008 was slightly cooler than 2007. This is probably due to a strong reduction of the transport of Atlantic water into the Barents Sea. The amount of ice in the Barents Sea in 2008 was low (Figure B2).

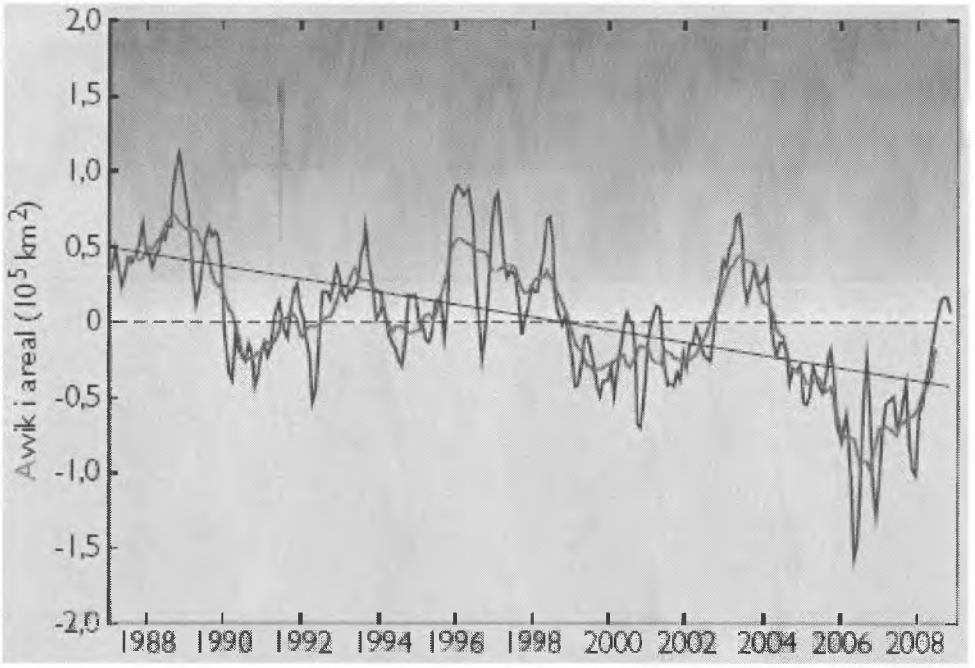

Figure B2. Ice area anomaly for the sector 25–45°E in the Barents Sea, which is the area with the highest variability in ice cover. Monthly mean (blue line) and 1 year moving average (red line) are shown relative to the mean ice area for the period 1987–2007. The straight line represents a linear trend over the period.

Decreasing levels of zooplankton

Compared with the two previous years, considerably less zooplankton was observed in the Barents Sea in 2008. This may be due to a lesser amount of Atlantic water being transported into area, but an increasing capelin stock grazing on zooplankton, mainly copepods and krill, may have contributed to the decrease.

Capelin up, blue whiting down

Based on the number of immature capelin, the stock prognoses indicate an increasing capelin stock the coming year. This is contrary to the prognoses for the other important plankton feeder in the Barents Sea, the young and immature stock (ages 1–4) of Norwegian spring-spawning herring. The year classes 2005–2008 of this stock are smaller than previous years. A decreasing amount of blue whiting is recorded. For polar cod the stock situation seems unchanged.

Healthy stock of Northeast Arctic haddock

The size of the spawning stock of Northeast Arctic cod is slowly increasing and is above the historical average. As in 2007, ICES emphasizes that it is of great importance for the development of this stock that the IUU (illegal, unregulated, unreported) fishery the Barents Sea is stopped. The exact stock size for the Northeast Arctic haddock is difficult to determine. However, the spawning stock is at a relatively high level and strong immature year classes, which will recruit to the spawning stock in the coming years, are observed. The third major demersal fish stock in the Barents Sea, the Greenland halibut, is slowly recovering from a period below historic levels.

The State of Char in the Arctic

C.D. Sawatzky and J.D. Reist

Freshwater Institute, Fisheries and Oceans Canada, Winnipeg, MB

October 15, 2009

Introduction

Arctic Char are the most northerly distributed freshwater fish species and occur in suitable habitats in all Arctic countries. They are widely distributed throughout the circumpolar north (Figure C1) from northernmost areas south to temperate regions (e.g., Switzerland, Italy) (Johnson 1980), with a latitudinal distribution of approximately 40°N to 84°N.

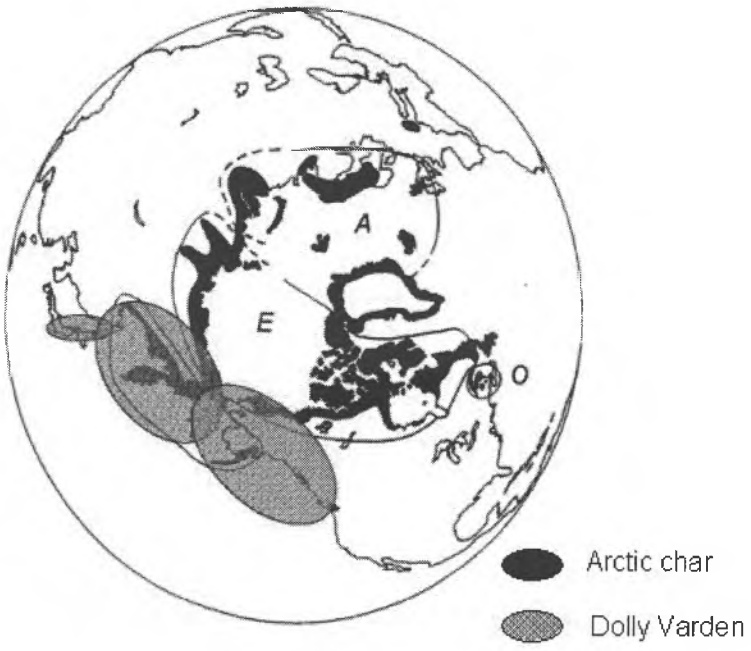

Figure C1. Global distribution of Arctic char and Dolly Varden.

The two most widely distributed groups are Arctic char (*Salvelinus alpinus*), a diverse primarily lake-adapted group (Figure C2), and Dolly Varden (*Salvelinus malma*), primarily a river-adapted group (Figure C3). Both occur as anadromous (sea-run) and freshwater resident forms. They are important components of northern aquatic ecosystems and are economically (subsistence food, commercial and sport fisheries) and culturally significant to northern communities (Conservation of Arctic Flora and Fauna 2001), particularly in Canada. For example, Arctic char made up approximately 45% by number of the top 15 species harvested in Nunavut between 1996 and 2001 (Priest and Usher 2004). The majority of the Canadian commercial Arctic char catch is taken in Nunavut fisheries at Rankin Inlet, Cambridge Bay, Pelly Bay and Nettilling Lake (DFO 2006).

Figure C3. Adult male anadromous Dolly Varden char in spawning condition captured in the Firth River, Yukon Territory, Canada. Photo by Jim Johnson.

Formal Status Assessments by Conservation Organizations

Several regional and/or national organizations conduct formal status assessments to conserve biodiversity; examples include the International Union for the Conservation of Nature (IUCN http://www.iucn.org/) based in Europe and Natureserve (http://www.natureserve.org/) based in North America. These are supplemented by formal assessment groups in many countries; e.g., in Canada the Committee on the Status of Endangered Wildlife in Canada (COSEWIC, http://www.cosewic.gc.ca/). All conduct assessments of various taxa (species or taxonomic units below species) according to established criteria and based upon the best available information. Summaries are shown in Figure C4 for IUCN assessments.

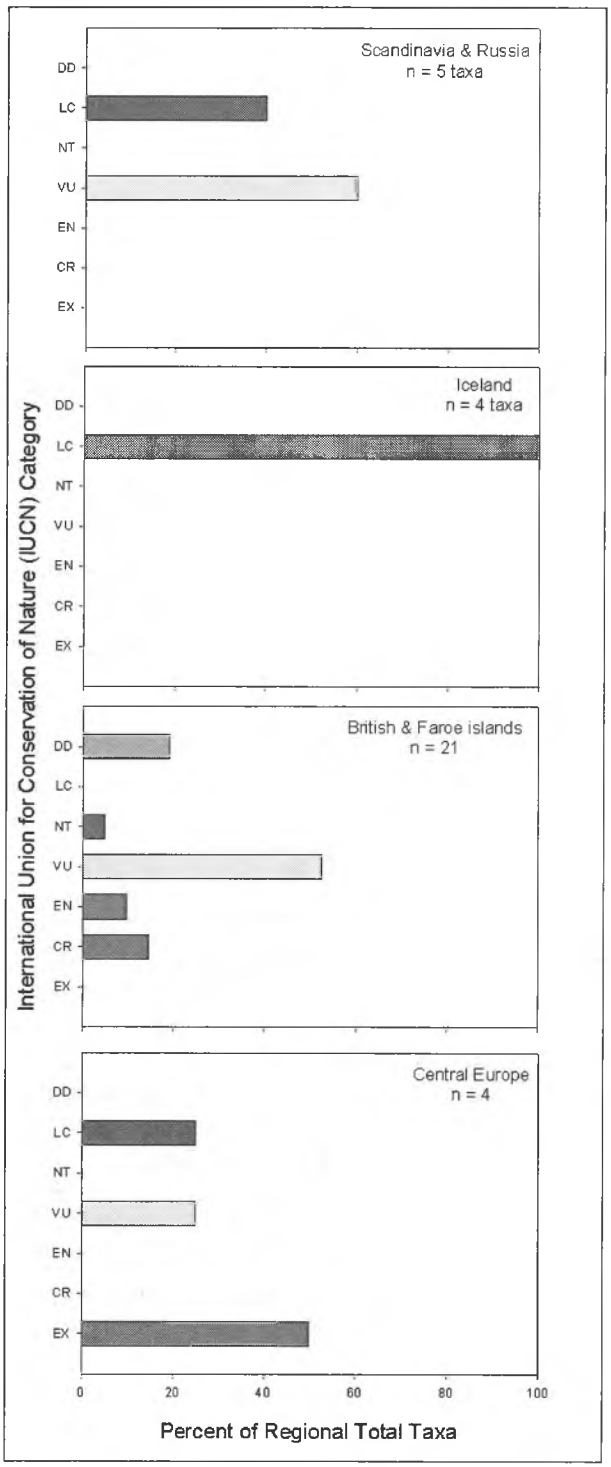

Figure C4. Percentages of European Char Taxa assessed at different levels of risk by IUCN criteria (http://www.iucn.org/; accessed 8 August 2009) for different regions. Note that there is much disagreement regarding the taxonomy used by IUCN, numbers of taxa are small, and assessments tend to be biased towards 'stressed' taxa. Colors indicate different groups of threat levels: gray – information lacking (DD = data deficient), green – assessed at minimal concern (LC = least concern, NT = near threatened), yellow – assessed at increased concern (VU = vulnerable), and, red – assessed at high concern (EN – endangered, CR – critically endangered, EX – extinct). Southern areas exhibit higher percentages of yellow and red threat groups.

Natureserve rankings are not plotted, and taxonomy is not comparable with that used by IUCN (i.e., North American species tend to represent multiple sub-specific taxa). For the five recognized species-level taxa in North America rankings are as follows:

- Southern (non-arctic) – three species are secure and one vulnerable (global rankings);
- Northern (Arctic) – one species is secure.

Natureserve rankings for sub-specific taxa (i.e., components of the above) provide additional understanding as follows:

- Within the continental USA, five of five distinct population groupings of bull char (*S. confluentus*, vulnerable as a species) rank as critically imperiled (n=1) or imperiled (n=4); assessment for 3–4 groups in Canada is underway;
- One southern taxon (*S. alpinus oquassa*) of the Arctic char complex is imperiled in southern Canada and northeastern United States (Natureserve = imperiled, COSEWIC = under assessment; northern Arctic char populations are secure);
- One southern taxon (*S. fontinalis timageamensis*) found in central Ontario of the brook char group is critically imperiled (Natureserve; COSEWIC = endangered);
- The southern taxon (*S. malma lordi*) of the Dolly Varden group is secure throughout its range (southern Alaska, British Columbia to Washington), and the northern taxon (*S. malma malma*) is secure throughout Alaska, however, it appears to be stressed in northwestern Arctic Canada (COSEWIC assessment underway; two of five anadromous populations stressed).

Conclusions

Virtually all stressors which are known to affect fish populations generally have been documented as affecting chars, a group which appears to be particularly susceptible to both local (e.g., exploitation) and pervasive (e.g., climate change) stressors as well as individual and cumulative effects of stressors. From the evidence presented above southern populations (or taxa) of chars, particularly the wider group related to Arctic char, appear to be at greater risk overall as evidenced by higher levels of conservation concern (i.e., more acute conservation status) and by greater percentage of extirpations particularly in Europe. Trends appear to be similar for North America. Two inescapable conclusions thus result: 1) southern populations of chars, particularly those isolated in lakes or requiring unperturbed river habitats, are at acute risk and given their probable evolutionary history represent an irreplaceable component of biodiversity of the Arctic char group; and, 2) southern populations are useful proxies of potential future effects and issues facing northern chars. Accordingly, appropriate care in addressing conservation, management, and stressors of both chars and their ecosystems is required particularly as wide-reaching changes occur throughout the north.

Goose Populations

M.J.J.E. Loonen[1], C. Zöckler[2], B. Ebbinge[3]

[1]University of Groningen, Arctic Centre
[2]UNEP-WCMC, Cambridge
[3]Alterra, Wageningen

March 20, 2008

Since the 1970's, many goose populations have gone through an impressive increase in size. In the last decade, the global goose population almost doubled from 12.5 million birds (Madsen et al. 1996) to a current total of 21.4 million (Wetlands International, 2006). Most of these population increases have coincided with large range extensions within the Arctic, but also into temperate regions. Changing agricultural practices have resulted in new, abundant and high quality food sources for wintering geese (Van Eerden et al. 1996, Fox et al. 2005). This has occurred while hunting pressure has decreased through improved legislative protection, a decline in the ratio of hunters per 1000 geese and the establishment of refuge areas.

Goose populations are intensively monitored. Population estimates are based on simultaneous counts in wintering areas, often supplemented with data on nesting densities, ring recoveries and sightings of colour-marked individuals. Wetlands International (www.wetlands.org) is the organisation which compiles all population data with help of its Goose Specialist Group (www.geese.nl/gsg).

Geese are common in many parts of the Arctic. All Arctic populations are migratory and their annual migration routes and stop over places involve a large proportion of the Northern Hemisphere, including almost all countries in North America, Europe and North, Central and East Asia. Goose populations have a direct and significant influence on Arctic ecosystems as exemplified by recent impacts on tundra vegetation due to expanding populations and via the role played by goslings and eggs as a food source for predators in the Arctic.

The most recent review of water bird populations (Wetlands International, 2006) considers several Arctic goose populations as declining. The declines are widely distributed across all flyways indicating a possible link to phenomena acting on a circumpolar scale. Figure E1 depicts the overall distribution of trends within Arctic goose populations. For nine percent of the population, there is no or insufficient information on trends. Thirty-six percent of the populations are still increasing, thirty-two percent are stable, but twenty-three percent are declining – a proportion slightly higher than compared with ten years ago (Madsen et al. 1996).

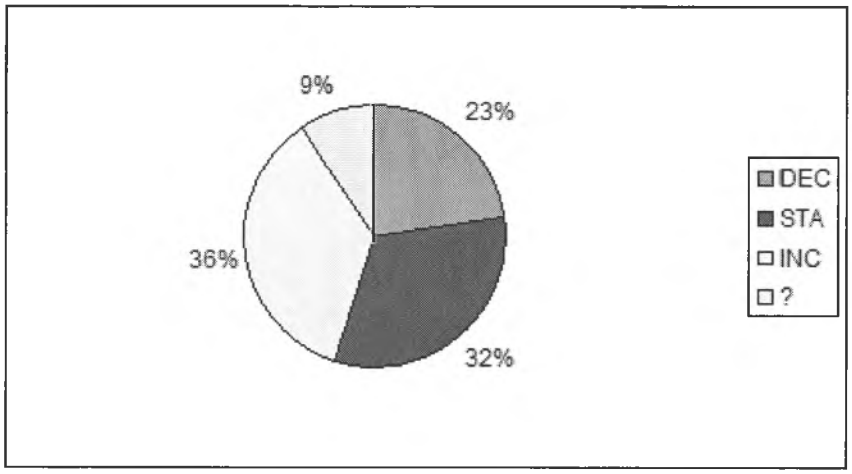

Figure E1. Trends in 47 Arctic Geese populations (Wetlands International, 2006). DEC - population decreasing; STA - population stable; INC - population increasing; ? - unknown

Arctic Impact Assessment

Arctic Climate Impact Assessment

Policy Document

Issued by the Fourth Arctic Council Ministerial Meeting
Reykjavík, 24 November 2004

The Arctic Council is a high-level, intergovernmental forum comprised of eight Member States (Canada, Denmark, Finland, Iceland, Norway, Russia, Sweden and the United States) and six Permanent Participants (Arctic Athabaskan Council, Aleut International Association, Gwich'in Council International, Inuit Circumpolar Conference, Russian Association of Indigenous Peoples of the North and the Saami Council) representing Arctic indigenous communities. The Arctic Council provides a mechanism to address the common concerns and challenges faced by the Arctic governments and people of the Arctic. In the last several years, the issue of climate impacts in the Arctic has been the subject of increased concern, as reflected in the Arctic Council's sponsorship, together with the International Arctic Science Committee, of the Arctic Climate Impact Assessment, the first comprehensive regional assessment of climate impacts [http://www.amap.no/acia/index.html]. Arctic Council Member States are committed to exercising leadership within the Arctic and globally to address the sources and multiple Arctic impacts and consequences of climate change and ultraviolet radiation, in accordance with the UNFCCC, as well as the Barrow and Inari Arctic Council Ministerial declarations.

Ministers of the Arctic Council meeting in Reykjavik, Iceland in November 2004 addressed the matter of Arctic climate change and variability as follows:

Welcome with appreciation the Arctic Climate Impact Assessment (ACIA) and the scientific work completed in evaluating and synthesizing knowledge on climate variability and change and increased ultraviolet radiation in the Arctic,

Note with concern the impacts documented by the ACIA that are already felt throughout the region. Climate change, and other stressors, presents a range of challenges for Arctic residents, including indigenous peoples,[1] as well as risks to Arctic species and ecosystems,

Recognize that the Arctic climate is a critical component of the global climate system with worldwide implications,

Note the findings of the ACIA with respect to climate change and **acknowledge** that such findings, as well as the underlying scientific assessment, will help inform governments as they implement and consider future policies on global climate change,

Endorse the ACIA policy recommendations for mitigation, adaptation, research, monitoring and outreach contained in the SAO Report to Ministers,

Acknowledge the need to consider the findings of the ACIA and other relevant studies in implementing their commitments under the UNFCCC and other agreements, including through adoption of climate change mitigation strategies across relevant sectors,

---

[1] The United States notes that the use of the term "peoples" in this policy document shall not be construed as having any implications as regard the rights which may attach to the term under international law.

Encourage Member States to take effective measures to adapt to and manage the environmental, economic and social impacts of climate change and ultraviolet radiation, *inter alia* through enhancing the access of Arctic residents to information, decision makers and institutional capacity building,

Encourage relevant national and international research bodies and sponsors to take into account the ACIA science recommendations in the planning, development and implementation of their programmes,

Decide to promote global, national and local awareness of the ACIA and any follow up activities through appropriate outreach activities,

Acknowledge the need to further organize the work of the Arctic Council and its subsidiary bodies based on the findings of the ACIA and direct the SAOs to report on the progress made at the 2006 Ministerial Meeting.

Senior Arctic Officials of the Arctic Council reported to Ministers on the work on the climate impacts carried out by the Arctic Council during Iceland's Chairmanship in response to the Minister's declarations at the October 2002 Ministerial Meeting in Inari, Finland. The text of their report is as follows:

BACKGROUND

The Barrow Ministerial Meeting of the Arctic Council in October 2000, endorsed, adopted, and established the Arctic Climate Impact Assessment (ACIA), requesting it to "evaluate and synthesize knowledge on climate variability and change and increased ultraviolet radiation, and support policy-making processes and the work of the Intergovernmental Panel on Climate Change (IPCC); further request that the assessment address environmental, human health, social, cultural and economic impacts and consequences, including policy recommendations."

Since then, a team of more than 300 leading Arctic researchers, indigenous representatives and other experts from fifteen nations has completed its work on the ACIA. They have distilled and synthesised available scientific information, traditional knowledge, and indigenous perceptions in order to examine how climate and ultraviolet radiation have changed in the Arctic, how they are projected to change in the future, and what the consequences of these changes will be for the Arctic and the world. The full assessment is published in a comprehensive science report and synthesised in an overview document "Impacts of a Warming Arctic", designed to be accessible to the lay person and the policy maker. The documents have been reviewed by more that 160 independent scientists and experts and made available to national reviews. Comments were taken into account by authors, who assume responsibility for the final document.

Ministers of the Arctic Council Meeting in Inari in October 2002 welcomed with appreciation the good progress of the ACIA and emphasized "the importance of continued dialogue on the consequences of climate change and on policy measures among national governments, indigenous and other local communities, regional administrations, the business community and scientific experts with the aim for a

transparent and open process, and of enhancing early capacity building to mitigate and adapt to the effects of climate change".

Since Inari, Senior Arctic Officials (SAOs) and representatives of the Permanent Participants have met with climate experts in Svalbard, Nuuk and The Hague to discuss the scientific findings of the ACIA and to further the dialogue among the Arctic states and others on climate change.

The Arctic Monitoring and Assessment Programme (AMAP), the Conservation of Arctic Flora and Fauna (CAFF) and the International Arctic Science Committee (IASC) participated in the ACIA Steering Committee. AMAP and CAFF were the conveners of a drafting group of representatives from Arctic Council Member States and Permanent Participants, that produced early drafts of recommendations to relate the findings from ACIA to the policy needs of the Arctic Council. SAOs then assumed responsibility for the drafting of these policy recommendations.

The ACIA is the world's most comprehensive and detailed regional climatic and ultraviolet radiation assessment to date and documents impacts that are already felt throughout the Arctic region. Climate change, together with other stressors such as ultraviolet radiation, presents a range of challenges for human health, culture and well-being of Arctic residents, including indigenous peoples and communities, as well as risks to Arctic species and ecosystems.

The authors of the overview document of the ACIA identified the following ten key findings:

1. The Arctic climate is now warming rapidly and much larger changes are projected.
2. Arctic warming and its consequences have worldwide implications.
3. Arctic vegetation zones are projected to shift, bringing wide-ranging impacts.
4. Animal species' diversity, ranges, and distribution will change.
5. Many coastal communities and facilities face increasing exposure to storms.
6. Reduced sea ice is very likely to increase marine transport and access to resources.
7. Thawing ground will disrupt transportation, buildings, and other infrastructure.
8. Indigenous communities are facing major economic and cultural impacts.
9. Elevated ultraviolet radiation levels will affect people, plants, and animals.
10. Multiple influences interact to cause impacts to people and ecosystems.

Such findings, as well as the underlying scientific assessment, will help inform governments as they implement and consider future policies on global climate change.

ARCTIC CLIMATE POLICY ACTIONS

In responding to climate change, Member States are taking two sets of actions: mitigation and adaptation. Both kinds of actions require extensive communication and education about climate change and its impacts. Further research, observations, monitoring and modelling is needed to refine and extend the ACIA findings.

Mitigation

To address the risks associated with climate change in the Arctic of the magnitude projected by the ACIA and other relevant studies, timely, measured and concerted action is needed to address global emissions. Even though overall emissions of greenhouse gases within the Arctic region are limited, there are important mitigation opportunities in the region that would contribute to sustainable development and global emission reduction efforts.

Mindful of their countries' share in total global greenhouse gas emissions, SAOs, taking into account specific national circumstances, recommend to Ministers that the Member States:

Consider the findings of the ACIA and other relevant studies in implementing their commitments under the UNFCCC and other agreements.

Adopt climate change mitigation strategies across relevant sectors. These strategies should address net greenhouse gas emissions and limit them in the long term to levels consistent with the ultimate objective of the UNFCCC, integrating mitigation and adaptation measures, building on partnerships, and, where synergies are possible, addressing other social, economic and environmental issues.

Promote the development and adoption of appropriate energy sources, uses, technologies and efficiencies. The International Partnership for Hydrogen Economy (IPHE) and The Carbon Sequestration Leadership Forum (CSLF), together with initiatives to promote renewable energy production and more efficient energy use, are examples of relevant initiatives.

Adopt policies and programmes that conserve and enhance carbon sinks and reservoirs in accordance with the principles of sustainable development.

Adaptation

While mitigation is necessary to address the risks associated with climate change, the scenarios used by the ACIA and elsewhere project that some climate change is inevitable, indicating that continued adaptation is needed.

Adaptation to climate change and its impacts in the Arctic must take into account the especially sensitive and vulnerable natural and human systems of the region. Special attention needs to be paid to strengthening the adaptive capacities of Arctic residents. Recognizing that not all impacts of climate change can be properly addressed through adaptation, the SAOs recommend to Ministers that the Member States:

Work closely with Arctic residents, including indigenous and local communities, to help them to adapt to and manage the environmental, economic and social

impacts of climate change and ultraviolet radiation change. Adaptation needs will vary. Arctic residents may need *inter alia* enhanced access to information, decision makers, and institutional capacity building to safeguard their health, culture and well-being.

Recognize that opportunities related to climate change, such as increased navigability of sea routes and access to resources, should be developed and managed in a sustainable manner, including through the consideration of environmental and social impacts and taking appropriate measures to protect the environment, local residents and communities.

Implement, as appropriate, adaptive management strategies for Arctic ecosystems, making use of local and indigenous knowledge and participation, review nature conservation and land and resource use policies and programmes, and to the extent possible reduce risks related to infrastructure damage, permafrost degradation, floods and coastal erosion, taking into account costs and benefits.

Research, Observations, Monitoring and Modelling

The authors of the ACIA have made recommendations for additional research, observations, monitoring and modelling. It is of particular importance to focus on those research needs that play a significant role in developing and applying mitigation and adaptation measures.

Therefore, the SAOs recommend to Ministers that the Member States:

Stress the importance of intensifying natural and social science research on impacts and adaptation, including studies to enhance understanding of fundamental processes and sustainability, procedures for integrating indigenous and local knowledge into scientific studies, and partnerships between indigenous peoples, local communities, and scientists in defining and conducting research and monitoring associated with Arctic climate and ultraviolet radiation changes.

Encourage relevant national and international research bodies and sponsors to take into account the ACIA science recommendations in the planning, development and implementation of their programmes.

Seek to expand and link circumpolar research and monitoring networks, including community-based networks, applying standardized methodologies focusing on year round observations of climate and ultraviolet radiation and their impacts on species and ecosystems, residents and communities, stressing seasonal variations. Given its international character and potential global significance, the Arctic ocean, its ice and atmosphere, are of special importance.

Seek to ensure that relevant data from research, observation, monitoring and modelling activities are made available to local, national and international research and monitoring programmes.

Recognize the need to consider how to conduct further studies of climate change within the Arctic region, especially through added focus on regional and climate variability, socio-economic impacts, vulnerabilities of Arctic human-environment systems, climate modelling, and use of historical and long-term data on climate variability.

Outreach

In order to ensure global, national and local awareness of the ACIA and any follow up activities, the SAOs recommend to Ministers that the Member States:

Disseminate the ACIA documents within international fora in order to advance co-operation to address the environmental, social, economic and cultural implications of climate change in the Arctic.

Promote the ACIA at the national and local level and explore the use of a variety of methods, languages and partners to engage Arctic residents.

Seek to provide Arctic residents and communities with information and knowledge on climate research and monitoring that they require to adapt to Arctic climate change, including taking advantage of new opportunities.

Encourage the incorporation of materials from the ACIA into educational, research and training programmes.

THE ROLE OF THE ARCTIC COUNCIL

Based on the findings of the ACIA, there is a need for the Arctic Council and its subsidiary bodies to further organize their work. Therefore, SAOs recommend to Ministers to:

- *Direct* relevant technical working groups of the Arctic Council to review the scientific chapters of the ACIA in the context of their ongoing and future work programmes and to report on the progress made at the 2006 Ministerial Meeting.

  Decide to keep under review the need for an updated assessment of climate change in the Arctic, drawing *inter alia* on the IPCC fourth assessment report and the results of the International Polar Year 2007-2009.

  Direct SAOs to nominate a focal point, to be responsible for an ACIA follow up, including an assessment of gaps in knowledge.

Communicate as appropriate, any Arctic Council ACIA follow-up actions to the Conference of the Parties to the UNFCCC.

MEMORANDUM FOR DISTRIBUTION

Subj: NAVY ARCTIC ROADMAP

Encl: (1) Navy Arctic Roadmap

1. Scientific evidence indicates that the Earth's climate is changing, and the most rapid changes are occurring in the Arctic. Because the Arctic is primarily a maritime environment, the Navy must consider the changing Arctic in developing future policy, strategy, force structure, and investment.

2. During the Chief of Naval Operations (CNO) Executive Board on 15 May 2009, CNO directed the establishment of Task Force Climate Change (TFCC) and the development of an Arctic roadmap for the Navy. Enclosure (1) provides a holistic, chronological list of Navy action items, strategic objectives, and desired effects regarding the Arctic for Fiscal Years (FY) 2010-2014.

3. The Navy Arctic Roadmap will remain in effect until promulgation of the next Quadrennial Defense Review (QDR) report in FY-14, when the roadmap will be reviewed and revised to incorporate QDR guidance.

5. Roadmap Execution	26
Appendix A. Navy Arctic Roadmap	28
Appendix B. References	32

Executive Summary

The Navy Arctic Roadmap provides a chronological list of Navy action items, objectives, and desired effects for the Arctic region from FY10-14. Focus areas include:

- Strategy, policy, missions, and plans
- Operations and training
- Investments in weapons, platforms, sensors, command, control, communications, computers, intelligence, surveillance, and reconnaissance (C4ISR), installations, and facilities
- Strategic communications and outreach
- Environmental assessment and prediction

Navy action items and objectives within this roadmap are intended to achieve the following desired effects:

- Developing strong cooperative partnerships with interagency and international Arctic stakeholders
- Actively and competently contributing to safety, security, and stability in the Arctic
- Acquiring the right capability at the right cost and right time to meet combatant commander requirements for the region
- The media, public, Department of Defense, and the interagency, and international communities recognizing the US Navy as a positive and active contributor to a safe, secure, and stable Arctic region
- Understanding when significant access for Arctic shipping and other maritime activity is likely to develop

This roadmap specifies Navy actions over three phases – FY10 (phase 1), FY11-12 (phase 2), and FY13-14 (phase 3). Significant action items in phase 1 include:

- Assessments of Fleet readiness and mission requirements in the Arctic region
- Development of Navy Strategic Objectives in the Arctic region
- Continued partnership-building with stakeholders in the region and conduct of a limited objective experiment (LOE) for the Arctic
- Continued monitoring of USAF's Polar Military Satellite Communications (MILSATCOM) program
- Advocacy for accession to the United Nations Convention on the Law of the Sea
- Developing a Navy position regarding combatant commander authorities and responsibilities for the Arctic
- Research and development of a next generation environmental prediction capability applicable to the Arctic

Phase 2 (FY11-12) significant actions include:

- Initiation of Capabilities Based Assessments regarding required Navy Arctic capabilities
- Development of recommendations to address Arctic requirements in Sponsor Program Proposals for the Navy's Program Objective Memorandum for FY14 (POM-14)
- Continuing biennial participation in Arctic exercises including ICEX-11, ICEX-13,

Arctic Edge and Arctic Care

- Formalizing new cooperative relationships that increase Navy experience and competency in search and rescue (SAR), maritime domain awareness (MDA), humanitarian assistance and disaster response (HA/DR) in the Arctic, and defense support of civil authorities (DSCA) in Alaska

Phase 3 (FY13-14) significant actions consist of:

- Execution of the Navy POM-14 budget initiatives that address Arctic requirements, and
- Initiation of combined and bilateral activities which support safety, security, and stability in the region

Director of Task Force Climate Change (TFCC) will provide the Chief of Naval Operations (CNO) quarterly reports on the progress of action items in this roadmap using both activity-based and effects-based metrics. TFCC will review and revise this roadmap every four years following promulgation of the Quadrennial Defense Review (QDR) and will incorporate QDR guidance as appropriate.

1. Introduction

The Chief of Naval Operations (CNO) examined Navy issues and concerns due to global climate change during a CNO Executive Board (CEB) on May 15, 2009. That CEB resulted in decisions to establish Task Force Climate Change (TFCC) and develop Navy Roadmaps first for the Arctic, and then later for global climate change responses more generally.

TFCC is a matrixed organization that runs across multiple Navy staff codes and warfare enterprises. Consisting of a Flag-level Executive Steering Committee, led by the Oceanographer of the Navy, and several senior level working groups, TFCC is tasked to make recommendations to Navy leadership regarding policy, strategy, force structure, and investments relating to the changing Arctic specifically and global climate change in general. TFCC invites advisory participants from interested Joint and interagency stakeholders including U.S. Northern Command (NORTHCOM); Commander, Pacific Fleet (COMPACFLT); U.S. European Command (EUCOM); the Office of Naval Research (ONR); the National Maritime Intelligence Center (NMIC); U.S. Coast Guard Headquarters; the National Oceanic and Atmospheric Administration (NOAA); the Office of the Secretary of Defense (OSD); the office of the Chairman of the Joint Chiefs of Staff (CJCS); and the Center for Naval Analyses (CNA).

TFCC's initial deliverable is this Navy Arctic Roadmap. TFCC's Navy Climate Change Coordination Office (NCCCO), under the Office of the Oceanographer of the Navy, will coordinate execution of the roadmap by TFCC.

2. Strategic Considerations

This roadmap considers a number of strategic drivers including national policy guidance, the changing Arctic environment, the potential increase in natural resource extraction and inter- and intra-Arctic shipping, the activity and interests of other Arctic nations, past and present Navy experience in the Arctic, and current Fleet capabilities and limitations for Arctic operations.

The primary policy guidance statements influencing this roadmap are the National Arctic Policy as defined in National Security Presidential Directive 66 / Homeland Security Presidential Directive 25 (NSPD 66/HSPD 25) and the Cooperative Strategy for 21st Century Seapower (CS21). The National Arctic Policy directs the Departments of State, Homeland Security, and Defense to develop greater capabilities and capacity, as necessary, to protect U.S. borders; increase Arctic maritime domain awareness (MDA); preserve global mobility; project a sovereign United States maritime presence; encourage peaceful resolution of disputes; cooperate with other Arctic nations to address likely issues from increased shipping; establish a risk-based capability to address hazards in the region including cooperative search and rescue (SAR), basing and logistical support; and evaluate the feasibility for using the Arctic for strategic sealift.

CS21 is the Navy, Coast Guard, and Marine Corps Maritime Strategy and applies equally to the Arctic as well as other maritime regions. The expanded core capabilities of

CS21 applicable to the Arctic include: forward presence, deterrence, maritime security, and humanitarian assistance/disaster relief (HA/DR) through the formation and sustainment of cooperative relationships with international partners. As in every other region, the naval services must be prepared to prevent or limit regional conflict when required.

The changing Arctic environment is a significant consideration of the roadmap. The Arctic is warming twice as fast as the rest of the globe. While significant uncertainty exists in projections for Arctic ice extent, the current scientific consensus indicates the Arctic may experience nearly ice free summers sometime in the 2030's. As mentioned in CS21, this opening of the Arctic may lead to increased resource development, research, tourism, and could reshape the global transportation system. These developments offer opportunities for growth, but also are potential sources of competition and conflict for access and natural resources. Reducing the uncertainty in these projections will enable the Navy to make better-informed investment and policy decisions. This is a key objective of this roadmap.

While the United States has stable relationships with other Arctic nations, the changing environment and competition for resources may contribute to increasing tension, or, conversely, provide opportunities for cooperative solutions. The importance of the Arctic region is identified in the strategic guidance of all Arctic nations; therefore, this roadmap considers the requirement for the governance framework provided by the United Nations Convention on the Law of the Sea (UNCLOS).

The Navy's Arctic experience and current operational capabilities and limitations provide the point of departure for this roadmap. Maintaining a presence in the region for decades, Navy experience spans Admiral Byrd's historic overflight of the North Pole in 1926, various campaigns in World War II, consistent activity during the Cold War, and Joint and combined exercises with surface, subsurface, aviation, and expeditionary forces today. This roadmap acknowledges that while the Arctic is not unfamiliar for the Navy, expanded capabilities and capacity may be required for the Navy to increase its engagement in this region.

3. Roadmap Overview

The action items, objectives, and desired effects in this five-year roadmap are organized into the following focus areas:

- Strategy, Policy, Missions, and Plans: Identify Navy's strategic objectives in the Arctic region and provide guidance to achieve these objectives
- Operations and Training: Identify required Navy activities to achieve Navy's strategic objectives in the Arctic region
- Investments (weapons, platforms, and sensors, command, control, communications, computers, intelligence, surveillance, and reconnaissance (C4ISR), installations, and facilities): Guide capability development
- Strategic Communications and Outreach: Guide public discussion

- Environmental Assessment and Prediction: Understand the current environmental changes and identify with high confidence a timeline for increased access in the region

For each focus area, action items are assigned to responsible Navy offices with suspense dates for completion. Supporting organizations are identified but are not limited to those listed.

4. Navy Arctic Roadmap

4.1 Strategy, Policy, Missions, and Plans

Desired Effect: The Navy is engaged in strong cooperative partnerships that preserve a safe, stable and secure Arctic region.

Roadmap Objective 1.1: To identify Navy's strategic objectives in the Arctic region and provide recommendations to operational staffs to achieve these objectives.

Action Item 1.1 Determine *Navy Strategic Objectives and Restrictions in the Arctic Region.*

Description: TFCC, with applicable Navy Component Commands (NCCs) and Combatant Commands (COCOMs), will analyze National, Joint, and Service strategies and policies, determine the desired end-state and strategic objectives for Navy, and translate these into measurable effects. TFCC will also identify undesired side-effects and unintended consequences in the Arctic region, expressing these results-without-side-effects as Navy goals for the Arctic region. These goals shall be reviewed and updated with this roadmap following each Quadrennial Defense Review (QDR). Applicable references will include but not be limited to:

- The U.S. Arctic Region Policy (NSPD-66/HSPD-25)
- National Strategy for Maritime Security (NSMS)
- National Defense Strategy (NDS)
- QDR Report
- Guidance for Development of the Force (GDF)
- Guidance for Employment of Forces (GEF)
- Navy Operating Concept (NOC)
- *A Cooperative Strategy for 21st Century Seapower*

Navy Arctic strategic objectives will be submitted for inclusion in subsequent versions of these documents, as applicable. TFCC will coordinate directly with USCG, and with the interagency community through the Maritime Security Interagency Policy Committee, to ensure Navy's strategic objectives are consistent with the U.S. Government's desired outcome in the Arctic region.

Lead: OPNAV N51
Support: OPNAV N31, N52, USFF, PACOM/CPF, NORTHCOM, EUCOM
Suspense: Q2, FY10

Action Item 1.2 Describe the strategic environment.

Description: TFCC will characterize the current and probable strategic environment in the Arctic region based on its predicted physical and political environment, and key stakeholders' interests in the region. This assessment will be reviewed and updated with this roadmap following each Quadrennial Defense Review (QDR). Additional elements of this assessment will include, but not be limited to:

- Current and predicted threats in order to determine the most dangerous and most likely threats in the Arctic region in 2010, 2015, and 2025.
- Focus on threats to U.S. national security, although threats to maritime safety and security may also be considered.
- Identify the relevant actors concurrent to the forecast timeframe.
- Determine incentives and motivations for each actor

Lead: OPNAV N2/N6C2
Support: ONI, NMIC, USFF, PACOM/CPF, NORTHCOM, EUCOM
Suspense: Q2, FY10

Action Item 1.3 Conduct *mission analyses*.

Description: Based on the Navy goals for the Arctic region and the results of the threat assessment, TFCC, with applicable Navy Component Commands (NCCs) and Combatant Commands (COCOMs), will conduct a thorough mission analysis in order to determine best courses of action to achieve Navy's strategic objectives in the Arctic region. Continuing to utilize the fundamentals of game theory, this analysis will consider the interdependencies between actors and actions in the Arctic and how incentives and decisions are influenced by other actors' decisions. This mission analysis shall be reviewed and updated with this roadmap following each Quadrennial Defense Review (QDR). Specific attention will be given to the following missions highlighted in the National Arctic Policy and CS21:

- Maritime Security
- Search and Rescue
- Humanitarian Assistance/Disaster Response (HA/DR)
- Defense Support of Civil Authorities (DSCA)
- Maritime Domain Awareness
- Strategic Sealift by the Naval Fleet Auxiliary Force (NFAF)
- Strategic Deterrence
- Ballistic Missile Defense

Lead: OPNAV N00X
Support: OPNAV N51, N31, USFF, PACOM/CPF, EUCOM, NORTHCOM, Naval War College (NWC)
Suspense: Q2, FY10

Action Item 1.4 Develop a five-year *Strategic Implementation Plan* (SIP) to achieve Navy's Strategies and Policies in the Arctic region for FY11-15.

Description: The *Navy Arctic Strategic Implementation Plan (NASIP)* will translate strategy and policy into action. This plan will be updated with this Arctic Roadmap every four years following the QDR, and include but not be limited to the following:

- Look forward and reason backwards, using the strategic environment description and mission analysis in *Action Items 1.2 & 2.3*.
- Anticipate other actors' actions or reactions and determine the implications for potential courses of action.
- Incorporate input from applicable Navy Component Commands (NCCs) and Combatant Commands (COCOMs) and translate Navy Whole Goals in the Arctic Region into a results-based list of specified actions
- Based on scientific facts, make actionable recommendations to operational staffs to achieve the desired strategic objectives.
- Inform and direct capability analysis and decisions.
- Inform future strategy and policy development including, but not limited to, updates to the U.S. Arctic Region Policy (NSPD-66/HSPD-25), National Strategy for Maritime Security (NSMS), National Defense Strategy (NDS), QDR, Guidance for the Employment of Forces (GEF), Navy Operating Concept (NOC), and *A Cooperative Strategy for 21st Century Seapower.*
- Include coordinating and collaborative efforts with USCG, and with the interagency community through the Maritime Security Interagency Policy Committee, to ensure consistency with the U.S. Government's desired outcome in the Arctic region and the actions of other Departments and Agencies.
- Incorporate NCC and COCOM input to ensure alignment among Navy stakeholders in the region.

Lead: OPNAV N51
Support: TFCC NCCCO, USFF, USCG, NOAA, ONR, OPNAV OJAG Code 10
Suspense: Q4, FY10

Action Item 1.5 Propose additional studies and research regarding Arctic security.

Description: TFCC will identify potential topics and areas for further research or study and recommend these to appropriate organizations, including but not limited to:

- Interagency Arctic Research Policy Committee
- Commission on Ocean Policy
- Office of Naval Research (ONR)
- National Science Foundation (NSF)
- Naval Post Graduate School (NPS)
- Naval War College (NWC)
- National Defense University's Institute of National Strategic Studies
- National Intelligence Council (NIC)
- Center for Naval Analyses (CNA)
- Center for New American Security (CNAS)
- Naval Studies Board (NSB)
- National Ice Center
- National Academy of Science (NAS)
- Naval Facilities Engineering Service Center (NAVFAC ESC)
- Commander Naval Installations Command (CNIC)

Lead: OPNAV N51
Support: OPNAV N2/N6, N31, N81, OJAG Code 10
Suspense: Q4, FY10

Action Item 1.6 Beginning for FY14, and biennially each POM year thereafter, consider required Navy Arctic capabilities in developing the Navy Strategic Plan.

Description: Navy Arctic requirements will be considered during the development of the Navy Strategic Plan using the following :

- Navy Strategic Objectives for the Arctic (*Action Item 1.1*)
- Arctic mission analysis and strategic environment descriptions (*Action Items 1.2 & 1.3*)
- Arctic-related CBA's (*Action Items 3.2 & 5.2*)
- Arctic Environmental Assessment & Outlook Reports (*Action Item 5.8*)

Lead: OPNAV N3/5
Support: OPNAV N31, N51, N2/6, TFCC NCCCO
Suspense: Q4, FY11

Roadmap Objective 1.2: Promote a safe, stable, and secure Arctic region by strengthening existing and fostering new cooperative relationships.

Action Item 1.7 Develop a Navy position on COCOM responsibilities in the Arctic for the Unified Command Plan (UCP).

Description: Currently, COCOM responsibility for the Arctic region is divided between U.S. EUCOM, U.S. NORTHCOM, and U.S. PACOM. TFCC will develop a recommended Navy position on COCOM responsibilities in the Arctic

based on the desired end-state(s) and recommended courses of action to achieve them. TFCC will review these responsibilities as necessary.

Action: OPNAV N51
Support: OPNAV N31, N2/N6, USFF, PACOM/CPF, EUCOM
Suspense: Q3, FY10

Action Item 1.8 Expand cooperative partnerships with Joint, interagency, and international Arctic Stakeholders.

Description: Navy partnerships in the Arctic region will provide capability and contribute to achieving the Navy's objectives and desired effects in the region. The process to develop and strengthen these partnerships will include:

- Evaluate existing agreements with the USCG, U.S. Air Force, U.S. Army, foreign militaries, and foreign government agencies/organizations (e.g. Canadian Coast Guard) that operate in the Arctic.
- Initiate discussions with the USCG, U.S. Air Force, U.S. Army, and foreign militaries to expand existing, or form new agreements concerning interoperability and collaborative efforts in the Arctic. Topic areas will include operations, training, and common investments to achieve economies of scale. Every attempt will be made to leverage existing venues (e.g. USN-USCG Staff Talks).
- Formalize new or revised agreements with the USCG, U.S. Air Force, U.S. Army, and foreign militaries concerning interoperability and collaborative efforts in the Arctic.

Lead: OPNAV N3/5
Support: OPNAV N51, OJAG Code 10, USFF, EUCOM, PACOM/CPF, NORTHCOM
Suspense: Q2, FY10 – Evaluate existing agreements
Q4, FY10 – Initiate discussions
Q1, FY12 – Formalize new or revised agreements
Q1, FY12 – Implement new agreements

Action Item 1.9 As applicable, provide support for U.S. accession to the United Nations Convention on the Law of the Sea (UNCLOS).

Description: TFCC will provide support for U.S. accession to UNCLOS as applicable to Navy's interests in the Arctic. Key aspects of this support will include, but not be limited to:

- Expression of Navy interest in the areas for which UNCLOS provides effective governance: freedom of navigation, treaty vs. customary law, environmental laws, and extended continental shelf claims.
- Development of talking points, information papers, or briefings for senior Navy leadership and Congressional staffs as requested.

- Expression of the related message that the Navy is committed to being responsible stewards of the environment. While being committed to conducting military readiness activities in an environmentally sound manner, the Navy is opposed to any framework which unreasonably restricts or prevents our ability to train and operate effectively.

Lead: OPNAV OJAG Code 10
Support: OPNAV N31, N51, N52, N2/N6,
Suspense: Ongoing/As requested

4.2 Operations and Training

Desired Effect: The Navy is a capable and active contributor to a safe, stable, and secure Arctic region.

Roadmap Objective 2: Develop competency in accomplishing Arctic missions assigned by combatant commanders.

Action Item 2.1 Conduct a *Fleet Readiness Assessment* for operating in the Arctic.

Description: A *Fleet Readiness Assessment* will identify current capabilities and limitations for operating in the Arctic environment. Suitability of current doctrine, such as ATP-17 (Navy Arctic Manual) will be evaluated, and consideration will be given to anticipated requirements based on mission and strategic environment assessments performed in *Action Items 1.2 & 1.3* of this roadmap. Specific attention will be given to the following:

- Strategic Sealift
- Maritime Security
- Search and Rescue
- Humanitarian Assistance/Disaster Response (HA/DR)
- Defense Support of Civil Authorities (DSCA)
- Maritime Domain Awareness (MDA)
- Strategic Sealift by the Naval Fleet Auxiliary Force (NFAF)
- Strategic Deterrence
- Ballistic Missile Defense
- C4ISR
- Integration with USCG capabilities

Lead: USFF
Support: TFCC NCCCO, OPNAV N31, N51, N2/N6, ONI, NMIC, USCG
Suspense: Q3, FY10

Action Item 2.2 Continue participation in periodic Arctic exercises and operations, and evaluate feasibility and requirement to expand these activities.

Description: The Navy has frequently participated in exercises, training events, and operations in the Arctic region including the state of Alaska. Continuing this participation will support the strategic objectives of this roadmap to develop Navy competency in the region and substantially contribute to a safe, secure, and stable region. By coordinating with the Arctic combatant commanders and the USCG, the Navy will consider engagement in the following periodic events and operations:

- ICEX-11, ICEX-13
- Arctic Edge (Formerly Northern Edge)
- Northern Eagle
- Innovative Readiness Training (IRT) initiatives under Alaska Command
- HA/DR
- DSCA (e.g. support to Exxon Valdez oil spill)
- Limited Objective Experiment (LOE) 7 (NORTHCOM lead)
- Arctic Care
- Arctic Crossroads

Lead: USFF
Support: PACOM/CPF, EUCOM, ONR, COMSUBFOR, ASL, COMSECONDFLT, COMTHIRDFLT, CNMOC, USCG
Suspense: FY10-14 (Ongoing)

Action Item 2.3 Increase the number of observers sent to, and hosted from the Arctic nation navies, and document knowledge gained from these exchanges into Navy Lessons Learned.

Description: COMSECONDFLT recently gained valuable lessons learned by observing the Canadian Navy's Operation NANOOK 2009. Increasing this practice and reciprocal opportunities for our foreign counterparts will yield more knowledge and understanding that will ensure safe and effective engagement in the Arctic. Knowledge gained from these exchanges will be included in Navy Lessons Learned.

Lead: USFF
Support: NORTHCOM, ALCOM, PACOM/CPF, EUCOM, ONR, COMSUBFOR, ASL, COMSECONDFLT, COMTHIRDFLT, CNMOC, OPNAV OJAG Code 10
Suspense: Q1, FY11

4.3 Investments

Desired Effect: The Navy has the right weapons, platforms, sensors, C4ISR capability, and installations and facilities at the right time and cost to meet combatant commander requirements in the Arctic region

Roadmap Objective 3: Provide weapon, platform, sensor and C4ISR capability, and installations and facilities required to implement Navy, DOD, and National policy regarding the changing Arctic region

Action Item 3.1 Monitor Polar MILSATCOM implementation.

Description: Navy will review the annual submission of the USAF Enhanced Polar Program for polar MILSATCOM and advocate continued funding. Sustainment of this program and development of a replacement in POM-12 is critical to Navy operations in the Arctic.

Lead: OPNAV N2/N6
Support: None
Suspense: Q4, FY10-FY14 (Annually)

Action Item 3.2 Initiate a *Capabilities Based Assessment* (CBA) for Naval Arctic capabilities.

Description: This assessment will be performed in accordance with JCIDS guidance in CJCSI 3170.01G and will include, but not be limited to the following:

- Assessment of current and required capability to execute undersea warfare, expeditionary warfare, strike warfare, strategic sealift, regional security cooperation, HA/DR, and DSCA.
- Assessment of current and required C4ISR capability.
- Assessment of current and required infrastructure, installations, and facilities in the region.
- Leveraging results from the studies and environmental assessment in *Action Items 3.2 & 5.7* of the roadmap, and the mission analysis and description of the strategic environment identified in *Action Items 1.2 & 1.3* of the roadmap.
- Assessment of the potential for leveraging Joint, interagency, and international partnerships addressed in *Action Item 1.8* of this roadmap.
- Potential for Joint, international, and interagency investments to find efficiencies and/or economies of scale

Lead: TFCC NCCCO
Support: OPNAV N2/N6C5, N31, N45, N46, N51, N8F, N81, N85, N86, N87, N88, USFF, USCG, CAN, NAVFAC ESC, CNIC
Suspense: Q1, FY11

Action Item 3.3 Identify *Arctic Capability Science and Technology (S&T) Needs* to assist with the development of required Naval capability for operating in the Arctic.

Description: TFCC will maintain a standing list of *Arctic Capability Science and Technology Needs* to annually inform Arctic science and research organizations

so that they may improve the Navy's capability for operating in the Arctic environment. These needs will be determined from the CBA conducted in *Action Item 3.2*, outreach to the scientific and academic community, and engagement with combatant commanders and the Fleet concerning Arctic requirements. Specific areas to address will include, but not be limited to:

- Undersea Warfare
- Expeditionary Warfare
- Strike Warfare
- Strategic Sealift
- Regional Security Cooperation
- HA/DR
- DSCA
- C4ISR
- Infrastructure

Lead: ONR
Support: OPNAV N8F, N81, N85, N86, N87, N31, N51, TFCC NCCCO, USCG, USFF
Suspense: Q2, FY11 (Annually)

Action Item 3.4 Investigate C4ISR interoperability with the U.S. Coast Guard.

Description: In anticipation of increased Joint USN-USCG operations in the region, this effort will assess to what extent the two services can communicate, exchange ISR data, and share C2 data. Capability gaps, and potential solutions to improve Arctic C4ISR interoperability between the services will also be identified. The overall objective of this effort will be to identify ways to improve sharing common MDA of the region to enhance interoperability.

Lead: OPNAV N2/N6
Support: OPNAV N31, N51, N81, N85, N86, N87, N88, ONI, NMIC, PEO C4I, TFCC NCCCO
Suspense: Q2, FY11

Action Item 3.5 Beginning with POM-14 and biennially each POM year thereafter, assess the Navy Strategic Plan's guidance, if any, relating to warfare capability in the Arctic, and address these requirements in Sponsor Program Proposals.

Description: If required, Sponsor Program Proposals will include recommendations relating to the Navy's Arctic capability gaps identified in the CBA in *Action Item 3.2* and will include, but not be limited to:

- Science and technology (S&T) needs from *Action Item 3.3*
- Research and development (R&D) requirements
- Leveraging Joint, interagency and international partnerships evaluated in

Action Item 1.8 of the roadmap to find efficiencies and/or economies of scale

Lead: OPNAV N2/N6, N4, N8F, N80
Support: OPNAV N81, N85, N86, N87, N88, N31, N51, TFCC NCCCO, NAVFAC
ESC, CNIC, USFF, USCG
Suspense: Q1, FY12

4.4 Strategic Communications and Outreach

Desired Effect: The media, public, government, DOD, and interagency, and international community believe the Navy is contributing to a safe, secure, and stable Arctic region

Roadmap Objective 4: To inform the media, public, government, Defense, and inter-agency, and international audiences regarding the Navy's policy, strategy, investments, intentions, and actions regarding the changing Arctic.

Action Item 4.1 Develop a Navy Arctic Strategic Communications Plan (SCP) for FY10-14.

Description: The Navy Arctic SCP for FY10-14 will provide a framework for how the Navy discusses the Arctic in the public and media, and will define the targeted audiences, organizations, venues, and milestones for communicating Navy action and outreach with regard to the Arctic. These will include but are not limited to:

- CHINFO Rhumblines
- Navy News
- Navy Times
- Stars and Stripes
- Naval Institute *Proceedings*
- Navy League's *Seapower* Magazine
- Social media venues (e.g. Facebook)
- Alaska Public Radio Network
- National Public Radio
- Military Channel
- Weather Channel
- Major US Newspapers
- Local & regional Alaska radio stations & newspapers

The SCP will be reviewed and updated every two years or as required by the Director, TFCC.

Lead: TFCC NCCCO
Support: OPNAV N51, CHINFO, MSC

Suspense: Q1, FY10

Action Item 4.2 Develop a Navy Arctic Outreach & Engagement Plan for FY10-14.

Description: The Navy Arctic Outreach & Engagement Plan will identify organizations the Navy will inform, be informed by, and partner with for achieving the objectives and desired effects of this roadmap. This outreach and engagement plan will be reviewed and updated every two years or as required by the Director, TFCC. Elements of this plan will include, but not be limited to:

- Socializing and requesting OSD designate TFCC as the Department of Defense (DOD) Executive Agent for the Arctic
- Providing DOD assets with *Arctic Environmental Assessment Reports* (*Action Item 5.7* of the roadmap), other TFCC products, and information and reports concerning the Arctic DOD, scientific, media, interagency, and international sources. These DOD assets will include but not be limited to:
    - NORTHCOM
    - EUCOM
    - PACOM
    - USFF
    - COMSECONDFLT, COMTHIRDFLT, COMSEVENTHFLT
    - COMSUBFOR
    - COMNAVSURFOR
    - COMNAVAIRFOR
    - OSD
    - CJCS
    - USAF Director of Weather
    - Arctic Submarine Lab (ASL)
    - Commander, Naval Meteorology and Oceanography Command
    - Office of Naval Intelligence (ONI)
- Establishing and maintaining consistent outreach with, and providing information related to the Navy Arctic Roadmap to U.S. government and interagency organizations involved in the Arctic. These organizations will include but not be limited to:
    - White House Office of Science and Technology Policy (OSTP), Council on Environmental Quality (CEQ)
    - Commission on Ocean Policy
    - Department of State's Arctic Policy Group
    - Department of Energy
    - NOAA
    - U.S. Coast Guard
    - NASA
    - USGS
    - National Geospatial Intelligence Agency (NGA)
- Establishing and maintaining consistent outreach with, and providing information related to the Navy Arctic Roadmap to scientific, research and

academic organizations involved in the Arctic. These organizations will include but not be limited to:

- National Science Foundation (NSF)
- National Academy of Science
- National Research Council
- U.S. Arctic Research Commission
- Naval Post Graduate School
- Naval War College
- National Defense University
- Office of Naval Research (ONR)
- Strategic Environmental Research and Development Program (SERDP)
- U.S. Army Corps of Engineers (USACE) Cold Regions Research Lab (CRREL)
- University of Washington's Applied Physics Lab Polar Science Center
- University of Colorado, Boulder
- University of California, Los Angeles
- Pennsylvania State University
- Wood Hole Oceanographic Institution
- University of Alaska, Fairbanks' International Arctic Research Center
- University of New Hampshire
- NASA's Jet Propulsion Laboratory
- NOAA's National Snow and Ice Data Center, National Climatic Data Center, National Weather Service, National Ocean Service, Climate Program Office, and Pacific Marine Environmental Laboratory
- Consortium for Ocean Leadership
- National Ice Center

- Establishing and maintaining consistent outreach with, and providing information related to the Navy Arctic Roadmap to international offices, agencies, governments, and militaries involved in the Arctic. These will include but not be limited to:
  - Canadian Navy
  - Royal Navy
  - UK Hydrographic Office
  - Russian Navy
  - Danish Navy
  - Norwegian Navy
  - International Ice Patrol
  - Japanese Maritime Self Defense Force (JMSDF)
  - Icelandic Coast Guard
  - Canadian Coast Guard
  - Russian Border Guard
- Establishing and maintaining consistent outreach with, and providing information related to the Navy Arctic Roadmap to indigenous peoples

within the state of Alaska. This will include adherence to relevant executive orders and legislation relating to consultation to Native American and Native Alaskan tribes and regional cooperations.

- Establishing and maintaining consistent outreach with, and providing information related to the Navy Arctic Roadmap to organizations within industry that will be working and investing in the Arctic region.

Lead: TFCC NCCCO
Support: CHINFO, ONR, NOAA, USCG. OPNAV OJAG Code 10
Suspense: Q1, FY10

4.5 Environmental Assessment and Prediction

Desired Effect: The Navy understands the changes and projections for the Arctic environment, specifically when and to what extent ice will recede allowing for increased maritime access to the Arctic.

Roadmap Objective 5: To provide Navy leadership and decision makers a comprehensive understanding of the current and predicted Arctic physical environment on tactical, operational, and strategic scales in time and space. The science-based timeline developed through this focus area will inform accomplishment of the action items and objectives within the other focus areas of this roadmap.

Action Item 5.1 Contribute to the development and implementation of the National Ocean Policy

Description: The White House Council on Environmental Quality (CEQ) is leading a National Ocean Policy Task Force that will deliver a National Ocean Policy which will include a framework for Marine Spatial Planning in the Arctic in December 2009. Navy contribution through the Office of the Secretary of Defense (OSD), Joint Chiefs of Staff (JCS), and Department of the Navy (DoN) will ensure the Navy's equities and strategic concerns regarding the Arctic are represented in both the final policy document, and in the implementation of that document.

Lead: OPNAV N45, TFCC NCCCO, OJAG Code 10
Support: None
Suspense: FY10-14 (Ongoing)

Action Item 5.2 Initiate a *Capabilities Based Assessment* (CBA) of the Navy's Arctic observing, mapping, and environmental prediction capabilities in the Arctic.

Description: This assessment will be performed in accordance with Joint Capability Integration and Development System (JCIDS) guidance in CJCS 3170.01G. It will evaluate the Navy's capability and requirements to observe the physical environment in the Arctic region, to include hydrographic, atmospheric,

oceanographic, and ice data, and will recommend future investments. This CBA also will evaluate the Navy's capability to predict air-ocean-ice conditions on tactical (hours-days), operational (days-weeks), and strategic (months-decades) scales. Specific emphasis will be placed on new capabilities that current technology may provide to reduce uncertainty in 10-30 year predictions of arctic ice coverage. Current and programmed systems will be assessed, and future investments will be recommended. This CBA will include, but not be limited to, the following elements:

- Assessment of previous or ongoing studies regarding the Arctic, climate change, and national security such as:
  - CNA, National *Security and the Threat of Climate Change* (2007)
  - Center for New American Security (CNAS), *Uncharted Waters: The U.S. Navy and Navigating Climate Change* (2008)
  - National Intelligence Council, *National Intelligence Assessment on the National Security Implications of Global Climate Change to 2030* (2008)
  - CNA, *Impact of Climate Change on Naval Operations in the Arctic* (2009)
  - CNA, *Global Climate Change and State Stability* (2009)
  - Pew Center on Global Climate Change, *National Security Implications of Global Climate Change* (2009)
  - OSD QDR, *Assessment of DOD infrastructure vulnerability* (ongoing)
  - GAO, *Survey of Federal Government Efforts to Adapt to a Changing Climate* (ongoing)
  - Strategic Environmental Research and Development Program (SERDP), *Climate Change Planning for Military Installations* (ongoing)
  - Naval Studies Board, *National Security Implications of Climate Change on U.S. Naval Forces* (ongoing)
- Assessment of existing and programmed DOD, interagency, and international observation programs, processes, and organizations for meeting Navy requirements:
  - National Ocean Policy
  - T-AGS multi-mission survey ships
  - National Ice Center
  - Study of Environmental Arctic Change (SEARCH)
  - Arctic Observing Network (AON)
  - Sustained Arctic Observing Network (SAON)
  - International Arctic Buoy Program
  - Space based monitoring (e.g. RADARSAT)
  - Extended Continental Shelf (ECS) Task Force and related efforts
  - Science Exercise (SCICEX) Science Accommodation Missions (SAMs)
  - National Ocean Partnership Program (NOPP efforts)

    - Russian-America Long Term Census of the Arctic (RUSALCA)
    - NOAA Arctic Program
    - Tiksi Arctic Observatory
    - APL-UW Polar Science Center experimentation
    - APL-UW Arctic glider surveys
    - University of Alaska, Fairbanks International Arctic Research Center
    - University of Washington, Applied Physics Laboratory's Polar Science Center
    - Woods Hole Oceanographic Institute
    - U.S. Army Corps of Engineers Cold Weather Research and Engineering Laboratory
    - Naval Facilities Engineering Service Center
- Assessment of FY09 validation and verification of numerical weather prediction capability
- Assessment of current and required architecture and computational capacity
- Evaluation of the potential for developing a coupled, air-ocean-ice, single-km resolution, non-hydrostatic prediction capability suitable for the Arctic region
- Potential for leveraging interagency partnerships with NOAA, DOE, NASA, and the National Ocean Partnership Program
- Potential for leveraging international partnerships

Lead: OPNAV N2/N6
Support: OPNAV N81, TFCC NCCCO, USFF, CNMOC, ONR
Suspense: Q1, FY11

Action Item 5.3 Continue SCICEX accommodation missions (SAMs).

Description: SCICEXs have provided the scientific community with data important to our understanding of the Arctic environment and predicting future changes. When operational requirements permit, SAMs will be conducted according to the Science Plans agreed to by the SCICEX Science Advisory and Interagency Committees.

Lead: COMSUBFOR
Support: USFF, OPNAV N87, ONR, ASL, NSF, LDEO, NSIDC, CRREL
Suspense: FY10-14 (Ongoing)

Action Item 5.4 Identify *Science and Technology Needs for Arctic Assessment and Prediction.*

Description: TFCC will maintain a standing list of science and technology needs for Arctic assessment and prediction to annually inform Arctic science and research organizations so that they may improve the Navy's understanding of the

current and predicted Arctic environment. These needs will be determined from the CBA conducted in *Action Item 5.2*, outreach to the scientific and academic community, and engagement with combatant commanders and the Fleet concerning Arctic requirements. Specific areas to address will include, but not be limited to:

- Hydrography
- Oceanography
- Ice Extent and Dynamics
- Meteorology
- Climate
- Geology and geophysics and engineering (foundation) properties of seafloor and substrates

Lead: ONR
Support: OPNAV N2/N6, TFCC NCCCO, NOAA, USFF, CNMOC
Suspense: Q4, FY10-14

Action Item 5.5 Develop cooperative partnerships for environmental observation and mapping with interagency and international Arctic stakeholders.

Description: Navy partnerships in the Arctic region will provide capability and contribute to achieving the Assessment and Prediction Objective and Desired Effects in this roadmap. The process to develop and strengthen these partnerships will include:

- Evaluate existing agreements with Arctic stakeholders, including but not limited to:
  - USCG
  - NOAA
  - NGA
  - U.S. Army Corps of Engineers Cold Regions Research and Engineering Laboratory (CRREL)
  - Interagency Arctic Research Policy Committee
  - U.S. Arctic Research Commission
  - National Science Foundation (regarding SERCH and AON)
  - Department of State (regarding SAON)
  - Hydrographic offices of the UK, Japan, and the Arctic Council Member States
  - Meteorological offices of the UK, Japan, and the Arctic Council Member States
  - Canadian Ice Service
  - Industry
- Initiate discussions with the Arctic stakeholders to expand existing, or form new agreements concerning collaborative efforts for environmental observation and mapping in the Arctic. Every attempt will be made to

leverage existing forums (e.g. quarterly Navy, NOAA, USAF Tri-Agency lunch). Topic areas will include but not be limited to:
    - Hydrographic, oceanographic, and meteorological data exchange
    - Joint investments to achieve economies of scale.
    - Cooperative hydrographic surveys in the Bering Strait choke points, logistic ports of debarkation, and in Fleet Arctic Operating areas to ensure safe navigation of Fleet (surface and subsurface) units operating in the region.
    - Become an active member of the proposed Arctic Hydrographic Commission.
- Formalize new or revised agreements with the Arctic environmental stakeholders.

Lead: TFCC NCCCO
Support: USFF, CNMOC, ONR, NOAA, USCG, OJAG Code 10
Suspense: Q2, FY10 – Evaluate existing agreements
Q4, FY10 – Initiate discussions
Q1, FY12 – Formalize new or revised agreements
Q1, FY12 – Implement new agreements

Action Item 5.6 Establish an interagency partnership to develop and implement a Next Generation Numerical Environmental Prediction (NEP) capability for coupled air-ocean-ice modeling.

Description: Environmental prediction capabilities exist, and are being programmed across DOD and the interagency community. Establishing a permanent partnership to synchronize these efforts towards a common goal of improving global environmental assessment and prediction will improve the Navy's understanding of the current, and projected Arctic environment – thereby achieving the Assessment and Prediction Objective and Desired Effects in this roadmap. The process to develop this partnership will include:

- Evaluate existing agreements with environmental prediction stakeholders, including but not limited to:
    - NOAA
    - NASA
    - Department of Energy and its subordinate national laboratories
    - USAF
    - US Group on Earth Observations
- Initiate discussions with these stakeholders to form a new collaboration agreement on environmental prediction. Every attempt will be made to leverage existing venues (e.g. quarterly Navy, NOAA, USAF Tri-Agency Lunch). Topic areas will include but not be limited to:
    - Leveraging existing programmed efforts (e.g. the National Unified Operational Prediction Capability – NUOPC)
    - Exploiting each agency's unique areas of expertise (e.g. data

assimilation for the Navy)
    - Reducing redundancy in research, development, and investment.
- Formalize the new agreement and begin implementation

Lead: TFCC NCCCO
Support: USFF, CNMOC, ONR, NOAA, USCG
Suspense: Q2, FY10 – Evaluate existing agreements
Q4, FY10 – Initiate discussions
Q1, FY12 – Formalize new or revised agreements
Q1, FY12 – Implement new agreements

Action Item 5.7 Beginning in FY10 for POM-14, and biennially each POM year thereafter, produce an *Arctic Environmental Assessment and Outlook Report* to inform Navy policy, strategy, and investment decisions.

Description: This biennial report will provide a comprehensive assessment of the state of the Arctic environment, including the oceanography, hydrography, meteorology, fisheries, ice-extent, and climatic trends. Also included will be projections based upon the latest scientific studies, research, and modeling efforts regarding future Arctic environmental conditions, with particular emphasis on the time-frame in which ice extent and thickness will allow for trans-Arctic shipping and significant increases in intra-Arctic shipping resource extraction, and eco-tourism.

Lead: TFCC NCCCO
Support: ONR, CNMOC, NPS
Suspense: Q4, FY10

Action Item 5.8 Beginning with POM-14 and biennially each POM year thereafter, assess the Navy Strategic Plan's requirements, if any, relating to Navy environmental observation, mapping, and numerical environmental prediction capability in the Arctic, and address these requirements in recommendations to Sponsor Program Proposals.

Description: If required, Sponsor Program Proposal recommendations relating to the Navy environmental observation, mapping, and numerical environmental prediction capability gaps will be based upon the CBA in *Action Item 5.2* and will include, but not be limited to:

- Science and technology (S&T) needs from *Action Item 5.3.*
- Research and development (R&D) requirements
- Leveraging Joint, interagency, and international partnerships evaluated in *Action Itesm 5.5 & 5.6* to find efficiencies and/or economies of scale
- Application of unmanned systems for observation and mapping

Lead: TFCC NCCCO
Support: USFF, CNMOC, ONR

Suspense: Q1, FY12

Action Item 5.9 Evaluate the re-establishment of ONR's High Latitude Program.

Description: In the past, ONR's High Latitude Program coordinated mission-driven science to address national security needs through scientific data gathering in the Arctic. ONR's High Latitude Program was a proven and effective funding agency that provided a wealth of knowledge to the Navy and the nation. Re-establishing this program, with emphasis on support to research of sea ice thickness using Navy submarines, will lead to improved understanding and prediction of Arctic ice extent and the timeline for increasing access in the Arctic.

Lead: ONR
Support: USFF, CNMOC, TFCC NCCCO
Suspense: Q4, FY11

Action Item 5.10 Initiate *Environmental Planning Documentation* for the Arctic region.

Description: The Navy's Director of Environmental Readiness (OPNAV N45) is coordinating the completion of a phased, comprehensive approach to environmental planning for Navy military readiness and scientific research activities at sea. This documentation is required by the Secretary of the Navy and regulations contained in Executive Order (EO) 12114 Environmental Effects Abroad of Major Federal Actions, the Marine Mammal Protection Act (MMPA), the Endangered Species Act (ESA), and the National Environmental Policy Act. Documentation for the Arctic region will cover at sea Fleet Training, and as practicable Acquisition-related research, development, test, and evaluation (RDT&E) activities sponsored by program executive offices (PEO), environmental effects of new systems that reach Initial Operating Capability (IOC), and ONR-sponsored science and technology activities.

Lead: USFF/CNMOC
Support: OPNAV N45, N31, ONR, NAVAIR, NAVSEA
Suspense: Q2, FY12

Action Item 5.11 Increase operations of unmanned systems for Arctic data collection, monitoring, and research.

Description: Using capabilities from the Naval Oceanography Program's Littoral Battlespace Sensing, Fusion, and Integration (LBSF&I) program, assets from the Commander, Naval Meteorology and Oceanography Command (CNMOC) will increase the temporal and spatial coverage of Arctic data collection, monitoring, and research in order to improve nautical charts, atmospheric and ocean models, estimates of ice extent and thickness, and climate change indicators. Specific capabilities will include, but not be limited to:

- Gliders systematically deployed to map oceanographic conditions
- Unmanned underwater vehicles (UUVs) for oceanographic and hydrographic data collection
- Buoys to collect atmospheric and ice-related data
- Evaluation of the potential for collecting atmospheric and ice-related data using unmanned aerial systems (UASs)

Lead: USFF/CNMOC
Support: OPNAV N86, N87, N2/N6, TFCC NCCCO, NOAA
Suspense: Q1, FY13

5. Roadmap Execution

The Oceanographer of the Navy, as Director, TFCC will oversee execution of this roadmap. Navy offices responsible for action items in this roadmap will report accomplishment status quarterly to TFCC's Navy Climate Change Coordination Office (NCCCO), led by the TFCC Deputy Director. The following additional action items will support execution of this roadmap:

Action Item 6.1 Identify costs for the assessments in this roadmap

Description: TFCC will evaluate the costs for the mission, threat, and capability based assessments in this roadmap and provide them to OPNAV N81 for consideration and potential inclusion in Navy's PR-11 end game decisions.

Lead: TFCC NCCCO
Support: N81, N00X
Suspense: Q1, FY10

Action Item 6.2 Develop metrics to assess roadmap execution status.

Description: TFCC will develop a set of both activity-based and effects-based metrics to assess accomplishment of the roadmap. The activity-based metrics will apply to the roadmap action items and objectives, while the effects-based metrics will apply to the roadmap's five desired effects.

Lead: TFCC NCCCO
Support: N81
Suspense: Q1, FY10

Action Item 6.3 Provide quarterly reports regarding roadmap execution to the CNO.

Description: TFCC will submit Quarterly Arctic Roadmap Execution Reports to the CNO via the DNS. These reports will provide an assessment of the accomplishment of the roadmap's action items, objectives, and desired effects using metrics developed by TFCC. These reports also will provide a summary of

significant Navy engagement and near-term future actions regarding the Arctic.

Lead: TFCC NCCCO
Support: OPNAV N2/6, N3/5, N4, N8, CHINFO, ONR, USFF, USCG, NOAA, OJAG Code 10
Suspense: Q1-Q4, FY10-14

Action Item 6.4 Evaluate the requirement for a classified annex to this roadmap and initiate development if required.

Description: The classified Annex to this roadmap will provide a list of actions from FY10-14 that will accomplish the roadmap objectives and desired effects in this document.

Lead: OPNAV N2/N6C2
Support: OPNAV N31, OPNAV N51, USFF, EUCOM, PACOM/CPF, NORTHCOM, ONI, NMIC
Suspense: Q2, FY10

Action Item 6.5 Review and revise the Navy Arctic Roadmap.

Description: TFCC will review and revise this roadmap every four years after promulgation of the Quadrennial Defense Review (QDR) and incorporate QDR guidance as appropriate. The revised roadmap will provide a 5-year action plan for FY 14-19 with Navy objectives and desired effects regarding the Arctic.

Lead: TFCC NCCCO
Support: OPNAV N2/6, N3/5, N4, N8, CHINFO, ONR, USFF, USCG, NOAA, OJAG Code 10
Suspense: Q1, FY14

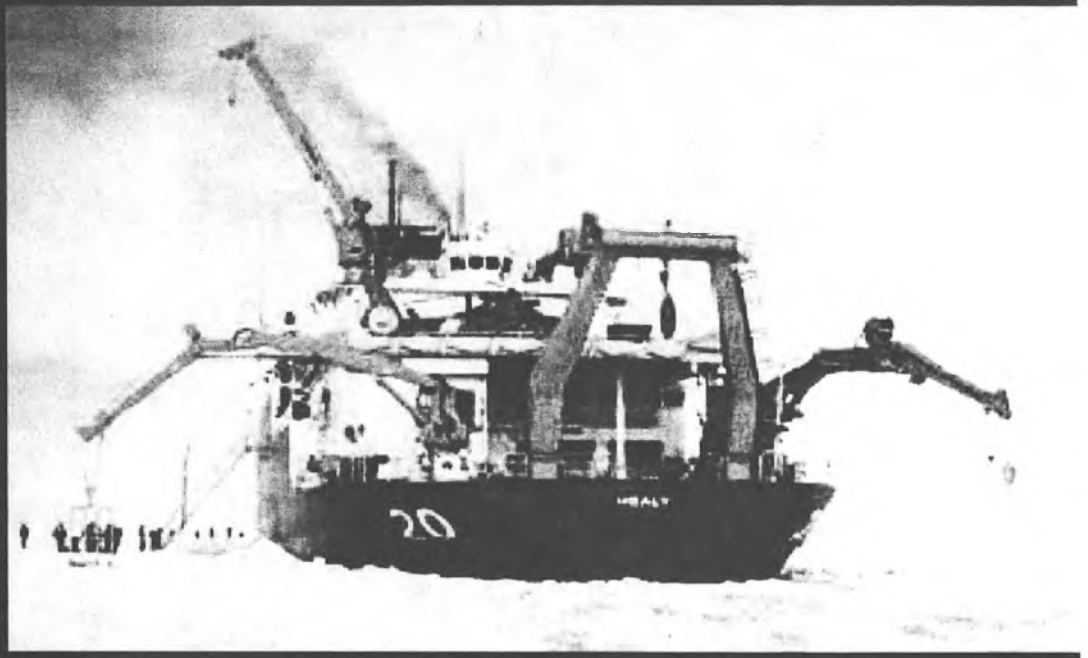
Arctic Changes Drive Coast Guard Mission Expansion North

Science is More Critical

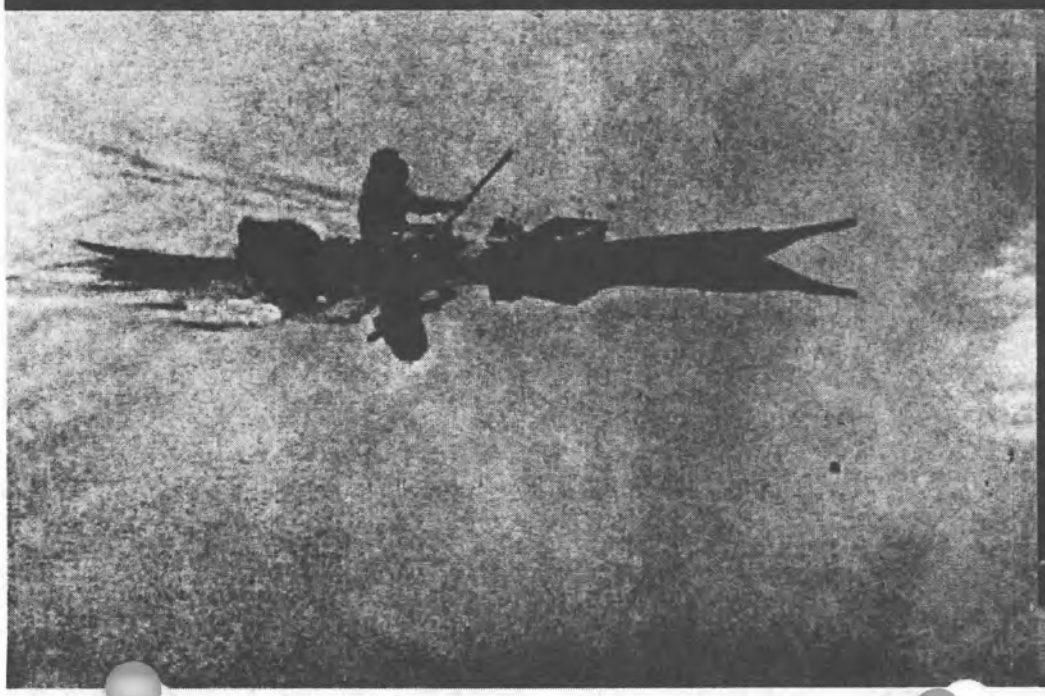
- Support of scientific endeavors
  - Research on climate change and its effects

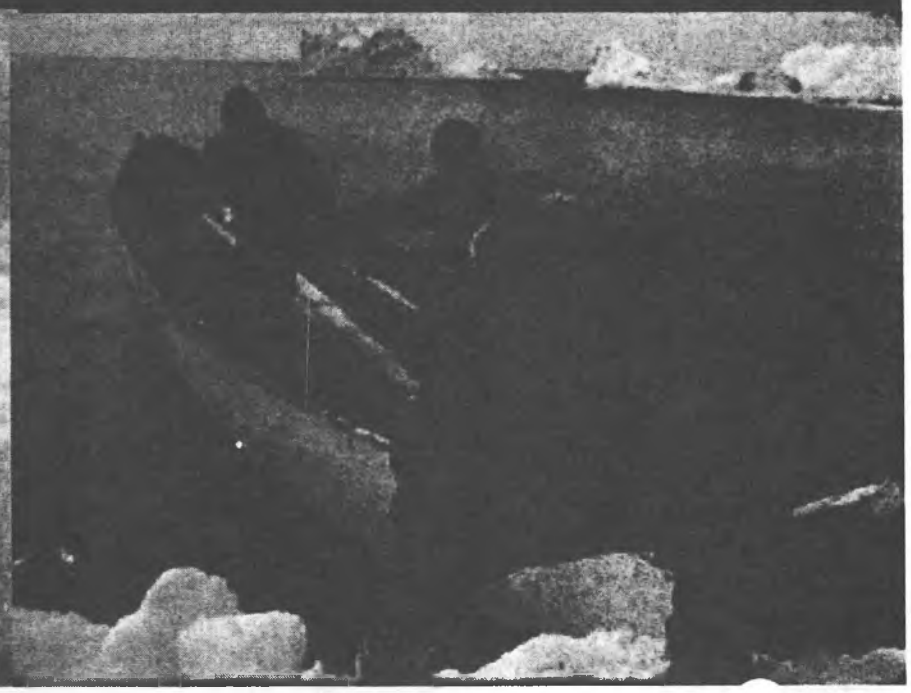


Homeland Security

Coastal Community Engagement

- Engagement with the peoples of the Northern regions of Alaska
  - Leverage thousands of years of experience
  - Promote environmental and cultural understanding





Arctic Ops Summer '08

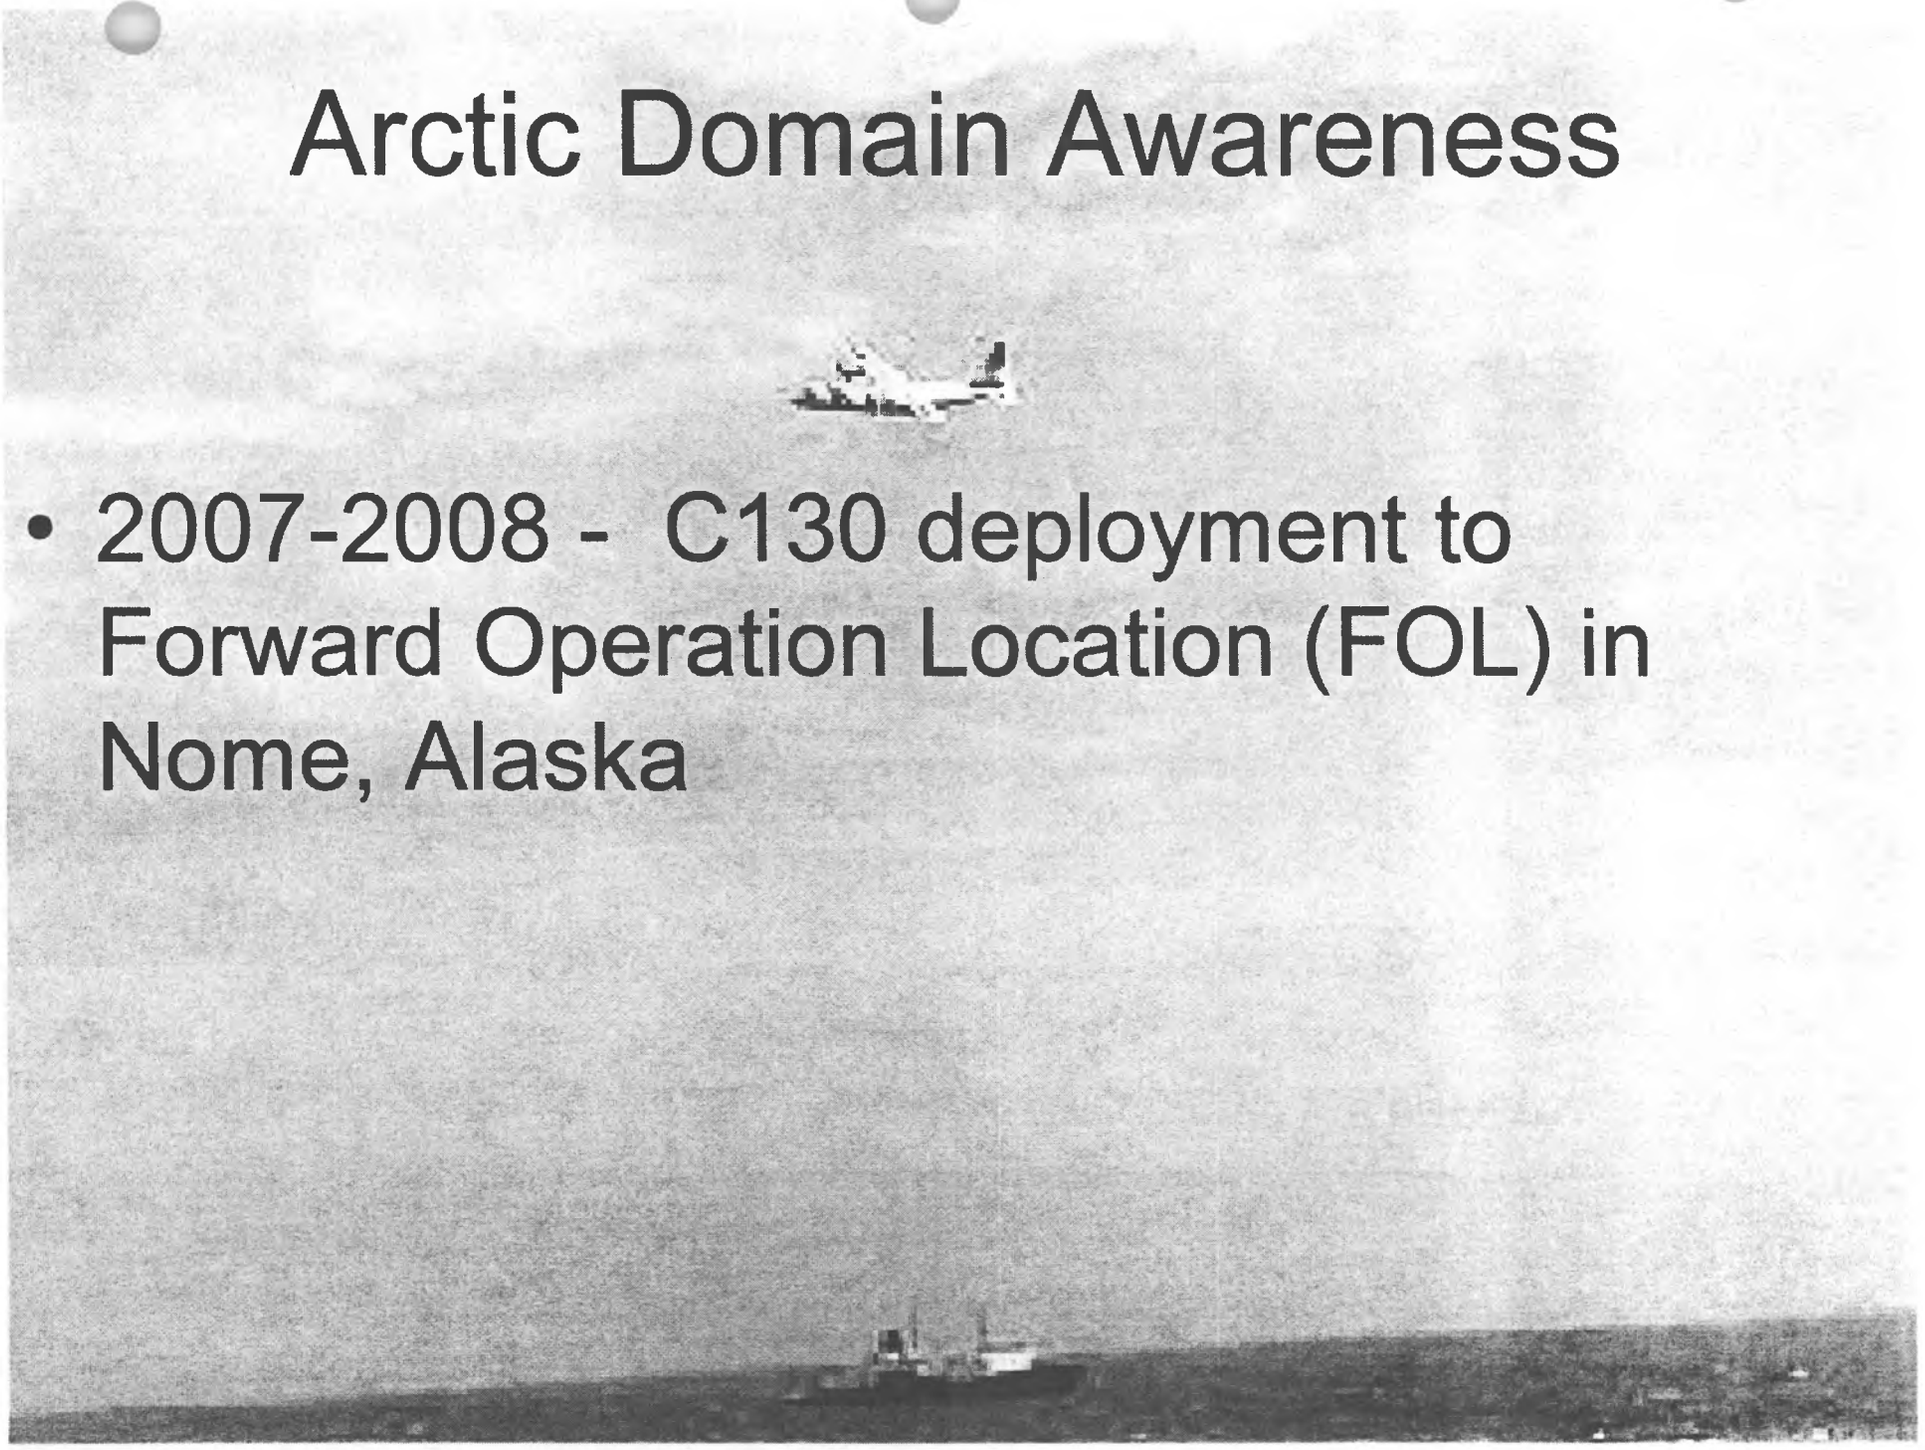
- Develop Arctic Domain Awareness
  - Nome C130 Deployment
- Cutter Operations
  - HEALY, POLAR SEA
- CGC SPAR Waterways Analysis & Management System
- International Search and Rescue Exercise
- Tailored Force Package Deployment
- Prudhoe Bay Maritime Security Deployment
- Coastal Community Engagement

Arctic Domain Awareness

- Air Patrols
  - 'Eyes on' above the Arctic Circle
  - Provide scientists platforms of opportunity

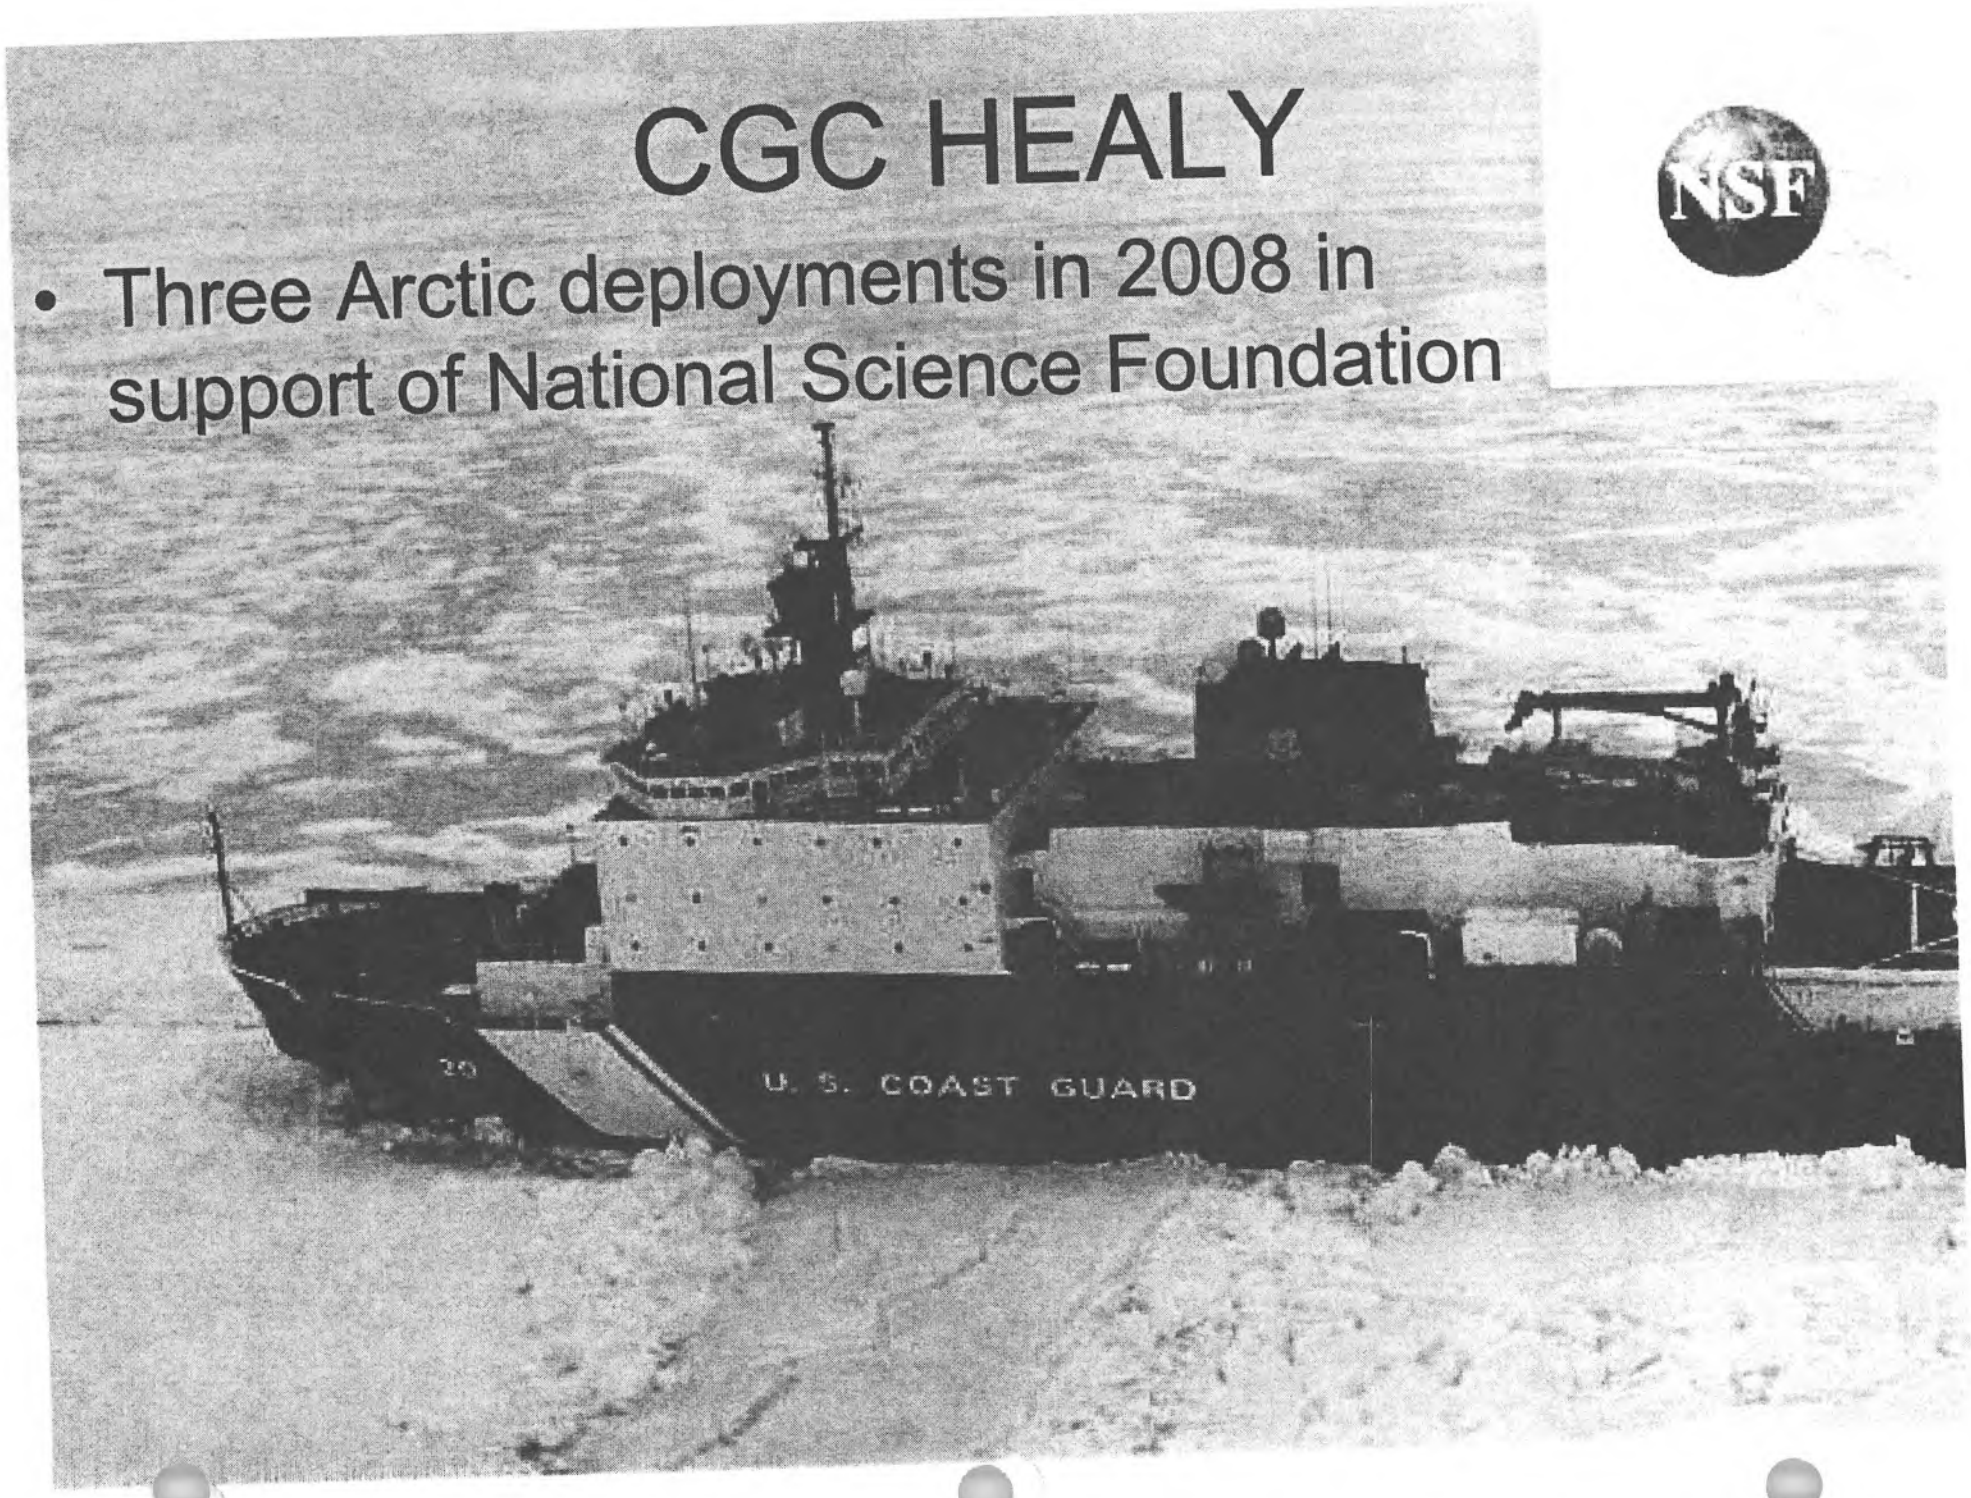
Arctic Domain Awareness

- 2007-2008 - C130 deployment to Forward Operation Location (FOL) in Nome, Alaska

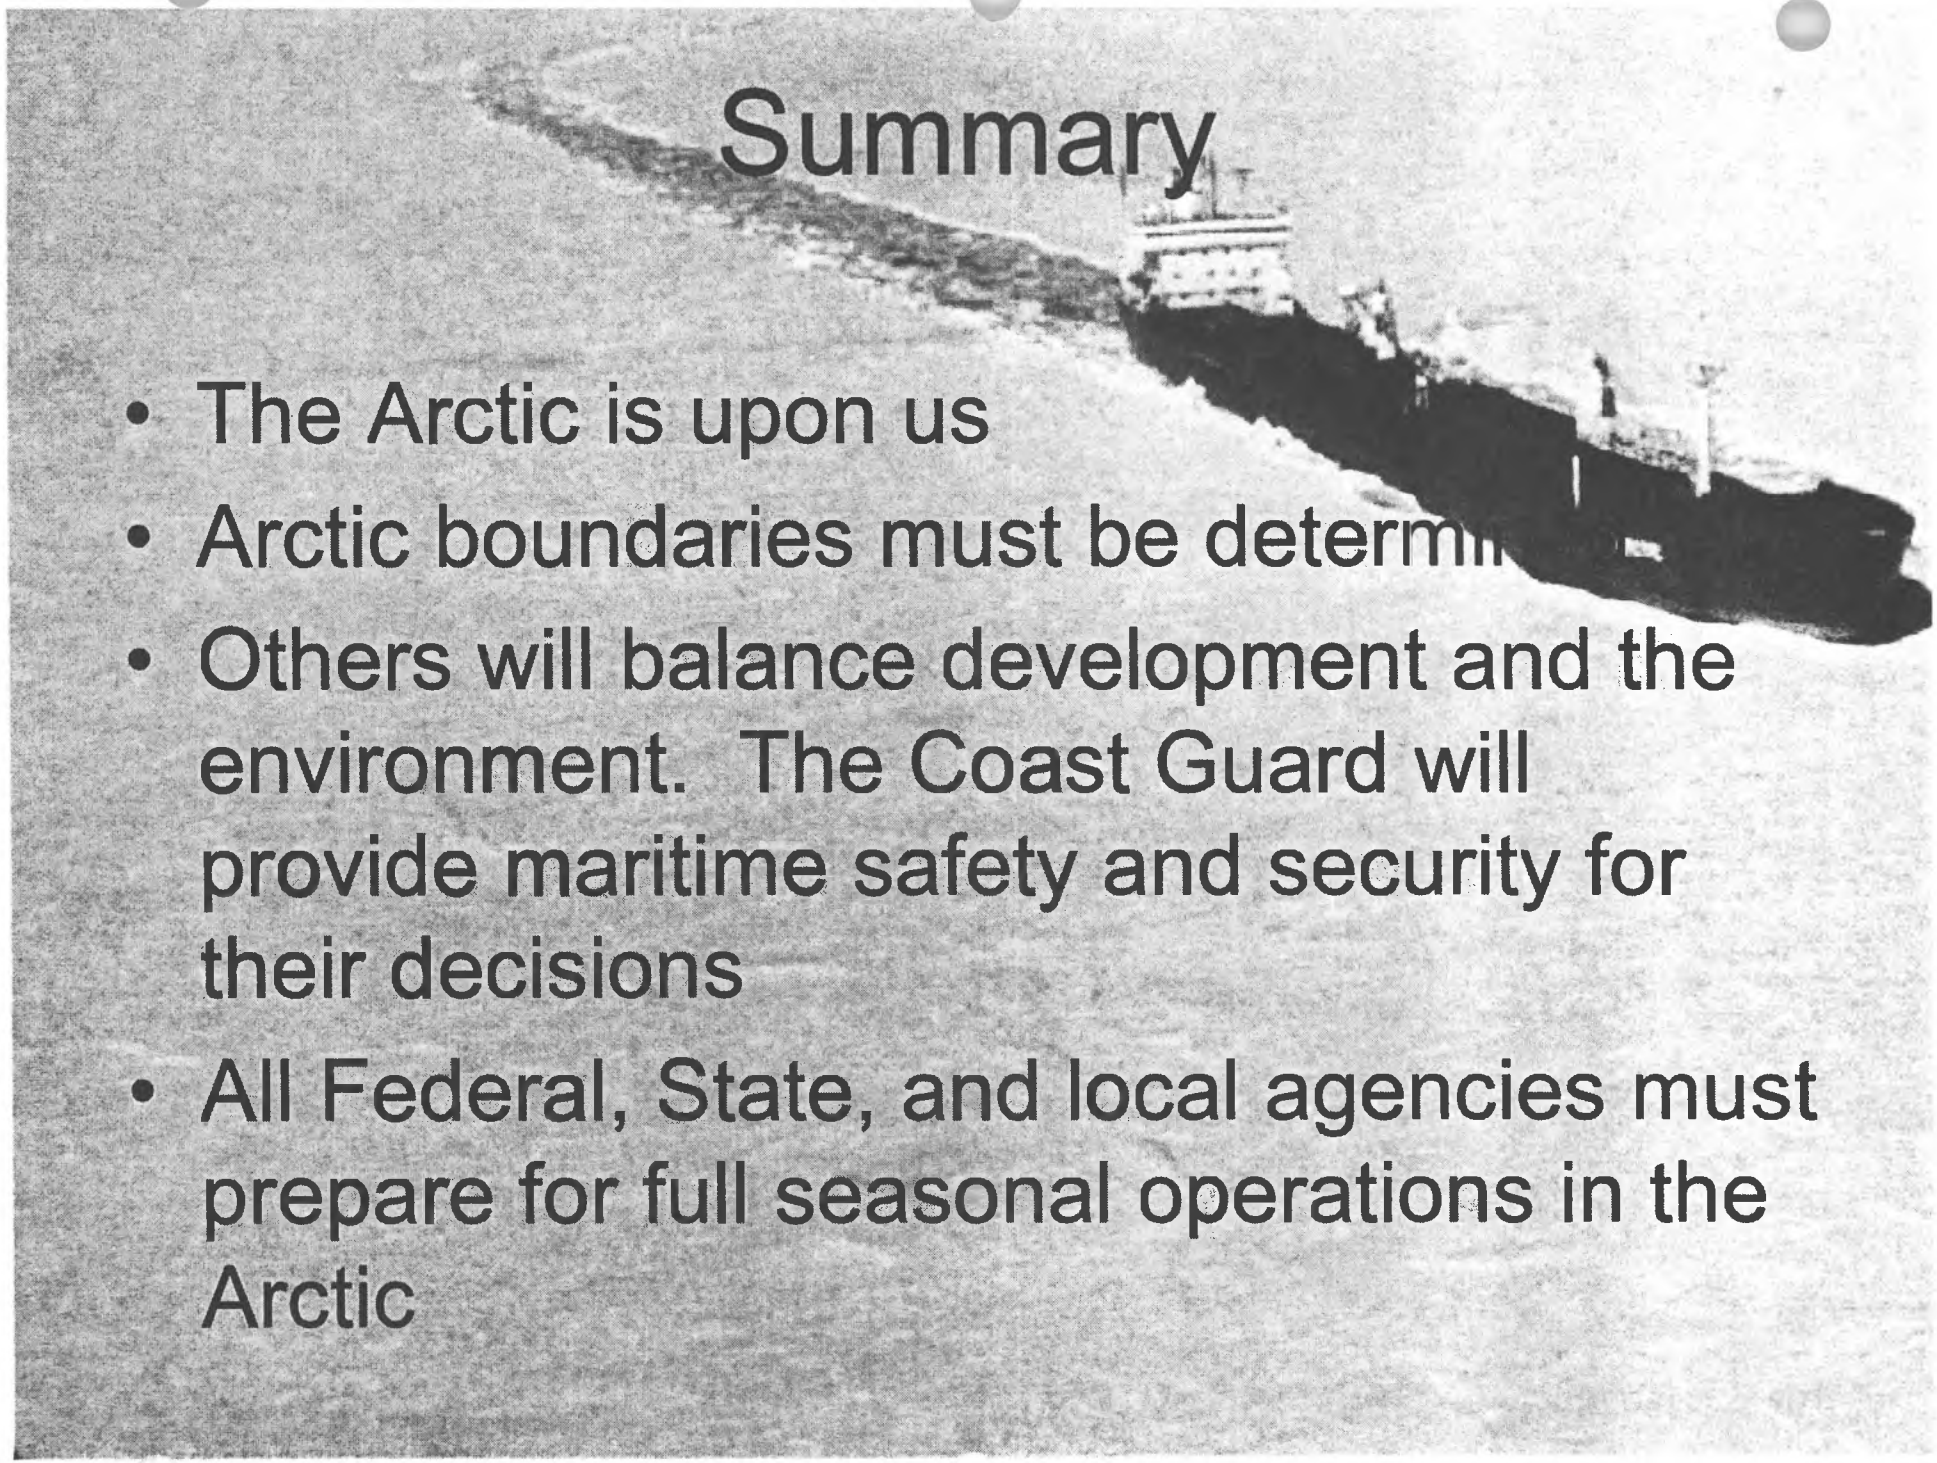


CGC HEALY

- Three Arctic deployments in 2008 in support of National Science Foundation



Summary



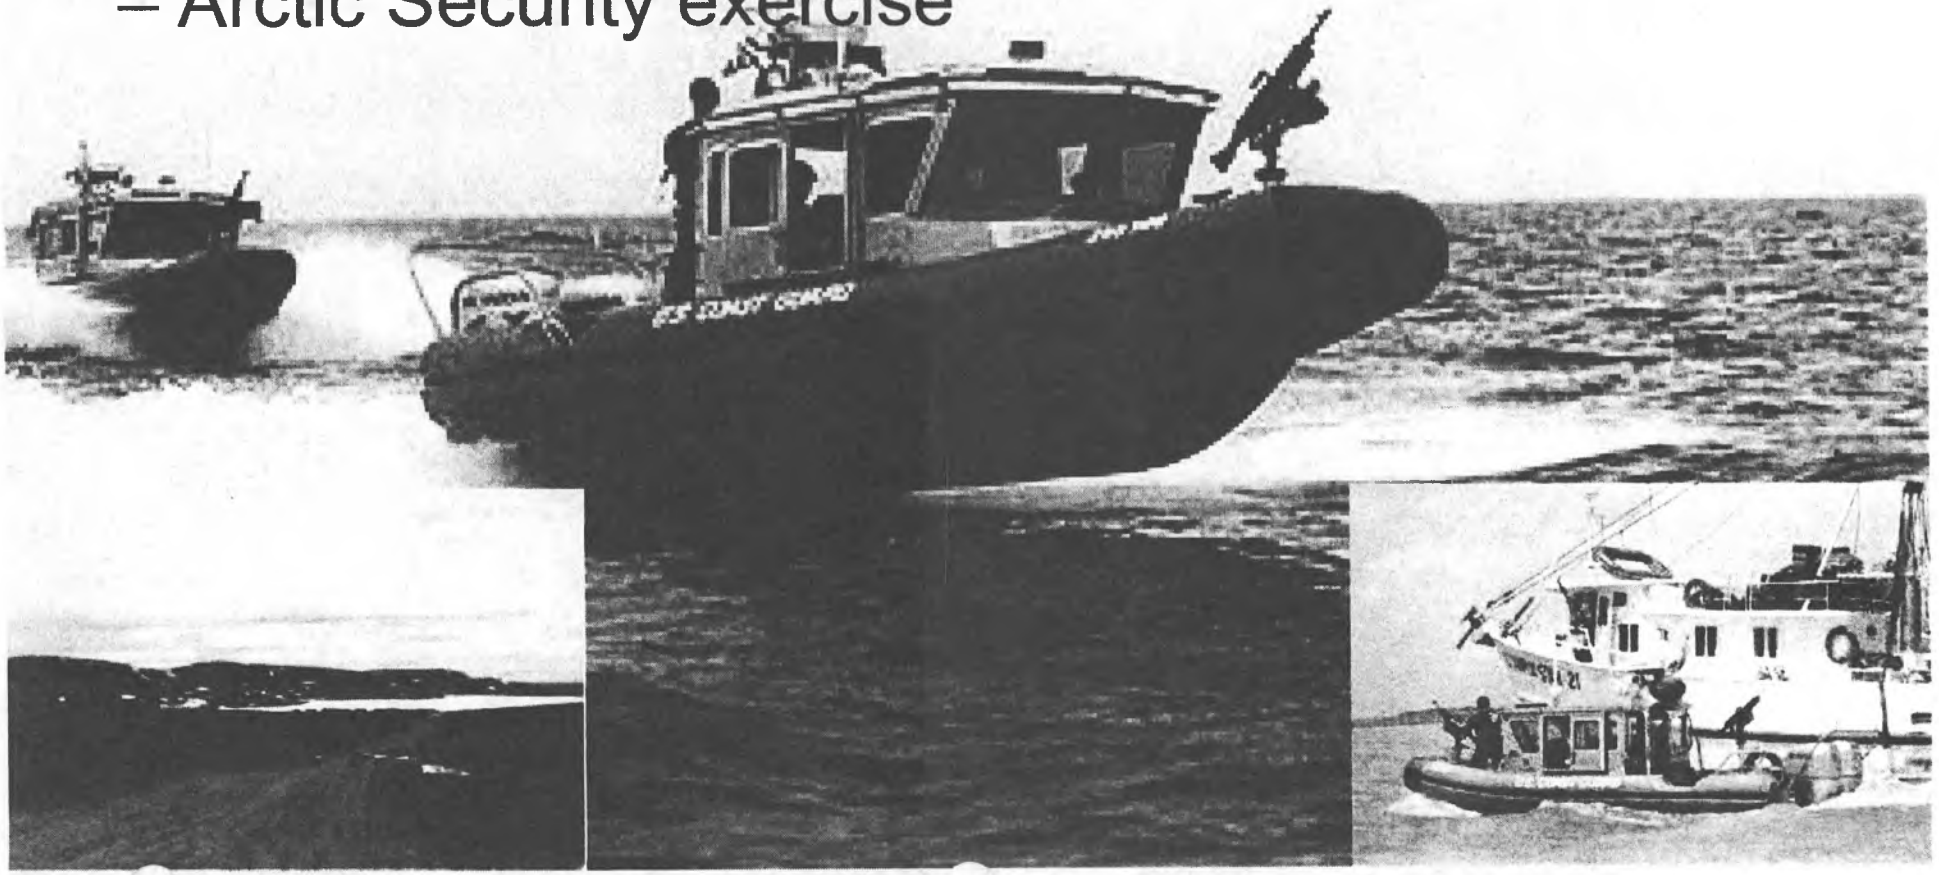
- The Arctic is upon us
- Arctic boundaries must be determi
- Others will balance development and the environment. The Coast Guard will provide maritime safety and security for their decisions
- All Federal, State, and local agencies must prepare for full seasonal operations in the Arctic

Way Ahead

- Potential establishment of one or more Forward Operating Locations on the North Slope and Western Alaska
- Collect lessons learned from summer operations
- Build operational requirements baseline

Prudhoe Bay Maritime Security Deployment

- 2008 - Prudhoe Bay, AK
  - Community/tribal liaison Team
  - Arctic Security exercise



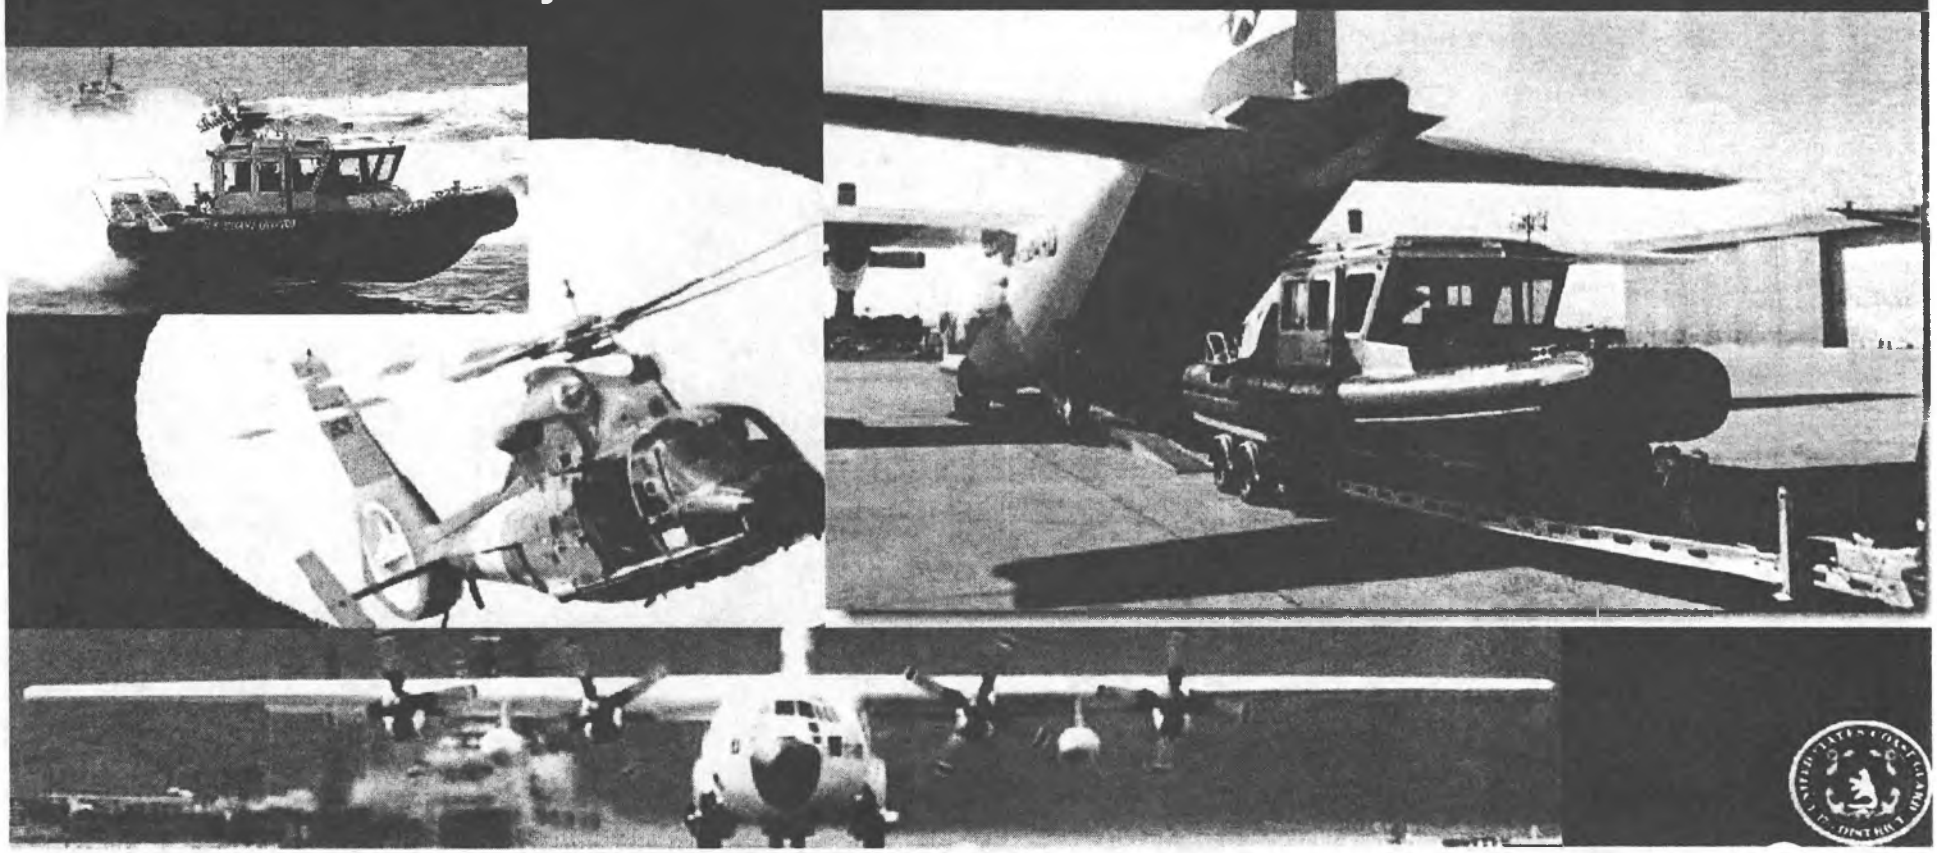
Auxiliary in the Arctic

- Provide boating safety services tailored to each Arctic Community's need.
- Conduct educational exchange on boating safety.
- Current plans for visits include Barrow, Kotzebue, Nome, and possibly some of the remote North Slope villages.

Homeland Security

Tailored Force Package

- August 2008 - Barrow, AK
  - 2 Helos and 2 25' small boats via C-130
  - Boating Safety Training Team
  - Community/tribal liaison Team



Joint Search and Rescue Exercise

- 2008 – Tentative plans to invite Arctic nations to participate to build partnerships and test our capabilities.

Norway

Canada

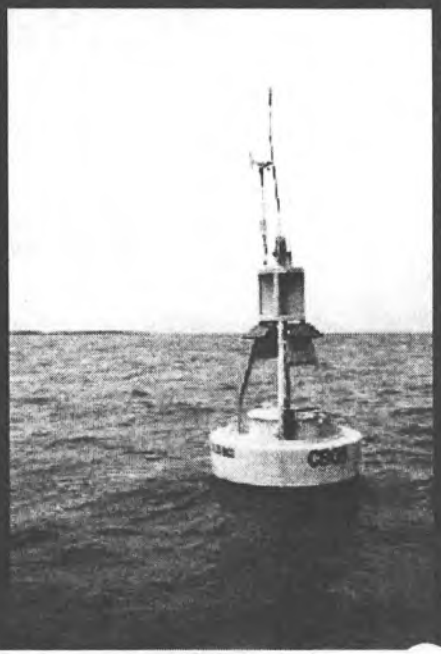
Denmark

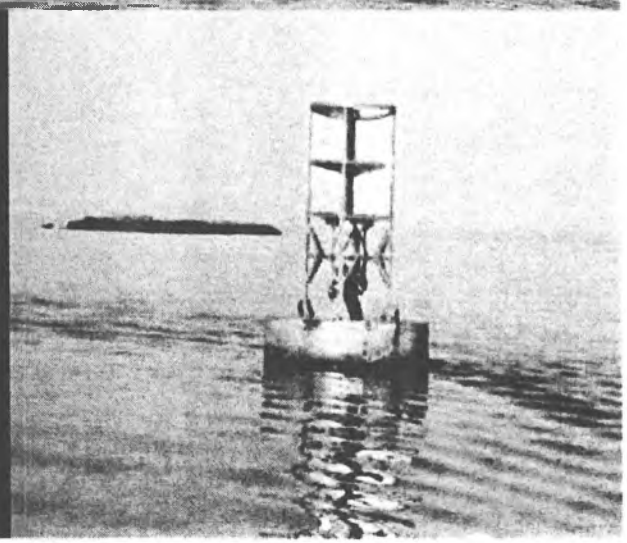
Russia

Homeland Security

CGC SPAR

- Waterways Analysis & Management System (WAMS) assessment/reassessment of North Slope





CGC POLAR SEA

- 2008 – Arctic mission instead of standby for Antarctic mission.

Alaska Climate Change Executive Roundtable Power Point Presentation

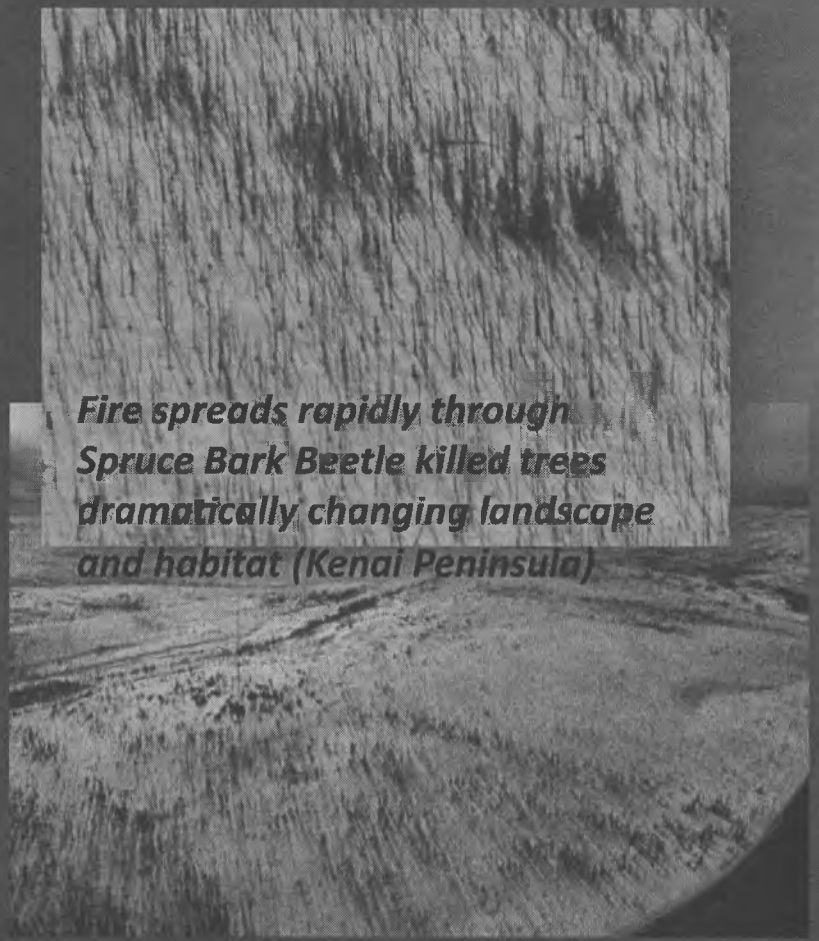
Alaska's
Climate Change Executive Roundtable:

Coordinating Federal and State Agency Efforts in the Great Land

State of the Arctic

March 18, 2010, Miami, FL

Alaska Climate Change Executive Roundtable (ACCER) Background



Fire spreads rapidly through Spruce Bark Beetle killed trees dramatically changing landscape and habitat (Kenai Peninsula)

- Established in 2007 at Alaska Forum on the Environment
- Mechanism for Federal and State science agencies in Alaska to share information about climate change activities and facilitate cooperation among agencies
- Evolved to planning & executing own activities

ACCER Membership

- Federal
  - DOI: USGS, MMS, FWS, BLM, NPS, BIA
  - DOC: NOAA (NWS, NMFS, NOS, AOOS)
  - USDA: FS
  - EPA
- State
  - Department of Environmental Conservation
  - Department of Natural Resources
  - Department of Fish and Game
  - Governor's Office

ACCER focus areas

- data integration and collaboration
- needs for down-scaled climate data and physical parameter monitoring networks
- sea level rise and physical hazard assessment
- forecasting biological species and habitat changes

Physical & Biological

- Projections of change – most important
- ID monitoring needs; mine historical data to show status & trends over time
- Next step: gap analysis

ACCER Data Integration And Collaboration

- History:
  - Established 2008
  - Groups have met regularly
- Structure:
  - Two groups: executive (policy) and technical
- Progress to date:
  - Initial focus is on developing compatible project tracking systems
  - Will then turn to metadata and data system integration

Science Summary:
This grant funds a collaborative effort to document geographic patterns of genetic variation in both prehistoric and modern human populations along the North Slope of Alaska and to assess how the ancient residents of arctic Alaska are related to contemporary Inupiaq populations throughout the circumarctic region. The research team will characterize maternally inherited mitochondrial (mt)DNA sequences, paternally inherited Y-chromosome markers, as well as biparentally inherited autosomal genetic markers in both the archaeologically derived prehistoric samples and the contemporary populations of the North coast of Alaska. Direct comparison of patterns of genetic variation in prehistoric populations and their possible modern descendants, and the placement of this biological variation in archaeological (temporal) context, is a powerful tool for the reconstruction of population history. Although the prehistoric genetic data will come from well-known archaeological contexts (e.g., Nuvuk), the research team will also directly date a subsample of the prehistoric material to confirm the temporal placement of the samples. They will also generate stable isotope data from the ancient samples to facilitate reconstruction of prehistoric diets, paleoecology of the region, and contribute to the reconstruction of ancient migration/colonization events. The data to be generated by this project, on both extant and prehistoric populations, will afford a definitive genetic characterization of the Inupiat people of the northwestern American arctic, and permit testing several hypotheses regarding the origin of the eastern arctic Inuit population. Additionally, the research undertaken here will permit a much more detailed analysis and understanding of the Thule expansion across the North American high arctic, one of the last [illegible] migrations and colonization events. A fuller understanding of this human dispersal will permit us to identify genetic signatures of rapid colonization, replacement versus admixing colonization models, and help clarify the origin and history of North American arctic populations.
Logistics Summary:
For this IPY collaboration involving 0732846 (O'Rourke, U Utah. LEAD) and 0732857 (Hayes, Northwestern University), scientists will document geographic patterns of genetic variation in both prehistoric and modern human populations along the North Slope of Alaska; further, they will assess how the ancient residents of arctic Alaska are related to contemporary Inupiaq populations throughout the Arctic. Field work will begin in February 2008 and continue seasonally through 2010. Logistics details are carried under 0732846, O'Rourke.
Support details under 0732846.

Alaska's Climate Change Strategy: Addressing Impacts in Alaska
Executive Summary

INTRODUCTION

In Alaska, climate change has begun to touch almost every aspect of the natural world and the human systems that have evolved around, and rely on, a set of stable and predictable climatic conditions and seasons. It is a world where a warming environment has already begun to render ground and building foundations unstable, disrupt transportation routes, and trigger phenomena placing coastal communities in imminent danger from flooding and erosion. Impacts have resulted in myriad consequences to residents of the state, to subsistence livelihoods, to the wildlife and vegetation in Alaska's terrestrial and marine environments, and to the many industries that support the Alaskan economy.

While these changes are of critical import to Alaskans, they have also garnered attention of leaders in the United States and around the world. The primary driving force has been the accelerated retreat of Arctic sea ice, which has been a catalyst for multi-disciplinary planning and has underscored the need for increased domestic and international cooperation. A navigable Arctic Ocean presents opportunities for shipping and commerce in the Northwest Passage and has elevated interest in developing fisheries and mineral resources. Consequently, this creates a need for additional and improved weather and navigational tools, research to better understand and manage our strategic assets, and increased efforts to provide national, environmental, and economic security. Widespread interest in the Arctic has also been elevated by the important role that the Earth's polar region plays in influencing climate and oceans on a global scale. What happens in Alaska has far-reaching and long-lasting implications.

Box 1. Sectors Addressed by the AAG Report

Alaska's economy and the health and well-being of its residents will be affected by climate change. Key impacts being addressed include:

Public Infrastructure

Impacts of climate change on public, private, or cooperatively owned infrastructure for the public good including buildings, transportation, shoreline protection, water and sanitation systems, and defense facilities.

Health and Culture

Climatic changes and associated changes in natural systems are increasing the potential for health impacts from vector-, water-, and food-borne diseases and are beginning to cause stress on subsistence communities. Erosion, changes in permafrost, and extreme events are already impacting coastal communities, sanitation infrastructure, and archaeological sites and gravesites. Weather related injuries and detrimental effects on mental health have also been associated with rapidly changing conditions.

Natural Systems

Impacts of changing climate on marine, terrestrial, and freshwater ecosystems will have implications for Alaska's economy and subsistence communities. Changes in fisheries and forest resources, modes of travel, and the diversity and location of different plant and animal species have both beneficial and adverse impacts on natural systems and the services they provide.

Other Economic Activities

Changing climate may affect all sectors of Alaska's economy dependent on weather conditions and/or the natural environment or reliant on engineered infrastructure that is threatened by changes. This sector addresses their adaptation needs and also explores possibilities for new and/or expanding potential economic development created by a warming environment.

The adaptation component of Alaska's climate change strategy contains adaptation options designed to reduce the vulnerability of Alaska's natural and human systems to climatic changes and examine the potential growth of economic opportunities that might arise.

The *Arctic Climate Impact Assessment*, a comprehensive assessment conducted by hundreds of scientists and indigenous peoples, confirms that the Arctic is now experiencing some of the most rapid and severe climate changes on earth and is extremely vulnerable to both observed and projected climate change and its effects. To address the impacts of climate change on Alaska, Governor Sarah Palin signed Administrative

Order 238 on September 14, 2007, which established and charged the Alaska Climate Change Sub-Cabinet to advise the Office of the Governor on the preparation and implementation of a comprehensive Alaska Climate Change Strategy (AO 238). This document represents the recommendations of the Adaptation Advisory Group (AAG), which was charged with evaluating and developing options to adapt to climate change. The report also provides additional background on projected climate and impacts for Alaska.

The types of recommendations contained in this report vary. The options range from new systems approaches and institutional structures to adoption of new or revised policies, initiatives, and other actions. The Sub-Cabinet will consider these, as well as recommendations from the Immediate Action Work Group, the Mitigation Advisory Group, and the Research Needs Work Group in the context of other complementary efforts. A comprehensive Climate Change Strategy for Alaska will then be drafted for consideration by the Governor. While no one report or event can set a definitive course of action in the dynamic and uncertain set of circumstances created by a changing climate, the work of the Adaptation Advisory Group establishes a foundation from which to make progress towards improving our individual and societal ability to adapt.

Impacts on Human and Natural Systems in Alaska

Over the past three decades, Alaska has experienced a sharp reduction in snow-cover extent and duration, shorter river- and lake-ice seasons, melting of mountain glaciers, sea-ice retreat and thinning, permafrost retreat, and increased depth of summer thaw. These changes are in turn affecting human and natural systems. The AAG, with the support of four Technical Working Groups, has developed options to adapt to these changes, i.e., to reduce the adverse impacts or take advantage of the opportunities presented by climate change (see Box 1).

Permafrost Thawing and Sea Ice Melting

Permafrost underlies most of Alaska. Air temperature, snow cover, and vegetation affect the temperature of the frozen ground and the depth of seasonal thawing. Recent decades of warmer temperatures have produced extensive thawing, which has resulted in increased coastal erosion, landslides, and sinking of the ground surface, as well as consequent disruption and damage to forests, buildings, infrastructure, and coastal communities. In addition, many industrial activities depend on frozen ground surfaces, and many northern communities rely on ice roads for transport of groceries and other materials. Continued warming will further impair transport by shortening the seasonal use of ice roads. Thawing is projected to accelerate under future warming, with as much as the top 10 to 30 feet of discontinuous permafrost thawing by 2100.

Sea ice off the Alaskan Coast is retreating and thinning, with widespread effects on marine ecosystems, coastal climate, human settlements, and subsistence activities. Recent studies estimate arctic-wide reductions in annual average sea-ice extent of about 5-10% and a reduction in average thickness of about 10-15% over the past few decades. Retreat of sea ice allows larger storm surges to develop, increasing the risk of inundation and increasing erosion on coasts already made vulnerable by permafrost thawing. Loss of sea ice also causes large scale changes in marine ecosystems, and threatens populations of marine mammals and polar bears that depend on ice. At the same time, the continued reduction of sea ice is very likely to increase the navigation season, and within several decades a seasonal opening of the Northern Sea Route is likely to make trans-arctic shipping feasible during summer months, although increasing ice movement will initially make shipping more difficult in some channels of the Northwest Passage.

Threats to Coastal Communities, Habitats, and Infrastructure

Alaska has more coastline than the other 49 states combined. Increases in the frequency and intensity of storm surges have triggered increased coastal erosion that is threatening a number of coastal villages. A recent report from the Government Accountability Office (GAO) indicated that 31 villages face imminent threats. Storm surges have also reduced the protection that barrier islands and spits provide to coastal habitats. Both coastal and inland infrastructure face threats due to the climate change. Thawing permafrost threatens water and sanitation infrastructure, and roads, buildings, pipelines, power lines and other infrastructure are threatened by coastal erosion and degrading permafrost.

Forest and Vegetation Changes

The Arctic region, particularly Alaska, is already experiencing major ecological impacts as a consequence of warming. Rising temperatures have caused northward expansion of boreal forest in some areas, significant increases in fire frequency and intensity, and unprecedented insect outbreaks. Current projections suggest that, due to increases in burn area per decade, the tundra-dominated landscape on Seward Peninsula will eventually be replaced by deciduous forest. In other areas, forested areas are likely to convert to bogs as permafrost thaws. Growing-degree days have increased by 20%, with benefits for agriculture and forest productivity on some sites, and reduced growth on others.

Sensitivity of Marine Ecosystems and Fisheries

The Gulf of Alaska and Bering Sea support marine ecosystems of great diversity and productivity as well as the nation's largest commercial fishery. Perhaps one of the most daunting threats lies in increasing acidification of the cold Alaskan waters. This would affect all organisms that possess calcifying shells, and these organisms play an integral role in the food web. Recent climate-related impacts observed in the Bering Sea include significant reductions in seabird and marine mammal populations, unusual algal blooms, abnormally high water temperatures, and low harvests of salmon on their return to spawning areas. Future projections for the Bering Sea suggest productivity increases at the base of the food chain, poleward shifts of some cold-water species, and negative effects on ice-dwelling species. Warmer temperatures will also affect commercial fisheries by inducing large northward shifts of fish and shellfish species. This would result in decreased harvesting of cold-water species such as salmon and pollock, and increased harvesting of other species.

Changes In the Diversity, Ranges, and Distributions of Species

The Arctic sub-region that includes Alaska, Chukotka, and the Western Canadian Arctic is home to over 70 percent of the rare plant species that occur only in the Arctic and a number of plant and animal species already classified as "threatened." Species concentrated in small areas, such as Wrangell Island, are particularly vulnerable to the direct effects of climate change combined with competition from migrating non-native species.

Increased Stress on Subsistence Livelihoods and Lifestyles

Subsistence makes an important contribution to livelihood in many isolated rural communities, especially but not exclusively for native peoples. Livelihoods that sustain indigenous communities include hunting, trapping, gathering, and fishing. These activities not only make significant contributions to the diet and health of many indigenous populations, but also play large and important social and cultural roles. Reduced or displaced populations of marine mammals, seabirds, and other wildlife, together with continuing thinning of sea-ice, have affected the safety and the dietary and economic well-being of subsistence communities.

ALASKA'S APPROACH TO ADAPTATION: RECOMMENDED OPTIONS

Climate change presents both potential impacts and opportunities for Alaskans and the Alaska economy. Developing a viable set of policies and actions to adapt to climate change requires recognizing the decentralized nature of government decision making, and the role of all levels of government. Successful adaptation will require engaging not only governments, but also private business, communities and community leaders, and individual households. Developing information on climate and other information needed for adaptation and making this information accessible is key to enabling these public and private entities to take action. Finally, an adaptation strategy must recognize both the need for immediate action to address observed effects of climate change (in some cases) as well as the importance of developing a foundation of data, policies, and knowledge about adaptation strategies that will enable successful adaptation over the long term.

The options recommended by the AAG are summarized below. These are actions that the state of Alaska, sometimes in partnership or cooperation with other agencies or organizations, can take to adapt to climate change. The options include actions such as increased coordination within and outside the state, data collection or assessment, regulatory or programmatic changes, capacity building and education, capital improvements, and financial assistance. In some cases the options may require new institutions or new legislative authority, but in many cases they have been designed to build on existing programs and staff.

Public Infrastructure

These options address the observed and projected impacts of climate change on Alaska's infrastructure, and include priority adaptation actions that the State of Alaska should take to address the impacts and their associated vulnerabilities. Public infrastructure is defined to include essential facilities and utilities under public, cooperative, or private ownership that deliver goods and services to communities. Such infrastructure includes infrastructure related to road, air, water, and other transportation (ranging from highways to landing strips); public buildings; seawalls and river shoreline protection; power, water, communication, and other utilities and their supporting structures; and national defense infrastructure. The goal of these options is to develop a system that increases the likelihood that Alaska has sustainable infrastructure to support communities in an uncertain environment.

The options developed for public infrastructure are designed to address three critical problems. First, the vulnerability of, and risk to, public infrastructure is growing. In some locations, entire Alaskan villages are at immediate risk; in other locations, critical roads and public buildings are at risk. Second, adaptive capacity for existing infrastructure is low, so new construction provides an opportunity for adaptation. Most public infrastructure is hard and fixed (for example, roads and buildings) and cannot easily alter its alignment, elevations, or structural foundation to accommodate coastal erosion or increased flood risk. Third, increased communication and coordination is critical. Increased communication and coordination across agencies, communities, and scientific and applied researchers is needed to adapt Alaska's public infrastructure.

The AAG is recommending a systems approach to reduce the impacts of climate change on Alaska's public infrastructure by accomplishing actions under three policies/programs.

PI-1 Create a Coordinated and Accessible Statewide System for Key Data Collection, Analysis, and Monitoring

Baseline data on the condition of current infrastructure and on regional and local environmental conditions needs to be collected, so that decision makers can identify what the problems are and where they occur, and what approaches are and are not working. Decision making also requires that projections of climate and other

information be based on the best science and collected empirical data. The Environmental Atlas of Alaska should be updated. The resulting information needs to be available to all interested parties.

PI-2 Promote Improvements that Use the Current Best Practice

Managing the risks and/or reducing the uncertainties associated with climate change will take time. Promoting sustainability, reducing operating costs, and protecting/extending the service life of existing infrastructure is always worthwhile. Simultaneously with PI-1, improvements to existing infrastructure that are worth doing regardless of climate change effects should be undertaken.

PI-3 Build to Last; Build Resiliency into Alaska's Public Infrastructure

As PI-1 and PI-2 are enacted and our knowledge base expands, new and upgraded infrastructure needs to be sited, planned, designed, and built to be resilient and sustainable in an uncertain environment. Systematic feedback with a performance review and analysis needs to be integrated into the public infrastructure funding, development, construction, and operations, so that planners and builders use "what works" and codes and standards are assessed and improved as needed to achieve the best results.

Natural Systems

The Natural Systems sector addresses the observed and projected impacts of climate change on Alaska's ecosystems and the services they provide. The AAG recommends priority adaptation actions that the state of Alaska should take to address the impacts and vulnerabilities associated with these impacts. Key impacts for Alaska include:

- those on marine ecosystems in the seas around Alaska and the communities and industries reliant on marine-based fisheries;
- changes in terrestrial ecosystems and in species' diversity, ranges, distribution, and abundance, with consequences for forestry and subsistence harvest of fish and wildlife; and
- changes to freshwater ecosystems, with consequences for freshwater appropriates and for freshwater species and the people who access and harvest the fish and wildlife.

The goal of the options below is to sustain natural ecosystem services in Alaska that meet society's essential needs, through adaptation to changing environmental conditions.

The five adaptation options recommended for this sector are targeted to sustaining the natural ecosystem services that meet Alaska's essential needs for food, water, renewable resource economies, community stability and safety, and cultural well-being. The recommendations build on existing state authorities and programs, and will move Alaska forward substantially in its ability to adapt to climate change impacts. Implementation of these options will require leadership and policy direction, as well as a moderate investment in staffing and funding to complete priority tasks. Through this work, the State will take a major step forward in integrating adaptive management to long-term climate change into the State's resource management programs and practices, so that it becomes a way of doing business and not a suite of separate initiatives.

NS-1 Fisheries Management

This option incorporates climate change into fisheries assessment and management and assists fishing communities and users in adaptation. This option includes several key elements: (1) review of the state's fishing-related statutes; (2) a comprehensive assessment of existing habitat, fish species, and stock

monitoring programs; (3) development of a centralized source of information on climate effects; and (4) development of a long-term strategy to work with fishing-reliant communities and business.

NS-2 Wildland Fire

This option would review and modify as appropriate Alaska's wildland fire policy and programs to address potential climate-induced increases in wildland fire frequency, size, and geographic location. Key elements include: (1) increasing the capacity of communities to initiate, complete, and implement Community Wildfire Protection Plans (CWPP); (2) reviewing selected wildland fire management practices for lands in Alaska; and (3) developing a comprehensive fuels management program to treat high-risk areas.

NS-3 Freshwater Management

This option addresses the effects of climate change on Alaska's freshwater resources through adaptive management, supported by improved hydrologic data. This option includes data collection, coordination, and protection. It also includes a review and adjustment as necessary of water management laws, policies, and practices in order to improve adaptive capacity.

NS-4 Invasive and Eruptive Species

Under this option, the state would expand its efforts to be an active partner with all levels of government and with other entities in addressing the problem of invasive and eruptive species in Alaska. The goal is to reduce introduction and spread of invasive species and eruptive species in the context of climate change.

NS-5 Fish and Wildlife

Under this option, the state would improve its capability to manage fish and wildlife species adaptively in Alaska to assure sustainable management of these important resources. The option includes two specific actions: (1) develop and adopt a more timely regulatory process for the harvest of wildlife; and (2) develop a coordinating framework that documents existing fish and wildlife monitoring efforts, identifies priorities for monitoring, and identifies gaps and potential for collaboration.

NS-6 Sustainable Agriculture

Under this option, the state would support and expand sustainable agriculture production and marketing in Alaska. This option recognizes the importance of local agriculture to Alaska's food security and seeks to develop an Alaska food policy and strategic plan that increases reliance on locally produced agricultural products. The option includes three specific actions: (1) encourage community-based agriculture and practices that optimize the use of the land and resources available; (2) research the magnitude and composition of food consumption in the state; and (3) research the sources of food supply and the risk associated with high reliance on imported foods.

Other Economic Activities

Some of Alaska's major economic activities, such as tourism and shipping, are highly dependent on weather conditions and/or the natural environment, both of which can be significantly affected by climate change. Some activities, such as mining and oil and gas exploration, rely on engineered infrastructure that is also potentially affected by climate, weather, and underlying environmental conditions. At the same time, climate change could create economic development opportunities in existing and new sectors. The options developed for this sector identify adaptive actions and options that contribute to the ability of sectors of the Alaska

economy not directly supported by living systems (e.g., fishing) to adapt to the effects of climate change and ensure the sustainability of a robust Alaska economy.

The recommendations in this sector focus on broad issues relevant to the economy as a whole, rather than actions designed to address the concerns of a particular economic group or industry. Three options are recommended.

EA-1 Evaluate Capability Needs for Potential Expansion of Arctic Economic Activities

This option recommends that the State recognize and address the potential for increased Arctic economic activities and identify gaps in infrastructure and the ability to provide an adequate presence in the Arctic coastal region to protect environmental resources, human health, and safety.

EA-2 Develop and Evaluate Scenarios for the Alaskan Economy

Components of the Alaska economy will experience varying impacts due to potential effects of climate change. An assessment of economic strengths, weaknesses, opportunities, and threats by sector is needed to better understand current and potential future components of the economy. This understanding will aid state agencies and other stakeholders in identifying and acting on optimum adaptive strategies and policies to help address future conditions. This option recommends conducting and managing a project to develop and evaluate possible economic scenarios for the State, based on potential climate change effects.

EA-3 Improve Availability of Mapping, Surveying, Charting and Imagery Data

Accurate, timely information about the distribution and magnitude of changes is needed to better address economic challenges and opportunities. This option recommends improving the availability of data, specifically real-time mapping, digital elevation model, and imagery, to better track and understand the impacts of climate change. This option would build on the work of the Statewide Digital Mapping Initiative and aid in transitioning between locations at the water-land interface.

Health and Culture

Climate change is being linked to increases in the geographic range and incidence of certain infectious and non-infectious diseases, new problems in sanitation and solid waste management, contaminant exposures, and diseases related to diet as well as mental health. Current programs are insufficient to identify and control these changes. To protect the health of humans, domesticated animals, and wildlife from the effects of climate change in Alaska, existing programs and activities need to be augmented to address these emerging concerns by developing new methods for surveillance and reporting of human and animal diseases.

The goal of the options recommended for this sector is to Improve adaptive capacity to maintain human health and healthy ways of life, reduce current and likely future increases in disease due to a changing climate, and prevent the destruction of gravesites, archaeological sites, and historic sites due to accelerated coastal and river erosion. Four options are recommended.

HC-1 Augment Surveillance and Control Programs for Vector-, Water-, and Food-borne Diseases

This option augments surveillance and control programs for vector-, water-, and food-borne diseases likely to become greater threats because of climate change. In addition, it develop educational programs for the public, health care providers, environmental staff, and others on approaches to reduce emerging disease threats.

HC-2 Community Health Impact Evaluations

This option develops a tiered approach to evaluate recommended adaptation and mitigation options to determine whether they could result in adverse health impacts and, if so, recommends approaches to reduce these risks.

HC-3 Assess Sanitation and Infrastructure Risks from Climate Change

This option assesses sanitation infrastructure and practices at risk from flooding, thawing permafrost, and other risks, or that are otherwise subject to changing conditions that significantly reduce performance in environmental health protection. This option would consider modification, rebuilding, or relocation of sanitation infrastructure to protect human and environmental health.

HC-4 Assess, Protect, and Develop Plans for Archaeological Sites and Gravesites

In cooperation with appropriate local, regional, and statewide entities, the state would assess archaeological sites and gravesites at risk from accelerated coastal and river erosion; convene archaeologists, anthropologists, Alaska Native elders, and others to discuss how best to address and prioritize sites at risk; and develop a plan for the protection or recovery of important at-risk sites. This option would also assist in identifying and opening new gravesites; convening a respectful discussion about gravesites while exploring best practices; and providing assistance for the relocation of existing at-risk gravesites.

Common Themes

Across the sectors, a number of common themes emerge for types of actions that will be needed to assist Alaska in adapting to climate change. These themes include needs for improving access to data, for community assistance, for coordination, and for education. Most of these themes are as relevant to mitigation as they are to adaptation. The recommendations fill a variety of needs that will greatly assist Alaskan efforts to address and respond to climate change. Four options that represent common themes across the sectors were developed.

CT-1 Establish an Alaska Climate Change Knowledge Network

This option recommends establishing an Alaska Climate Change Knowledge Network (ACCKN) to provide an effective, collaborative means to manage data and foster its use for adaptation. Where appropriate, the ACCKN would organize, consolidate, integrate, and archive data, information, and knowledge related to climate change. The network would serve as a point of coordination for National Oceanic and Atmospheric Administration's (NOAA's) proposed Regional Climate Center in Alaska.

CT-2 Coordinate Implementation of Alaska's Efforts to Address Climate Change

This option recommends that Alaska's efforts to address climate change continue to be coordinated internally to ensure synergy among State agency efforts, unified and strategic interaction with federal agencies, and effective outreach and education.

CT-3 Community Climate Impact Assistance

An array of state, federal, and regional entities are responsible for delivering services to Alaskan villages, rural communities, and urban centers, but specific policies and regulatory constraints produce conflicting directives that prevent the coordinated delivery of vital services that will enable endangered villages, traditional culture, and vulnerable communities to adapt in the face of climate change. There is a need to establish a coordinating

entity with the ability to navigate these multiple bureaucracies and to leverage their resources to support vulnerable communities in emergency response, relocation, subsistence concerns, and other priorities.

CT-4 Promote Climate Change Science through K-12 Education

This option promotes development of curriculum and training to support climate change education in grades K-12.

Governor's Subcabinet on Climate Change Reports

Alaska's Climate Change Strategy: Addressing Impacts in Alaska
Executive Summary

INTRODUCTION

In Alaska, climate change has begun to touch almost every aspect of the natural world and the human systems that have evolved around, and rely on, a set of stable and predictable climatic conditions and seasons. It is a world where a warming environment has already begun to render ground and building foundations unstable, disrupt transportation routes, and trigger phenomena placing coastal communities in imminent danger from flooding and erosion. Impacts have resulted in myriad consequences to residents of the state, to subsistence livelihoods, to the wildlife and vegetation in Alaska's terrestrial and marine environments, and to the many industries that support the Alaskan economy.

While these changes are of critical import to Alaskans, they have also garnered attention of leaders in the United States and around the world. The primary driving force has been the accelerated retreat of Arctic sea ice, which has been a catalyst for multi-disciplinary planning and has underscored the need for increased domestic and international cooperation. A navigable Arctic Ocean presents opportunities for shipping and commerce in the Northwest Passage and has elevated interest in developing fisheries and mineral resources. Consequently, this creates a need for additional and improved weather and navigational tools, research to better understand and manage our strategic assets, and increased efforts to provide national, environmental, and economic security. Widespread interest in the Arctic has also been elevated by the important role that the Earth's polar region plays in influencing climate and oceans on a global scale. What happens in Alaska has far-reaching and long-lasting implications.

Box 1. Sectors Addressed by the AAG Report

Alaska's economy and the health and well-being of its residents will be affected by climate change. Key impacts being addressed include:

Public Infrastructure

Impacts of climate change on public, private, or cooperatively owned infrastructure for the public good including buildings, transportation, shoreline protection, water and sanitation systems, and defense facilities.

Health and Culture

Climatic changes and associated changes in natural systems are increasing the potential for health impacts from vector-, water-, and food-borne diseases and are beginning to cause stress on subsistence communities. Erosion, changes in permafrost, and extreme events are already impacting coastal communities, sanitation infrastructure, and archaeological sites and gravesites. Weather related injuries and detrimental effects on mental health have also been associated with rapidly changing conditions.

Natural Systems

Impacts of changing climate on marine, terrestrial, and freshwater ecosystems will have implications for Alaska's economy and subsistence communities. Changes in fisheries and forest resources, modes of travel, and the diversity and location of different plant and animal species have both beneficial and adverse impacts on natural systems and the services they provide.

Other Economic Activities

Changing climate may affect all sectors of Alaska's economy dependent on weather conditions and/or the natural environment or reliant on engineered infrastructure that is threatened by changes. This sector addresses their adaptation needs and also explores possibilities for new and/or expanding potential economic development created by a warming environment.

The adaptation component of Alaska's climate change strategy contains adaptation options designed to reduce the vulnerability of Alaska's natural and human systems to climatic changes and examine the potential growth of economic opportunities that might arise.

The *Arctic Climate Impact Assessment*, a comprehensive assessment conducted by hundreds of scientists and indigenous peoples, confirms that the Arctic is now experiencing some of the most rapid and severe climate changes on earth and is extremely vulnerable to both observed and projected climate change and its effects. To address the impacts of climate change on Alaska, Governor Sarah Palin signed Administrative

Order 238 on September 14, 2007, which established and charged the Alaska Climate Change Sub-Cabinet to advise the Office of the Governor on the preparation and implementation of a comprehensive Alaska Climate Change Strategy (AO 238). This document represents the recommendations of the Adaptation Advisory Group (AAG), which was charged with evaluating and developing options to adapt to climate change. The report also provides additional background on projected climate and impacts for Alaska.

The types of recommendations contained in this report vary. The options range from new systems approaches and institutional structures to adoption of new or revised policies, initiatives, and other actions. The Sub-Cabinet will consider these, as well as recommendations from the Immediate Action Work Group, the Mitigation Advisory Group, and the Research Needs Work Group in the context of other complementary efforts. A comprehensive Climate Change Strategy for Alaska will then be drafted for consideration by the Governor. While no one report or event can set a definitive course of action in the dynamic and uncertain set of circumstances created by a changing climate, the work of the Adaptation Advisory Group establishes a foundation from which to make progress towards improving our individual and societal ability to adapt.

IMPACTS ON HUMAN AND NATURAL SYSTEMS IN ALASKA

Over the past three decades, Alaska has experienced a sharp reduction in snow-cover extent and duration, shorter river- and lake-ice seasons, melting of mountain glaciers, sea-ice retreat and thinning, permafrost retreat, and increased depth of summer thaw. These changes are in turn affecting human and natural systems. The AAG, with the support of four Technical Working Groups, has developed options to adapt to these changes, i.e., to reduce the adverse impacts or take advantage of the opportunities presented by climate change (see Box 1).

Permafrost Thawing and Sea Ice Melting

Permafrost underlies most of Alaska. Air temperature, snow cover, and vegetation affect the temperature of the frozen ground and the depth of seasonal thawing. Recent decades of warmer temperatures have produced extensive thawing, which has resulted in increased coastal erosion, landslides, and sinking of the ground surface, as well as consequent disruption and damage to forests, buildings, infrastructure, and coastal communities. In addition, many industrial activities depend on frozen ground surfaces, and many northern communities rely on ice roads for transport of groceries and other materials. Continued warming will further impair transport by shortening the seasonal use of ice roads. Thawing is projected to accelerate under future warming, with as much as the top 10 to 30 feet of discontinuous permafrost thawing by 2100.

Sea ice off the Alaskan Coast is retreating and thinning, with widespread effects on marine ecosystems, coastal climate, human settlements, and subsistence activities. Recent studies estimate arctic-wide reductions in annual average sea-ice extent of about 5-10% and a reduction in average thickness of about 10-15% over the past few decades. Retreat of sea ice allows larger storm surges to develop, increasing the risk of inundation and increasing erosion on coasts already made vulnerable by permafrost thawing. Loss of sea ice also causes large scale changes in marine ecosystems, and threatens populations of marine mammals and polar bears that depend on ice. At the same time, the continued reduction of sea ice is very likely to increase the navigation season, and within several decades a seasonal opening of the Northern Sea Route is likely to make trans-arctic shipping feasible during summer months, although increasing ice movement will initially make shipping more difficult in some channels of the Northwest Passage.

Threats to Coastal Communities, Habitats, and Infrastructure

Alaska has more coastline than the other 49 states combined. Increases in the frequency and intensity of storm surges have triggered increased coastal erosion that is threatening a number of coastal villages. A recent report from the Government Accountability Office (GAO) indicated that 31 villages face imminent threats. Storm surges have also reduced the protection that barrier islands and spits provide to coastal habitats. Both coastal and inland infrastructure face threats due to the climate change. Thawing permafrost threatens water and sanitation infrastructure, and roads, buildings, pipelines, power lines and other infrastructure are threatened by coastal erosion and degrading permafrost.

Forest and Vegetation Changes

The Arctic region, particularly Alaska, is already experiencing major ecological impacts as a consequence of warming. Rising temperatures have caused northward expansion of boreal forest in some areas, significant increases in fire frequency and intensity, and unprecedented insect outbreaks. Current projections suggest that, due to increases in burn area per decade, the tundra-dominated landscape on Seward Peninsula will eventually be replaced by deciduous forest. In other areas, forested areas are likely to convert to bogs as permafrost thaws. Growing-degree days have increased by 20%, with benefits for agriculture and forest productivity on some sites, and reduced growth on others.

Sensitivity of Marine Ecosystems and Fisheries

The Gulf of Alaska and Bering Sea support marine ecosystems of great diversity and productivity as well as the nation's largest commercial fishery. Perhaps one of the most daunting threats lies in increasing acidification of the cold Alaskan waters. This would affect all organisms that possess calcifying shells, and these organisms play an integral role in the food web. Recent climate-related impacts observed in the Bering Sea include significant reductions in seabird and marine mammal populations, unusual algal blooms, abnormally high water temperatures, and low harvests of salmon on their return to spawning areas. Future projections for the Bering Sea suggest productivity increases at the base of the food chain, poleward shifts of some cold-water species, and negative effects on ice-dwelling species. Warmer temperatures will also affect commercial fisheries by inducing large northward shifts of fish and shellfish species. This would result in decreased harvesting of cold-water species such as salmon and pollock, and increased harvesting of other species.

Changes In the Diversity, Ranges, and Distributions of Species

The Arctic sub-region that includes Alaska, Chukotka, and the Western Canadian Arctic is home to over 70 percent of the rare plant species that occur only in the Arctic and a number of plant and animal species already classified as "threatened." Species concentrated in small areas, such as Wrangell Island, are particularly vulnerable to the direct effects of climate change combined with competition from migrating non-native species.

Increased Stress on Subsistence Livelihoods and Lifestyles

Subsistence makes an important contribution to livelihood in many isolated rural communities, especially but not exclusively for native peoples. Livelihoods that sustain indigenous communities include hunting, trapping, gathering, and fishing. These activities not only make significant contributions to the diet and health of many indigenous populations, but also play large and important social and cultural roles. Reduced or displaced populations of marine mammals, seabirds, and other wildlife, together with continuing thinning of sea-ice, have affected the safety and the dietary and economic well-being of subsistence communities.

ALASKA'S APPROACH TO ADAPTATION: RECOMMENDED OPTIONS

Climate change presents both potential impacts and opportunities for Alaskans and the Alaska economy. Developing a viable set of policies and actions to adapt to climate change requires recognizing the decentralized nature of government decision making, and the role of all levels of government. Successful adaptation will require engaging not only governments, but also private business, communities and community leaders, and individual households. Developing information on climate and other information needed for adaptation and making this information accessible is key to enabling these public and private entities to take action. Finally, an adaptation strategy must recognize both the need for immediate action to address observed effects of climate change (in some cases) as well as the importance of developing a foundation of data, policies, and knowledge about adaptation strategies that will enable successful adaptation over the long term.

The options recommended by the AAG are summarized below. These are actions that the state of Alaska, sometimes in partnership or cooperation with other agencies or organizations, can take to adapt to climate change. The options include actions such as increased coordination within and outside the state, data collection or assessment, regulatory or programmatic changes, capacity building and education, capital improvements, and financial assistance. In some cases the options may require new institutions or new legislative authority, but in many cases they have been designed to build on existing programs and staff.

Public Infrastructure

These options address the observed and projected impacts of climate change on Alaska's infrastructure, and include priority adaptation actions that the State of Alaska should take to address the impacts and their associated vulnerabilities. Public infrastructure is defined to include essential facilities and utilities under public, cooperative, or private ownership that deliver goods and services to communities. Such infrastructure includes infrastructure related to road, air, water, and other transportation (ranging from highways to landing strips); public buildings; seawalls and river shoreline protection; power, water, communication, and other utilities and their supporting structures; and national defense infrastructure. The goal of these options is to develop a system that increases the likelihood that Alaska has sustainable infrastructure to support communities in an uncertain environment.

The options developed for public infrastructure are designed to address three critical problems. First, the vulnerability of, and risk to, public infrastructure is growing. In some locations, entire Alaskan villages are at immediate risk; in other locations, critical roads and public buildings are at risk. Second, adaptive capacity for existing infrastructure is low, so new construction provides an opportunity for adaptation. Most public infrastructure is hard and fixed (for example, roads and buildings) and cannot easily alter its alignment, elevations, or structural foundation to accommodate coastal erosion or increased flood risk. Third, increased communication and coordination is critical. Increased communication and coordination across agencies, communities, and scientific and applied researchers is needed to adapt Alaska's public infrastructure.

The AAG is recommending a systems approach to reduce the impacts of climate change on Alaska's public infrastructure by accomplishing actions under three policies/programs.

PI-1 Create a Coordinated and Accessible Statewide System for Key Data Collection, Analysis, and Monitoring

Baseline data on the condition of current infrastructure and on regional and local environmental conditions needs to be collected, so that decision makers can identify what the problems are and where they occur, and what approaches are and are not working. Decision making also requires that projections of climate and other

information be based on the best science and collected empirical data. The Environmental Atlas of Alaska should be updated. The resulting information needs to be available to all interested parties.

PI-2 Promote Improvements that Use the Current Best Practice

Managing the risks and/or reducing the uncertainties associated with climate change will take time. Promoting sustainability, reducing operating costs, and protecting/extending the service life of existing infrastructure is always worthwhile. Simultaneously with PI-1, improvements to existing infrastructure that are worth doing regardless of climate change effects should be undertaken.

PI-3 Build to Last; Build Resiliency into Alaska's Public Infrastructure

As PI-1 and PI-2 are enacted and our knowledge base expands, new and upgraded infrastructure needs to be sited, planned, designed, and built to be resilient and sustainable in an uncertain environment. Systematic feedback with a performance review and analysis needs to be integrated into the public infrastructure funding, development, construction, and operations, so that planners and builders use "what works" and codes and standards are assessed and improved as needed to achieve the best results.

Natural Systems

The Natural Systems sector addresses the observed and projected impacts of climate change on Alaska's ecosystems and the services they provide. The AAG recommends priority adaptation actions that the state of Alaska should take to address the impacts and vulnerabilities associated with these impacts. Key impacts for Alaska include:

- those on marine ecosystems in the seas around Alaska and the communities and industries reliant on marine-based fisheries;
- changes in terrestrial ecosystems and in species' diversity, ranges, distribution, and abundance, with consequences for forestry and subsistence harvest of fish and wildlife; and
- changes to freshwater ecosystems, with consequences for freshwater appropriates and for freshwater species and the people who access and harvest the fish and wildlife.

The goal of the options below is to sustain natural ecosystem services in Alaska that meet society's essential needs, through adaptation to changing environmental conditions.

The five adaptation options recommended for this sector are targeted to sustaining the natural ecosystem services that meet Alaska's essential needs for food, water, renewable resource economies, community stability and safety, and cultural well-being. The recommendations build on existing state authorities and programs, and will move Alaska forward substantially in its ability to adapt to climate change impacts. Implementation of these options will require leadership and policy direction, as well as a moderate investment in staffing and funding to complete priority tasks. Through this work, the State will take a major step forward in integrating adaptive management to long-term climate change into the State's resource management programs and practices, so that it becomes a way of doing business and not a suite of separate initiatives.

NS-1 Fisheries Management

This option incorporates climate change into fisheries assessment and management and assists fishing communities and users in adaptation. This option includes several key elements: (1) review of the state's fishing-related statutes; (2) a comprehensive assessment of existing habitat, fish species, and stock

monitoring programs; (3) development of a centralized source of information on climate effects; and (4) development of a long-term strategy to work with fishing-reliant communities and business.

NS-2 Wildland Fire

This option would review and modify as appropriate Alaska's wildland fire policy and programs to address potential climate-induced increases in wildland fire frequency, size, and geographic location. Key elements include: (1) increasing the capacity of communities to initiate, complete, and implement Community Wildfire Protection Plans (CWPP); (2) reviewing selected wildland fire management practices for lands in Alaska; and (3) developing a comprehensive fuels management program to treat high-risk areas.

NS-3 Freshwater Management

This option addresses the effects of climate change on Alaska's freshwater resources through adaptive management, supported by improved hydrologic data. This option includes data collection, coordination, and protection. It also includes a review and adjustment as necessary of water management laws, policies, and practices in order to improve adaptive capacity.

NS-4 Invasive and Eruptive Species

Under this option, the state would expand its efforts to be an active partner with all levels of government and with other entities in addressing the problem of invasive and eruptive species in Alaska. The goal is to reduce introduction and spread of invasive species and eruptive species in the context of climate change.

NS-5 Fish and Wildlife

Under this option, the state would improve its capability to manage fish and wildlife species adaptively in Alaska to assure sustainable management of these important resources. The option includes two specific actions: (1) develop and adopt a more timely regulatory process for the harvest of wildlife; and (2) develop a coordinating framework that documents existing fish and wildlife monitoring efforts, identifies priorities for monitoring, and identifies gaps and potential for collaboration.

NS-6 Sustainable Agriculture

Under this option, the state would support and expand sustainable agriculture production and marketing in Alaska. This option recognizes the importance of local agriculture to Alaska's food security and seeks to develop an Alaska food policy and strategic plan that increases reliance on locally produced agricultural products. The option includes three specific actions: (1) encourage community-based agriculture and practices that optimize the use of the land and resources available; (2) research the magnitude and composition of food consumption in the state; and (3) research the sources of food supply and the risk associated with high reliance on imported foods.

Other Economic Activities

Some of Alaska's major economic activities, such as tourism and shipping, are highly dependent on weather conditions and/or the natural environment, both of which can be significantly affected by climate change. Some activities, such as mining and oil and gas exploration, rely on engineered infrastructure that is also potentially affected by climate, weather, and underlying environmental conditions. At the same time, climate change could create economic development opportunities in existing and new sectors. The options developed for this sector identify adaptive actions and options that contribute to the ability of sectors of the Alaska

economy not directly supported by living systems (e.g., fishing) to adapt to the effects of climate change and ensure the sustainability of a robust Alaska economy.

The recommendations in this sector focus on broad issues relevant to the economy as a whole, rather than actions designed to address the concerns of a particular economic group or industry. Three options are recommended.

EA-1 Evaluate Capability Needs for Potential Expansion of Arctic Economic Activities

This option recommends that the State recognize and address the potential for increased Arctic economic activities and identify gaps in infrastructure and the ability to provide an adequate presence in the Arctic coastal region to protect environmental resources, human health, and safety.

EA-2 Develop and Evaluate Scenarios for the Alaskan Economy

Components of the Alaska economy will experience varying impacts due to potential effects of climate change. An assessment of economic strengths, weaknesses, opportunities, and threats by sector is needed to better understand current and potential future components of the economy. This understanding will aid state agencies and other stakeholders in identifying and acting on optimum adaptive strategies and policies to help address future conditions. This option recommends conducting and managing a project to develop and evaluate possible economic scenarios for the State, based on potential climate change effects.

EA-3 Improve Availability of Mapping, Surveying, Charting and Imagery Data

Accurate, timely information about the distribution and magnitude of changes is needed to better address economic challenges and opportunities. This option recommends improving the availability of data, specifically real-time mapping, digital elevation model, and imagery, to better track and understand the impacts of climate change. This option would build on the work of the Statewide Digital Mapping Initiative and aid in transitioning between locations at the water-land interface.

Health and Culture

Climate change is being linked to increases in the geographic range and incidence of certain infectious and non-infectious diseases, new problems in sanitation and solid waste management, contaminant exposures, and diseases related to diet as well as mental health. Current programs are insufficient to identify and control these changes. To protect the health of humans, domesticated animals, and wildlife from the effects of climate change in Alaska, existing programs and activities need to be augmented to address these emerging concerns by developing new methods for surveillance and reporting of human and animal diseases.

The goal of the options recommended for this sector is to Improve adaptive capacity to maintain human health and healthy ways of life, reduce current and likely future increases in disease due to a changing climate, and prevent the destruction of gravesites, archaeological sites, and historic sites due to accelerated coastal and river erosion. Four options are recommended.

HC-1 Augment Surveillance and Control Programs for Vector-, Water-, and Food-borne Diseases

This option augments surveillance and control programs for vector-, water-, and food-borne diseases likely to become greater threats because of climate change. In addition, it develop educational programs for the public, health care providers, environmental staff, and others on approaches to reduce emerging disease threats.

HC-2 Community Health Impact Evaluations

This option develops a tiered approach to evaluate recommended adaptation and mitigation options to determine whether they could result in adverse health impacts and, if so, recommends approaches to reduce these risks.

HC-3 Assess Sanitation and Infrastructure Risks from Climate Change

This option assesses sanitation infrastructure and practices at risk from flooding, thawing permafrost, and other risks, or that are otherwise subject to changing conditions that significantly reduce performance in environmental health protection. This option would consider modification, rebuilding, or relocation of sanitation infrastructure to protect human and environmental health.

HC-4 Assess, Protect, and Develop Plans for Archaeological Sites and Gravesites

In cooperation with appropriate local, regional, and statewide entities, the state would assess archaeological sites and gravesites at risk from accelerated coastal and river erosion; convene archaeologists, anthropologists, Alaska Native elders, and others to discuss how best to address and prioritize sites at risk; and develop a plan for the protection or recovery of important at-risk sites. This option would also assist in identifying and opening new gravesites; convening a respectful discussion about gravesites while exploring best practices; and providing assistance for the relocation of existing at-risk gravesites.

Common Themes

Across the sectors, a number of common themes emerge for types of actions that will be needed to assist Alaska in adapting to climate change. These themes include needs for improving access to data, for community assistance, for coordination, and for education. Most of these themes are as relevant to mitigation as they are to adaptation. The recommendations fill a variety of needs that will greatly assist Alaskan efforts to address and respond to climate change. Four options that represent common themes across the sectors were developed.

CT-1 Establish an Alaska Climate Change Knowledge Network

This option recommends establishing an Alaska Climate Change Knowledge Network (ACCKN) to provide an effective, collaborative means to manage data and foster its use for adaptation. Where appropriate, the ACCKN would organize, consolidate, integrate, and archive data, information, and knowledge related to climate change. The network would serve as a point of coordination for National Oceanic and Atmospheric Administration's (NOAA's) proposed Regional Climate Center in Alaska.

CT-2 Coordinate Implementation of Alaska's Efforts to Address Climate Change

This option recommends that Alaska's efforts to address climate change continue to be coordinated internally to ensure synergy among State agency efforts, unified and strategic interaction with federal agencies, and effective outreach and education.

CT-3 Community Climate Impact Assistance

An array of state, federal, and regional entities are responsible for delivering services to Alaskan villages, rural communities, and urban centers, but specific policies and regulatory constraints produce conflicting directives that prevent the coordinated delivery of vital services that will enable endangered villages, traditional culture, and vulnerable communities to adapt in the face of climate change. There is a need to establish a coordinating

entity with the ability to navigate these multiple bureaucracies and to leverage their resources to support vulnerable communities in emergency response, relocation, subsistence concerns, and other priorities.

CT-4 Promote Climate Change Science through K-12 Education

This option promotes development of curriculum and training to support climate change education in grades K-12.

IMMEDIATE ACTION WORKGROUP

RECOMMENDATIONS TO THE GOVERNOR'S SUBCABINET ON CLIMATE CHANGE

MARCH 2009

THIS PAGE IS INTENTIONALLY BLANK

Commissioner Hartig and Members of the Governor's Subcabinet on Climate Change:

The Immediate Action Workgroup (IAWG) is pleased to provide its recommendations regarding the actions and policies that we believe should be implemented in 2009 and 2010. This is the second report provided to the Climate Change Subcabinet and follows up on recommendations and actions taken as a result of our April 17, 2008 report to the Subcabinet.

The IAWG has continued at the request of Commissioner Hartig, chairman of the Climate Change Subcabinet, to collaboratively examine the needs of communities that are under imminent threat from conditions that may be attributed to climate change phenomena.

The membership of the Immediate Action Workgroup has remained consistent from the previous year with one exception. Added to the IAWG is a representative from the National Oceanic and Atmospheric Administration, Amy Holman, Lead for NOAA's Alaska Regional Collaboration Team. Her participation has contributed greatly to our understanding of the data and research that is needed in the near future. The IAWG would likely benefit from additional agency participation. The spirit of cooperation and serious collaboration has infused our meetings and we believe resulted in meritorious recommendations for near-term actions by the Subcabinet and the State of Alaska.

Last year we described our recommendations in terms of a *recipe for success*. The members and others participating with the Immediate Action Workgroup have now worked together for over a year, both directly on the Immediate Action Workgroup's tasks and on leveraging resources and ideas resulting from the Workgroup's collaboration. From this experience, we are more certain about the value of this *recipe for success.* The ingredients are a diversity of resources. The recipe brings together organizations to address climate change issues and impacts. Therefore, we wish to repeat the recipe originally stated in last year's report.

Immediate Action Workgroup's Recipe for Success

Step 1: ***Begin by developing a collaborative organizational structure that can focus the combined capabilities of local, regional, state, and federal stakeholders on the problems at hand.*** Identify what expertise is available; which organization has the authority, capability, and potential funding to lead the combined effort; and, identify where functional gaps exist that need to be filled. Local communities severely affected by impacts most likely from climate change should be encouraged to establish a project coordinator position to interact with all other organizations and be an advocate for funding through grants and other means to implement needed evaluations and action plans.

Team work is essential. Relying on one agency to carry out the mission risks both waste and lack of action. These problems, which primarily affect small, isolated communities are difficult to address and because of this are easily ignored. Only through continual focus and intelligent decision making can we adequately address their problems.

Step 2: ***Discuss the nature and extent of the potential climate change impacts and create an applied approach to addressing significant impacts, as described in Step 3.*** A scenario analysis could compare community impacts with the full range of plausible future conditions (minor sea level rise to significant rise this century, continuation of historical storms to increased intensity of storms, gradual thawing of permafrost to quick melt of permafrost, historical trend of subsistence species populations to reduced availability of subsistence resources, etc.).

Step 3: ***Identify the communities at risk, timeframe, and the true needs to address climate change impacts.*** Once, communities at risk are identified and the timeframe established before major damages/losses occur, recognize that communities in jeopardy under all plausible scenarios warrant special consideration. ***Develop a methodology for prioritization of needs based on the risk to lives, health, infrastructure, homes, businesses, subsistence harvests, significant cultural attributes, and the quality of life.*** Villages with declining populations, which already cannot support continuation of vital services such as a school, would likely be a lower priority than those which are likely to sustain viable communities during the foreseeable future.

Next, determine the true needs of coastal communities subjected climate change impacts. Do they require additional land for population growth; are coastal storm damages increasing to potentially catastrophic levels; is melting permafrost destroying the foundation for structures in the community; will sufficient numbers of future subsistence resources be available to sustain the community at its current location; when will key facilities (airport, power, school, water supply, etc.) be lost so the community could not continue to function with dignity; and, is the community frequently needing emergency declarations to cope with disasters and impending disasters?

Step 4: ***Develop measures that meet the stated needs and combine those measures into alternative plans for comparison.*** Document the pros and cons of each alternative, obtain local input on community values, evaluate the environmental effects of each plan, and provide estimated costs for implementing each alternative. Determine the challenges of concurrent budgeting and meeting regulatory requirements where a collaborative effort with other agencies and organizations is proposed to implement the alternatives. Select the plan that provides the best overall balance to meet local needs and is cost effective, sustainable, engineered soundly, and environmentally acceptable. Above all, be action oriented and recognize that communities need immediate action to address what is in some cases inevitable, severe impact to infrastructure and community well being.

NEAR TERM FOCUS FOR IMMEDIATE ACTION WORKGROUP

The Immediate Action Workgroup of the Governor's Executive Subcabinet on Climate Change was established to address known threats to communities caused by coastal erosion, thawing permafrost, flooding, and fires.

Objective: Close a planning and execution gap identified by Governor Palin and the Congressional delegation by creating a unifying mechanism to assist the communities of Newtok, Shishmaref, Kivalina, Koyukuk, Unalakleet, and Shaktoolik[1]. These communities face imminent threats of loss of life, loss of infrastructure, loss of public and private property, or health epidemics caused by coastal erosion, thawing permafrost and flooding.

Plan of Action: The Immediate Action Workgroup will do the following:

- ***Conduct Workgroup meetings involving community leaders from the threatened villages to build a common understanding of the relative risks*** in each community using the following four criteria which individually or collectively create an urgent situation:
  - Safety of life during a reasonably foreseeable storm or flood event;
  - Potential loss of infrastructure critical for community viability (school, fuel tanks, power plant, water / sewer provisions);
  - Health threats to the community as defined by CDC or the Health Department (disease, reoccurring illnesses, unusually high frequency of illnesses); and
  - Potential loss of 10 percent or more of residential dwellings.
- ***Prioritize projects or actions to mitigate the community's most urgent risks*** through protecting or relocating threatened buildings and structures, affecting an emergency evacuation plan, or to address present or imminent health threats.
- ***Prepare recommendations for an oversight planning body and its authorities to provide successful coordination between each of these communities and all appropriate state and federal agencies*** to ensure the successful completion of projects or other actions identified by this effort.
- ***If warranted, make recommendations on the scope of additional assessments of protective seawall designs for the purpose of examining whether particular engineering designs may be successful*** in 1) providing a window to protect a community, enabling it to develop a multi-year relocation plan; or 2) provide long-term protection of the community such that a relocation may not be necessary in the foreseeable future.
- ***Identify and propose changes to laws and policies*** (state and federal) ***that currently impede the ability of agencies to timely execute appropriate actions*** necessary for imminent threat circumstances in these and other communities.

---

[1] The IAWG used the GAO 2004 report, which identified 9 highly threatened communities (Shishmaref, Newtok, Kivalina, Koyukuk, Unalakleet, Barrow, Bethel, Kaktovik, and Point Hope) to initially examine the nature of imminent threats at its November 6, 2007 meeting. Based upon the November 6 meeting and a November 19 / 20, 2007 Roundtable meeting conducted by then Senator Stevens, the IAWG focused its work with the communities of Shishmaref, Newtok, Kivalina, Koyukuk, Unalakleet and Shaktoolik.

EXECUTIVE SUMMARY
IMMEDIATE ACTION WORKGROUP:
ACCOMPLISHMENTS AND RECOMMENDATIONS

This executive summary is a consolidated list of Accomplishments, Immediate Actions and required Strategic and Community Assistance Recommendation Policies and budget estimates developed by the Immediate Action Workgroup of the Governor's Alaska Climate Change Subcabinet. The policies have been expanded from last year's report to help identify a strategic approach for addressing climate change, which has a likelihood of impacting every community in Alaska. The policies have also been detailed by adding definitions and interpreting the meanings of terms used in various policy statements.

These collective recommendations represent an intensive collaborative effort undertaken in an open public forum to address the immediate needs of the State, with a specific focus on six communities in peril: Newtok, Shishmaref, Kivalina, Koyukuk, Unalakleet, and Shaktoolik. We have attempted to expand our focus beyond the six communities originally accepted as imminently threatened last year, and have determined the likelihood that additional communities are in need of assistance in coping with similar problems.

These recommendations will help the Subcabinet develop a State Climate Change Strategy. This executive summary can be used as a reference point, but should be read within the context of the entire report, which summarizes the state of the six communities in peril, immediate and near-term actions to protect them, along with the policies and implementation recommendations and accompanying rationale.

These immediate actions combined with the policy recommendations were developed to serve as a template and model to assist other Alaska communities in an effective manner as they may become or are impacted by erosion and other natural hazards that seem to be increasing in number and severity.

Detailed community descriptions can be found in the Community Profiles section beginning on page 13.

ACCOMPLISHMENTS OF IMMEDIATE ACTION WORKGROUP: FY 08 SUPPLEMENTAL AND FY09 FUNDING

The IAWG brings an important element to the State's response to the changing Arctic. Unlike other workgroups, the IAWG is tasked with advising the Governor's Climate Change Subcabinet and the Legislature on what actions are needed in the next 12 – 18 months to prevent disasters that would likely result in loss of human life and infrastructure. These potential disasters are most likely to impact small, remote villages and are easiest to see from that community level.

The IAWG was started under the leadership of Commissioner Hartig as a way to initiate actions without awaiting a lengthy planning and analysis phase by recognizing actions to be taken now, to minimize impacts affecting these remote communities sitting on the edge of the changing environment.

The IAWG used several tools:

- A very preliminary list of the most impacted communities;
- A mission given by Commissioner Hartig;
- A small group of relevant and focused agencies;
- A determination to do something as we all agreed something was worth doing;
- An invitation to the communities and others to participate in identifying the solutions through local initiatives, ideas and effort; and
- Recognition of fiscal realities.

The process employed was innovative and included:

- Meetings every two weeks;
- Focus on only 6 communities identified as imminently threatened;
- Identify actions that were needed to prevent loss of life and infrastructure;
- Determine resources – funding, information and coordination – needed to advance those actions;
- Recommend to Legislature and Administrative decision makers to take actions by applying resources to the most immediate needs;
- Learn lessons from the IAWG's experiences;
- Incorporate and encourage local initiatives;
- Keep focused and invite collaboration;
- Demonstrate results; and
- Don't foreclose options if at all possible.

The key messages the IAWG would like to convey to the Subcabinet are:

- The IAWG has been successful. This success is largely due to leveraging the State's resources through coordination and collaboration with other State and Federal agencies, and with regional and community organizations.(See Accomplishments section page 27.

- The IAWG has not addressed or decided whether a community should relocate, as that is not within the authorization of the Workgroup and for each community, it is an issue that needs data, analysis and substantial coordination that is well beyond the IAWG's scope.

  IAWG Guiding Principle: *Immediate actions should preserve the widest range of options available to communities. To do this substantial coordination is needed to identify, collect and analyze data to make the most effective decisions for long-term viability and sustainability.*

- The IAWG has not defined nor relied on definitions of what climate change is, but rather has identified phenomena from which communities are being threatened and impacted. The likelihood these phenomena are from climate change is believed to be high.

The key findings from the 2009 IAWG's efforts are:

- **Immediate recommended actions are to protect what we have** – including infrastructure and human life.

- Replace the IAWG, which is an ad-hoc body, with a formal, standing committee or workgroup embedded in the State's administrative operations. This will ensure continued success of leveraging the State's resources through coordination and collaboration with other State and Federal agencies, and with regional and community organizations.

- Many potentially affected communities have been identified (See Appendix A). This requires an analysis process to determine the seriousness of the potential impact and to then act in a methodical fashion to prevent loss of life and infrastructure and protect what is already in place. (See Policies 1 -4)

- Construction standards have long been to build bigger and stronger, but building resilient structures that can be relocated may be the more important principle to successfully meet the challenges that climate change brings.

Summary of Accomplishments for Kivalina, Koyukuk, Newtok, Shaktoolik, Shishmaref and Unalakleet

Develop Suite of Emergency Plans and Training/Drills ($500,000 State leveraged $100,000 Federal)

State resources were provided to the Alaska DHS&EM to work jointly with each community and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion. All community efforts are underway.

Funding was also provided to DNR/Division of Forestry for a Community Wildfire Protection Plan (CWPP) for Koyukuk, which will be accomplished by Division of Forestry in conjunction with the community, Tanana Chiefs Conference, Inc. and the Alaska Fire Service.

Anticipated Completion of Suite of Emergency Plans for All Six Communities - Calendar Year End 2009.

In addition, DHS&EM, based on its efforts from 2008 -09, has developed a sub-regional approach to create, train and conduct community drills for the suite of emergency management plans. It is now anticipated that this sub-

regional approach will reduce the cost by almost half of the initial appropriation in FY09. DHS&EM will focus its efforts on the Y-K Delta, Western and Northern Regions of Alaska.

Community Mitigation and Relocation Planning and Coordination

DCCED/DCRA staff is working with local governments, whether City, Tribes or both in each of the communities to develop proposals for the community planning grants that addresses both the IAWG's recommended immediate actions for the communities, while striving to incorporate each of their specific needs.

- **Kivalina** – community planning needs to work through issues given that the Community has identified a site it wishes to move to, but that the USACE does not believe is an adequate site, e.g. it is underlain with permafrost which would require many feet of fill material to provide a good foundation for buildings and insulate the permafrost from thawing under the new village location.
- **Koyukuk** – community planning needs to work through confusion in the community and among agencies about what the options for the current community site are if relocation does occur. The community will also likely benefit from a planning effort that considers the three primary options communities have: staying in place -and what structural changes would need to happen to make that possible, migrating – having access to higher elevations of land and what infrastructure is needed to provide that opportunity so that when both private and public decisions are made options exist to ensure safety for both the investment and community members and if necessary – relocating, which is a longer-term, complex effort.
- **Newtok** – through the collaborative efforts of the Newtok Planning Group – which is a model for local community, state and federal partnerships to address complex issues – the community planning efforts have enabled the community to advance its already innovative successes by utilizing planning funds for:
  - The design of an evacuation shelter at Mertarvik as the Newtok Traditional Council hired the Cold Climate Housing Center;
  - Planning resources to conduct site suitability analysis and future community layout at the identified new community site of Mertarvik.
- **Shaktoolik** – community planning needs to address this community's highest threats, which is its precarious location when sea surges occur. The surges result in the community becoming an island, and then it is doubly threatened by storms throwing logs that are naturally beached on the shore at Shaktoolik. During this past year a reconnaissance study for an evacuation road was completed through the joint cooperative effort of the Shaktoolik community, Kawerak, and the Denali Commission. The State is being requested to fund $500k, for a road design. Development of an evacuation shelter within the existing community is also being considered as a cost effective and near-term action
- **Shishmaref** – community planning needs to coordinate with the various organizations to effectively plan for the needs of an entire community. Here too, Shishmaref will likely benefit from a planning effort that considers the three primary options communities have: staying in place -and what structural changes would need to happen to make that possible, migrating – having access to higher land and what infrastructure is needed to provide that opportunity so that when both private and public decisions are made options exist to ensure safety for both the investment and community members, and if necessary – relocating, which is a longer-term, complex effort.
- **Unalakleet** – community planning needs to coordinate with the various organizations in Unalakleet. However, given the strength of the community, its support from Kawerak, DOT/PF and USACE projects that were being constructed and/or ready to bid, the community planning effort hasn't had the level of critical need as with the other 5 communities. However, Unalakleet has the same issues as Shaktoolik with storm surges – the community may become an island, or mostly an island and the threats of logs being thrown due to the storms is a deadly threat.

Anticipated Planning Grant Awards to All Communities – By Calendar Year End 2009.

Reduce State Capital Budget Expenditures by Leveraging State Funding

Last year the IAWG received advice from the USACE that State participation in erosion control projects for Alaska could improve funding from federal sources. USACE, as a member of the IAWG, commented that the strategy to align and coordinate state funding to receive Corps federal funds worked well. Moreover, the USACE-Alaska received at least $40 million in a supplemental for Alaskan projects from a $60 million fund for projects nationwide. This was in large part a result of a commitment of the State's funding to 35% of project costs.

- **Kivalina** – $3.3 million from the State to the Northwest Arctic Borough leveraged $12.5 million from USACE for revetments and another $500,000 from USACE for design of additional revetment for Phase 1-Ocean-side revetment.
- **Koyukuk** – No State construction funds were appropriated in FY 2009. However the USACE has been conducting a feasibility study for the Community and the Community Planning Grant will help to coordinate this study with the Community's needs and ideas to protect its infrastructure and community members.
- **Newtok** – During the past year relationships between the community and DOD's Innovative Readiness Team Program (IRTP) has been established. This program offers military assets for community projects that are used as training opportunities for military units. With the FY10 recommended funding of $2 million for materials, the IRT brings $5 million of resources to help construct the evacuation shelter, and develop a materials site for roads and an airstrip. In FY09 DOT/PF received a combined state/federal funding of $1.7 million for constructing the evacuation road
- **Shaktoolik** – No State construction funds were appropriated in FY 2009. However, Kawerak and the Denali Commission have completed a road reconnaissance study, which if funding from state is forth coming would be leveraged 5-fold.
- **Shishmaref** – No State construction funds were appropriated in FY 2009. However, the USACE has been diligent and consistent in its efforts to design and construct revetment, and for FY 2010 $3 million is recommended by the IAWG to fund revetment work in Shishmaref. In the past 2 years the USACE has provided $11 million of construction and design work.
- **Unalakleet**– $5 million in State funds was appropriated in FY 2009 to leverage an additional $18.5 million from USACE to build necessary revetment structures. In addition, by coordinating with DOT/PF mobilization and demobilization costs were saved on this project as the project will use the heavy equipment already in the community.

ADOT/PF Preliminary Engineering & Early Coordination

State resources were provided to ADOT/PF for early coordination and its participation with the USACE to design and develop shoreline protection measures. Coordination resulted in working with community, DCCED and USACE to utilize existing data and identify missing data.

Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans will result from early coordination.

DOT/PF believes these activities may lead to reduced long-term capital construction costs as material sites closer to construction activities are identified and developed. Cost savings can be expected by reducing barging charges and increased competition to provide materials, such as armor rock for revetments.

Specifically for Newtok, ADOT/PF has been actively reviewing the USACE road design and provided appropriate design standards. The ADOT/PF Facilities Division is also serving as a reviewer for the evacuation building design.

FY 10 Funding Recommendations

Communities	Description	Recommended Amount
For the NW and Western regions of Alaska that have suffered the most number of declared disasters over the last 30 years.	Continue Developing Suite of Emergency Plans to ensure no loss of life during disasters. Conduct trainings, planning workshops on sub-regional basis, thereby reducing costs.	$500,000 (Not in Governor's Budget) DHS&EM will explore other funding opportunities, e.g. Denali Commission and CIAP for the most threatened regions in Alaska.
Unidentified, but those Communities in Need of Planning to Prevent Loss of Infrastructure and/or Life	Alaska Climate Change Impact Mitigation Program – Community Planning DCCED/DCRA	$300,000 ($300,000 in Governor's Budget)
Unknown – Communities where USACE is actively addressing erosion and maybe flooding issues	DOT/PF Preliminary Engineering and Early Coordination	$500,000 ($100,000 in Governor's Budget)
Kivalina	DNR – DGGS Geologic and Hazardous Mapping to identify sites acceptable for evacuation road, site and identifying relocation sites.	$180,000 Funded through Federal CIAP. Funds now available at DGGS, but hiring freeze precludes having human resource capacity needed to do the work.
	Revetment work and community planning will continue from funds appropriated in FY 08 Supplemental and FY 09	$0
Koyukuk	DOT/PF for Evacuation Road and Upgrade Existing Road. Conduct reconnaissance, engineering studies, preliminary engineering and environmental work and final design.	$800,000 ($400,000 in Governor's Budget0
Newtok	Material for evacuation shelter road from barge landing and building materials for evacuation shelter.	$2,000,000 Leveraging more than $5,000,000 from Federal agencies – IRT and USACE

Communities	Description	Recommended Amount
Shaktoolik	State funding for partial funding of Evacuation Road design and engineering. This will leverage funds from Kawerak, Denali Commission and BIA.	$500,000 (Not in Governor's Budget) Leverages $2,500,000 from other cooperating organizations
	Shaktoolik should request from Congress to be added to the Alaska Coastal Erosion Program under authority of Section 117.	IAWG reaffirms Shaktoolik should make this request.
	DNR – DGGS Geologic and Hazardous Mapping to identify sites acceptable for evacuation road, site and identifying relocation sites.	$180,000 Funded through Federal CIAP Program. Funds now available at DGGS, but hiring freeze precludes having human resource capacity needed to do the work.
Shishmaref	Construction to complete the additional 550 feet of ocean-side rock revetment or protect the northeastern edge of the community including the sewage lagoon and washeteria. Another $3,500,000 is needed for this section. USACE and others are working together to identify sources for this needed funding.	$3,000,000 This leverages USACE $500,000 for design of this section (Phase 3), and augments the $10.5 million USACE has already expended for design and construction of 1,350 feet.
	Feasibility Studies and Hazardous and Geologic Mapping Studies are needed. Without the siting and design work of evacuation road, airport, port and other community infrastructure sites cannot be done.	No funding has been identified.
Unalakleet	Funding from FY09 from State and USACE should be sufficient to build the revetment. Coordination with community entities, USACE, DCCED, DOT/PF is needed.	IAWG affirms meetings to develop funding strategy should be scheduled. Unalakleet should take the lead to bring agencies together to develop a funding strategy.
	Old high school gym is scheduled to be torn down. It could be moved to higher ground and serve as an emergency evacuation community center	$1,000,000 (Not in Governor's Budget – funding request received after deadline.)

Strategic and Community Assistance Recommendation Policies

The following summarizes IAWG's policy recommendations, which are further detailed in the Policy section of this report as well as in Appendix A. The IAWG has created working relationships that can help to advance these recommendations in a meaningful and cost-effective manner, which is why the IAWG is *recommending that the Subcabinet refer the next steps to advance these policies back to the IAWG.*

Based on the IAWG's 2009 efforts where we brought together information and data from various agencies to identify the next six communities in need of immediate action, we found:

- There is no consistency in criteria, timeline, weighting, data acquisition technique or analysis to determine if impacts are from climate change.
- No framework exists for the comprehensive identification, analysis, and dissemination of current data or the methodical acquisition of new research to support new policy options.
- Without new policy options state and federal agencies are severely limited in their ability to integrate or identify data, research, programs or projects necessary to mitigate or prevent impacts to communities.
- We were unable to, with confidence; identify the next six communities for immediate action.

The IAWG then combined these findings with what most in public service already know, and that is many capital projects need years of planning, engineering, design and time to identify complementary federal funding.

From this, the IAWG recommends:

- **An integrated, multi-agency and inter-governmental approach to effectively identify and address the needs of communities that are potentially in peril.**

The outcome and benefit of this integrated approach has:

- Significant potential to save money on public infrastructure, avoid costly delays, save funds through economies of scale and combining mobilization, mitigate the effects and costs of disaster relief and recovery.

POLICY 1: ESTABLISH A STATEWIDE SYSTEM TO DOCUMENT, ASSESS, AND ANALYZE CURRENT AND PLANNED PUBLIC INFRASTRUCTURE IN ORDER TO PROTECT EXISTING AND FUTURE INVESTMENTS AND PREVENT THREATS TO LIFE IN AN UNCERTAIN ENVIRONMENT

The Immediate Action Workgroup offers a model for a statewide system that integrates information from all state departments, local entities, and federal agencies on current and planned public infrastructure and capital projects in communities currently or potentially affected by climate change. This system will enable a more rapid identification of community needs and vulnerabilities, and more informed decisions on the future repair, retrofit, replacement, or relocation of critical infrastructure. Further, the IAWG believes, this statewide system will create a more cost-effective means to make decisions about public infrastructure needed to ensure community safety and economic viability.

IAWG Recommended Action to Subcabinet: Adopt Policy 1 and provide the IAWG with guidance to develop implementation options for this policy. At a minimum the guidance should instruct that options should include identifying benefits, challenges, and effective organizational structures for implementation. This integrated system

will create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance should also include melding the relevant Adaptation and Mitigation Advisory Groups' products with this statewide system to reach a desired outcome of integrated actions in order to address what seems to be increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective statewide system.

POLICY 2: SUNSET THE IMMEDIATE ACTION WORKGROUP AND DIRECT THE RELEVANT STATE AGENCIES TO ESTABLISH AN INTERAGENCY COLLABORATION WITH EACH OTHER, ALONG WITH RELEVANT FEDERAL AGENCIES AND COMMUNITIES. THIS COLLABORATIVE REQUIRES REGULARLY SCHEDULED MEETINGS TO COORDINATE INFORMATION, PLANNING, EVALUATION AND DECISIONS ON PUBLIC INFRASTRUCTURE FOR THOSE COMMUNITIES IMPACTED BY CLIMATE CHANGE PHENOMENA.

The Immediate Action Workgroup believes that the outcomes and results of its ad hoc collaborative efforts over the past year have been exceedingly useful and should be integrated into agencies' operational efforts. This policy recommendation should be viewed as an interim step to implementing Policy 1 above. Once Policy 1 is established as a strategic operational mechanism, then this Interagency Collaborative should be integrated, reformulated or discontinued, depending on the structure and needs of the statewide system.

IAWG Recommended Action to Subcabinet: Adopt Policy 2 and provide the IAWG with guidance to develop options to accommodate the transition described in Policy 2. At a minimum the guidance should instruct that options include identifying benefits, challenges, and effective organizational structures for implementation. This precursor to an integrated system will set the framework to create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance to the IAWG should also include melding the relevant Adaptation and Mitigation Advisory Groups' products into options for Policy 2. This would be in an effort to reach the desired outcome of taking integrated actions to address the increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective interagency collaborative while a statewide integrated system is being established.

POLICY 3: ASSISTANCE TO COMMUNITIES IN PERIL MUST UTILIZE COMPREHENSIVE INTEGRATED PLANNING AND VIABLE, FUTURE-ORIENTED SOLUTIONS WITH FUNDING THAT ALLOWS FOR SUSTAINABILITY WHETHER THE COMMUNITY REMAINS IN PLACE, USES A MIGRATION STRATEGY OR NEEDS TO RELOCATE.

The Immediate Action Workgroup believes that comprehensive integrated planning must be used to implement solutions for communities in peril. The planning process must integrate the expertise and resources available from the various state and federal agencies as well as community and regional stakeholders. Flexible funding streams should be sought; and may need to be created, to accommodate the needs associated with preserving the options available for protecting public infrastructure and preventing loss of life. These options range from staying in a community's current location, to a migration strategy, to full relocation. All of these options should integrate the concepts of sustainability into the design, location, and attributes of projects, and if relocating, into future settlements. (See IAWG Sustainability Considerations in Appendix B) Existing and new funding mechanisms for responding to climate change hazards should also provide for adaptation and mitigation measures. In seeking funds for adaptation and mitigation, an examination of current federal and State statutes needs to be conducted to identify

limitations in addressing these measures. The Stafford Act, for example, limits the ability of the State to deal effectively with communities in peril.

IAWG Recommended Action to Subcabinet: Adopt Policy 3 and provide the IAWG with guidance to develop implementation options for this policy. At a minimum the guidance should instruct that options should include identifying benefits, challenges, and effective organizational structures for implementation. This comprehensive planning system is a key component to create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance to the IAWG should also include melding the relevant Adaptation and Mitigation Advisory Groups' products with comprehensive integrated planning to reach a desired outcome of integrated actions in order to address what seems to be increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective comprehensive integrated planning system, which also must be a key component of the statewide system identified in Policy 1.

POLICY 4: THE STATE OFALASKA WILL LEAD A COORDINATING EFFORT TO DEVELOP A COMPREHENSIVE STATEWIDE DATA COLLECTION AND EVALUATION SYSTEM THAT PROVIDES FOUNDATIONAL INFORMATION FOR COMMUNITY AND BUSINESS DECISIONS AND SOLUTIONS LEADINGTO EFFECTIVE RESPONSES AND ADAPTATION STRATEGIES TO ADDRESS CLIMATE CHANGEIMPACTS.

Through the Subcabinet Climate Change Strategy process, various components of a statewide data collection and evaluation system have been identified, yet components need to be coordinated in order to understand and use the information effectively. The phenomena of climate-related impacts are not well understood and the impacts themselves are also uncertain. The State of Alaska, playing the coordinating role, will bring together state agencies, university resources, and federal and local stakeholders to develop an effective data collection and evaluation system. The likely outcomes of this effort will be to identify what data exists in order to build forward from existing data and maps; what format it is in and what technology is needed for the systems to "talk" with each other; what data is needed but missing; and what funding is needed to identify, collect, analyze and disseminate data in order to address impacts from climate change phenomena. Response strategies should be developed through adaptation impact analysis and modeling to identify near-term scenarios for options ranging from protecting what's in place, migration and full relocation.

IAWG Recommended Action to Subcabinet: Adopt Policy 4 and provide the IAWG with guidance to develop implementation options for this policy. At a minimum the guidance should instruct that options should include identifying benefits, challenges, and effective organizational structures for implementation. This comprehensive data system is another key component to create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance to the IAWG should also include melding the relevant Adaptation and Mitigation Advisory Groups' products with this statewide data collection and evaluation system to reach a desired outcome of integrated actions in order to address what seems to be increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective integrated data system. This system must also be a key component of the statewide system identified in Policy 1.

COMMUNITY PROFILES

COMMUNITY INFRASTRUCTURE INVESTMENT

The IAWG determined from the DCCED/DCRA – RAPIDS Database that the public infrastructure investment in the six communities for which the IAWG has focused a good deal of its efforts over the past year stands at $293 million.

One of the IAWG's foundational principles is identify and recommend immediate actions that can be taken to protect the infrastructure and public investment that is already in place.

Based on this, the investment levels for the six communities are included here.

Public Investment Based on Information from DCCED/DCRA RAPIDS Database		
Community	Years	Public Infrastructure Investment
Kivalina	1992-2009	$ 25,606,507
Koyukuk	1987-2009	$ 27,213,704
Newtok	1985-2009	$ 21,733,479
Shaktoolik	1988-2012	$ 16,616,589
Shishmaref	1988-2011	$ 56,096,483
Unalakleet	1989-2011	$ 145,721,705
		$ 292,988,467

KIVALINA

Location and Climate

Kivalina is at the tip of an 8-mile barrier reef located between the Chukchi Sea and Kivalina River. It lies 80 air miles northwest of Kotzebue. The community lies at approximately 67.726940° North Latitude and -164.533330° (West) Longitude. (Sec. 21, T027N, R026W, Kateel River Meridian.) Kivalina is located in the Kotzebue Recording District. The area encompasses 1.9 sq. miles of land and 2.0 sq. miles of water. Kivalina lies in the transitional climate zone which is characterized by long, cold winters and cool summers. The average low temperature during January is -15; the average high during July is 57. Temperature extremes have been measured from -54 to 85.

Snowfall averages 57 inches, with 8.6 inches of precipitation per year. The Chukchi Sea is ice-free and open to boat traffic from mid-June to the first of November.

Photo 2: Work crew at eroded shoreline in Kivalina. (Credit: Colleen Swan)

History, Culture and Demographics

Kivalina has long been a stopping-off place for seasonal travelers between arctic coastal areas and Kotzebue Sound communities. It is the only village in the region where people hunt the bowhead whale. At one time, the village was located at the north end of the Kivalina Lagoon. It was reported as "Kivualinagmut" in 1847 by Lt. Zagoskin of the Russian Navy. Lt. G.M. Stoney of the U.S. Navy reported the village as "Kuveleek" in 1885. A post office was established in 1940. An airstrip was built in 1960. Kivalina incorporated as a City in 1969. During the 1970s, new houses, a new school and an electric system were constructed in the village. Prior to 1976, high school students from Noatak would attend school in Kivalina, and board with local families.

Severe erosion and wind-driven ice damage have forced the community to explore options related to safety, mitigation and relocation. A federally-recognized tribe is located in the community -- the Native Village of Kivalina. The population of the community consists of 96.6 percent Alaska Native or part Native. Kivalina is a traditional Inupiat Eskimo village. Subsistence activities, including whaling, provide most food sources. The sale or importation of alcohol is banned in the village. During the 2000 U.S. Census, total housing units numbered 80, and vacant housing units numbered 2. U.S. Census data for Year 2000 showed 82 residents as employed. The unemployment rate at that time was 25.45 percent, although 65.11 percent of all adults were not in the work force. The median household income was $30,833, per capita income was $8,360, and 26.4 percent of residents were living below the poverty level.

Facilities, Utilities, Schools, and Health Care

Wells have proven unsuccessful in Kivalina. Water is drawn from the Wulik River via a 3-mile surface transmission line, and is stored in a 700,000-gallon raw water tank. It is then treated and stored in a 500,000-gallon steel tank. Water is hauled by residents from this tank. One-third of residents have tanks which provide running water for the kitchen, but homes are not fully plumbed. The school and clinic have individual water and sewer systems. Residents haul their own honeybuckets to bunkers. A new landfill and honeybucket disposal site were recently completed. A Master Plan is underway to examine sanitation alternatives at the new community site.

Electricity is provided by AVEC. There is one school located in the community, attended by 127 students. Local hospitals or health clinics include Kivalina Clinic.

Kivalina is classified as an isolated village, it is found in EMS Region 4A in the Maniilaq Association Region. Emergency Services have coastal and air access. Emergency service is provided by volunteers and a health aide

Economy and Transportation

Kivalina's economy depends on subsistence practices. Seal, walrus, whale, salmon, whitefish, and caribou are utilized. The school, City, Maniilaq Association, village council, airlines, and local stores provide year-round jobs. The Red Dog Mine also offers some employment. Six residents hold commercial fishing permits. Native carvings and jewelry are produced from ivory and caribou hooves. The community is interested in developing an Arts and Crafts Center that could be readily moved to the new community site.

The major means of transportation into the community are plane and barge. A State-owned 3,000' long by 60' wide gravel airstrip serves daily flights from Kotzebue. Crowley Marine Services barges goods from Kotzebue during July and August. Small boats, ATVs, and snowmachines are used for local travel. Two main hunting trails follow the Kivalina and Wulik Rivers.

Photo 3: Coastal storm threatens critical infrastructure in Kivalina. (Credit: Colleen Swan)

KOYUKUK

Location and Climate

Koyukuk is located on the Yukon River near the mouth of the Koyukuk River, 30 miles west of Galena and 290 air miles west of Fairbanks. It lies adjacent to the Koyukuk National Wildlife Refuge and the Innoko National Wildlife Refuge. The community lies at approximately 64.880930° North Latitude and -157.701030° (West) Longitude. (Sec. 17, T007S, R006E, Kateel River Meridian.) Koyukuk is located in the Nulato Recording District. The area encompasses 6.2 sq. miles of land and 0.1 sq. miles of water. The area experiences a cold, continental climate with extreme temperature differences. The average daily high temperature during July is in the low 70s; the average daily low temperature during January ranges from 10 to below zero. Sustained temperatures of -40 degrees are common during winter. Extreme temperatures have been measured from -64 to 92. Annual precipitation is 13 inches, with 60 inches of snowfall annually. The River is ice-free from mid-May through mid-October.

Photo 4: Runway located in the floodplain in Koyukuk. (Credit Cynthia Pilot)

History, Culture, and Demographics

The Koyukon Athabascans traditionally had spring, summer, fall, and winter camps, and moved as the wild game migrated. There were 12 summer fish camps located on the Yukon River between the Koyukuk River and the Nowitna River. Friendships and trading between the Koyukon and Inupiat Eskimos of the Kobuk area has occurred for generations. A Russian trading post was established at nearby Nulato in 1838. A smallpox epidemic, the first of several major epidemics, struck the Koyukon in 1839. A military telegraph line was constructed along the north side of the Yukon around 1867, and Koyukuk became the site of a telegraph station. A trading post opened around 1880, just before the gold rush of 1884-85. The population of Koyukuk at this time was approximately 150. Missionary activity was intense along the Yukon, and a Roman Catholic Mission and school opened downriver in Nulato in 1887. A post office operated from 1898 to 1900. Steamboats on the Yukon, which supplied gold prospectors, peaked in 1900 with 46 boats in operation. A measles epidemic and food shortages during 1900 tragically reduced the Native population by one-third. Gold seekers left the Yukon after 1906, but other mining activity, such as the Galena lead mines, began operating in 1919. The first school was constructed in 1939. After the school was built, families began to live at Koyukuk year-round. The City was incorporated in 1973.

A federally-recognized tribe is located in the community -- the Koyukuk Native Village. The population of the community consists of 91.1 percent Alaska Native or part Native. Residents are primarily Koyukon Athabascans with a subsistence lifestyle. During the 2000 U.S. Census, total housing units numbered 55, and vacant housing units numbered 16. Vacant housing units used only seasonally numbered 16. U.S. Census data for Year 2000 showed 40 residents as employed. The unemployment rate at that time was 23.08 percent, although 41.18 percent of all adults were not in the work force. The median household income was $19,375, per capita income was $11,342, and 35.11 percent of residents were living below the poverty level.

The community has experienced increased flooding from both the Yukon and Koyukuk Rivers and residents are considering moving to higher ground.

Facilities, Utilities, Schools, and Health Care

The City provides treated well water at the washeteria. Households are not plumbed, and residents use honeybuckets. The school and washeteria use City water, with sewage disposal into a lagoon. As of May 2003 seven households are on the flush/haul system. The landfill is newly-completed. Electricity is provided by City of Koyukuk. There is one school located in the community, attended by 22 students. Local hospitals or health clinics include Koyukuk Health Clinic. Koyukuk is classified as an isolated village, it is found in EMS Region 1C in the Central Region. Emergency Services have river and air access, and are within 30 minutes of a higher-level satellite health care facility. Emergency service is provided by volunteers and a health aide.

Economy and Transportation

There are few full-time jobs in the community; the city, tribe, clinic, school, and store provide the only year-round employment. BLM fire fighting, construction work, and other seasonal jobs often conflict with subsistence opportunities. Two residents hold commercial fishing permits. Trapping and beadwork supplement incomes. Subsistence foods include salmon, whitefish, moose, waterfowl and berries.

The State-owned 2,645' long by 60' wide lighted gravel runway provides year-round transportation. The river is heavily traveled when ice-free, from mid-May through mid-October. Cargo is delivered by barge about four times each summer. Numerous local trails and winter trails to Chance and Nulato are used by residents. Snowmachines, ATVs, and riverboats are used for local transportation.

NEWTOK

Location and Climate

Newtok is on the Ninglick River north of Nelson Island in the Yukon-Kuskokwim Delta Region. It is 94 miles northwest of Bethel. The community lies at approximately 60.942780° North Latitude and -164.629440° (West) Longitude. (Sec. 24, T010N, R087W, Seward Meridian.) Newtok is located in the Bethel Recording District. The area encompasses 1.0 sq. miles of land and 0.1 sq. miles of water. Newtok is located in a marine climate. Average precipitation is 17 inches, with annual snowfall of 22 inches. Summer temperatures range from 42 to 59, winter temperatures are 2 to 19.

Photo 5: Flooding during coastal storm in Newtok. (Credit: Stanley Tom)

History, Culture, and Demographics

The people of Newtok share a heritage with Nelson Island communities; their ancestors have lived on the Bering Sea coast for at least 2,000 years. The people from the villages of Nelson Island and Newtok are known as Qaluyaarmiut, or "dip net people." Only intermittent outside contact occurred until the 1920s. In the 1950s the Territorial Guard found volunteers from Newtok while they were traveling to Bethel. Tuberculosis was a major health problem during this period. In the late 1950s, the village was relocated from Old Kealavik ten miles away to its present location to escape flooding. A school was built in 1958, although high school students were required to travel to Bethel, St. Mary's, Sitka or Anchorage for their education. This was often their first exposure to the outside, and students returned with a good knowledge of the English language and culture. A high school was constructed in Newtok in the 1980s. A City was incorporated in 1976, but it was dissolved on Jan. 28, 1997. Due to severe erosion, the village wants to relocate to a new site called Mertarvik, approximately 5 miles away on Nelson Island. In November 2003, the 108th Congress passed S. 924, allowing the village to relocate to Nelson Island, authorizing an exchange of lands between the U.S. Fish and Wildlife Service and the Newtok Native Corporation, allowing the relocation.

A federally-recognized tribe is located in the community -- the Newtok Traditional Council. The population of the community consists of 96.9 percent Alaska Native or part Native. Newtok is a traditional Yup'ik Eskimo village, with an active subsistence lifestyle. Relative isolation from outside influences has enabled the area to retain its traditions and customs; more so than other parts of Alaska. The sale or importation of alcohol is banned in the village. During the 2000 U.S. Census, total housing units numbered 67, and vacant housing units numbered 4. U.S. Census data for Year 2000 showed 101 residents as employed. The unemployment rate at that time was 24.63 percent, although 52.13 percent of all adults were not in the work force. The median household income was $32,188, per capita income was $9,514, and 30.99 percent of residents were living below the poverty level.

Facilities, Utilities, Schools, and Health Care

Water is pumped from a lake into a water treatment plant, then hauled from a storage tank. In winter, melted ice is used when water in the storage tank runs dry or freezes. Households are not plumbed, and honeybuckets are used. A washeteria is available. The health clinic uses flush/haul tanks and the schools have individual wells. Refuse collection is provided, and a new landfill has been completed, but ADOT/PF has determined that it is too close to the airport. The community needs to relocate and rebuild facilities on Nelson Island in order to ensure its safety and way of life. A community Master Plan is being developed. Electricity is provided by Unqusrag Power Company. There is one school located in the community, attended by 107 students. Newtok Health Clinic was recently completed by the Denali Commission. Newtok is classified as an isolated village, it is found in EMS Region 7A in the Yukon/Kuskokwim Region. Emergency Services have coastal and air access. Emergency service is provided by a health aide.

Economy and Transportation

The school, clinic, village services, and commercial fishing provide employment. Subsistence activities and trapping supplement income. Twenty-seven residents hold commercial fishing permits. A State-owned 2,202' long by 35' wide gravel airstrip provides chartered or private air access year-round; major improvements are under construction. A seaplane base is also available. Boats, skiffs, and snowmachines are used for local transportation and subsistence activities. Winter trails are marked to Chevak (50 mi.), Tununak, Toksook Bay, Nightmute, and Manaryarapiaq (33.8 mi.) Barges deliver cargo during the summer months.

Photo 6: Flooding during coastal storm in Newtok. (Credit: Stanley Tom)

SHAKTOOLIK

Location and Climate

Shaktoolik is located on the east shore of Norton Sound. It lies 125 miles east of Nome and 33 miles north of Unalakleet. The community lies at approximately 64.333890° North Latitude and 161.153890° (West) Longitude. (Sec. 23, T013S, R013W, Kateel River Meridian.) Shaktoolik is located in the Cape Nome Recording District. The area encompasses 1.1 sq. miles of land. Shaktoolik has a subarctic climate with maritime influences when Norton Sound is ice-free, usually from May to October. Summer temperatures average 47 to 62; winter temperatures average -4 to 11. Extremes from -50 to 87 have been recorded. Average annual precipitation is 14 inches, including 43 inches of snowfall.

Photo 7: Lot inundation at Shaktoolik. (Credit: Steve Ivanoff)

History, Culture, and Demographics

Shaktoolik was the first and southernmost Malemiut settlement on Norton Sound, occupied as early as 1839. Twelve miles northeast, on Cape Denbigh, is "Iyatayet," a site that is 6,000 to 8,000 years old. Reindeer herds were managed in the Shaktoolik area around 1905. The village was originally located six miles up the Shaktoolik River, and moved to the mouth of the River in 1933. This site was prone to severe storms and winds, however, and the village relocated to its present, more sheltered location in 1967. The current site in increasingly threatened by storms and ocean surges and residents are considering relocation to higher ground. The City was incorporated in 1969.

A federally-recognized tribe is located in the community -- the Native Village of Shaktoolik. The population of the community consists of 94.8 percent Alaska Native or part Native. It is a Malemiut Eskimo village with a fishing and subsistence lifestyle. The sale or importation of alcohol is banned in the village. During the 2000 U.S. Census, total housing units numbered 66, and vacant housing units numbered 6. Vacant housing units used only seasonally numbered 1. U.S. Census data for Year 2000 showed 68 residents as employed. The unemployment rate at that time was 27.66 percent, although 56.69 percent of all adults were not in the work force. The median household income was $31,875, per capita income was $10,491, and 6.09 percent of residents were living below the poverty level.

Facilities, Utilities, Schools, and Health Care

Water is pumped three miles from the Togoomenik River to the pumphouse, where it is treated and stored in a 848,000-gallon insulated tank adjacent to the washeteria. A piped water and sewage collection system serves most homes. Seventy-five percent of households have complete plumbing and kitchen facilities. The school is connected to City water, and has received funding to develop a sewage treatment system to serve the entire community. The City burns refuse in an incinerator. The landfill needs to be relocated; the current site is not permitted. Electricity is provided by AVEC. There is one school located in the community, attended by 57 students. Local hospitals or health clinics include Shaktoolik Clinic. Shaktoolik is classified as an isolated village, it is found in EMS Region 5A in the Norton Sound Region. Emergency Services have coastal and air access. Emergency service is provided by a health aide.

Economy and Transportation

The Shaktoolik economy is based on subsistence, supplemented by part-time wage earnings. Thirty-three residents hold commercial fishing permits. Development of a new fish processing facility is a village priority. Reindeer herding also provides income and meat. Fish, crab, moose, beluga whale, caribou, seal, rabbit, geese, cranes, ducks, ptarmigan, berries, greens and roots are also primary food sources.

Shaktoolik is primarily accessible by air and sea. A State-owned 4,000' long by 75' wide gravel airstrip is available. The Alex Sookiayak Memorial Airstrip allows for regular service from Nome. Summer travel is by 4-wheel ATV, motorbike, truck, and boat; winter travel is by snowmachine and dog team. Cargo is barged from Nome, then lightered to shore. The community has no docking facilities.

Photo 8: Log inundation at Shaktoolik. (Credit: Steve Ivanoff)

SHISHMAREF

Location and Climate

Shishmaref is located on Sarichef Island, in the Chukchi Sea, just north of Bering Strait. Shishmaref is five miles from the mainland, 126 miles north of Nome and 100 miles southwest of Kotzebue. The village is surrounded by the 2.6 million-acre Bering Land Bridge National Reserve. It is part of the Beringian National Heritage Park, endorsed by Presidents Bush and Gorbachev in 1990. The community lies at approximately 66.256670° North Latitude and -166.071940° (West) Longitude. (Sec. 23, T010N, R035W, Kateel River Meridian.) Shishmaref is located in the Cape Nome Recording District. The area encompasses 2.8 sq. miles of land and 4.5 sq. miles of water. The area experiences a transitional climate between the frozen arctic and the continental Interior. Summers can be foggy, with average temperatures ranging from 47 to 54; winter temperatures average -12 to 2. Average annual precipitation is about 8 inches, including 33 inches of snow. The Chukchi Sea is frozen from mid-November through mid-June.

Photo 9: Erosion near Shishmaref homes. (Credit: Brice Eningowuk)

History, Culture, and Demographics

The original Eskimo name for the island is "Kigiktaq." In 1816, Lt. Otto Von Kotzebue named the inlet "Shishmarev," after a member of his crew. Excavations at "Keekiktuk" by archaeologists around 1821 provided evidence of Eskimo habitation from several centuries ago. Shishmaref has an excellent harbor, and around 1900 it became a supply center for gold mining activities to the south. The village was named after the Inlet and a post office was established in 1901. The City government was incorporated in 1969. During October 1997, a severe storm eroded over 30 feet of the north shore, requiring 14 homes and the National Guard Armory to be relocated. Five additional homes were relocated in 2002. Other storms have continued to erode the shoreline, an average of 3 to 5 feet per year on the north shore. In July 2002, residents voted to relocate the community. The U.S. Army Corps of Engineers and the State of Alaska have cooperated in an effort to stabilize the shoreline. This effort is continuing.

Photo 10: Failed sea wall. (Credit: Brice Eningowuk)

A federally-recognized tribe is located in the community -- the Native Village of Shishmaref. The population of the community consists of 94.5 percent Alaska Native or part Native. It is a traditional Inupiat Eskimo village with a fishing and subsistence lifestyle. The sale or importation of alcohol is banned. During the 2000 U.S. Census, total housing units numbered 148, and vacant housing units numbered 6. Vacant housing units used only seasonally numbered 4. U.S. Census data for Year 2000 showed 173 residents as employed. The unemployment rate at that time was 16.43 percent, although 51.81 percent of all adults were not in the work force. The median household income was $30,714, per capita income was $10,487, and 16.27 percent of residents were living below the poverty level.

Facilities, Utilities, Schools, and Health Care

Water is derived from a surface source, is treated and stored in a new tank. Shishmaref is undergoing major improvements, with the construction of a flush/haul system and household plumbing. Nineteen HUD homes have been completed, and 71 homes remain to be served. The new system provides water delivery, but the unserved homes continue to haul water. Honeybuckets and the new flush tanks are hauled by the City. The school, clinic, Friendship Center, City Hall and fire hall are connected to a sewage lagoon. A new landfill is planned for the City; an access road is under construction. Electricity is provided by AVEC. There is one school located in the community, attended by 173 students. Local hospitals or health clinics include Katherine Miksruaq Olanna Health Clinic. The clinic is a qualified Emergency Care Center. Shishmaref is classified as an isolated village, it is found in EMS Region 5A in the Norton Sound Region. Emergency Services have coastal and air access. Emergency service is provided by a health aide. Auxiliary health care is provided by the City Volunteer Fire Department/Emergency Services.

Economy and Transportation

The Shishmaref economy is based on subsistence supplemented by part-time wage earnings. Two residents hold a commercial fishing permit. Year-round jobs are limited. Villagers rely on fish, walrus, seal, polar bear, rabbit, and other subsistence foods. Two reindeer herds are managed from here. Reindeer skins are tanned locally, and meat is available at the village store. The Friendship Center, a cultural center, and carving facility, was recently completed for local artisans.

Shishmaref's primary link to the rest of Alaska is by air. A State-owned 5,000' long by 70' wide paved runway is available. Charter and freight services are available from Nome. Most people own boats for trips to the mainland.

UNALAKLEET

Location and Climate

Unalakleet is located on Norton Sound at the mouth of the Unalakleet River, 148 miles southeast of Nome and 395 miles northwest of Anchorage. The community lies at approximately 63.873060° North Latitude and -160.788060° (West) Longitude. (Sec. 03, T019S, R011W, Kateel River Meridian.) Unalakleet is located in the Cape Nome Recording District. The area encompasses 2.9 sq. miles of land and 2.3 sq. miles of water. Unalakleet has a subarctic climate with considerable maritime influences when Norton Sound is ice-free, usually from May to October. Winters are cold and dry. Average summer temperatures range 47 to 62; winter temperatures average -4 to 11. Extremes have been measured from -50 to 87. Precipitation averages 14 inches annually, with 41 inches of snow.

Photo 12: Log inundation at Unalakleet. (Credit: Steve Ivanoff)

History, Culture, and Demographics

Archaeologists have dated house remnants along the beach ridge from 200 B.C. to 300 A.D. The name Unalakleet means "from the southern side." Unalakleet has long been a major trade center as the terminus for the Kaltag Portage, an important winter travel route connecting to the Yukon River. Indians on the upper river were considered "professional" traders who had a monopoly on the Indian-Eskimo trade across the Kaltag Portage. The Russian-American Company built a post here in the 1830s. In 1898, reindeer herders from Lapland were brought to Unalakleet to establish sound herding practices. In 1901, the Army Signal Corps built over 605 miles of telegraph line from St. Michael to Unalakleet, over the Portage to Kaltag and Fort Gibbon. The City was incorporated in 1974.

A federally-recognized tribe is located in the community -- the Native Village of Unalakleet. The population of the community consists of 87.7 percent Alaska Native or part Native. Unalakleet has a history of diverse cultures and trade activity. The local economy is the most active in Norton Sound, along with a traditional Unaligmiut Eskimo subsistence lifestyle. Fish, seal, caribou, moose, and bear are utilized. The sale of alcohol is prohibited in the community, although importation and possession are allowed. During the 2000 U.S. Census, total housing units numbered 242, and vacant housing units numbered 18. Vacant housing units used only seasonally numbered 6. U.S. Census data for Year 2000 showed 258 residents as employed. The unemployment rate at that time was 14.57 percent, although 48.61 percent of all adults were not in the work force. The median household income was $42,083, per capita income was $15,845, and 11.04 percent of residents were living below the poverty level.

Facilities, Utilities, Schools, and Health Care

Water is derived from an infiltration gallery on Powers Creek, is treated and stored in a million-gallon steel tank. The water source is not sufficient during extremely cold weather, and a feasibility study is underway. One hundred ninety households are connected to the piped water and sewer system and have complete plumbing. Only two households haul water and honeybuckets. Residents haul refuse to the baler facility for transportation to the landfill. Refuse collection is available for commercial customers. Matanuska Electric Association owns and operates the electrical system in Unalakleet, through the Unalakleet Valley Electric Cooperative. Electricity is provided by Unalakleet Valley Electric Cooperative. There is one school located in the community, attended by 210 students. Local hospitals or health clinics include Euksavik Clinic. The clinic is a qualified Emergency Care Center. Unalakleet is classified as an isolated town/Sub-Regional Center, it is found in EMS Region 5A in the Norton Sound Region. Emergency Services have river and air access. Emergency service is provided by volunteers and a health aide.

Economy and Transportation

Both commercial fishing for herring, herring roe, and subsistence activities are major components of Unalakleet's economy. One hundred nine residents hold commercial fishing permits. Norton Sound Economic Development Council operates a fish processing plant. Government and school positions are relatively numerous. Tourism is becoming increasingly important; there is world-class silver salmon fishing in the area.

Unalakleet has a State-owned 6,004' long by 150' wide gravel runway which recently underwent major improvements; and a gravel strip that is 2,000' long and 80' wide. There are regular flights to Anchorage. Cargo is lightered from Nome; there is a dock. Local overland travel is mainly by ATVs, snowmachines and dogsleds in winter.

ACCOMPLISHMENTS

KIVALINA	
IAWG Recommendation and Agency Actions	**Status**
Develop Suite of Emergency Plans and Training/Drills State resources were provided to the Alaska DHS&EM to work jointly with Kivalina and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion.	Developing plans, trainings and drills will begin in February and will be completed by end of 2009.
Community Mitigation and Relocation Planning and Coordination DCCED/DCRA staff is working with both the City and Tribe to develop a proposal for a community planning grant that addresses the IAWG's recommended immediate actions for the community through the Alaska Climate Change Impact Mitigation Program.	Discussions and collaborations are in progress between DCRA and the City and Tribe of Kivalina. It's likely a community planning grant/contract will be in place in June 2009.
Reduce State Capital Budget Expenditures by Leveraging Other Resources State provided $3.3 million to the Northwest Arctic Borough to begin construction of a revetment to protect vulnerable shoreline of community USACE engineers obtained a supplemental appropriation from Congress in 2008 to complete the revetment protection of the Oceanside shoreline of Kivalina thereby securing the shore for a minimum of 15 years.	Phase 1-Ocean-side revetment: USACE constructed 400 ft of revetment in 2008; 1200 in 2009. Cost: $12.5 mm. NWAB will construct 400 ft with $3.3mm. Phase 2 - Lagoon-side revetment: USACE began design during the Winter 2009.
ADOT/PF Preliminary Engineering & Early Coordination State resources were provided to ADOT/PF for early coordination and its participation with the USACE to design and development of shoreline protection measures. Coordination resulted in working with community, DCCED and USACE to utilize existing data and identify missing data. Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans will result from early coordination.	See DOT's accomplishments later in this section.

KOYUKUK	
IAWG Recommendation and Agency Actions	**Status**
Develop Suite of Emergency Plans and Training/Drills State resources were provided to the Alaska DHS&EM to work jointly with Koyukuk and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion. Funding was also provided to DNR/Division of Forestry for a Community Wildfire Protection Plan (CWPP). Work on this project will be accomplished by Division of Forestry in conjunction with the community, Tanana Chiefs Conference, Inc. and the Alaska Fire Service. Project will identify fuel types in conjunction with community infrastructure to determine levels of risk. Fuel reduction projects will be designed and ranked for treatments. FY09 budget was $25K for this project.	Developing plans, trainings and drills has been initiated and will be completed by end of 2009. Initial work is under-way with a Reimbursable Services Agreement (RSA) in place between DOF and DMVA. Community meetings will begin in February-09, risk assessment summer-09, draft plan fall-09, completion by spring 2010.
Community Mitigation and Relocation Planning and Coordination DCCED/DCRA staff is working with Koyukuk to develop a proposal for a community planning grant that addresses the recommended immediate actions for the community through the Alaska Climate Change Impact Mitigation Program.	Discussions and collaborations are in progress between DCCED/DCRA and the Village of Koyukuk. It's likely a community planning grant/contract will be in place in June 2009.
Reduce State Capital Budget Expenditures by Leveraging Other Resources FY 10 Governor's budget includes $400k to DOT/PF to design village evacuation road to higher ground USACE and others are working with Koyukuk to complete an expedited erosion/flooding assessment and held two public meetings to discuss alternative plans and receive input. A draft feasibility report is currently being prepared but the community remains divided on the acceptability of identified alternative plans.	USACE has conducted and led a feasibility study on alternative flood damage reduction planning for the Village. DCCED/DCRA and others are now assisting the community in its review and identifying options and actions.
ADOT/PF Preliminary Engineering & Early Coordination State resources were provided to ADOT/PF for early coordination and its participation with the USACE. Coordination resulted in working with community, DCCED and USACE to utilize existing data and identify missing data. Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans, will result from early coordination.	See DOT's accomplishments later in this section.

NEWTOK	
IAWG Recommendation and Agency Actions	**Status**
Develop Suite of Emergency Plans and Training/Drills State resources were provided to the Alaska DHS&EM to work jointly with Newtok and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion.	Developing plans, trainings and drills has been initiated and will be completed by end of 2009.
Community Mitigation and Relocation Planning and Coordination Newtok received a community planning grant through the DCCED/DCRA's new, legislatively created Alaska Climate Change Impact Mitigation Program. These funds are being used for: • The design of an evacuation shelter. The community hired the Cold Climate Housing Center; • Planning resources to conduct site suitability analysis and future community layout at the identified new community site- Mertarvik.	The Village of Newtok has a fully executed community planning grant for the preparation of a design analysis report and 35% design drawings for an emergency evacuation center that will be built at Mertarvik, on Nelson Island. Cold Climate Housing Research Center has been hired by the Village of Newtok to design a sustainable and energy efficient emergency shelter and carry out the project.
Reduce State Capital Budget Expenditures by Leveraging Other Resources - ADOT/PF received $3.3 million from the State Legislature for Newtok. $1.8 million of this appropriation is being combined with an $800,000 grant from the Federal Economic Development Administration (EDA). DCCED is the grantee to EDA to build a barge landing and upland staging area to allow for landing of supplies, equipment and personnel at the Mertarvik site. - ADEC secured resources to drill and develop water well at the Mertarvik site. - AEA secured funds to build a fuel pipeline to allow fuel offloading from the Newtok River to fuel tanks at the generator site in Newtok - Commitment received from the Innovative Readiness Training Program in the U.S. Department of Defense to conduct a military training effort at Mertarvik with the intention of helping the community build roads, an emergency shelter and a quarry for material at Mertarvik. - Community members and the tribal council have financed and built 3 homes at Mertarvik.	Completed by July 2009. DCCED and DOT signed their project agreement 3/15/2008. Treated well water will be available by August 2009. **To be completed** in Spring/Summer 2009. $2 million in Governor's FY2010 Budget for materials to construct evacuation shelter. $5 million estimated for FY2011. Materials being contributed by federal IRT Program for roads, evacuation shelter and quarry development. IRT effort will

NEWTOK	
IAWG Recommendation and Agency Actions	**Status**
- USACE prepared designs for the road from the barge landing to the proposed evacuation center at Mertarvik in cooperation with ADOT. Corps is working with the IRT to provide NEPA documentation, obtain a Coastal Zone Consistency Determination, and Water Quality Certification. This should help expedite processing of needed permits when it is determined which agency will provide funding and staff for construction support of the IRT building a base camp in 2009.	commence Summer 2009. USACE road design was completed by March 1, 2009. Corps signed a Project Partnering Agreement with the Newtok Tribal Council in Jan 09 to enable construction of a road and evacuation center at Mertarvik if/when Federal funding is received.
ADOT/PF Preliminary Engineering & Early Coordination Newtok community and airport relocation alternatives (approx $70k) and Mertarvik Barge Landing Project design (approx $150k) ADOT/PF received state resources and used approximately $70,000 to survey the Newtok/Mertarvik Village Relocation site and surrounding airport relocation alternatives. The DOT Contractor acquired aerial mapping utilizing existing photography previously acquired by the Army Corps of Engineers, which had been aerotriangulated, and by flying a new series of more detailed photography. Products included digital topography files at 5' contours, and 1 inch = 200 feet planimetric detail maps. These products will help with further evaluation of airport relocation alternatives for the community. The level of surveying provided will also help with actual design efforts for the airport, and will reduce the need for additional survey work during the design phase of the project. Approximately $1.8 million is being used to help complete the Mertarvik Barge Landing Project design. Coordination has resulted in working with community, DCCED and USACE to utilize existing data and identify missing data. Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans, will result from early coordination.	Barge landing project is scheduled for construction completion by July 15, 2009. See DOT accomplishments later in this section.

SHAKTOOLIK	
IAWG Recommendation and Agency Actions	**Status**
Develop Suite of Emergency Plans and Training/Drills State resources were provided to the Alaska DHS&EM to work jointly with Shaktoolik and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion.	Developing plans, trainings and drills has been initiated and will be completed by end of 2009.
Community Mitigation and Relocation Planning and Coordination DCCED/DCRA staff is working with the Village of Shaktoolik to develop a proposal for a community planning grant that addresses IAWG's recommended immediate actions for Shaktoolik through the Alaska Climate Change Impact Mitigation Program.	Discussions and collaborations are in progress between DCCED/DCRA and the Village of Shaktoolik. It's likely a community planning grant/contract will be in place in June 2009.
Reduce State Capital Budget Expenditures by Leveraging Other Resources Kawerak completed a preliminary design/reconnaissance report of the evacuation road and a route to a safe high ground site, and has identified multiple sources of funding for engineering and design for FY10.	In Dec. 2008, Kawerak with Denali Commission funding, completed a reconnaissance study for siting an evacuation road
ADOT/PF Preliminary Engineering & Early Coordination State resources were provided to ADOT/PF for early coordination and its participation with the USACE. The Corps initiated a shoreline protection study under Section 103 of its Continuing Authority Program to determine what alternatives would provide reasonable solutions to erosion and storm damage. Coordination resulted in working with community, DCCED and USACE to utilize existing data and identify missing data. Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans will result from early coordination.	See DOT's accomplishments later in this section.

SHISHMAREF	
IAWG Recommendation and Agency Actions	**Status**
Develop Suite of Emergency Plans and Training/Drills State resources were provided to the Alaska DHS&EM to work jointly with Shishmaref and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion.	Developing plans, trainings and drills has been initiated and will be completed by end of 2009.
Community Mitigation and Relocation Planning and Coordination DCCED/DCRA staff is working with Shishmaref to develop a proposal for a community planning grant that addresses the IAWG's recommended immediate actions for the community through the Alaska Climate Change Impact Mitigation Program.	Discussions and collaborations are in progress between DCRA and the City and Tribe of Shishmaref. It's likely a community planning grant/contract will be in place in June 2009.
Reduce State Capital Budget Expenditures by Leveraging Other Resources USACE engineers secured additional funding through the 2008 Federal Supplemental Appropriation from Congress for construction of rock revetments at $10.5 mm. IAWG recommends a $3 million request in FY10 Governor's budget to begin construction of a revetment to protect the most vulnerable shoreline of community. USACE is also expending $500k on design work for the additional revetment needed to protect the community. $3 million for final phase of revetment in Governor's Budget for FY10.	**Phase 1:** 600 feet of rock revetment completed in Sep 08. **Phase 2:** 750 feet of rock revetment under contract to be completed by Oct 09. **Phase 3:** 550 feet of rock revetment under design in 2009; construction funding needed. **Phase 4:** 1,225 feet to be surveyed in 2009; of this 325 feet will be new rock revetment and 900 feet will be raising existing revetments when funding is provided. Environmental studies were initiated for a programmatic EIS for community relocation with limited funding.
ADOT/PF Preliminary Engineering & Early Coordination State resources were provided to ADOT/PF for early coordination and its participation with the USACE to design and development of shoreline protection measures. Coordination resulted in working with community, DCCED and USACE to utilize existing data and identify missing data. Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans, will result from early coordination.	Geotech data collection and analysis completed in 2008 for assessment to site evacuation/relocation road. See DOT's accomplishments later in this section.

UNALAKLEET	
IAWG Recommendation and Agency Actions	**Status**
Develop Suite of Emergency Plans and Training/Drills State resources were provided to the Alaska DHS&EM to work jointly with Unalakleet and prepare a suite of emergency plans including Emergency Operations, Community Evacuation and Hazard Mitigation, along with training, and conducting community drills to provide readiness in case of a disaster, most likely flooding and/or erosion.	Developing plans, trainings and drills will begin in February and will be completed by end of 2009.
Community Mitigation and Relocation Planning and Coordination DCCED/DCRA staff is working with Unalakleet to develop a proposal for a community planning grant that addresses the IAWG's recommended immediate actions for the community through the Alaska Climate Change Impact Mitigation Program.	Discussions and collaborations are in progress between DCCED/DCRA and the City and Village of Unalakleet. It's likely a community planning grant/contract will be in place in June 2009.
Reduce State Capital Budget Expenditures by Leveraging Other Resources $5 million provided by the Alaska Legislature to the City of Unalakeet to build a section of a shoreline revetment designed by the Corps for a vulnerable portion of the beach USACE engineers obtained construction funding from the 2008 Supplemental Appropriation by Congress for a portion of the 1,500 foot rock revetment facing the ocean. This revetment is designed to provide long term protection for the Unalakleet waterfront ADOT/PF has secured resources from FAA to protect shoreline of the section of beach threatened by erosion adjacent to the airport.	USACE design work is complete and the construction contract is being advertised. Proposals were received Feb 20th and selection of a contractor is expected in April 2009. Construction could be completed in 2010 – if sufficient funds are available. Airport shoreline revetment completed.
ADOT/PF Preliminary Engineering & Early Coordination State resources were provided to ADOT/PF for early coordination and its participation with the USACE. Coordination resulted in working with community, DCCED and USACE to utilize existing data and identify missing data. Timely site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies, which all need to be conducted prior to developing erosion protection or relocation design plans will result from early coordination.	See DOT's accomplishments later in this section.

ACCOMPLISHMENTS BY AGENCY

Division of Homeland Security & Emergency Management
$400,000 State funding and $125,000 Federal funding

Based on the IAWG's April 17, 2008 Recommendations Report to the Governor's Subcabinet on Climate Change, the DHS&EM was funded to develop a suite of comprehensive emergency plans for the six communities in peril (Kivalina, Koyukuk, Newtok, Shaktoolik, Shishmaref, and Unalakleet). Each of the six communities will receive an emergency operations plan, continuity of operations plan, emergency evacuation plan, and the training to execute these plans. Since June 2008 DHS&EM representatives have made initial visits to each of the communities to develop a community planning team, initial hazard analysis, and a basic outline schedule on what is to come in the next year. Ecology & Environmental (E&E) was selected as the contractor to execute the comprehensive emergency planning. E&E has made their first string of visits to the communities. During these visits, members for the communities received ICS training, initial planning drafts, and community and emergency planning workgroup meetings were conducted. The contractor will be making a final visit at the end of Summer 2009/ Fall 2009, which will result in finalizing training, completed plans, and community adoption of the plans. The overall goal is to have comprehensive emergency plans for each of the 6 communities in peril by the Fall sea storm season of 2009.

Not only have the communities received ICS training and emergency plans, but they have been invited to DHS&EM tri-annual preparedness workshops with various themes ranging from before, during, and after a disaster, to creating a resilient community. Also during these workshops the communities are being exposed to the division SERC/LEPC (State Emergency Response Committee/ Local Emergency Planning Committee) meetings. Other workshops communities have attended include the Western Alaska Evacuation Workshop. This session brought communities from all over Western Alaska to work together on emergency planning issues, and mutual aid issues. The outcome of this training has helped the six communities in peril build better ties, relationships and communications with neighboring communities within their regions.

Since **Developing the Suite of Emergency Plans and Training/Drills began,** Alaskan communities are becoming more involved with hazard mitigation, emergency planning, response, and training in partnership with DHS&EM.

Alaska Department of Commerce Community and Economic Development –
Division of Community and Regional Affairs
$500,000

Alaska Climate Change Impact Mitigation Program
Alaska's Twenty Fifth Legislature established the Alaska Climate Change Impact Mitigation Program (ACCIMP) with funding to address the immediate planning needs of communities imminently threatened by climate change-related impacts such as erosion, flooding, storm surge, and thawing permafrost. The ACCIMP is being administered by the Alaska Department of Commerce, Community, and Economic Development, Division of Community and Regional Affairs (DCRA).

The ACCIMP is being delivered through grants to meet specific objectives. The program initially directs the majority of grant funds at communities identified as imminently threatened by the Governor's Subcabinet on Climate Change, Immediate Action Workgroup (IAWG). These communities are Shishmaref, Kivalina, Newtok, Koyukuk, Unalakleet and Shaktoolik.

The ACCIMP is providing non-competitive funding to these communities for Community Planning Grants to address the recommendations for immediate actions made by the IAWG in its Recommendations Report to the

Governor's Subcabinet on Climate Change, April 17, 2008. Development of community planning and/or hazard impact assessment grants for the six communities named above is currently underway.

The balance of ACCIMP funds will be offered as competitive mini-grants to eligible communities for hazard impact assessments to identify climate change-related natural hazards such as erosion, flooding, storm surge, thawing permafrost, and wildfires, and to provide recommendations for further action by the community.

Solicitation for the competitive mini-grant program opened January 12, 2009 and ended February 16, 2009.

Alaska Department of Transportation & Public Facilities
Infrastructure and Erosion Control Design and Environmental Permitting
$600,000

This funding is allowing the Department of Transportation and Public Facilities to begin early project coordination with the affected communities as well as other State and Federal Agencies. The US Army Corps of Engineers has conducted several studies regarding erosion control structures and other relocation options that the department needs to review and examine. The department also needs to begin to collect available engineering data and identify gaps in data for additional investigations.

Funding will also allow for preliminary engineering investigations to begin so that project development can move ahead in an orderly, timely, and efficient manner. Site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies will all need to be conducted prior to developing erosion protection or relocation design plans. Because all likely project scenarios will involve extensive environmental documentation and permitting, it is critical that the project development process start as early as possible.

Work to Date:

- Approximately $70,000 used for a survey of the Newtok/Mertarvik Village Relocation site and surrounding airport relocation alternatives;
- Approximately $150,000 for the Barge Landing Project design (both detailed in the Newtok Accomplishments); and
- Approximately $240,000 has been allocated to the Northern Region to begin early coordination with the affected communities as well as other State and Federal Agencies. Preliminary engineering and data collection efforts are currently underway. Project deliverables include:
    - *Unalakleet Project Coordination with USACE, ADCCED, and Denali Commission*
    - *Electronic Resource Library, including index*
    - *Data Gap Identification and Collection Plan*
    - *U.S. Corp of Engineer Plan Reviews and Coordination*
    - *Agency Stakeholder Contact List*
    - *Permitting Agency Contact List*
    - *Coastal Erosion Power Point Presentation*
    - *Community meeting notes and Summaries*
    - *DCRA Website Coordination*
    - *Report identifying existing coastal processes and alternatives as related to sediment transport for the affected communities, including a sediment budget for the communities*
    - *Other preliminary tasks, such as collecting environmental, geotechnical, and survey data are also scheduled to be performed this spring/summer*

Department of Natural Resources
Statewide Update on Community Wildfire Protection Planning Efforts and Funding

Appendix A also includes the list of communities with Community Wildfire Protection Plans (CWPP) completed or underway.

Funding for the completion of CWPP's has been sporadic and has come from several different sources and agencies. The Division of Forestry in conjunction with the Alaska Wildland Fire Coordination Group (AWFCG) has recognized the need for a National Fire Plan Coordinator position in Alaska to oversee the coordination, funding and implementation of the CWPP effort statewide. The agencies are working toward this goal, and in the meantime are completing work by utilizing various agency budgets and staff as time and funding permits.

The National Economic Stimulus Plan has allocations for Wildland Fire Management in both the House and Senate passed versions of the bill. While final funding levels will be established by the conference committee, significant funding will become available to complete new CWPPs and to implement hazard fuel reduction projects recommended by these plans. Funding will flow through established programs via the U.S. Forest Service, State and Private Forestry Programs to the State through the Division of Forestry.

In addition, under the Climate Change Subcabinet, both the Natural Systems Adaptation Technical Workgroup and the Forestry, Agricultural and Waste Mitigation Technical Workgroups have proposals for continuing CWPP work as part of their recommendations to their respective Advisory Groups.

U.S. Army Corps of Engineers Planning, Design and Construction

Funding for the Corps participation in IAWG identified projects in 2008 was provided by Congress from a Supplemental Appropriation ($40m), the Alaska Coastal Erosion Program ($5.4m), the Tribal Partnership Program ($689k), and the Continuing Authorities Program ($114k). This enabled construction contracts for rock revetment projects at Shishmaref, Kivalina and Unalakleet to be advertised and awarded at Shishmaref and Kivalina. Due to high initial bids at Unalakleet, the contract documents were revised and readvertised so construction proposals could be evaluated in March 09. Designs for additional phases of construction continued at Shishmaref, Kivalina, and Newtok under the Alaska Coastal Erosion program. Under the Tribal Partnership Program the Alaska Baseline Erosion report was drafted which evaluated the erosion risk at 179 communities and identified 26 Priority Action Communities. A final report is due in April 09. Studies were continued at Shaktoolik, Point Hope, Nome, Chefornak, Koyukuk, and Barrow regarding erosion and/or flooding problems.

National Oceanic and Atmospheric Administration

The National Oceanic and Atmospheric Administration is working with the IAWG to define priorities for the tide and water level stations, weather observations, geodetic control information and ice forecasting, called for in the IAWG April 2008 report.

In December 2008, the NOAA Alaska Regional Collaboration Team submitted a tide gauge priority list incorporating IAWG interests can be found at:
http://www.ppi.noaa.gov/NOAA_ARCTic/docs/AKTideGaugePriority_ARCTic.pdf This list will be used by the Center for Operational Oceanographic Products and Services to guide future deployments: The next step will be for the State to help NOAA identify facilities (e.g. pier) with communications and power in the priority areas where the gauges can be sited. The upcoming release of the National Wave Observation Plan will include

several new sites along the west coast, based on IAWG input, for buoys and other instrumentation. The plan will describe an ideal state and implementation of the proposed network will be affected by feasibility, availability of funding, and national prioritization.

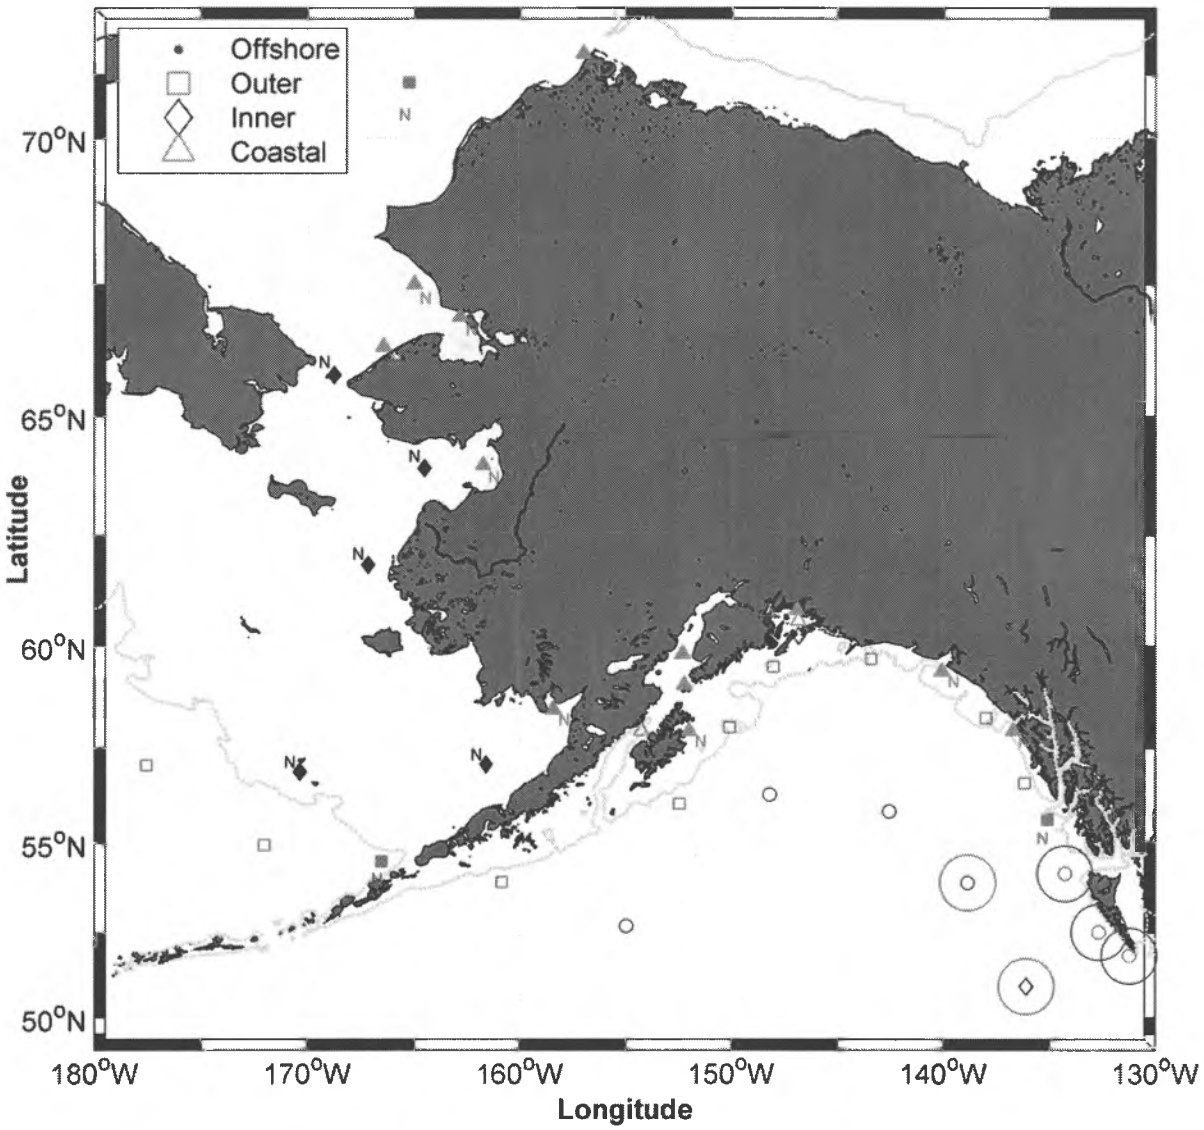

Figure 1: Proposed ideal locations of wave observing infrastructure - IAW input influnced the addition and location of the new sites along the west coast

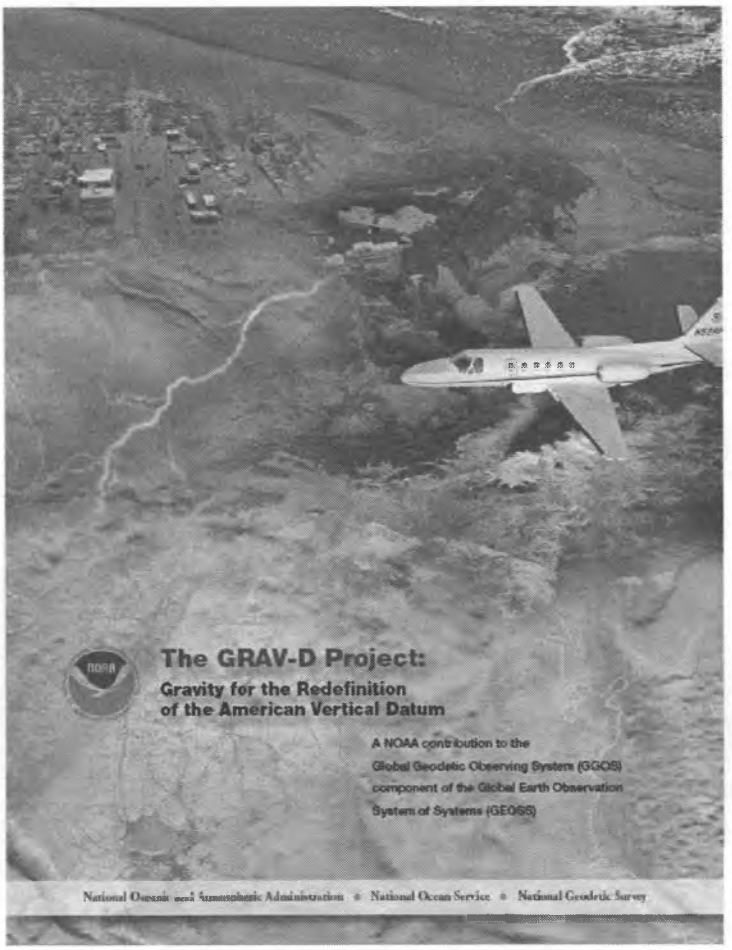

Figure 2: Alaskan Littoral Regions (excluding the Aleutians) and Southern Alaska are the first two areas of the country to be addressed.

Improved geodetic control will be achieved through the agency's "Gravity for the Re-definition of the American Vertical Datum" program which is awaiting appropriations. This program will reduce vertical positioning errors from ~2 meters to ~2 centimeters and will be complimented by the Alaska Statewide Digital Mapping Initiative.

Efforts are also underway to formally document the priorities for enhanced ice forecasting.

IMMEDIATE ACTIONS FOR COMMUNITIES

2009 Immediate Action Funding Recommendations			
Community	**Immediate Actions Identified to Prevent Loss of Life and Infrastructure**	**Past and Future Budget Notes**	**IAWG Action**
All Six Communities DHS&EM is advancing these Emergency Plans in each of the six communities. It anticipates all 6 to be completed by calendar end 2009.	**Develop Suite of Emergency Plans and Training/Drills** (Alaska DHS&EM is lead) Emergency Operations, Community Evacuation, Hazard Mitigation Fire Management (Koyukuk only-DNR is lead) Purpose: Best chance to reduce loss of life and property when natural disasters occur. Coordinate with community planning projects to ensure dollars go as far as possible.	**FY09 - $400,000 appropriated in Capital Budget to DHS&EM**. DHS&EM RSA $25,000 to DNR for Koyukuk Fire Management Plan. DHS&EM will also provide $100,000 federal funds match. **State's Return on Investment:** DHS&EM estimates for every $1 spent on preparation, $4 saved in response.	**FY10 IAWG Budget Recommendation: $500,000 (not included in Governor's Budget)** **IAWG continues to support this important and initial step to ensure preparedness for communities, and prevent harm to infrastructure.** **IAWG has identified over 150 communities as potentially in peril. See Appendix A.** **DHS&EM will explore other funding opportunities, e.g. Denali Commission and CIAP for the most threatened regions in Alaska.**
All Six Communities	**Community Climate Change Mitigation and Relocation Planning** Funding for future relocation planning efforts for each community require coordination and resources both at the community and agency levels. Communities need funding and technical assistance to support/augment local capacities. Rational and collaborative planning needs to examine alternatives (e.g. shoreline	**FY 08 Supplemental** - Initial funding was included in this Budget bill to develop relocation planning resources. IAWG 2009 Policy Recommendations addresses how to identify communities, assess and analyze their mitigation and relocation needs due to impacts likely caused by climate change phenomena.	**FY10 IAWG Budget Recommendation: $300, 000 ($300,000 included in Governor's Capital Budget)**

2009 Immediate Action Funding Recommendations			
Community	**Immediate Actions Identified to Prevent Loss of Life and Infrastructure**	**Past and Future Budget Notes**	**IAWG Action**
	stabilization/protection vs. relocation) and identify the opportunities for implementation. **Cost Effective:** When coordinated, Emergency Preparedness, Community Relocation and other community project planning and project developments have cost-effective results.		
All Six Communities	**Reduce Capital Budget Expenditures** - Through inter-agency and local coordination identify capital cost savings by aligning timing of projects requiring heavy equipment. - State should establish co-sponsorship funding to ensure Alaska attracts federal funds for its priority projects. - Find/develop Western Alaska rock source to reduce costs. **35% Funding Co-Sponsorship:** Based on recommendations from former Senator Stevens at recent roundtables and other meetings.	**Immediate and Near Term Capital Budget Estimates: Former Senator Ted Stevens suggested that the** State should be prepared to match/augment federal funds with a target of 35% of erosion control and mitigation capital costs.[2] This will ensure the highest likelihood that federal funds will be allocated to Alaska, given the competitive nature of these funds.	**2009 - IAWG Reaffirms this recommendation of 35%, or at least at a level that encourages State-Federal partnership funding to protect existing communities and infrastructure from threats by climate related impacts.**

[2] March 24, 2008 Email from P. Opheen, USACE Alaska District: Water Resources Development Act of 1986: the following sections set the basis for the USACE cost sharing policies including in both the Planning Guidance Notebook and the Digest of Water Resources Policies and Authorities. Section 103 mandated cost sharing for construction of flood control and other purposes. Section 104 mandated cost sharing for feasibility studies, and preliminary engineering design (PED). It states in part that (para (a)(1)) "The Secretary shall not initiate any feasibility study for a water resources project after the date of enactment of this act unto; appropriate non-Federal interests agree, by contract to contribute 50 percent of the cost for such study...". It further states in paragraph (b) Planning and Engineering: "The Secretary shall not initiate any planning of engineering authorized by this Act for a water resources project until appropriate non-Federal interest agree, by contract to contribute 50 percent of the cost ...".

Although Senator Stevens has sponsored authorizing legislation to conduct coastal erosion projects for Alaskan Native Villages at 100 percent federal cost the authorization did not change budgetary policy or procedures, or the Administration's policies on mandating cost sharing for Civil Works studies, PED or construction. The budget guidance addresses non-budgetable (policy non-compliant) studies and projects by addressing them in what is known as increment 9 of the budget submission reflecting our capability to perform the work.

2009 Immediate Action Funding Recommendations			
Community	**Immediate Actions Identified to Prevent Loss of Life and Infrastructure**	**Past and Future Budget Notes**	**IAWG Action**
All Six Communities	**Preliminary Engineering and Early Coordination** Funding will allow for preliminary engineering investigations to begin so that project development can move ahead in an orderly, timely, and efficient manner. Site surveys, material source investigations, hazard mapping, geotechnical and hydrologic studies, and environmental documentation and permitting studies will all need to be conducted prior to developing erosion protection or relocation design plans. Because all likely project scenarios will involve extensive environmental documentation and permitting, it is critical that the project development process start as early as possible. Will also allow for early coordination between agencies and affected communities and a review of existing data, reports, and plans.	**FY09 - $600,000 appropriated in Capital Budget to ADOT** USACE, ADOT, HS&EM, DCCED have all identified Shishmaref, Kivalina, Shaktoolik and Unalakleet as of significant risk where - a phased and coordinated approach to project development is needed to ensure infrastructure and community-wide safety.	**FY10 IAWG Budget Recommendation $500,000 ($100,000 included in Governor's Capital Budget)**
All Six Communities – and to Address What will Likely Become a Statewide Need	**Identify and Develop a Data Strategy** to support government, community and business decisions. IAWG 2009 Policy #4 further details its Data Collection and Coordination Strategy originally presented in its 2008 Report.	**IAWG did not provide any budget estimates for this Strategy in FY 09.** **IAWG reaffirms its support for this important element.**	**FY 10 IAWG Budget Recommendation $0** **Some funding for travel for community participants may be useful.**
All Six Communities	**Data Needed to Advance IAWG Recommendations** - Data for developing emergency and other community plans. (EM is familiar with the data needed.) - Horizontal and vertical control data for establishing plans for relocation and evacuation routes based on what flood levels have	IAWG has been working with NOAA and providing input on priorities for data and informational needs in Alaska. Until a Data Strategy (interagency effort) is conducted, identifying and collecting the data needed will likely not be done in a systematic way to ensure projects can move forward as needed.	**Some funds for data collection may be used through the various activities identified in IAWG Recommendations.**

2009 Immediate Action Funding Recommendations			
Community	**Immediate Actions Identified to Prevent Loss of Life and Infrastructure**	**Past and Future Budget Notes**	**IAWG Action**
	historically happened - note there is good horizontal and vertical control data at the Red Dog Port which is directly applicable to Kivalina). - Weather observation stations should be established and tied into the current, closest data collection sites for monitoring weather-related storm data whether from ice jams, seasonal river rise, storms, storm surges or floods. - A template to develop a Continuity of Operations (COOP) Plan is available on DMVA/DHSEM's website - Yukon River Intertribal Watershed Council model may be useful too. - Integrate with Western Communities Evacuation Plan. -Work with NOAA to document ice forecasting requirements, and - To reduce vertical control errors from 2 m to 2 cm.		**IAWG recommends the state work with NOAA to 1) identify suitable locations for tide and water level stations in the IAWG's priority areas (see Appendix B) and 2) develop an viable implementation plan and schedule. These stations should include a meteorological sensor suite.** **IAWG recommends that the state support the appropriation of federal funds to implement the Gravity for the Re-definition of the American Vertical Datum program.**
All Six Communities and to Address Statewide Need	**IAWG Recommendations: Identify and conduct coordinated strategy.** - Through inter-agency and local coordination identify cost savings, such as - Align timing of projects requiring heavy equipment. - State needs to establish a fund to ensure co-sponsorship is available if/when federal funds.	**Described in Recommended Policy 1 and 2**	**No Budget Identified**

2009 Immediate Action Funding Recommendations			
Community	Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	IAWG Action
	- Find/develop Western Alaska rock source to reduce costs. - Local coordination is needed to assist with planning efforts and project alignment. - Local capacity building and augmenting community's administrative capacity is required.		

KIVALINA

Situation Description: Ongoing erosion and flooding concerns have caused problems for a number of years. The recently installed seawall was ineffective at arresting erosion and was severely damaged with sections completely destroyed during the minor storm events of 2006. The USACE has an approved project for 3,300 linear feet of rip rap revetment with a current estimated cost of $26 million. With the recent fluctuations in fuel costs this estimate is still likely low. The USACE constructed 400 ft of revetment in 2008 and plans to construct another 1200 ft in 2009, at a contract cost of $12.5 million. The NW Arctic Borough intends to construct the last 400 ft in 2010. Erosion is threatening the waste storage containment area located at the dump site. This is a potential environmental catastrophe for the surrounding water bodies. It will contaminate the area where subsistence activities are still practiced i.e. fishing and storage of fish on the lagoon side of the island.

Description of Immediate Need: 2000 LF is needed to *provide interim protection* for critical structures and residences on the ocean-side of the island while long-term plans for Kivalina are worked through. Anticipated contract cost is $16M[3]. USACE awarded 1,600 feet of revetment at a cost of $12.5 million (400 ft constructed in 2008 nd 1200 ft to be constructed in 2009). NW Arctic Borough intends to fund construction of the last 400 ft in 2010.

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	IAWG Action
Revetment/Erosion Control Project **Near-term (next 18-24 months):** Construction of 2000 LF linear feet of rip rap revetment with a current estimated cost of $16 M .to protect critical structures and residences on the ocean-side of the island where catastrophic erosion is taking place. **Intermediate-term:** Construction of 1300 LF of rip rap revetment to provide interim protection to critical structures and residences at the lagoon side of the island. Estimated cost is $10 M. Total anticipated revetment project is $26 M. (protection for both ocean-side and lagoon-side of island).	**FY09 - $3.3 million appropriated in Capital Budget, to the NW Arctic Borough** Phase 1: USACE – 400ft built in 2008 and 1200 ft in 2009. Another 400 ft ($3.3 from NWAB) will be built in Summer 2010. Phase 2: Lagoon-side 1300 ft revetment: USACE began design during Winter 2009. Intermediate-term Estimated State Capital Funding needed – $5.8 million.	**FY10 –** **NWAB and USACE will complete Phase 1 with funds appropriated in FY09 timeframe.**

[3] The base bid for the project is $3.9 M for constructing 400 LF of rock revetment, with a total cost of $4.5 million. This contract includes four options to construct 400 LF each at approximately $2.4 million each, if funds are received before Mar 09. A contractor mobilization cost of $375,000 would also be required for the second year of construction.

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	IAWG Action
State of Alaska should serve as 3rd Party Reviewer for geologic aspects of USACE (Relocation) Assessment Reports Alaska DGGS as lead.	**FY09 Budget Estimate:** $12,000[4] DGGS was only able to conduct a preliminary in-house review of USACE reports; full review awaits. (Unable to complete due to staffing levels.)	**Late FY 09/FY10 – IAWG recommends DGGS conduct using CIAP funding already in hand. Hiring freeze will be a hindrance to this action.**
Relocation Feasibility Study Geologic Mapping (Alaska DGGS as lead).	**Budget Estimate:** $180,000	**Late FY09/FY10 - Funding for mapping approved through CIAP funds for 1 or 2 communities only. If hiring freeze lifted, study may begin in 2009.**
Evacuation Road Feasibility Study: NWAB and Denali Commission – leads	DGGS/Geologic Mapping is needed first	

[4] This budget estimate is only for DGGS review of geologic aspects of the USCOE's relocation assessment reports. Broader, full review would involve many more participants and may not be appropriate for DGGS to lead. For review of all aspects, I suggest DCCED take the lead and draw on DGGS as well as other appropriate agencies. A larger budget estimate is needed if this is the intent. (Rod Combellick, DGGS edits to March 20, 2008 draft IAWG Recommendations Report).

KOYUKUK		
Situation Description: There are three types of serious threats/impacts facing Koyukuk –erosion, flooding, and fires. The entire village of Koyukuk lies within the floodplain of the Yukon River. Erosion occurs during anytime the river is open and specifically during high flow events on the Yukon River. These events happen throughout the year, including floods during spring breakup ice jam events; spring/ summer/fall significant rainfall events; wind, and permafrost melt at Koyukuk and upstream. These floods are often severe, inundating a majority of the Village and sometimes requiring evacuation of citizens to other villages. These problems have been persistent and serious enough – often flood warnings provide only a 2 hour window to evacuate – that the community has begun planning efforts to relocate themselves to higher ground above the floodplain of the Yukon River upon nearby Koyukuk Mountain.		
Overarching Problem: No definite timeline or authorities for erosion control and/or relocation makes it difficult to plan for needed erosion control projects and relocation. It's difficult to coordinate and focus resources.		
Immediate Actions Identified to Prevent Loss of Life and Infrastructure	**Past and Future Budget Notes**	**IAWG Action**
FY10 Immediate Action and capital budget recommendation is for DOT/PF to conduct Engineering Studies: reconnaissance study, preliminary engineering and environmental work, and final design for an evacuation road. **Upgrade Existing Road:** Ensure road is passable during flooding. Tribal Administrator believes that riprap along the lower part of the road near the river is all that's needed. Portions of the airport were done in 2006. **Review Feasibility/Options Report:** Koyukuk, DGGS, ADOT/PF, and DCCED should review the USACE Recommendations Report to provide feedback/reality check to the USACE Report was recently provided to Koyukuk community. USACE representatives travel to Koyukuk to meet with community. USACE draft report proposes relocation of the community to higher ground because 11 structures are at risk from erosion and most other structures are in the flood plain. *Regulatory issues identified to allow current community to remain as a fish camp or the like.* **Coordination Among:** Koyukuk, USACE, ADOT/PF, DCCED, DHS&EM for preliminary engineering, planning, and funding strategy.	**FY09 Capital Budget included funding for Feasibility Review.** Coordination and reviews during FY08 & FY09 were covered in FY08, FY08-Supplemental, or FY 09 Capital Budget (with Community Planning grants and DHS&EM Emergency Planning/Training).	**FY10 IAWG Budget Recommendation $800,000 ($400,000 included in Governor's Capital Budget)**

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	IAWG Action
Elevate Current Structures: Koyukuk has identified this action as a means to prevent damage to infrastructure from floods. The community will work through existing organizations, such as Tanana Chiefs Conference, DCRA, AHFC, Interior Housing Authority to seek technical assistance and funding.		Provided Koyukuk with organizations and agencies to contact for assistance.
Build Evacuation/Emergency Center: Ensure Koyukuk has an emergency shelter. Need to address issues in Feasibility Report and identify decisions acceptable to community and funders. **IAWG Comments:** Recommended actions/next steps for the Shelter have been provided to the Community by the USACE in the report identified in Project 2. If Koyukuk wants to move forward with the USACE recommendation, then studies (geological, etc.) need to be conducted to ensure the selected site is satisfactory. A project cooperation agreement will need to be signed between the community and the USACE. Recent experience with similar projects shows this is not a significant effort. A clear process for site assessment, etc. along with a funding strategy will need to be developed. Permitting and environmental coordination is ongoing. No significant issues have arisen for ESA, wetlands, or SHPO, though coordination will continue.	**FY11 or Future Capital Budget: Evacuation Center Construction Estimate:** $4.5 million.	

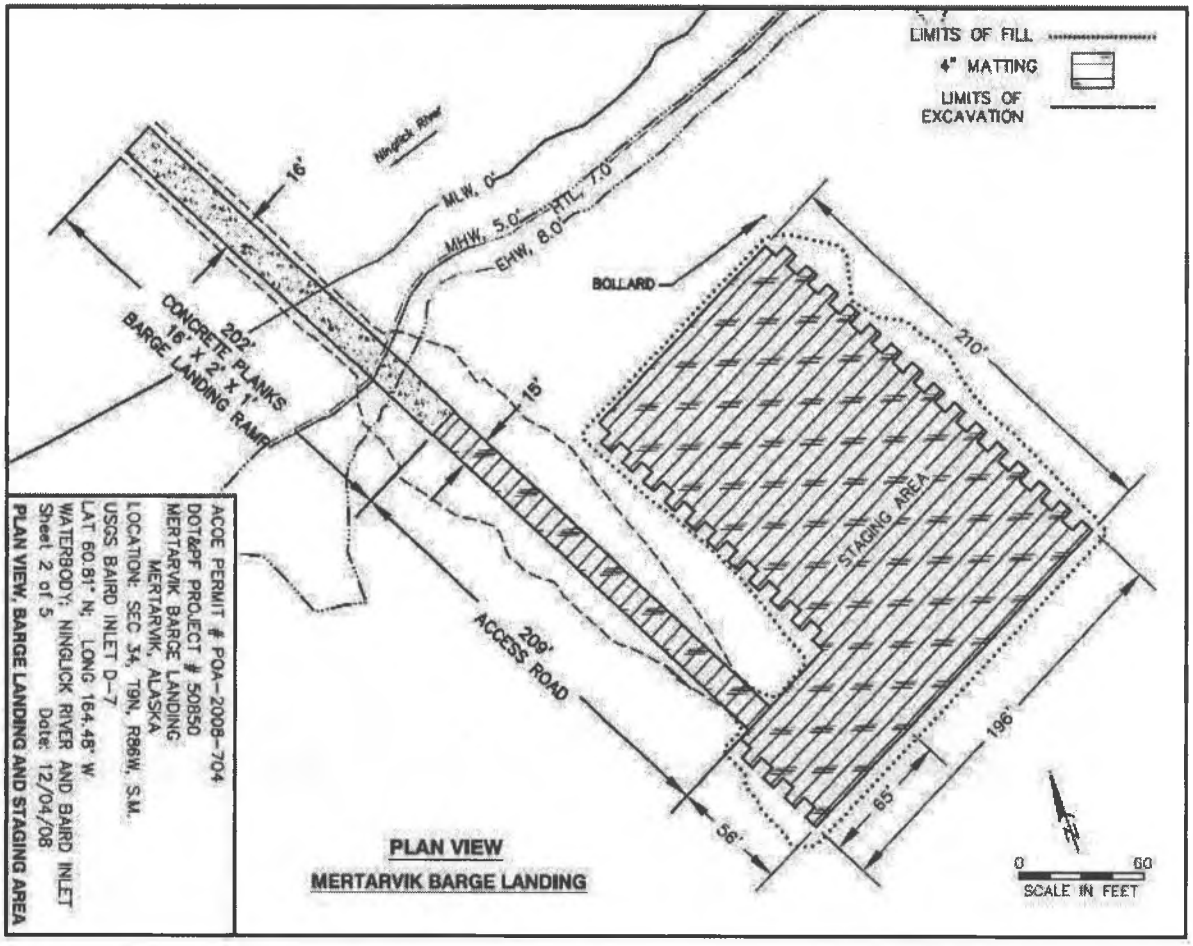
NEWTOK

Situation Description: Newtok facilities – both public and private – have already been severely damaged by erosion and storm surge flooding due to lack of sea ice, and it's anticipated that continued erosion and destruction of public and private facilities are imminent. Problems endemic to many rural Alaska communities, such as a lack of adequate drinking water and sanitary sewage disposal, have been worsened by the erosion and flooding.
Overarching Problem: No definite timeline or authorities for erosion control and/or relocation makes it difficult to plan for needed erosion control projects. It's difficult to coordinate and focus resources without funding sources and timeline.

USACE Status: Designs are underway for the road from the barge landing to the evacuation center at the new town site for Newtok. USACE does not currently have funding to construct the road, which is estimated at $15 million.

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	IAWG Action
Build Staging Area for Barge Landing – Ensure ability to receive supplies. **FY 10 Capital Budget** of $2mm will develop material site and produce rock for **construction of barge staging area, evacuation center road**, and IRT camp facility construction staging area. Construction will be completed through an Innovative Readiness Training exercise, estimated at $3.5-$5 Million, beginning in summer 2009. In the 2009 construction season the barge landing and staging area will be completed at the Mertarvik site. A **fuel distribution header and pipe** will be built at the Newtok existing town site that will allow for barges to offload fuel to supply fuel for electrical generation. In 2009 the Innovative Readiness Training program in the Department of Defense has agreed to begin development of the Mertarvik site as a military training exercise. U.S. Navy has located an office at ADEC to coordinate this project. **Build Road to Evacuation Site** – Ensure community has access to shelter (1.5 miles). **Build Evacuation Center/Shelter** – Ensure community has an emergency shelter (approx 4,000 sq ft + 2,000 sq ft equipment shelter).	**FY09 Capital Budget includes partial funding to DOT&PF combined with an $800k EDA grant to complete barge landing and staging area at Mertarvik by July 15, 2009.** IRT Road project will be worked on from July 15-Sept. 1, 2009 with Newtok Project as its national top project. CCHRC design of evacuation shelter significantly reduced costs. FY08 Supplemental Capital Budget included $279,000 coordination and planning funds for staging, landing, road and shelter. **Coordination Among** Newtok, USACE, ADOT/PF, DCCED, and the Newtok Planning Group have determined what road standards are needed and how to leverage resources to build the road and shelter. USACE and Newtok Tribal Council entered into a Project Partnering Agreement in Jan 09. Coordination was expanded to Navy in FY2009 and it was determined that building the Evacuation Shelter	**FY10 IAWG Budget Recommendation: $2,000,000 (included in Governor's Capital Budget- and will leverage Federal IRT funding of $3.5-$5 million.)** **FY 11 funding recommendation: $5 million to develop quarry for materials use by IRT**

	can be used as a training exercise for IRT. ADEC-Village Safe Water completed new well at current site.	
Airport Planning - Step 1 – Site Selection ADOT/PF recently received approval for a second year of wind and geotechnical studies by FAA. Four runway alternatives are being studied. Selection of a preferred alternative is expected by spring 2009.	**IAWG Comment:** Scenarios should be identified for a new airport with various functionalities that can then be reflected in different cost structures.	



Conceptual design of Mertarvik Barge Landing and Staging Area. ADOT/PF

SHAKTOOLIK		
Situation Description: The community is vulnerable to erosion when fall storms hit the sand and gravel spit upon which the community resides. There is no breakwater to protect the community from destructive waves from Norton Sound when storms come from the southwest. In severe storms, the community becomes an island. The beaches have historically been susceptible to damage and erosion from storm conditions, tidal surges, and from the sea ice conditions. Logs that float down the Yukon change from being protective to becoming destructive during storms surges. Several areas along the coastline used by the people in Shaktoolik are vulnerable to erosion and flooding during the storm season Over the past three floods natural barriers have eroded substantially. **Overarching Problem:** No definite timeline or authorities for erosion control and/or relocation makes it difficult to plan for needed erosion control projects and relocation. It's difficult to coordinate and focus resources.		
Immediate Actions Identified to Prevent Loss of Life and Infrastructure	**Past and Future Budget Notes**	**IAWG Action**
Preliminary Relocation Site Assessment for relocating village. **Corps Section 103 Storm Damage Reduction Study** Initiated and progressing to evaluate protection of strategic locations in the community and the water supply. **Evacuation Road – Approx 8.5 miles** **Step 1:** FY 09: Reconnaissance Study, funded by Denali Commission (completed) **Step 2:** FY 10: Road Design and Engineering The recon study is adequate to begin the permit process for coastal engineering. **Step 3:** Unknown timing for Construction **Coordination Among Shaktoolik, Kawerak, Federal, and State Agencies:** Funding, design, etc.	FY08 Supplemental included funds (estimate is $150,000) for preliminary relocation site assessment. (DCRA Community Planning Grant – in 2009.) Land Exchange (12a) for identified relocation site is needed. Local Community, Village Corporation, and Regional (Kawerak) are working on this. GPS coordinates identified in 2008. **Road Budget Estimate:** Reconnaissance Study estimates road design at $3mm. Current commitments from Denali Commission for $1mm, Kawerak for $1mm, and BIA- IRR $500k pending, high priority projects. Shaktoolik/Kawerak are requesting State for $500k "match". Funding should be pursued and coordinated to develop both the permits and road design, concurrently.	**FY 10 IAWG Recommendation: $500k from state to leverage other funding for design of Shaktoolik relocation road. (Not in Governor's Capital Budget)** **Village of Shaktoolik needs to request Congress it be added to the Alaska Coastal Erosion Program under authority of Section 117.** **Examine shorter term solution of constructing evacuation shelter in existing community to allow safe shelter in case of flooding.**
Hazard Mapping Study Geologic Mapping (Alaska DGGS as lead)	**DGGS Budget Estimate:** $180,000 **USACE CAP limit:** $3 million Federal with 35 % local match required for construction. Current funds: $70,000 available for study.	**FY10 IAWG Recommendation: ~$180,000 DGGS will only be able to study 1 or 2 communities in 2009 due to funding. Hiring Freeze is a hurdle.**
Cabins and 30kw Generator Shaktoolik identified that Cabins built for emergency use.	Community is moving forward with this project for emergency housing along new Evacuation Road route.	

SHISHMAREF

Situation Description: Shishmaref has been threatened by erosion for many years with recent increases due to the lack of sea ice during the fall storm season. A partially completed USACE project is providing protection for portions of the shoreline.

USACE Description of Need: The washeteria and lagoon are not protected, but 750 LF is under contract by USACE to install by Oct 09. The length was determined by funds availability. USACE anticipates the contractor will mobilize for the Summer 2009 to complete that segment. This increment of rock revetment was awarded for $10.5 million for construction cost, which would protect homes and a church. Another 550 feet of rock revetment for the northeastern area is under design and needed to protect the washeteria and the sewage lagoon at an estimated cost of $7.75mm – funding is still needed. Revetment needs to be extended for the protection of the southern end of the Village by 325 ft and raise the other 900 existing ft – funding is needed.

Overarching Problem: No definite timeline or authorities for erosion control and/or relocation makes it difficult to plan for needed erosion control projects. It's difficult to coordinate and focus resources without funding sources and timeline.

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	Action Taken
Funding Strategy Coordination: Shishmaref, USACE, ADOT/PF, and DCCED **<u>Revetment/Beach Erosion Control Project</u>** **Phase 1: 600 feet of rock revetment completed in Sep 08.** **Phase 2: 750 feet of rock revetment under contract to be completed by Oct 09.** **Phase 3: 550 feet of rock revetment under design in 2009; construction funding needed.** **Phase 4: 1,225 feet to be surveyed in 2009; of this 325 feet will be new rock revetment and 900 feet will be raising existing revetments when funding is provided.** 750 ft section will provide protection to the North shore including the washeteria and sewage lagoon. USACE construction contract: $10.5 million for 750 ft.; $25 million for remaining project. **FY10 State/Federal Coordination:** USACE will provide revetment design (at a cost of $500k) for Phase 3 of erosion control revetments. State may provide $3 million for construction.	**For FY08 & FY09:** Coordination covered in current and/or FY08 Supplemental. **As of April 2008: FY10 and FY11 Recommendation for Capital Budget** (Estimate) was $8.5 million or 35% of $25 million based on USACE estimates for revetment/erosion protection funding. USACE secured funding in 2008 Federal Supplemental.	**FY 10 IAWG Recommendation: $3 million (included in Governor's Capital Budget) and leverages USACE funding)** **The State identified $3 million was needed to complete the additional 550 feet of Oceanside rock revetment to protect the northeastern edge of Shishmaref, including the sewage lagoon and washeteria.**

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	Action Taken
Relocation Planning – Road, Geologic Site, Airport and Port Site Master Plan, Community Planning **Relocation Road Reconnaissance Assessment** ($500k for assessment - Road from mainland) **Lead:** ADOT/PF and Shishmaref **Shishmaref Relocation Feasibility Study** Tin Creek has been identified as the Community's choice, but without Feasibility Study, a decision can't be made whether it is a satisfactory relocation site. **Community Relocation Planning** – Funded in 08/09 continuing effort **New Airport Master Plan and Site Location for Port**	**Community Comment:** Potential Gravel Haul Road to new Airport. Geotech data (being done Mar-April 2008). The USACE has been approved to perform a feasibility study at full Federal expense to analyze the relocation options for the community of Shishmaref. No funds are currently available. NRCS did some site identification previously. *Environmental studies were initiated for a programmatic EIS of community relocation with limited funding.* **IAWG Comments:** **Scenarios Needed** for A/P and Port should be identified for a new airport with various functionalities that can then be reflected in different cost structures. **Coordination Needed:** Shishmaref – city, tribe school, DCCED/DCRA USACE, ADOT/PF Having local capacity and a coordinator is needed to assist with these planning efforts and projects at the local level – capacity and administrative capacity building. **Completion Date:** Dates can't be determined until funding source identified/authorized.	**IAWG recommends community meetings and joint collaboration with state and federal agencies that can bring resources in terms of technical capability and funding to support these efforts.**

UNALAKLEET

Situation Description: Unalakleet is susceptible to erosion damages along various locations in the community. Particularly along an NRCS gabion revetment that has been damaged by storms. The recommended project is a 1,500 foot long rock revetment which would be constructed along the alignment of the existing NRCS gabion basket revetment. The NRCS project would be removed or covered by the USACE project. $20-30 million is the most current estimate available. Another threat is the logs that float down the Yukon, in that they change from being protective to becoming destructive during storms surges.

USACE Status: Design for 1500 ft of rock revetment is complete and is being advertised for construction and proposals due by Feb 20, 2009.

Overarching Problem: No definite timeline or authorities for erosion control and /or relocation makes it difficult to plan for needed erosion control projects. Difficult to coordinate and focus resources without funding sources and timeline.

Immediate Actions Identified to Prevent Loss of Life and Infrastructure	Past and Future Budget Notes	Action Taken
USACE has completed design work and is evaluating contractor proposals for a construction contract. Construction is scheduled for completion in 2010 if sufficient funds are available. **FY10 Unalakleet identified the opportunity to move Old School Gym to higher ground for use as an Emergency Shelter. –** Assessing sites for higher ground evacuation identified as immediate need in 2008 along with design and location of evacuation road (and shelter). **Gym Move Capital Budget Estimate is $1mm** Cost estimates were identified after Governor's Budget was submitted to Legislature.	**FY 09 Capital Budget funding of $5mm obtained for revetment and erosion control project and leveraged USACE funds from Congressional Supplemental** (35% of $13.5 million project), and coordinate this project with ADOT/PF's 2008 Airport Erosion control project. Construction completed in 2010 if sufficient funds available. 2008 funding was critical if take advantage of heavy equipment in 2009 season that will already be in place for ADOT/PF – Airport projects. Estimated cost savings: Based on discussions throughout the IAWG process, cost savings could be substantial if the same heavy equipment is used for multiple projects, thereby minimizing mobilization/demobilization costs. Based on input from ADOT/PF and USACE, the most effective means to achieve cost savings will be to synchronize state and federal projects so they can be jointly advertised but awarded separately. Local Street Projects cost benefits using equip while in place – forego additional mob/de-mobilization costs.	**IAWG Recommendation: Need funding strategy to ensure erosion/revetment project is done in 2009/2010. (Unalakleet/DCCED/USACE.)** **FY10 IAWG recommendation: Community should pursue funding for Gym Move with the Legislature and Alaska Delegation. Estimated budget is $1million**

POLICIES

Strategic and Community Assistance Recommendation Policies

Last year, the IAWG recommended policies to advance comprehensive integrated planning and a comprehensive statewide data collection and evaluation system. In this 2009 report, we carry those recommendations forward as Policy Recommendations 3 & 4, and include additional detail to them, which the IAWG believes will help to effectively initiate and implement those policies.

IAWG adds two new policy recommendations, and because they are more strategic and overarching in nature, those policies are identified as Policies 1 & 2. Policy 1 addresses how Alaska could create an integrated system of information, analysis and evaluation to make cost-effective decisions on public infrastructure, and Policy 2 addresses the role of the Immediate Action Workgroup and helps to advance Policy 1.

IAWG's policy recommendations, for which the justification is further detailed in Appendix A, are described in this section. The IAWG has created working relationships that can help to advance these recommendations in a meaningful and cost-effective manner, which is why the IAWG is *recommending that the Subcabinet refer the next steps to advance these policies back to the IAWG.*

One of the anticipated outcomes of the IAWG's 2009 efforts was to identify the "next six" communities in need of immediate action, due to impacts from climate change phenomena.

Climate change phenomena have been identified as:

- Lack of sea ice
- Change in extent of sea ice
- Timing of sea ice
- Increased effects of storm surges unbuffered by shorefast ice
- Erosion due to flooding or permafrost melt
- Flooding
- Permafrost melt
- Wild fires

The various IAWG participating agencies were able to identify over 150 communities of concern based on their mission-specific programs. ***However, not one agency had analyzed their actions, nor responded to community needs based on climate change.***

Based on the IAWG's 2009 efforts where we brought together information and data from various agencies to identify the next six communities in need of immediate action, we found:

- There is no consistency in criteria, timeline, weighting, data acquisition technique or analysis to determine if impacts are from climate change.
- No framework exists for the comprehensive identification, analysis, and dissemination of current data or the methodical acquisition of new research to support new policy options.
- Without new policy options state and federal agencies are severely limited in their ability to integrate or identify data, research, programs or projects necessary to mitigate or prevent impacts to communities.
- We were unable to, with confidence, identify the next six communities for immediate action.

- Many state and federal agencies and academia are researching potential projects, programs and research efforts to assist communities that are impacted, or potentially impacted by climate change phenomena. However, each agency is working from differing sets of assumptions, approaches and timelines.

- State and federal agencies are severely limited by this lack of integration for data, research, and program or project development.

- This environment of uncertainly increases the risk of many communities of facing extreme risks from the unknown effects of natural disasters.

- The traditional "stove-piped" approach of creating and managing government programs ensures a narrow, myopic view of community needs and places the individual programs in competition for approval and funding.

- This segregated approach increases the uncertainty of funding but decreases the potential for meaningful and comprehensive assistance.

- The State of Alaska, just as the federal government, plans for and manages programs primarily through individual departments. The priorities are set usually during budget formulation for the next budget cycle. However, many capital projects need years of planning for engineering study and design and for the identification of federal funding. These funding decisions occur for each individual agency and often are without consideration of other state or federal projects that may be in potential conflict for the same community or region.

From these findings, the IAWG recommends:

- **An integrated, multi-agency and inter-governmental approach to effectively identify and address the needs of communities that are potentially in peril.**

The outcome and benefit of this integrated approach has:

- Significant potential to save money on public infrastructure, avoid costly delays, save funds through economies of scale and combining mobilization, mitigate the effects and costs of disaster relief and recovery.

POLICY 1: ESTABLISH A STATEWIDE SYSTEM TO DOCUMENT, ASSESS, AND ANALYZE CURRENT AND PLANNED PUBLIC INFRASTRUCTURE IN ORDER TO PROTECT EXISTING AND FUTURE INVESTMENTS AND PREVENT THREATS TO LIFE IN AN UNCERTAIN ENVIRONMENT

The Immediate Action Workgroup offers a model for a statewide system that integrates information from all state departments, local entities, and federal agencies on current and planned public infrastructure and capital projects in communities currently or potentially affected by climate change. This system will enable a more rapid identification of community needs and vulnerabilities, and more informed decisions on the future repair, retrofit, replacement, or relocation of critical infrastructure. Further, the IAWG believes, this statewide system will create a more cost-effective means to make decisions about public infrastructure needed to ensure community safety and economic viability.

1) **A statewide system to make timely and cost effective decisions for both the public and private sectors must include:**
    a. Identifying all data on public and critical infrastructure from:
        i. State agencies
        ii. Federal agencies
        iii. Denali Commission
        iv. Local governmental entities, including tribal entities
        v. Non-governmental organizations
        vi. Private sector
        vii. Academia
    b. Consolidating and linking together data to:
        i. Enable queries for agencies and communities
        ii. Improve quality of data and databases
    c. Analyzing data to:
        i. Identify and fill gaps in data
        ii. Determine status and capability of current infrastructure
        iii. Determine useful life and future plans for repair, renovate, retrofit, replacement, or relocation
        iv. Determine vulnerabilities to climate/weather and other environmental/economic factors
        v. Identify all funding and budget streams
        vi. Identify conflicts between agency plans
        vii. Resolve conflicts for timely implementation
    d. Integrating policy to:
        i. Improve policy coordination between agencies – timing, impacts, integration
        ii. Determine effects of proposed policies
        iii. Test assumptions of climate, economic trends and strategic directions
        iv. Determine effects of non-state policies and budgets
        v. Update analyses for new data information
            1. Weather patterns/flood plains/mapping
            2. Economic assumptions
            3. Changes in demographics
        vi. Document out-year O&M costs
        vii. Calculate life cycle costs
        viii. Contribute data to budget formulation

2) **A statewide system to make timely and cost effective decisions for both the public and private sectors must be based on a collaborative decision making model that consistently includes:**
    a. Key stakeholders
    b. Identified timelines and outcomes
    c. Streamlined process to minimize unnecessary effort and transaction costs of developing and carrying out the statewide system

3) **A statewide system to make timely and cost effective decisions for both the public and private sectors must be based on an organizational structure that likely possesses the following characteristics:**
    a. Executive order to establish and create structure
    b. Senior State Executive as manager
    c. Small staff

d. Non-centralized and non-bureaucratic system
e. Implementation (planning and building capital projects) is through existing agencies/authorities
f. Monitor to make sure things progress in proper order
g. Identify and integrate new opportunities, such as the likelihood of cap and trade
h. Identify and integrate old challenges, such as timely processing of permits and integrating sustainability into communities and economies in remote Villages

Rationale:

- The number of communities potentially impacted by climate change phenomena is growing
- The locations of these communities are spread across the entire state of Alaska.
- The ability to identify which community or piece of infrastructure is most at risk cannot effectively be done given current procedures that are not linked and coordinated.
- Coordinating and linking procedures, organizational structures and leveraging budgets will be most effective if a collaborative approach is used to identify, assess, and make and implement decisions.

Implementation – Initial Steps

IAWG Recommended Action to Subcabinet: Adopt Policy 1 and provide the IAWG with guidance to develop implementation options for this policy. At a minimum the guidance should instruct that options should include identifying benefits, challenges, and effective organizational structures for implementation. This integrated system will create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance should also include melding the relevant Adaptation and Mitigation Advisory Groups' products with this statewide system to reach a desired outcome of integrated actions in order to address what seems to be increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective statewide system.

POLICY 2:	**SUNSET THE IMMEDIATE ACTION WORKGROUP AND DIRECT THE RELEVANT STATE AGENCIES TO ESTABLISH AN INTERAGENCY COLLABORATIVE WITH EACH OTHER, ALONG WITH RELEVANT FEDERAL AGENCIES AND COMMUNITIES. THIS COLLABORATION REQUIRES REGULARLY SCHEDULED MEETINGS TO COORDINATE INFORMATION, PLANNING, EVALUATION AND DECISIONS ON PUBLIC INFRASTRUCTURE FOR THOSE COMMUNITIES IMPACTED BY CLIMATE CHANGE PHENOMENA.**

The Immediate Action Workgroup believes that the outcomes and results of its ad hoc collaborative efforts over the past year have been exceedingly useful and should be integrated into agencies' operational efforts. This policy recommendation should be viewed as an interim step to implementing Policy 1 above. Once Policy 1 is established as a strategic operational mechanism, then the IAWG should be integrated, reformulated or discontinued, depending on the structure and needs of the statewide system.

Implementation – Initial Steps

IAWG Recommended Action to Subcabinet: Adopt Policy 2 and provide the IAWG with guidance to develop options to accommodate the transition described in Policy 2. At a minimum the guidance should instruct that options include identifying benefits, challenges, and effective organizational structures for implementation. This precursor to an integrated system will set the framework to create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance to the IAWG should also include melding the relevant Adaptation and Mitigation Advisory Groups' products into options for Policy 2. This would be in an effort to reach the desired outcome of taking integrated actions to address the increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective interagency collaborative while a statewide integrated system is being established.

POLICY 3: ASSISTANCE TO COMMUNITIES IN PERIL MUST UTILIZE COMPREHENSIVE INTEGRATED PLANNING AND VIABLE, FUTURE-ORIENTED SOLUTIONS WITH FUNDING THAT ALLOWS FOR SUSTAINABILITY WHETHER THE COMMUNITY REMAINS IN PLACE, USES A MIGRATION STRATEGY OR NEEDS TO RELOCATE.

The Immediate Action Workgroup believes that comprehensive integrated planning must be used to develop and implement solutions for communities in peril. The planning process must integrate the expertise and resources available from many state and federal agencies working with community and regional stakeholders. Flexible funding streams should be sought; and may need to be created, to accommodate the needs associated with preserving the options available for protecting public infrastructure and preventing loss of life. These options range from staying in a community's current location, to a migration strategy, to full relocation. All of these options should integrate the concepts of sustainability into the design, location, and attributes of projects, and if relocating, into future settlements. Existing and new funding mechanisms for responding to climate change hazards should also provide for adaptation and mitigation measures. In seeking funds for adaptation and mitigation, an examination of current federal and State statutes needs to be conducted to identify limitations in addressing these measures. The Stafford Act, for example, limits the ability of the State to deal effectively with communities in peril.

Implementation – Initial Steps

- **IAWG Recommended Action to Subcabinet:** Adopt Policy 3 and include guidance to the IAWG to develop more detailed implementation options in coordination with the appropriate stakeholders

Five major actions are necessary to address and advance assistance to communities in peril. Each of the five includes a description of the action, rationale and implementation steps for each action.

---

1) **Comprehensive Integrated Planning must include:**
   a. Suite of Community Emergency Planning Efforts.
      i. Community Evacuation Plans.
      ii. Community Emergency Operation Plans.
      iii. Hazard Mapping, Hazard Analysis, and Mitigation Plans.

iv. Preparedness Activities to include outreach, training, and exercises.

b. Community Wildfire Protection Plans for communities at significant risk of wildfire.

c. Expansion of Comprehensive Community Plans to encompass strategic options to address and mitigate climate change impacts of stay in place, migrate and if necessary, relocation

d. Community-based decision making approach will ensure continued focus to achieve the necessary end result.

e. Local, Regional, Tribal, State, and Federal partnerships.

f. Strategies that address incorporated and unincorporated community eligibility for the National Flood Insurance Program (NFIP), which likely require statutory changes by the State of Alaska.

g. Enhancement and expansion of DCCED/DCRA's partnership with the Alaska Coastal Management Program (ACMP) to enable more effective assistance to the communities in peril and at significant risk.

h. A strategy to consolidate various programmatic and grant reporting requirements into a single format that reinforces comprehensive integrated planning.

i. A strategy to collect and utilize needed data and to develop data where gaps exist, including sustainability principles and strategies. (See Policy 2).

Implementation actions:

- Inclusion of native villages, tribal governments, and other land owners in collaboration with agencies during the planning process provides a wide range of benefits from broad-based community support and commitment to specifics such as land relocation issues. Communities take the lead and receive significant support from state and federal entities.
- Ease the administrative burden on remote communities by establishing a shared web-based system as an initial step toward consolidating program and grant reporting requirements into a single format.
- Identify coordinating and participating agencies and develop necessary Memoranda of Agreement (MOAs).

Rationale:

➢ Comprehensive planning has multiple benefits identified throughout this document. Comprehensive planning increases the ability to address complicated land exchanges involving multiple parties with permitting such as complying with NEPA requirements. NEPA requires the review of the effects of all federal, federally-assisted, and federally-licensed actions at any proposed new village site, including, but not limited to: Estate permits, endangered species, coastal consistency, essential fish habitat, and a host of other regulations and requirements recognizing agencies with funding or potential projects. Increased collaboration should focus on solutions such as a Programmatic EIS that can be developed which addresses many of the general issues involved in a proposed relocation. Once a lead agency is identified for NEPA some of the challenges the lead federal agency may encounter include, and can be most effectively addressed through coordination and cooperation, are:

- Identification of coordinating and participating agencies and development of necessary Memoranda of Agreement (MOAs).
- Identification of funding to undertake a NEPA analysis if such funding is not in the current project budget.

- Waiting for a disaster event that forces relocation will result in unnecessary risks to life/safety and extraordinarily complex response/relocation/recovery.
- Foundational plans (flood plain mapping, orthographic and geologic mapping, hazard mitigation planning, community and regional emergency and evacuation plans) are critical building blocks for comprehensive community relocation planning. Only through integration of these plans can we characterize possible relocation sites, identify hazards, and locate potential construction materials resources
- Adoption of a formal State Hazard Mitigation Program integrated with federal hazard mitigation programs would help protect current investments in communities and preserve the options during the decision making process for possible relocation.
- Preparedness activities provide opportunities for communities to test and modify plans in non-emergency situations.
- A Comprehensive Community Relocation Plan is essential to informed planning for communities in peril and is anticipated to significantly reduce costs compared to disaster-related response costs coupled with non-comprehensive approaches to mitigation and relocation.
- The full costs of not relocating a community in peril, e.g. erosion control at a current site and repair/replacement of essential public facilities should be considered when developing relocation policies and priorities. This analysis should also review projected costs based on different timeframes to relocate. This can provide policy makers as well as taxpayers better information from which to consider cost effective alternative.
- Unincorporated communities are not currently eligible for the National Flood Insurance Program (NFIP) and the State must address this issue. Under existing statutes, the Legislature has responsibility for land-use issues for unincorporated areas of the state. Therefore DCCED and the Department of Public Safety, Division of Fire and Life Safety should develop recommendations and implementation strategies for the Legislature to consider, that addresses incorporated and unincorporated community eligibility in the NFIP.
- Imperiled communities are overwhelmed with the level of paperwork and documentation required by various agencies for grant and regulatory and other compliance. Alaska's small remote villages have the capability but lack the staff to handle this onerous documentation and reporting requirement for each funding stream.. It would greatly help viability and functionality of a remote village if funding agencies could, wherever possible, collaborate and provide integrated report/documentation that could serve the purpose of all funding agencies.
- Obtaining and administering government funds can be a challenge for small communities. Local capacity limitations place many rural communities at a competitive funding disadvantage. Because there is no dedicated funding source for erosion and/or relocation, imminently threatened communities must rely upon existing programs to meet erosion/relocation needs, yet few have the expertise to identify, write, secure and administer grants.

---

2) **Flexible Funding Streams must accomplish**:

a. Analysis of projected costs of all viable relocation alternatives, including the costs of remaining in place

b. Emergency, hazardous and evacuation plans for communities in peril to prevent loss of life when a natural disaster occurs

c. A means of prioritizing project funding from many sources for many communities for the most effective results. This includes providing capacity building opportunities in communities by funding local training or consulting efforts, where needs have been identified.

d. State funding to attract federal funds.

e. Sufficient full-time employee positions for state agencies taking a lead or participative role to address expanded agency functions.

Implementation Actions:

- Develop investment guidelines and priorities to address critical infrastructure for communities-in-peril. Guidelines should include an assessment to identify critical needs, similar to the DCCED RUBA program. Guidelines must consider the need to swiftly respond to emerging changes in climate, hazards, and research.
- State appropriations must be synchronized with federal appropriations to better position our coastal erosion needs in the federal process. State appropriations should be distributed through a grant process consistent with the Policy recommendation in paragraph 3. DCCED should be the coordinating agency. Distribution of funds the first year will come with a requirement to identify the Immediate Actions scope, schedule and budget prior to the release of funds for any construction contracts.
- Identify funding to undertake a NEPA analysis if such funding is not in the current project budget. Funding sources, such as through AHFC, encompass new construction but not funds to rehabilitate a damaged structure or one that needs to be moved out of imminent danger, even when the costs of doing so may be substantially less than replacement (e.g., less than $20,000 to save a home). A funding mechanism is needed to stage structures, to stabilize and move infrastructure in imminent danger before the damage is inflicted. Identifying secondary and preventative protections can be accomplished through agency coordination with the community. However, specific assessment tools are lacking as are the entities most appropriate to apply them. These must be identified and applied in a coordinated and site specific effort. The tool(s) should identify at-risk facilities appropriate to move and the means to decide on exact relocation measures – how to move, where to move, whether to elevate or relocate away from threat.
    - Roles and Responsibilities: Each responsible agency must identify barriers to making coordinated decisions on infrastructure investments in threatened and newly designated communities (relocation sites). This process should identify needs to revise existing policies, statutes, and regulations or to create new ones to effectively address communities-in-peril and optimize the current community efforts to keep moving forward in the process.
    - Community in Peril: Newtok finds itself in a Catch-22, or a no-win, situation. Plans to relocate, combined with the imminent threat of flooding and erosion, has rendered Newtok ineligible for capital funding for improvements to existing infrastructure (e.g., water and sewer, bulk fuel tanks, power plant, and clinic) to meet needs at the current village until the relocation is complete or substantially complete. The ability to divert designated resources to the new village site is hampered by policies that create barriers to investment in non-existent communities.
- Any upgraded facilities or new facilities must be protected against imminent environmental threats, such as flooding and erosion, consistent with Administrative Order No. 175.

Rationale:

- Current funding streams neither require nor enable comprehensive analysis of comparative costs, of critical path for construction, or identifying potential conflicts with other projects..
- This long-term problem cannot be addressed with short-term personnel.
- Recent changes to Section 117 of the Consolidated Appropriations Act of 2005, PL 108-447, Division C - Energy and Water Development Appropriations Act, 2005, were intended to streamline the ability of the Secretary of the Army to react to situations in Alaska, but the change only reduced the 15 year cycle to a 2 year cycle. This act states in part as follows:
  "SEC. 117. Notwithstanding any other provision of law, the Secretary of the Army is authorized to carry out, at full Federal expense, structural and non-structural projects for storm damage prevention and reduction, coastal erosion, and ice and glacial damage in Alaska, including relocation of affected communities and construction of replacement facilities." However, even with this streamlined authority, without state appropriations federal funds alone will likely not be made at a level to meet immediate needs.
- AO224 potentially presents investment barriers for possible new locations sites. Other standards and requirements also present barriers to investment in new developing communities. For example, ADOT/PF policy suggests that emerging communities have a minimum of twenty-five residents, a post office, and a school before a project will be considered by the Project Evaluation Board. In addition, there is a minimum population requirement of twenty-five children for construction of a new school. Under these guidelines, the deferment of infrastructure investment can be expected to create hardships on relocating communities. Because village relocation is likely to be an incremental process, there will be populations at both locations (the current village and the new village site) and needs must be met concurrently.
- If a disaster affects any community in peril before it is improved or relocated, there is a serious risk to safety of life. Also there will be extraordinarily costs for response and recovery. Further, the state and federal disaster statutes require that all other possibilities be exhausted before relocation is considered.

---

3) **Formulate a strategy to implement the Sustainable Community Relocation policy.** The strategy must define the process for addressing the specific needs of a community and the broader needs of a region. Specifically, the strategy must result in a work plan based on principles of sustainability and articulate cooperative working relationships through the specific assignment of roles and responsibilities across agencies, communities, and others along with resources, data and other information needs.

   a. DCCED will serve as the overall coordinating agency to formulate and implement the strategy.
   b. DMVA will serve as the lead agency for the Suite of Community Emergency Planning Efforts.
   c. DNR will serve as the lead agency for Community Wildfire Protection Plans.
   d. DNR will serve as the lead agency for geologic mapping and geologic hazards evaluation.
   e. DCCED will serve as the coordinating agency for the Expansion of Comprehensive Community Plans to encompass Relocation.
   f. DCCED will serve as the coordinating agency to develop and coordinate mechanisms that support community-based decision making.
   g. DCCED will serve as the coordinating agency for coordinating and formalizing Local/Regional, Tribal, State, and Federal partnerships.
   h. DCCED and the Department of Public Safety, Division of Fire and Life Safety will serve as the coordinating agencies to develop recommendations and implementation strategies that address incorporated and unincorporated community eligibility in the National Flood Insurance Program.

Implementation actions:

- Utilize Denali Commission or similar MOU methodology to help address needed collaboration.
- Relocation sustainability community principles shall include:
  - Economic viability including:
    - Renewable / alternative energy technologies, green building design and land use planning
    - Guidelines for ensuring sustainability, including ICLEI Global Sustainability principals and cultural sustainability
    - Guidelines for prioritizing strategies and associated funding streams for erosion and relocation, including mitigation and the alleviation of hazards in proposed location
- Develop a clearing house type function, including planning and technical assistance that will help jump start the process.

Rationale:

- Wherever possible, existing strategies and plans should be used after examination and determined to be effective in the uncertain environment of climate change. Immediately begin a coordinated system to identify potential resources and actions. Through regular meetings of government agencies and stakeholders, we can confidently identify, update deconflict, and integrate projects and funding sources from federal, state and regional/local sources to effectively address the most vulnerable needs. The IAWG recommends using as a model the Denali Commission's MOU process for this process.
- The IAWG believes that DCCED should be the lead coordinating agency for relocation assistance. This is consistent with the current authority of DCCED While there is no formally designated state lead on coordinating relocation assistance, there is considerable authority for a state lead to coordinate ongoing activities and policies on specific hazards such as erosion. This authority has been vested in DCCED through:
  - administrative Order 175,which designates the former Department of Community & Regional Affairs (now DCCED) to be the State's lead on coordinating capital investments where there is a potential for flood and erosion damage.
  - AO231 and AO239 both direct DCCED to be the State's coordinating agency to propose long-term solutions to on-going erosion issues.

  Other authorities identify DCCED as the State's lead coordinating agency:
  - DCCED's Division of Community and Regional Affairs is the State agency, which Article 10, Section 14 of the Alaska Constitution mandates be "...established by law in the executive branch of the state government to advise and assist local governments."
  - DCCED serves as the Governor's appointed state coordinating agency for the National Flood Insurance Program and the Flood Mitigation Assistance Program (Alaska Administrative Order No. 175).
  - DCCED has statutory mandates for Planning Assistance for Development and Maintenance of District Coastal Management Plans (AS 44.33.781. This authority directs DCCED to provide a program of research, training and technical assistance to coastal resource districts within the Alaska Coastal Management Program (ACMP).

- Enhancement and expansion of DCCED/DCRA's partnership with the Alaska Coastal Management Program (ACMP) will enable more effective assistance to those communities in peril and at significant risk due to erosion. Most of the communities currently identified as communities in peril are coastal communities.

➢ It is appropriate to broaden DCCED planning roles to include the process of examining the need for, deciding on, and coordination relocation. As the lead agency, DCCED will assist the community (or community efforts) by providing guidance on where to get assistance, how to access resources, and to bring all the players together – which by working together the agencies and communities will then leverage resources for emergency preparedness, community infrastructure – including housing, education, health, environmental and related needs. Designating a lead coordinating agency does not preclude each agency from using its authorities and expertise and moving its projects forward for which it is responsible.

➢ A Relocation policy will provide non-profit organizations and NGO's such as Engineers Without Borders a better sense of how they can play an effective role and augment resources.

---

4) **Develop statutes for Statewide Programs, with dedicated funding assurances, to mitigate hazards to enhance community viability and sustainability.**

a. Statewide Hazards Analysis and Risk Mitigation Program through DMVA
b. Statewide collection of field data on hazards in priority areas lacking information through DNR
c. Statewide Vulnerability Assessment Program through DMVA

Implementation actions:

- DMVA shall develop recommendations for a Statewide Program to proactively address mitigation hazards that is not contingent, directly or indirectly, on the declaration of a federal disaster upon which current funding streams are based.
- Identify local rock and gravel sources for western Alaska communities in peril that will support infrastructure construction at relocation sites.

Rationale:

➢ Well-formulated state statutes will provide clear guidance and support, with associated funding, for ongoing, comprehensive programs. The recent federal funding trend of pre-designating funds for various states has reduced the amount of funds available to states, thus increasing the competitiveness for such funds and decreasing the likelihood of receiving any significant needed mitigation funding.

➢ Identification of local sources for rock and gravel is integral to any relocation planning and will significantly impact viable community alternatives.

---

5) **Identify and call for required changes to federal statutes, such as the Stafford Act, that would enhance Alaska's ability to deal effectively with communities in peril and other communities with significant risk.**

Implementation actions:

- Designated state agencies shall develop similar recommendations for changes to existing federal legislation and seek support from appropriate national organizations.

- DMVA shall develop recommendations for changes to the Stafford Act and seek direct support from NEMA (National Emergency Management Association) and its member states.
- The Legislature should support needed changes in federal law through a legislative resolution.
- The Alaska Municipal League should support needed changes in federal law through a supporting AML Resolution.

Rationale:

- Federal competitive mitigation grants rely on a cost-benefit analysis detrimental to the realities of Alaska. Alaskan projects often benefit a small population but at high costs. This results in Alaskan projects being considered of lower national priority. In addition, the cost-benefit analysis does not include the consequence of not mitigating a known hazard. Any investment in hazard mitigation will save many times the investment when the disaster occurs. The Immediate Action Workgroup believes that an effective mitigation and prevention strategy and associated funding, will significantly reduce the risk to public safety and the costs of recovering from any climate or weather disaster. The Stafford Act is written for responding to an actual or imminent disaster. It was not envisioned to be used when the disaster is inevitable as is now the case with changing sea ice, melting permafrost and extreme variations in weather. These inevitable disasters can be identified by DHS&EM and appropriately addressed through the National Emergency Management Association legislative process with companion support from Alaska's congressional delegation. Direct action from the Alaska Legislature and the Alaska Municipal League, through personal companion efforts and through resolutions, would strengthen efforts to seek needed changes.

POLICY 4: THE STATE OFALASKA WILL LEAD A COORDINATING EFFORT TO DEVELOP A COMPREHENSIVE STATEWIDE DATA COLLECTION AND EVALUATION SYSTEM THAT PROVIDES FOUNDATIONAL INFORMATION FOR COMMUNITY AND BUSINESS DECISIONS AND SOLUTIONS LEADINGTO EFFECTIVE RESPONSES AND ADAPTATION STRATEGIES TO ADDRESS CLIMATE CHANGE IMPACTS.

Through the Subcabinet Climate Change Strategy process, various components of a statewide data collection and evaluation system have been identified, yet components need to be coordinated in order to understand and use the information effectively. The phenomena of climate-related impacts are not well understood and the impacts themselves are also uncertain. The State of Alaska, playing the coordinating role, will bring together state agencies, university resources, and federal and local stakeholders to develop an effective data collection and evaluation system. The likely outcomes of this effort will be to identify what data exists in order to build forward from existing data and maps; what format it is in and what technology is needed for the systems to "talk" with each other; what data is needed but missing; and what funding is needed to identify, collect, analyze and disseminate data in order to address impacts from climate change phenomena. Response strategies should be developed through adaptation impact analysis and modeling to identify near-term scenarios for options ranging from protecting what's in place, migration and full relocation.

Implementation – Initial Steps

IAWG Recommended Action to Subcabinet: Adopt Policy 4 and provide the IAWG with guidance to develop implementation options for this policy. At a minimum the guidance should instruct that options

should include identifying benefits, challenges, and effective organizational structures for implementation. This comprehensive data system is another key component to create the knowledge base from which informed decisions can be made to set priorities and allocate resources. The guidance to the IAWG should also include melding the relevant Adaptation and Mitigation Advisory Groups' products with this statewide data collection and evaluation system to reach a desired outcome of integrated actions in order to address what seems to be increasing impacts due to climate change phenomena. The IAWG should work with others throughout the state and federal agencies to develop options, request input, questions and concerns that will need to be addressed in order to create an effective integrated data system. This system must also be a key component of the statewide system identified in Policy 1.

1) **A State led coordinated approach, which results in a comprehensive data collection and evaluation system must ensure data is identified, collected, analyzed, and available to users and policy makers. This coordinating effort is a foundational step to develop a comprehensive system and should:**
    a. Identify suites of data and indicators needed to support policy and strategy decisions for government, communities and businesses.
    b. Catalog currently available data, archived data mapping and/or GIS products (ref DCRA Community Maps) and entities collecting the data that reflect community infrastructure and ownership, site characteristics, known risks and changes in environmental conditions.
    c. Provide data from information outside of existing main databases to gather information such as snow accumulations, wildlife populations, energy usage, permafrost temps, geophysical data on glaciers.
    d. Identify what collaborative MOUs among data custodians and data collectors exists and are needed.
    e. Identify processes for collection of field and local data where lacking and potential costs and timetables.
    f. Ensure data includes cultural and traditional knowledge and recognizes the confidentiality of historical sites and proprietary rights of cultural artifacts.
    g. Identify gaps in data and determine how gaps should be prioritized for funding in order to develop a comprehensive statewide database. An example of a data gap is the current need for reliable flood hazard determination data including high water marks of record, detailed analysis of the flood plain, and base flood elevations.
    h. Identify how to establish a central data access website that links collaborators and data collectors/custodians and enables ready access to current information in both electronic and paper formats.
    i. Identify options to integrate analysis and modeling with data collection efforts and databases to provide the necessary interpretations to inform decision making.

Implementation action:

- Establish a small, yet knowledgeable workgroup to conceptualize and begin detailing the above items, with co-chairs from state and federal agencies. The Immediate Action Workgroup could serve as a functional model for this effort.
- Utilize the work and outcomes on data collection and an evaluation system from the efforts under the auspices of the Subcabinet, bringing together the information identified above into a central distribution node/link
- As data sources are added, augment the existing information with the areas not just identified, but described in 1 above.

- Create recommendations along with rationale, budget projections, and identify cooperative agreements (MOU or MOA) to strengthen the comprehensiveness and applicability of the data products.

Rationale:

- Alaska's communities in peril face complex issues that can only be effectively addressed by understanding factors surrounding the range of options from protecting what's in place, supporting migration and potential for full relocation. These factors and options are also relevant for business decisions and planning for their futures. The viability and sustainability of communities and businesses hinges on the availability of accurate, comprehensive data that potentially relates to their at-risk circumstances.
- Significant knowledge building is required to identify a system that incorporates the items listed in 1 above with data bases and products developed to date (including community, flood plain, fire, and permafrost maps). It is imperative that those who have authorities to collect and those who need to use this data work together, in a collaborative manner, to design a collection, analysis and dissemination/application system if it is to be effective.
- The number of potentially affected communities impacted by climate change phenomena will grow and will require a systems approach if the State of Alaska is to effectively address the increased needs for each community on a prioritized basis.
- A coordinated approach will create more useful information for state, community and business decision makers to use:
    - With a higher degree of confidence to effectively make investment and budgeting decisions for the community at risk, and
    - For expediting permits.

Potential outcomes:

1) A blueprint, clearinghouse or prototype site to establish a web-based system as an integral step toward development of a statewide collection and evaluation system.
2) A State lead coordinating agency or university will be identified along with resources needed to incorporate and disseminate an effective data collection and evaluation system. Recommendations on the following items shall be made to the Subcabinet:
    a. MOUs that are needed with appropriate state and federal agencies and other collaborating entities.
    b. An evaluation system to include comprehensive community planning products and establish a priority system for regions of the state that encompasses communities and businesses in peril from risks either common to or unique within the region (wildfires, glacial retreat and avalanches, ice jams and river floods, and coastal inundation.
    c. Flexibility in funding, including receipt of federal funds and in kind local support for the lead agency and other organizations that actively engage in identification, collection, analysis and dissemination with this management tool to:
        - Support dissemination of the data to available users and policy makers.
        - Prioritize projects that address identified gaps in existing data.
        - Support collection and presentation of new field data to fill identified gaps in priority areas.
        - Align data priorities with priority communities in peril for monitoring trends in risk,
        - Provide sufficient data to identify, on a statewide basis, those communities with significant risk but not in immediate risks. Some of these data needs have been identified by the IAWG,

such as mapping and geologic data needs. Data needs have also been identified by the IAWG by focusing on the changes likely occurring due to climate change: increased wildfires, storm surges, lack of sea ice, flooding, and melting permafrost.

d. Obtain funding for this comprehensive system by considering opportunities within existing grant and additional funding sources to conduct data-related research. Analyze current funding streams for requesting additional supports through a state supplemental /capital budget request, should other sources of funding not prove viable.

---

2) **Encourage local communities to take leadership in addressing their unique situations by conducting a climate change assessment and developing locally implementable response strategies through current adaptation impact modeling to identify near-term climate change impacts for both protecting in-place and sustainability relocation scenarios:**

a. Encourage Alaska communities to use the ICLEI model, or other multi-step climate impact planning models, which focuses on a review of scientific data to identify expected climate change impacts and opportunities a community should expect and develop a set of responses/actions to possible changes.

Implementation actions:

- Work with the Alaska Municipal League and Regional For-Profits and Non-Profits who in turn will work with their communities to identify near-term climate change impacts and ensure community's plans accommodate new monitoring and research data. The "milestones community planning model", such as the ICLEI method, has been used to identify emerging impacts and opportunities and develop a set of responses that can be incorporated into local plans.
    - An ICLEI method of community milestone planning should be established in immediate or near-term actions to allow new climate change impacts or opportunities to be factored into the relocation or protect- in- place plan.

Rationale:

➢ The effects of near- term climate changes impacts (as opposed to immediate threats) are not fully identified at this time or adequately documented in existing data products. Further research and data collection into physical and cultural changes will present additional elements to be incorporated into adaptation and relocation plans during various stages of implementation.

APPENDICES

APPENDIX A

THE CASE FOR STRATEGIC INTEGRATION: WHY IAWG RECOMMENDED POLICES ARE NEEDED

IAWG Recommended Polices Are Needed

This section provides background and findings to explain why the set of IAWG recommended policies are needed. The IAWG has created working relationships that can help to advance these recommendations in a meaningful and cost-effective manner.

Background

One of the anticipated outcomes of the IAWG's 2009 efforts was to identify the "next six" communities in need of immediate action, due to impacts from climate change phenomena.

Climate change phenomena have been identified as:

- Lack of sea ice
- Change in extent of sea ice
- Timing of sea ice
- Increased effects of storm surges unbuffered by shorefast ice
- Erosion due to flooding or permafrost melt
- Flooding
- Permafrost melt
- Wild fires

This next six would then be in addition to the first six identified, which of course are:

- Kivalina
- Koyukuk
- Newtok
- Shaktoolik
- Shishmaref
- Unalakleet

In order to identify the "next six" the IAWG brought together information from the various member agencies participating in the IAWG, plus the U.S. Governmental Accountability Office , which to some measure, through Congressional interest, brought attention to Alaska's communities potentially in peril due to impacts resulting from climate change phenomena.

The various agencies were able to identify communities of concern for the IAWG based on each agency's mission specific programs. ***However, not one agency had analyzed their actions, nor responding to community needs based on climate change.***

It's useful to restate that the **IAWG did not define climate change**, but rather identified and based its recommended actions on impacts to communities likely resulting from ***climate change phenomena.***

Findings

By bringing together information from participating agencies, the IAWG found:

- The ability to clearly identify and define impacts as resulting from climate change is difficult because:
  - Data are inadequate to analyze and distinguish between normal weather and climate variability or to determine how the current trends will continue to affect Alaskan communities.
  - No framework exists for the comprehensive identification, analysis, and dissemination of current data or the methodical acquisition of new research to support new policy options.

    - *IAWG Policy 4 specifically identifies next steps to address this.*

- Many state and federal agencies and academia are researching potential projects, programs and research efforts to assist communities that are impacted, or potentially impacted by climate change phenomena. However, each agency is working from differing sets of assumptions, approaches and timelines.
    - The IAWG has compiled a list of more than 150 communities identified by one or more agencies as potentially impacted by climate change phenomena. There is no consistency in criteria, timeline, weighting, data acquisition technique or analysis. (see pages 85 - 89)

- State and federal agencies are severely limited by this lack of integration for data, research, and program or project development. Therefore, this environment of uncertainly increases the risk of many communities of facing extreme risks from the unknown effects of natural disasters. The traditional "stove-piped" approach of creating and managing government programs ensures a narrow, myopic view of community needs and places the individual programs in competition for approval and funding. This segregated approach increases the uncertainty of funding but decreases the potential for meaningful and comprehensive assistance.

- The State of Alaska, just as the federal government, plans for and manages programs primarily through individual departments. The priorities are set usually during budget formulation for the next budget cycle. However, many capital projects need years of planning for engineering study and design and for the identification of federal funding. These funding decisions occur for each individual agency and often are without consideration of other state or federal projects that may be in potential conflict for the same community or region.
    - An integrated, multi-agency and inter-governmental approach is needed to effectively identify and address the needs of communities that are potentially in peril.
    - This integrated approach has significant potential to save money on public infrastructure, avoid costly delays, save funds through economies of scale and combining mobilization, mitigate the effects and costs of disaster relief and recovery.

    - *IAWG Policy 1 specifically identifies next steps to address this.*
    - *IAWG Policy 3 is integral to Policy 1, but is such a key component, that the IAWG created a separate Policy Recommendation for integrated, collaborative planning to align timing of activities, funding and other resources, which likely reduce costs.*

- An integrated, multi-agency and intergovernmental approach using existing government databases, agencies, and programs will take effort to design and implement. However, the State of Alaska can expect immediate improvements in productivity, planning, and public confidence from collaboration.

    - An interim, but not ad hoc, IAWG must be authorized to create a framework for increased continued collaboration among relevant agencies and academia.

    - *IAWG Policy 2 specifically identifies next steps to address this.*

In this appendix, you'll find:

- ***Summary*** of characteristics or criteria each organization used to identify actions for communities based on each agency's programs and missions.
- Compiled list of where agencies are actively providing assistance to communities either due to disasters, potential disasters or preventing disasters.
- Each agency's detailed characteristics or criteria used to identify whether to act or provide assistance to a community. These appear in the following order:
  - U.S. Government Accountability Office (GAO)
  - U.S. Corps of Engineers (USACE)
  - Alaska Dept. of Commerce, Community and Economic Development (DCCED)
  - Dept. of Military and Veterans Affairs – Division of Homeland Security & Emergency Management (EM)
  - Alaska Dept. of Transportation and Public Facilities (DOT)
  - Alaska Dept. of Natural Resources – Division of Forestry (DNR)

SUMMARY OF CRITERIA AGENCIES HAVE USED TO RESPOND OR IDENTIFY COMMUNITY NEEDS

IAWG – 2008 Recommendation Report: 6 communities identified

- Communities were identified in GAO's Previous Report and/or at 11/07 Climate Change/AML meeting
- Life/safety risk during storm/flood events
- Loss of critical infrastructure
- Public health threats
- Loss of 10% or more of residential dwellings

GAO – Current Community Relocation Assessment: 15 communities identified

- Communities Self-Identified
- Or other agencies recommended them to GAO –
- Response to US Senate directive to identify
- and make recommendations for communities facing significant erosion or flooding impacts
- Not based on analysis of impact due to climate change phenomena
- Community wants to relocate in whole or in part to address flooding and erosion issues

USACE – Communities Impacted by Erosion Only (Not Flooding): 21 communities identified

- Critical Infrastructure at Risk (for example, Schools, Utilities, Transportation)
- Cultural Importance
- Subsistence and Shoreline Use
- Environmental Hazard (EX: Landfills, Sewer Lines, Sewage Lagoons, Fuel Tanks)
- Human Health and Safety
- Housing and Population Affected
- Housing in Parallel

DCCED – Potential that a community faces significant impacts due to climate change phenomena in the next 18 – 24 months, based on the following criteria: 32 communities identified

- Life/safety risk during storm/flood events
- Loss of critical infrastructure
- Public health threats
- Loss of 10% or more of residential dwellings

Emergency Management: 119 communities identified

- Number of communities named in stated disaster declarations for flooding, storm surge, and other water events since 1978. The communities are group by river system or coastal area.
- Potential threats to safety or life
- Existing public infrastructure threatened by weather or climate hazards

DOT/PF: 60 communities identified

- Those communities in which DOT/PF believes climate change phenomena has to a high degree necessitated proposed, partial and recently completed projects

DNR- Division of Forestry : 40 communities identified

Actions based on funding for and identification of communities which would benefit from Community Wildlands Prevention Planning (CWPPs).

INFORMATION ON GAO ENGAGEMENT

Engagement subject: Alaska Native Village Relocation Efforts

Source for the work: GAO is conducting this work in response to a request made by the Senate Subcommittee on Disaster Recovery, Committee on Homeland Security and Governmental Affairs

Objective/key questions: This is an update to GAO's December 2003 study, *Alaska Native Villages: Most are Affected by Flooding and Erosion, Few Qualify for Federal Assistance* (GAO-04-142). Key questions are: (Q1) What flooding and erosion threats do Alaska Native villages currently face? (Q2) What federal and state programs are available to assist villages facing potential disasters? (Q3) What is the status of efforts to assist relocating villages? (Q4) How do federal programs provide and prioritize assistance to threatened villages?

Status: GAO has visited seven villages and spoken with various federal, state, and local government agencies. We have completed the design phase of our work and are currently conducting field work to address our key questions. We expect to have a completed report by mid-May 2009.

Villages visited: Alatna, Allakaket, Kivalina, Koyukuk, Shaktoolik, Shishmaref, and Unalakleet.

Other villages of interest: Chefornak, Elim, Golovin, Hughes, Huslia, Kipnuk, Newtok, and Nulato.

Agencies contacted: Departments of Agriculture; Defense's Army Corp of Engineers; Health and Human Service's Indian Health Service; Homeland Security's Federal Emergency Management Agency; Housing and Urban Development; the Interior's Bureau of Indian Affairs, Bureau of Land Management, U.S. Fish and Wildlife Service, and National Park Service; and Transportation's Federal Aviation Administration. We have also spoken to officials from the Denali Commission, the Bering Strait Housing Authority, the Maniilaq Association, the Tanana Chiefs Conference, Kawerak, the Northwest Arctic Borough, and the State of Alaska's Department of Environmental Conservation, Department of Commerce, Community, and Economic Development, and Division of Homeland Security and Emergency Management.

USACE Criteria for Assessing Community Needs

Assigning Response Priorities for Erosion and Flooding in Alaskan Communities

Overview

There is a heightened awareness that many Alaskan communities are suffering from erosion and flooding impacts. When looking to identify those in most need, certain criteria can be utilized to differentiate between the issues in each community. Appropriate criteria for differentiating between communities need to focus upon the characteristics that make up a community. Remote Alaska villages typically are largely native, have a significant interest in culture and tradition, rely heavily upon air and water transportation, have economies that are more based in subsistence/trade/barter than upon the exchange of money for goods and services, and typically do not have the ability to internally raising funds to support develop or maintenance of facilities, infrastructure, or measures for protection against natural phenomenon.

Criteria and Factors

Criteria for assigning priority typically will have one or two factors influencing the criteria's magnitude of concern. Single factor criteria are ones that are general descriptors i.e. Does the community have the ability to pay for a project? A two factor criteria is influenced by two measures i.e. How severely is development being damaged and what is the timeline for the damage?

Developing Criteria and Rankings

No single person should believe they can make the determinations of what criteria are to be used, how to scale the criteria, how to weight the criteria, or assigning values for criteria for items being ranked. A typical approach to develop these items is to assemble an "expert panel" of individuals from the area of expertise needed. These experts are typically not policy makers or agency executives. These individuals are those who work most closely to the actual problems and are integrally involved in formulating, describing, and developing solutions.

Alaska Baseline Erosion Risk Criteria Workshop

A workshop was held at Alaska District to develop the risk criteria for which the communities can be assessed.

A focus of discussion at the workshop was the identification of Evaluation Factors for scoring the relative Severity of Expected Erosion Damages across communities. After initial brainstorming and screening, a list of Evaluation Factors was identified for further consideration for ranking communities based upon the level of information available in the ABEA Erosion Information Papers (EIPs). Relative weights were identified for each factor. The identified factors and weights are presented in Table 1.

Table 1 – Workshop Identified Evaluation Factors and Weights	
Evaluation Factor	**Relative Weight**
Infrastructure (School, Utilities, Transportation, Critical)	3
Life Safety	3
Subsistence and Shoreline Use Being Limited	2
Setting/Geographic Location	1
Time Until Damage	3
Population	1
Housing In Parallel	2
Environmental Hazard	3
Cultural Importance	1
Percent Of Affected (Numbers of Structure/People)	2
Commercial/Public/Store/Church/Community Infrastructure	2
Source: Meeting Minutes provided to Tetra Tech by Melanie Harrop, 1/23/08.	

Further consideration of the identified factors following the meeting resulted in the following recommendations:

1) "Population" and "Percent of Affected" be combined into one category: "Housing and Population Affected" – these categories seem to be similar and may have the effect of doubling the weight for the impact on housing.

2) "Time until Damage" be removed as a Severity of Damage Evaluation Factor and instead by rated and multiplied by the Severity of Damage Score for each community as a more appropriate way of scoring the relative Erosion Risk at each community. (See Section 3).

3) Several of the headings have suggested editorial changes

Table 2 presents the suggested changes to the identified Evaluation Criteria.

Table 2 – Suggested Revisions to Identified Evaluation Factors

Evaluation Factor	Relative Weight
Critical Infrastructure (for example, School, Utilities, Transportation)	3
Human Health and Safety	3
Subsistence and Shoreline Use	2
Community Setting/Community Geographic Location	1
~~Time Until Damage~~	~~3~~
Housing and Population Affected	1
Housing in Parallel	2
Environmental Hazard (for example, Landfills, Sewer Lines, Sewage Lagoons, Fuel Tanks)	3
Cultural Importance	1
~~Percent Of Affected (Numbers of Structure/People)~~	~~2~~
Commercial/Public/Store/Church/Community Infrastructure	2

Incorporation of Risk Consideration into Methodology

There are various definitions of risk. The Corps of Engineer's report Beyond Expected Value: Making Decisions under Risk and Uncertainty (USACE, IWR Report 02-R-4 (Dick Males); September 2002) provides the following simplistic definition of risk and uncertainty:

> *"Risk is the chance of something bad happening. Uncertainty is a characteristic of a situation in which a number of possibilities exist but we do not know which of them will occur. Uncertainty exists because of natural variability and knowledge gaps."*

The entire BEA study is a risk analysis (examination of erosion risk) across communities throughout the state. Due to the number of communities with potential problems, Alaska District is proceeding with the study in an iterative manner to systematically assess the relative risk across communities and prioritize follow-on detailed study activity on those communities at the highest perceived risk first.

Risk analysis as applied to the Corps Civil Works problems can be viewed as having three components:

- Risk assessment;
- Risk communication; and
- Risk management.

In Risk Analysis and Risk Informed Decision Making: An Overview (USACE; Planning Ahead, Volume 10, Issue 10 (Brian Harper/David Moser) November, 2007), these three components are described as follows:

- Risk assessment is a systematic process for quantifying and describing the nature, likelihood, and magnitude of risk associated with a situation, action, or event. The assessment includes consideration of relevant uncertainties.

- Risk management is the process used to identify, evaluate, select, implement, monitor and modify actions taken to alter levels of risk. The goal of risk management is scientifically sound, cost-effective, integrated actions that reduce risks while taking into account economic, environmental, social, cultural, ethical, political and legal considerations.

- Risk communication is the open, two-way exchange of information and opinion about hazards and risks leading to a better understanding of the risks and better risk management decisions.

The prioritization exercise which is the topic of this memo is a form of risk assessment where the *Severity of Damage* ratings estimate the relative nature and magnitude of erosion risk in each community and the *Time Until Damage* ratings estimate the likelihood/timing of the expected event. Together, these two factors can provide the basis for prioritizing communities for further evaluation. The following relationship is recommended:

Erosion Risk Ranking = Severity of Damage Score * Time until Damage Score

Risk assessment should also explicitly consider the uncertainties that are inherent to our estimates of the *Severity of Damage* and *Time until Damage*. Based on the preliminary level of data (in many cases anecdotal, subjective descriptions) available for the EIP's, the largest source of uncertainty for both scale ratings is likely information gaps (for example; no data available, overly general information available, or uncertainty in reliability of available data).

During the rating of "Time until Damage" for each community, a rating of the relative confidence in the score also be recorded. This allows explicit consideration of the uncertainty in the ratings by providing another layer of information (For example, "We think Community X has a rating of 20 however because of uncertainty in our estimate of Time until Damage, its rating could range from a 15 to a 25. This information is useful for informing the prioritization decision making process and allows for flexibility in selecting communities for further study.

Severity of Damage Evaluation Factor Rating Criteria:
Through research by the PDT, input from the workshop, and recommendations by Tetra Tech, a consultant to the Corps assisting on the Baseline Erosion Assessment, the following criteria have been developed. Tetra Tech compiled these thoughts and with their additional insight, submitted the following criteria. These are now the proposed that will be utilized is assessing the risk for each community. Table 3 documents these criteria.

USACE Table 3 – Draft Rating Criteria for Severity of Damage Evaluation Factors			
Evaluation Factor	**Weight**	**Scoring Criteria**	
Critical Infrastructure (for example, School, Utilities, Transportation)	3	Low Impact (1)	• One item of critical community infrastructure at risk • Loss of infrastructure would not result in loss of community sustainability • Damage could be repaired or alternative service restored in less than 1 month
		Medium Impact (2)	• More than one item of critical community infrastructure at risk • Loss would not result in loss of community sustainability • Damage could be repaired or alternative service restored between 1 and 6 months
		High Impact (3)	• More than one item of critical community infrastructure at risk • Loss would impact community sustainability • Repaired or establishment of alternative service would take more than 6 months
Human Health and Safety	3	Low Impact (1)	• Situations that would cause life safety concerns or negatively affect ability to provide emergency services are not likely • Ingress/egress to/from community not at risk • Community has ability to mitigate or avoid life safety concerns
		Medium Impact (2)	• Only rare events would threaten life safety • Access to or from community by land or airport threatened • Quick and easy access to emergency services is available

Human Health and Safety (continued)		High Impact (3)	• Erosion damage is expected to result in human health and safety concerns • Critical health/safety services facility at risk • Portions or all of the population cut-off from emergency services • Air &/or road access at great risk or impassable to all or a portion of community
Subsistence and Shoreline Use	2	Low Impact (1)	• Minor and temporary interruptions that are a nuisance but made up in same year • Damage could be repaired locally, for example regarding boat launch access each spring • Access is altered but not of substantial consequence or inconvenience
		Medium Impact (2)	• Frequent loss or disruption of access to subsistence or damage to important shoreline uses • Structural mitigation of risk practicable solution but may disrupt high value traditional use and access areas • Critical habitat &/or use areas mild to moderately threatened; traditional practices inconvenienced but not disrupted
		High Impact (3)	• Interruptions sever enough to impact supply on a continual basis • Critical habitat &/or use areas severely threatened; traditional practices limited to focus on survival • Structural mitigation of risk possible but may eliminate or harm vital subsistence/shoreline use area

Community Setting/Community Geographic Location	1	Low Impact (1)	• Land is readily available in erosion free zones for new development or relocations • Soils, hydrology/hydraulic conditions not conducive to erosion; aggregate resources available locally if erosion protective measures needed • Land use controls in place and/or safe land area between shoreline and development exists
		Medium Impact (2)	• Lands in erosion free zones are limited, precluding new development or relocations into safe areas • Soils and hydrologic/hydraulic conditions conducive to erosion • Limited distance between shoreline and development but safe zones available and some local resources to assist with mitigating problem
		High Impact (3)	• High erosion rates and flooding • Poor soils conducive to erosion, permafrost melt possible added impact • No or limited safe land areas to move structures; community on barrier islands or spit • Community is hub of goods/services supporting other communities in region/sub-region
Housing and Population Affected	1	Low Impact (1)	• Less than 10 % of population/housing affected • Alternative housing available
		Medium Impact (2)	• 10 to 25% of population/housing affected • Alternative housing available but limited
		High Impact (3)	• Over 25% of population/housing • Limited to no alternative housing available

Housing in Parallel	2	Low Impact (1)	• Only a few waterfront structures and limited associated infrastructure at risk (one time loss)
		Medium Impact (2)	• Multiple Rows of structures parallel to waterfront and limited associated infrastructure improvements are at risk (expected future recurrence of damages)
		High Impact (3)	• Multiple Rows of structures parallel to waterfront and extensive associated infrastructure improvements are at risk (higher level of expected future recurrence of damages)
Environmental Hazard (for example, Landfills, Sewer Lines, Sewage Lagoons, Fuel Tanks)	3	Low Impact (1)	• Minor issue that can be easily addressed at the time of damage • Impact can be addressed locally
		Medium Impact (2)	• Moderate environmental effect that will require limited intervention by an external agency for a limited period of time
		High Impact (3)	• Large issue that will require extensive intervention by one or more external agencies for an extended period of time • Damage or loss will impact the entire population or high % of population, such as contaminated water supply • If erosion causes environmental impact that has long term impacts &/or impacts to other communities or region may suffer (such as hazardous substances, fuel facilities or landfills eroding into an anadromous stream)
Cultural Importance	1	Low Impact (1)	• Minor or temporary disruption in cultural/traditional activities with no lingering negative impacts • Minimal expected damage to known cultural and historic resources

Cultural Importance (continued)		Medium Impact (2)	• Intervention required for community to continue with cultural/traditional activities • Some cultural resources are lost, but rarely occurs without appropriate records being taken to catalog what resources have been lost.
		gh Impact (3)	• Cultural resource being lost at a high rate with little or no ability to catalog and record what is being lost. • Traditional practices are being abandoned to focus solely on life-safety and survival.
Commercial/Non-Residential	2	Low Impact (1)	• Impacts have no or little affect on overall community cash flow • Little and only temporary impact to a community's ability to operate their commercial facilities with minor interruptions • Little or no exterior financial support is necessary to re-establish full capacity
		Medium Impact (2)	• Impacts have moderate impact on overall community cash flow • Impacts to a community's commercial infrastructure will require significant external assistance to come back to full capacity • Loss of commercial infrastructure can be handled at an alternative site or location (such as a 2nd local store, or other commercial/public dock facilities)
		High Impact (3)	• Impacts have severe, dramatic affect on cash flow of a community • The ability to operate the commercial sector for the community is severely impacted • Loss of commercial infrastructure will impact entire community (such as loss of a single store, with no replacement facilities); or ability to gather materials or have goods and services brought in is no longer possible (i.e. a commercial dock is destroyed with no replacement or alternate facilities)

Revised Strawman Matrix

Following the workshop, Tetra Tech prepared a prioritization ranking framework that incorporates the risk assessment factors described in the recommendations in this memorandum. The framework is presented in Table 4 and provided as an electronic file (Excel spreadsheet) under separate cover.

The spreadsheet file would allow the District to enter accepted scoring values for each Evaluation Factor in Table 3 from drop down lists, apply user defined weights (currently set to those in Table 3), select accepted scoring values for Time until Damage, and select accepted values for Confidence in Time until Damage estimates. The spreadsheet calculates a Damage Score based upon the Evaluation Factors and their respective weights, and calculates Community Ranking Scores with uncertainty based upon user selected confidence in the Time until Damage rating. (Note that the scores shown in Table 4 are for example only and do not reflect scores developed for any specific communities.)

DCCED/DCRA Criteria

DCCED/DCRA sent the following email to Field Personnel requesting assistance to identify communities they believed met the IAWG's criteria for communities potentially impacted from climate change phenomena.

From: Boothby, Taunnie L (CED)
Sent: Friday, December 05, 2008 4:27 PM
To: Mello, Christopher P (AIDEA); Magee, Gregory L (DEC); Ruby, Scott (CED)
Cc: Jollie, Tara L (CED); Black, Michael L (CED); Cox, Sally A (CED); McKay, Peter J (CED); St Amour, Ruth R (CED)
Subject: Requesting your assistance on behalf of Deputy Commissioner Mike Black and DCRA Tara Jollie

Good Afternoon,

On behalf of Deputy Commissioner Mike Black and DCRA Director Tara Jollie, we are asking for your recommendations of communities that may need immediate action to prevent loss of life, health or great property damage. This list will be compiled for dialogue during the Immediate Action Workgroup of the Governor's Climate Change Subcabinet.

We are requesting this input because you are the subject matter expert in your fields and your vast knowledge of the communities across the State. This experience is vital to the discussion and we appreciate your time.

Below is a brief summary of what has happened and what the criteria to consider when recommending communities.

On April 17, 2008, the Immediate Action Workgroup (IAWG) released their final report and recommendations to the Governor's Subcabinet on Climate Change for the initial six communities experiencing climate change related affects, namely Kivalina, Koyukuk, Newtok, Shaktoolik, Shishmaref, and Unalakleet.

Currently the IAWG are collecting a list of additional communities for discussion purposes on a potential second round of communities.

DCRA has determined our mission statement for this task to be the following:

Identify the next set of communities facing the most significant impacts due to climate change in the next 18 – 24 months, based on the following criteria:

(1) Life/safety risk during storm/flood events
(2) Loss of critical infrastructure
(3) Public health threats
(4) Loss of 10% or more of residential dwellings

Communities recommended to date:

Akiak
Alakanuk
Atmautluak
Chefornak
Diomede
Golovin
Kotlik
Kwethluk
Kwigillingok
Little Diomede
Napakiak
Nelson Lagoon

This list is not an inclusive list of communities affected by Climate Change.

We are asking for your recommendations of communities based on the DCRA mission statement for this task. Please provide your input via e-mail to taunnie.boothby@alaska.gov and tara.jollie@alaska.gov by close of business Dec 12, 2008.

Thank you,
Taunnie L. Boothby, CFM

Alaska Division of Homeland Security & Emergency Management
Compiled in November 2008
Summary of Alaskan Flood Disasters
1978-2008
Sorted by Region, Community and Year

This summary includes only the communities and flooding events resulting in a state disaster declaration. The same event often affects several communities, sometimes widely separated. Flooding events result from:

- Rainfall
- Ice jam
- Storm surge
- Wind driven waves
- Snow melt
- Rising ground water

Alaska DOT&PF - Erosion Control Projects: 1998 – 20099

Used to Identify Communities Potentially Impacted by Climate Change
Updated 12/3/2008

In addition to the projects listed below, ADOT & PF addresses permafrost warming/melting on every road in the interior. Major routes include the Alaska Highway, Glenn Highway, Tok Cutoff, Richardson Highway, Parks Highway, Elliott Highway, Dalton Highway, Denali Highway, and the Edgerton Highway. Northern Region Maintenance and Operations spends approximately $10M per year on combating warming/melting permafrost. This is the funding level provided and does not reflect ADOT&PF's estimate of need.

Proposed or Current Design Projects	Funding Source	Project #	Description
Barrow Arctic Research Center Road	FHWA	76970	Relocate access road to Research Center due to erosion of Stevenson Street.
Chignik Bay Airport	CIAP		Airport Access Culvert Replacement
Chignik Lagoon Runway Repairs	GF/CIAP		Proposed project
Coldfoot Airport Erosion Control	FAA	60851	Protect the Coldfoot airport and access road from imminent erosion by the Koyukuk River.
Emmonak Airport Rehabilitation - Stage II	FAA	62641	Included in the scope of the Airport Project is to Relocate the existing powerline to the Airport due to River Erosion
mmonak Flood Permanent Repairs Airport/Clinic Road	FHWA	62754	Repair damage to airport access road caused by recent flooding.
Galena Campion Road Erosion Protection	FHWA	61653	Relocate a portion of Campion Road to avoid erosion of approximately 2 miles of the existing alignment that is threatened by the Yukon River.
Gambell Evacuation Road	FHWA	62973	Repair and extend road used for evacuation of village during annual coastal floods from large westerly storms.
Glenn Highway Erosion MP 62.4	GF		Proposed
Glenn Hwy Realignment MP 78	GF		Proposed
Hughes Airport Improvements	FAA	60245	Address the current flood threat to the facility by raising the grade of the airport and relocating the apron, and possible relocation.
Kivalina Airport Permanent Repairs	FEMA	76926	Repair eroded side slopes and safety area at the airport eroded during 2005 Bering Sea Storm. Protect the most severely damaged portion of the side slopes with a stone revetment.
Kotzebue Roads - Shore Avenue	FHWA	60788	Reconstruct Shore Avenue to provide erosion protection from storms and long-shore currents.

Proposed or Current Design Projects	Funding Source	Project #	Description
Little Diomede Helipad Improvements	FAA	61470	Repair ice scour damage to helipad embankment, repair lighting damage from Storm Events.
Nanwalek Airport	AIP		
Newtok/Mertarvik	GF		
Noatak Airport Relocation	FAA	61478	Airport Relocation due to erosion by the Noatak River
Nome Council Permanent Repairs	FHWA		This project is currently in Construction to repair damages to the Nome Council Road due to the 2005 Bering Sea Storm. A hardened rock structure is being constructed in selected areas to aid in future protection of the road.
North Slope Borough Road Improvements	FHWA	76972	Relocate access road connection to Cake Eater Road due to erosion of Stevenson Street.
Nulato Airport Road	None		Project includes armoring embankment and raising grade to stop flooding and erosion by the Yukon River.
Nunam Iqua Airport Rehabilitation	FAA		Part of the scope of this project is to Construct a road to the airport to eliminate the Boardwalk Access. Currently, the boardwalks are damaged from flooding from both fall storms, and spring ice jam events, and have to be repaired. This project will Construct a road above flood levels to the airport.
Parks Highway Erosion Protection MP 72	CIAP		Willow Creek – Proposed
Point Hope Evacuation Road Extension	FHWA	76968	Construct an evacuation road extension to an elevation above flood levels.
Point Hope Evacuation Road Rehabilitation	FHWA	76966	Rehabilitate and raise grade of road used for evacuation of village from storm surge and flooding.
Portage Glacier Highway	CIAP		Erosion Protection – Proposed
Quigillingok Airport	GF		Currently addressing land acquisition issues
Seward Highway Culvert Replacement	CIAP		Proposed
Shageluk Airport Access Road Improvements	FHWA	62171	Raise roadbed or realign to minimize impact of flooding by Innoko River.
Shishmaref Airport Masterplan	FAA		Masterplan activities evaluating airport relocation options related to Community relocation.
Shishmaref Relocation Road	FHWA	76776	Reconnaissance study to construct road to access Ear Mountain Material source for material to relocate Shishmaref village due to severe erosion from storms.
Sterling Highway Realignment MP 153.2	FHWA		Proposed

Active Projects Needing Additional Funding	Funding Source	Project #	Description
Gambell Evacuation Road		62973	Current Cost estimates indicate there is not enough funding to complete road to far side of the island. The community has requested additional funding for the project, and DOT&PF is considering the request.
Kivalina Airport Permanent Repairs		76926	The engineer's estimate for the rip rap revetment along the taxiway of the airport is considerably higher than initial FEMA estimates. DOT&PF currently has a request to FEMA for the additional funding, but we are unsure if FEMA will approve the request.
Kotzebue Roads - Shore Avenue		60788	This project is currently designed with an additive alternate to provide a hardened rock structure along the first 1000' of the project, North of Lake Street. Depending on how the bids come in this additive may or may not be awarded. The city has also identified an area of erosion concerns North of the Shore Avenue project limits along the beach.
Point Hope Evacuation Road Extension		76968	Current Cost estimates indicate there is not enough funding to construct the evacuation road to the length requested by the community.
Shishmaref Relocation Road/Airport sterplan		76776	Currently DOT&PF is funded to prepare a Reconnaissance Study and perform masterplan studies. No funding for construction has been identified.
me Council Road			FHWA ER funded project will not permanently protect the airport from erosion damage. Additional needs include grade raises/slope protection.

Projects Completed	Funding Source	Project #	Description
Chignik Airport Access Road	FHWA		Shore Protection
False Pass Airport	AIP		Replaced 1/3 of Runway (10 years ago)
Girdwood Airport Erosion Protection	AIP Surface Maintenance		Surface maintenance effort
Homer – Burbank Culvert	GF		Constructed by Maintenance
Homer Spit Fishing Lagoon	FHWA		Dynamically stable beach/beach nourishment project
Homer Spit Road and Trail shore protection	FHWA		Construction Complete
Hooper Bay Airport	AIP/GF		15 years ago – major project; smaller projects within last 5 years
Hyder	GF/FHWA		Completed several erosion projects
Kivalina Airport	FEMA		Shore Protection
Kodiak – Pasagshak Road	FHWA		Shore protection – constructed
Kodiak Ferry Terminal	FHWA		Shore Protection
Koyukuk Airport Improvements			Completed Airport Improvements to increase airport elevation above 100 year flood levels.
Ninilchik Access Road	GF		Shore Protection – Maintenance
Platinum Airport	AIP		Erosion issues – FY 09 Construction
Sand Point Runway Armor Stone	GF		
Shaktoolik Airport Permanent Repairs			Completed Airport Repairs to the Safety Area and Nav Aids due to the 2005 Bering Sea Storm flooding.
Skagway	FHWA		Completed Tiaya River Erosion Control Project
Solomon and Safety Sound Waysides Permanent Repairs			Both waysides were damaged during the 2005 Bering Sea Storm event. The Boardwalks were repaired and replaced where needed, and roads and parking areas were repaired.
Unalakleet Beach Road Permanent Repairs			Constructed repairs and a new hardened rock structure along the Beach Road that was damaged in the 2005 Bering Sea Storm.
Unalakleet Airport Access Road	FHWA		Dynamically stable beach/berm breakwater project – constructed
Unalaska Airport	GF		Constructed
Unalaska Airport	GF		Corrected a big erosion issue in last 5 years
Unalaska East Point and Ballyhoo Road	FHWA		Shore protection – completed

APPENDIX B
FORMAL SUBMISSIONS FROM AND TO THE IAWG

STATE OF ALASKA
DEPARTMENT OF
COMMERCE
COMMUNITY AND
ECONOMIC DEVELOPMENT
Office of the Commissioner

Sarah Palin, Governor
Emil Notti, Commissioner

December 11, 2008

Mr. John H. Dunnigan
Assistant Administrator for Ocean Services & Coastal Management
NOAA
1305 East-West Highway
Silver Spring, MD 20910

Dear Mr. Dunnigan:

The State of Alaska has embarked on an ambitious and timely process of examining the issues, approaches and solutions to the impacts of a warming arctic environment. As part of that effort, the Governor has appointed members of her cabinet to serve as her Climate Change Sub-cabinet advisory body. The chair of the Sub-cabinet is Commissioner Larry Hartig of the Department of Environmental Conservation. Subsequently, Commissioner Hartig established an Immediate Action Work Group to identify actions and policy development the work group feels is necessary in the immediate future. I serve as State co-chair while Patricia Opheen of the Corps of Engineers serves as the federal co-chair of the work group. Although we have a very limited membership, we are extremely pleased that Amy Holman of your organization has consented to serve on our work group.

On behalf of the State of Alaska and the Immediate Action Work Group of the Governor's Sub-cabinet for Climate Change, I commend NOAA for participating in our efforts. I also am excited that NOAA is seeking additional data on the weather, sea level heights and tidal ranges of Alaska's oceans. Lack of data on tides and weather patterns on the Alaskan coastlines is a substantial barrier to understanding what changes may be occurring in relation to climate change phenomena.

It is our understanding that NOAA plans to establish new tidal gauges and meteorological monitoring sites along Alaska's coast. The Immediate Action Work Group called for additional tide and water level stations in our April 2008 recommendations report to the Governor. Our top ten priority areas for placement of these stations (including meteorological instrument packages) are:

1. Bering Straits- Wales or Little Diomede;2. Norton Sound – Unalakleet ; 3. Kuskokwim Bay – Platinum; 4. Arctic Ocean – Barrow; 5. Bristol Bay – Dillingham; 6. St Lawrence Island – Savoonga or Gambell; 7. Bering Sea – Hooper Bay or Scammon Bay; 8. Alaska Peninsula – Nelson Lagoon; 9. Cape Lisburne; 10. Nelson Island – Metarvik.

2

TO: Tessa Rinner, Director of Programs, Denali Commission

Date: January 9, 2009

RE: **Immediate Action Workgroup (IAWG) Comments to FY 2009 Commission Work Plan**

Comments prepared by: Jamilia George, State Co-Chair Representative to the Denali Commission

The Immediate Action Workgroup is a jointly chaired state-federal working group formed to make recommendations on projects, policies and goals that can be initiated or accomplished in a 12 – 18 month period (January 2009 – July 2010), for communities facing imminent threats of loss of life, loss of infrastructure, loss of public and private property or health epidemics due in–part to a changing climate.

IAWG members include DCCED, NOAA, USACE, DEC, DOT, DHS&EM, Denali Commission, ANTHC and others. All meetings are public and many rural community leaders participate in person and by teleconference. Deputy Commissioner Mike Black (DCCED) and Trish Opheen (USACE) are co-chairs.

Members identified 3 reports as highly relevant in reaching consensus on policy, project and budget recommendations for rural infrastructure: USACE – Baseline Erosion Assessment; Military & Veterans Affairs 30 Year Review of Disasters in Alaska; and the GAO Revised Report on Relocating Alaska Rural Communities. Central to the decision making process is the ability of rural communities to effectively identify known risks and hazards. In this regard, hazard mitigation planning on a regional level s critical. Funding for such planning is limited at both the state and federal level under current administrative and congressional regulations.

The Denali Commission FY 2009 Work Plan and revised policies and procedures recognize the importance of regional planning, support and strategy to sustainable infrastructure and community vitality. The IAWG believes that the Work Plan as drafted should include the opportunity for rural communities to apply for funding of Regional Hazard Mitigation Plans. The IAWG members understand the Commission's support of regional planning to be a necessary component to the decision-making process for funding infrastructure investment at the Commission. The IAWG therefore requests that the Work Plan be amended to include a modest but reasonable pool of funds **for purposes of establishing Regional Hazard Mitigation planning. It is the recommendation of the IAWG that $1,000,000. for Fiscal Year 2009 be included in the Work Plan for this purpose.**

For further information supporting the above comments and request, please contact Deputy Commissioner Mike Black (DCCED), Trish Opheen (USACE) or John Madden (DHS & EM).

December 3, 2008

To: Governor's Sub-Cabinet on Climate Change
From: The Interagency Hydrology Committee for Alaska
Subject: Hydrology Needs for Alaska

The Interagency Hydrology Committee for Alaska (IHCA) is an organization of technical specialists working for Federal, State, borough, and local governments and Federally recognized tribes, who coordinate the collection and interpretation of data related to water resources and climate throughout the State of Alaska.

As you are well aware, climate change, particularly current warming trends in the high latitudes, is leading to changes in Alaska's freshwater, estuarine, and marine environments. One of the best measures of the rate and magnitude of change, and perhaps the most impacted natural resource in terms of both timing and quantity changes, is in fact water volume and associated characteristics. For example, rivers and lakes freeze over later in the year and become ice-free earlier in the year, permafrost is thawing, and precipitation patterns are changing. Agencies and communities in Alaska have become increasingly aware of the emerging and potential effects of climate change. However, the authorities charged with protecting the public safety and managing natural resources in the best public interest require appropriate information and tools to take specific actions in response to and preparation for changing environments.

IHCA has developed the following list of topics that are especially important to detecting, quantifying, and adapting to climate-driven change and recommend that research and monitoring in support of state and local needs be encouraged and supported with the highest priority:

- Extent of permafrost and the effects of changing permafrost on subsurface hydrology, aquifer yield, and lake draining or formation;
- Baseline flow and water volume conditions of rivers and lakes versus changing spatial and temporal hydrologic patterns, such as changes in seasonality, flood magnitude, and drought severity;
- The spatial and seasonal distribution, timing, intensity, and state of precipitation;
- Freeze-up, break-up, ice thickness, and ice jams on lakes and rivers;
- Extent of glacier mass changes, the contribution of glacier melt to streamflow, and frequency of outburst floods;
- Geologic and geotechnical trends related to active layer detachments, mass wasting, and sloughing;
- Avalanche timing, prevalence, and trends;
- Socio-economic cost to address changing conditions of water availability and quality;
- Erosion and sediment transport effects resulting from changes in runoff patterns;
- Short and long term planning for water supply, demand, and support infrastructure to mitigate emerging and anticipated environmental change.

IHCA will be happy to provide additional details, including specific agency projects and outstanding needs that will benefit from the hydroclimatic research listed here. We are also happy to provide technical support to your group upon request.

Sincerely,

Steven A. Frenzel
Chair, Interagency Hydrology Committee for Alaska

DEFINITIONS FOR IAWG

MITIGATION AND ADAPTATION

As stated in the Arctic Climate Impact Assessment, "The science suggests that responding to this challenge will require two sets of actions; one, *mitigation*, to slow the speed and amount of future climate change by reducing greenhouse gas emissions; and the other, *adaptation,* to attempt to limit adverse impacts by becoming more resilient to the climate changes that will occur while society pursues the first sect of actions," (ACIA, 2004). It is important to note that mitigation in the context of the Alaska Department of Military & Veterans' Affairs and FEMA, is consistent with adaptation in improving infrastructure to minimize damage from natural disaster events. (Final Commission Report, Alaska Climate Impact Assessment Commission, March 17, 2008).

SUSTAINABILITY

World Commission on Environment and Development

Sustainability is "meeting the needs of the present without compromising the ability of future generations to meet their own needs." (Bruntland Report, WECD, 1987- broad, most commonly accepted definition, as set out by the World Commission on Environment and Development (WCED)

EPA Sustainable Infrastructure Initiative

Looking forward, EPA wants to promote practices that encourage utilities and their customers to address existing needs so that future generations will not be left to address the approaching wave of infrastructure needs that will result from aging infrastructure.

SEA ICE

Defined by World Meteorological Organization in numerous terms:
http://www.aari.nw.ru/gdsidb/XML/sea_ice_nomenclature.html

For purpose of our work, refer to landfast sea ice: http://mms.gina.alaska.edu/supp/Definition.pdf

Excerpt: Numerous definitions of landfast ice exist in the literature, which consider to different extents all the processes that occur in the nearshore zone in the presence of sea ice. According to Weaver (1951) "fast ice or landfast ice is the young coastal ice which, in stationary sheets, builds seaward from the shore of landmasses … by being more or less attached to the shore, or by being otherwise confined". The World Meteoroligical Organization (1970) defines fast ice as "Sea ice which remains fast along the coast, where it is attached to the shore, to an ice wall, to an ice front, or over shoals, or between grounded icebergs". Stringer *et al.* (1978) define the fast ice zone as "the area generally shoreward of the 20m isobath with quite stable ice much of the year" and only include ice contiguous with the shore. Barry *et al.* (1979) list three criteria that can distinguish landfast ice from other forms of sea ice: "(i) the ice remains relatively immobile near the shore for a specified time interval; (ii) the ice extends from the coast as a continuous sheet; (iii) the ice is grounded or forms a continuous sheet which is bounded at the seaward edge by an intermittent or nearly continuous zone of grounded ridges".

Furthermore, according to the WMO, sea ice can be classified as either landfast ice or pack ice, while Weaver describes drift ice as a third category, which is "transitionary between the fast ice and the polar pack ice". Similarly, Stringer *et al.* define a category for ice in the shear zone between the landfast ice and pack. (AK-03-06, MMS-71707), Mahoney, et.al.

ARCTIC

The **Arctic** is the area around the earth's North Pole. The Arctic includes parts of Russia, Alaska, Canada, Greenland, Lapland and Svalbard as well as the Arctic Ocean. The 10°C (50°F) July isotherm is commonly used to define the border of the Arctic region.
From: http://www.knowledgerush.com/kr/encyclopedia/Arctic/

RIVERINE

FLOOD - A flow beyond the carrying capacity of a channel.

EROSION - The wearing away of land by the action of natural forces. On a river the carrying away of material by wave action or flow of water.

COASTAL

FLOOD - A water level above the highest estimated tide.

EROSION - The wearing away of land by the action of natural forces. On a beach, the carrying away of beach material by wave action, tidal currents, and littoral currents.

Erosion/Deposition is an ongoing natural process, not a unique event, often times increased during flooding.

Flooding is a unique natural event, the boundaries of which can be influenced by the extent of erosion.

Planning/Program/Project Integration

Immediate Action Workgroup
Policy 1 Recommendation

Step 1: Data

- Identify all data on public and critical infrastructure
  - State agencies
  - Federal agencies
  - Denali Commission
  - Local and tribal entities
  - Non-governmental organizations
  - Private sector
  - Academia
- Consolidate/link together the data
- Enable queries for agencies and communities
- Improve quality of data and databases

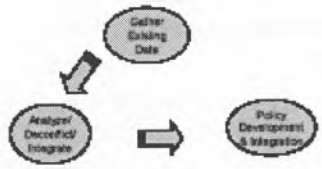
Step 2: Analysis

- Identify and fill gaps in data
- Determine status and capability of current infrastructure
- Determine useful life and future plans for repair, renovate, retrofit, replacement, or relocation
- Determine vulnerabilities to climate/weather and other environmental/economic factors
- Identify all funding and budget streams
- Identify conflicts between agency plans

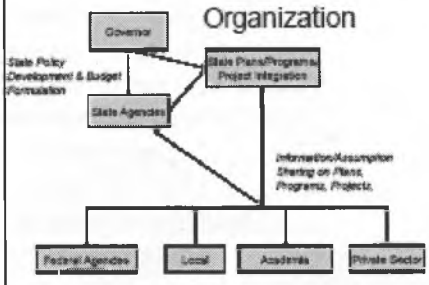
Step 3: Policy Integration

- Improve policy coordination between agencies – timing, impacts, integration
- Determine effects of proposed policies
- Test assumptions of climate, economic trends and strategic directions
- Determine effects of non-state policies and budgets
- Update analyses for new data information
  - Weather patterns/flood plains/mapping
  - Economic assumptions
  - Changes in demographics
- Document out-year O&M costs
- Calculate life cycle costs
- Contribute data to budget formulation

Implementation Steps For Integrating Plans, Programs, and Projects



Organization



IAWG Sustainability Considerations

The common idea for sustainability uses the Brundtland Commission definition of sustainable development to view a community's present needs:

> *"without compromising the ability of future generations [in a rural community] to meet their own needs".*

Alaska's Small Communities Could be Sustainable – viable in the near term - to the extent they are resilient to interrelated vulnerabilities presented by climatic/ecological changes.

Larger communities face a very different scale of sustainability issues.

National or international economic forces impacting financial conditions increase sensitivity within a community. These forces originate outside of the immediate locale such as energy and resource extraction operations.

A Sustainable Community is Able to Respond to Climate Impacts and to Become Resilient.

Local government can be organized in many ways to achieve this: as a conventional city/local government, tribal entity or it may rely on a traditional town hall or congregational meeting structure.

Minimum Level of Population.

What is likely needed is for the community to have a minimum level of population to continue basic functions of:

- education,
- economic structure
- public safety,
- community water / sewer,
- management of the waste stream, and
- cohesive culture and social presence.

Additionally, an intrinsic part of sustainability requires directly linking a community's viability to the costs of energy and transportation, which frequently are based on factors not directly associated with a minimum population level. A viable community, whether it remains in its location, or if migration or relocation occurs requires:

- viable connections to transportation systems, and
- affordable and appropriate energy.

Protect in Place.

Critical to a community's sustainability is its population. If people relocate to larger urban centers, sometimes called out migration, the remaining community may be reduced to a level that cannot maintain needed services and infrastructure. To insure that this out migration does not lead to the original community's loss of culture and social presence, it is important that the community prepare and plan to "protect in place" and evaluate possible contingencies including a relocation plan.

Weighted Sustainability Index.

The question being asked in some arenas is whether and at what point a community should be considered for climate impact responses. A weighted sustainability index should be used to determine when climactic influences impacting a small community are strong enough to warrant a response. Small communities could be very sustainable while others may be critically impacted.

This index could include:

- economic measurements,
- current energy usage and viable energy alternatives,
- access to subsistence resources,
- population change, along with
- available municipal, private, state and federal programs.

The local weighting factors for a community's relocation would depend on:

- estimating present and future time tables, programs and costs (all to be determined),
- ecological/climatic change modeling of impacts and opportunities
- consideration of all stakeholders' interests.

IAWG Recommendation to Review Funding Structure for Public Infrastructure O&M And Protect Public Infrastructure Investment and Prevent Loss of Life

The Immediate Action Workgroup identified, as we believe the Subcabinet and the PI - TWIG have also recognized, that maintenance of the State's infrastructure is a critical immediate action to prevent loss of life and infrastructure due to impacts from climate change phenomena.

The IAWG also recognized that the policy issues to address budgeting for maintenance is beyond the scope of its work, but identified it as a significant item warranting the immediate action to encourage and support your efforts to advance changes in policy.

The ***guiding principles*** supporting the IAWG's recommendation to the Subcabinet and PI-TWIG are:

- Protecting Alaska's infrastructure investment that is already in place is an immediate need.
- Authorization and funding of an Infrastructure Maintenance Capital Fund, if well-structured would be an effective tool:
    - Use revenue sharing model
    - Use prioritization mechanism to identify projects
        - Coordinate plans for capital projects in a given community for cost-effectiveness
        - Utilized by both State and Local entities
            - When local is the lead, supported with engineering and professional assistance by State (ADOT) or Federal (USACE)

The IAWG's rationale and ideas for policy changes on maintaining infrastructure investment follow.

Effective and sustainable shore-protection structures must be an integral part of the state's climate change adaptation strategy and must be supported by a long-term maintenance funding program.

- The State of Alaska has vital national and state interest in the stability and behavior of coastal structures around its coastline, to ensure public safety – for both life and infrastructure investments and for the economic health of many coastal communities.
- The dominant coastal structure between Alaskan ports, harbors, navigation channels and the sea are rubble mounds. These include breakwaters, revetments, jetties, and groins. Other types of structures are common and include seawalls, piers, and bluff protection.
    - They are used for protecting harbors, wave reduction within harbors, retaining sediment, protecting navigation waterways, shoreline protection, and bluff protection.
- The purpose of maintenance is to ensure the long-term viability of public infrastructure investment, public safety and economic health by:
    - Protecting harbors and inlets that are important commercial and military navigation links
    - Protecting shore-based infrastructure
    - Providing beach and shoreline stability control
    - Stabilizing navigation channels
    - Protecting navigation, coastal communities, roadways, bridges, etc.
    - Providing flood protection
    - Providing recreational activities

While most navigation structures are federally owned and maintained, most shore-protection structures are locally owned and maintained, yet funded by the State.

The cost of replacing existing coastal protection infrastructure investment is high, and the cost of responding to a disaster is exorbitant. The State of Alaska needs to improve the means and methods for reducing these costs. If can do this by:

- Regular preventative maintenance efforts can substantially reduce risks, save lives and property, and reduce full replacement costs and can extend the life of investment for 50 or more years.
- Reducing the design and construction costs of coastal structures by employing risk, life-cycle, and reliability analysis techniques in both planning and design studies in order to develop more efficient designs.

Alaska has aging infrastructure requiring maintenance:

- Most of these structures were originally built in the early 1900's and have been extended and rehabilitated many times.
- Maintenance of existing inlets becomes more important each year as ship traffic and ship drafts increase.
- As the inlet-protecting jetties erode, dredging costs can increase at an alarming rate. In addition, maintenance of existing revetments and other shoreline structures is becoming more important with increasing coastal population.
- As a result, inspection, repair, and rehabilitation of existing structures represents a large part of coastal rubble-mound work within the state while new construction of this class of structure represents a diminishing fraction of the projects.

Challenges and suggestions for changes to an Infrastructure Maintenance Policy:

- State builds, and then a community is responsible for maintenance.
    - How does a community get funding to maintain?
    - How is infrastructure inspected?
        - ADOT isn't sure of what the infrastructure inventory is
            - ADOT needs an inventory of what is out there. DCRA-Rapids Database has been identified as the preferred inventory database
        - ADOT isn't sure of the condition of infrastructure and doesn't have funding for inspections
            - Problems are discovered when there is an emergency or almost emergency situation and a community alerts DOT about a problem
- Create an Infrastructure Maintenance Capital Fund for ADOT and local governments to draw on to:
    - Conduct inspections for infrastructure and facilities, and allow ADOT or others to maintain in a timely manner

      Examples: Beach nourishment—5 years is a standard maintenance timeframe.
    - Funds could be used for design work, upgrade riprap structures and rock revetments to replace the rock decreasing the amount of decay.
        - Develop a mechanism to prioritize projects; some ideas are:
            - Eligible for funds if a community had a certain type of structure—or possibly expand (revetment or beach nourishment)
            - Local—would need guidance from USACE or ADOT—to ensure appropriate work being conducted – to maintain life of structure.
            - When local government is responsible for—maybe factor into a revenue sharing formula, or perhaps based on Legislative districts, capital matching grants. (ex: —$1500 per mile for road maintenance; will need p/ft rock revetment formula to fund local projects)

APPENDIX C
DOCUMENT PRESENTATIONS AND SUBMISSIONS

Document Presentations and Submissions

This section includes only some of the handouts and presentation materials presented at the IAWG meetings. All materials can be found at the **IAWG Website:**
http://www.climatechange.alaska.gov/IAWG.htm

- **For Each IAWG Meeting Listed in Appendix D:**
  - Agendas
  - Meeting Summaries
  - Working Drafts Which Became Sections of this IAWG Recommendations Report
  - Public Meeting Notices

- **Presentations by Alaska Dept. of Transportation and Public Facilities:**
  - Infrastructure and Erosion Control, Beach Nourishments Efforts
  - Shore Protection, Nourish or Armor?

- **Presentation by Dept. of Commerce, Community & Economic Development**
  - Community Databases Managed by Division of Community & Regional Affairs:
    - 10 Databases – see page 1XX of this report for descriptions

- **Presentation by Dept. of Natural Resources – Division of Coastal and Ocean Management**
  - Coastal Impact Assessment Program (CIAP)
    - Additional materials complementing those in this report, starting on page 1XX

- **August 28, 2008 Status and Progress Presentations by IAWG Member Agencies**
  - Six Communities in Peril, Division of Homeland Security & Emergency
  - Management Status of Project Actions for IAW Alaskan Communities, US Army Corps of Engineers
  - Community Projects, Dept. of Transportation and Public Facilities

To: MARGARET KING
Subject: RE: IAWG 12/22 Agenda and 12/5 Meeting Notes

Marge,
I did listen in on most of todays tele. I just wanted to inform you and the IAWG that the village of Deering has been dealing with their erosion problem for quite some time. In fact, I recently received their Capitol Projects request and first on their list of priorities is Phase 3 of their beach erosion protection project. I worry about them as when you go there in the summer, frequent strong storms has eroded the beach line very close to the homes. In fact, one more large storm and some of these homes will fall into the sea. The village has been quite passive about the issue as they have worked directly with the legislators who represent this election district for funding for erosion control. Since the State is taking the lead in identifying villages facing serious erosion problems, and will ultimately find the resources to mitigate the problem, I do think they do need to get on the State list.

DATA RESOURCE GUIDE

Division of Community and Regional Affairs
www.commerce.state.ak.us/dcra/

Alaska Community Database – contains community profiles for more than 390 places in Alaska, the majority of which are communities. An interactive database provides a wide range of community-based information and data for planning, policy-making and technical assistance decisions.

Alaska Community Directory – current information on community officials and contacts. The online system is updated throughout the year,

Community Maps – online versions of the community profiles maps. These maps include information on these maps includes, but is not limited to: land status; platted boundaries; land use (for example, public, commercial and residential improvements, boat haul-out areas, etc.); topography; latitude and longitude points (for emergency response purposes); sensitive and natural hazard areas; as-built information.

Municipal Finances – The information in this database is derived from certified financial statements and financial audits that are submitted annually by municipalities. DCRA staff review the audits and certified financial statements and enter the information into the database to allow further analysis. DCRA has compiled this information since 1985. Only the latest information is shown on the Community Profiles page. However, if you want Municipal Finance data for earlier years you can contact Research and Analysis staff with you request.

Capital Projects Database – information on capital projects administered by over 20 State and federal agencies. Information includes project descriptions, funding levels and project status for over 20,000 capital projects past and present.

Economic Development Resource Guide (EDRG) – is designed to bring together in one place an inventory of programs and services that can provide economic development assistance to Alaska communities and businesses.

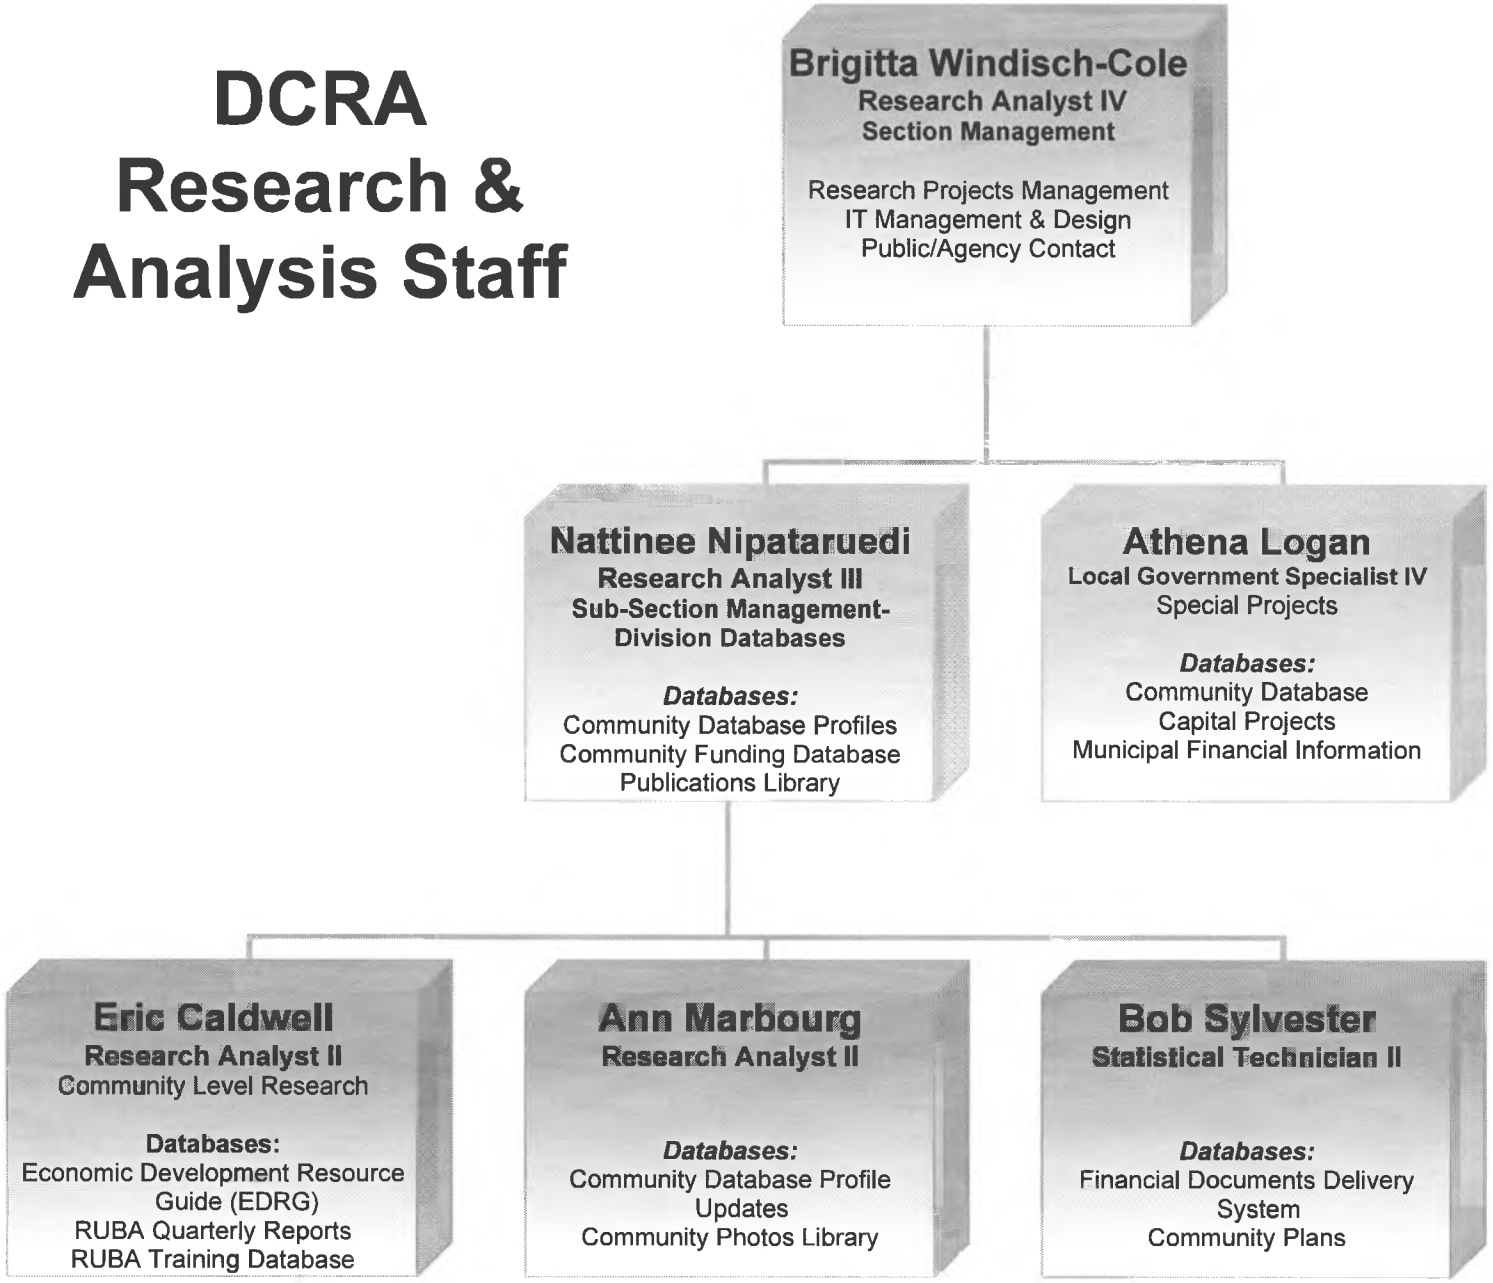
Community Funding Database – contains information on past and current funding to communities administered by the Division of Community and Regional Affairs, such as Mini-Grants, CDBG, Legislative Grant, etc. ***(Note: this does not include any projects that were funded through another Department or Division)***

Financial Documents Delivery System – Online copies of municipal budgets and financial statements submitted to the Division. Municipal budgets date back to FY2000. The year-end financial statements date back to FY1998 and consist of either an audit or city-prepared financial statement certified as true and complete by the local governing body.

Community Plans Library – houses an assortment of plans for communities. Documents include, community plans, comprehensive plans, and more.

Community Photo Library – contains community photos submitted by staff and the public

DCRA Research & Analysis Staff



Coastal Impact Assistance Program

The Energy Policy Act of 2005 (Public Law 109-58) was signed into law by President Bush on August 8, 2005. Section 384 of the Act establishes the Coastal Impact Assistance Program (CIAP) which authorizes funds to be distributed to Outer Continental Shelf (OCS) oil and gas producing states to mitigate the impacts of OCS oil and gas activities.

Under the CIAP, the Secretary of the Interior is authorized to distribute to producing

- States, and
- Coastal political subdivisions (CPS's)

$250 million for each of the Federal fiscal years (FY) 2007 through 2010. This money will be shared among Alabama, Alaska, California, Louisiana, Mississippi, and Texas and will be allocated to each producing state based upon allocation formulas prescribed by the Act. Further, the CIAP allocates money to the eligible CPS's of the states identified above.

Pursuant to the Act, a producing state or CPS shall use all amounts received under this section for one or more of the following five authorized uses:

Authorized Uses:

1. Projects and activities for the conservation, protection, or restoration of coastal areas, including wetland.
2. Mitigation of damage to fish, wildlife, or natural resources.
3. Planning assistance and the administrative costs of complying with CIAP.
4. Implementation of a federally-approved marine, coastal or comprehensive conservation management plan.
5. Mitigation of the impact of OCS activities through funding of onshore infrastructure projects and public service needs.

IAWG Comments on CIAP

Only Authorized Uses 3 and 5 above apply to the Immediate Action Workgroup's efforts.

Of this,

- Authorized Use 3: Planning assistance and the administrative costs of complying with CIAP - has been funded annually, while
- Authorized Use 5: Mitigation of the impact of OCS activities through funding of onshore infrastructure projects and public service needs has never been funded.

Yet, Authorized Use 5 could be valuable in developing projects that address immediate needs, including evacuation roads at Point Hope, Kivalina, etc. Shaktoolik and Shishmaref could be included but is only allowed funding under the State, while other authorizations are allowed for Coastal Political Subdivisions.

COASTAL IMPACT ASSISTANCE PROGRAM

Section 384 of the Energy Policy Act of 2005 established the Coastal Impact Assistance Program (CIAP). The Act authorizes the U.S. Department of Interior, Minerals Management Service to distributed $250 million annually for the years 2007 through 2010 to Outer Continental Shelf (OCS) oil and gas producing states and coastal political subdivisions (CPSs) to mitigate the impacts of OCS oil and gas activities.

Per a formula prescribed by the Act, Alaska's eight eligible CPSs will receive a combined total of 35 percent of Alaska's allocation. The remaining 65 percent is allocated directly to the state.

In 2007 and 2008 Alaska was allocated 1 % of the national CIAP funds. Due to the recent Chukchi Lease Sale, MMS has projected that Alaska's allocation will increase to be between 12% and 17 % of the national CIAP allocation in 2009 and 2010. MMS will announce final allocation in April 2009.

The tables below show the annual and total projected CIAP allocations to the state and the CPSs for both the high and low estimates.

Allocation Directly to State (65% of total to state)

	Total	2007	2008	2009	2010
Low end (12% of total federal funds for 2009 and 2010)	**30,982,500.00**	1,576,250.00	1,576,250.00	18,915,000.00	18,915,000.00
High end (17% of total federal funds for 2009 and 2010)	**56,745,000.00**	1,576,250.00	1,576,250.00	26,796,250.00	26,796,250.00

Allocation Directly to CPSs - Low end (35 % of total to state)

	Total	2007	2008	2009	2010
Municipality of Anchorage	**3,581,566.76**	137,767.88	137,767.88	1,653,025.50	1,653,025.50
Bristol Bay Borough	**17,627.72**	665.86	665.86	8,148.00	8,148.00
Kenai Peninsula Borough	**1,544,770.72**	59,435.36	59,435.36	712,950.00	712,950.00
Kodiak Island Borough	**1,902,235.04**	73,170.52	73,170.52	877,947.00	877,947.00
Lake & Peninsula Borough	**898,096.08**	34,518.54	34,518.54	414,529.50	414,529.50
Matanuska-Susitna Borough	**816,488.30**	31,399.15	31,399.15	376,845.00	376,845.00
North Slope Borough	**7,187,406.52**	276,448.76	276,448.76	3,317,254.50	3,317,254.50
Northwest Arctic Borough	**6,119,288.86**	235,343.93	235,343.93	2,824,300.50	2,824,300.50
Total	**22,067,500.00**	**848,750.00**	**848,750.00**	**10,185,000.00**	**10,185,000.00**

Allocation Directly to CPSs - High end (35 % of total to state)

	Total	2007	2008	2009	2010
Municipality of Anchorage	**4,959,109.00**	137,767.88	137,767.88	2,341,786.12	2,341,786.12
Bristol Bay Borough	**24,417.72**	665.86	665.86	11,543.00	11,543.00
Kenai Peninsula Borough	**2,138,895.72**	59,435.36	59,435.36	1,010,012.50	1,010,012.50
Kodiak Island Borough	**2,633,857.54**	73,170.52	73,170.52	1,243,758.25	1,243,758.25
Lake & Peninsula Borough	**1,243,537.32**	34,518.54	34,518.54	587,250.12	587,250.12
Matanuska-Susitna Borough	**1,130,525.80**	31,399.15	31,399.15	533,863.75	533,863.75
North Slope Borough	**9,951,785.28**	276,448.76	276,448.76	4,699,443.88	4,699,443.88
Northwest Arctic Borough	**8,472,872.62**	235,343.93	235,343.93	4,001,092.38	4,001,092.38
Total	**30,555,000.00**	**848,750.00**	**848,750.00**	**14,428,750.00**	**14,428,750.00**

DNR/Division of Coastal and Ocean Management
July 2008

TO: IAWG Members
FROM: Steve Weaver, ANTHC
DATE: 10/29 – 11/3/08 (Series of emails to M. King)

I've tried to capture my thinking about climate change data and effectively using that data by creating 3 tools: (1) Community Planning Strategy - on page 2; (2) Key Data Points – on page 3, and (3) Community Vulnerability Assessment Tool – described below.

Together these tools summarize a conceptual climate change adaptation strategy of (1) local empowerment and (2) providing understandable and actionable data that can be integrated into on-going community planning.

Link to Funding: I think this kind of framework is essential to an **incremental** relocation strategy where we are trying to *fund most of adaptation infrastructure expenses thru the existing traditional funding framework*. Virtually all current public works projects started as a local constituent legislative request or funding agency application.

To effectively use existing capital project processes will require communities to anticipate the impact of climate change and identify climate change infrastructure projects as high priority.

I originally put these concept papers together to show ANTHC staff how our climate change project might fit in to the big picture.

ANTHC is beginning work on a Community Vulnerability Assessment (CVA) tool (Tool 3).

The vulnerability tool would be a platform to list key data points and use that as a basis for establishing relative vulnerability. The outcome of the assessment would be a reference point integrated into overall community planning and a basis for application for climate change impact project funding.

This is why we hope to partner with the IAWG/Climate Change Effort so a consensus on what the "key indicators" are can be built and a broader acceptance of the tool facilitated.

I think the CVA tool could potentially include a conceptual community planning strategy as an appendix. How it can be utilized to facilitate better community planning and document and support an application for climate change adaptation project funding would make it a more useful tool.

We have the project funded, and are now looking for working partners.
Our plan is to:

- Write a draft community vulnerability assessment tool (CVA)*, then
- Test it in at least one rural Alaska Native community, preferably where ANTHC has a funded sanitation project – likely an ANTHC in-house vs. contractor implemented project
- Our intent is that the outcome product will be structured to be better aligned and suited to a broad application base.
- Develop a detailed work plan or schedule of completion in place – with a '09 outcome.

We believe this is "ground floor" opportunity.

If anyone, the IAWG, or individual agencies, are interested in working with us, please let me know.

Date: October 14, 2008
From: Steven M. Weaver, P.E. - ANTHC
Subject: An Adaptation Strategy to Prepare for Climate change in Alaska (version2)

My recommendation for the primary theme for a statewide adaptation strategy is: local empowerment. By that I mean give local leaders the information, the tools and the opportunity to incorporate climate change adaptation in to their current community plans. The goal is to inspire and inform residents to maximize the opportunity for orderly transition.

Climate change adaptation can be most effective not as a separate report or initiative, but as an integral component of all community planning and improvement. To accomplish that goal it seems to me that five basic deliverables are needed:

(1) A central systematic source of current environmental data from which local authorities and design professionals know "what is" and how "what is" has been changing. I am thinking an internet portal and custodial agency to index and link existing sites, identify the data gaps and organize the requests to fill those gaps. This site could include a new "Environmental Atlas" to replace the one published by the University of Alaska in 1984.

(2) A statewide set of climate zone profiles summarizing the environmental changes expected based on the best science. The definition of the "best science" needs to be established and consistently used/systematically updated on a statewide basis.

(3) Local vulnerability assessment tool
   a. Town site vulnerability & monitoring requirements
   b. Infrastructure component vulnerability
   c. Economic impacts
   d. Natural environment impacts (e.g. permafrost changes, and animal & plant migration, etc)

(4) Local adaptation information and prioritization tool
   a. Relocation and incremental relocation strategies
   b. Life cycle infrastructure replacement/relocation/strengthening strategies
   c. Community land use/expansion strategies
   d. Economic change/opportunity
   e. Example community/personal behaviors and activities that can make a difference

(5) A statewide information framework to register vulnerability assessments, share successful adaptation projects/outcomes, classify threat levels, organize coordinated responses, and resource prioritization & allocation methodologies.

DATE PUB.10/14/08, VERSION 3 -ANTHC

Climate Zone Profile

	PROJECTION YEARS		
	10	50	100
Sea level rise & potential for event intensity change			
Land temperature change			
Water temperature change			
Air temperature change			
Precipitation change & event intensity change			
Changes in months of the year with ice cover			

NOTES: (1) This is a survey of climate change expectations based on the best science currently available. It is developed based on empirical data collection, modeling and scientific analysis. The purpose of this information is to assist Alaska's community leaders with community planning to better adapt to our changing environment. This data is periodically updated see www.climatechange._____ for most current information.

(2) This data could also be displayed in a series of maps - the goal is to identify key data needed to do effective aligned community planning and then display it in a way that is useable and actionable by local leaders and industry professionals.

APPENDIX D

COMMUNITY PARTICIPANTS AND IAWG MEETING SCHEDULE AND AGENDA ITEMS

IAWG Members and Community Participants

IAWG Members

Mike Black, Co-Chair (DCCED)
Trish Opheen, Co-Chair (USACE)
Amy Holman (NOAA)
Luke Hopkins (AML)
Bob Pawlowski (Legislative Budget & Audit Committee Representative)
John Madden (DMVA/DHS&EM)
Chris Maisch (ADNR - Forestry)
Mike Coffey (ADOT/PF – Maintenance & Operations)
George Cannelos (Denali Commission)
Larry Hartig (Chair Climate Change Subcabinet and ADEC Commissioner)

Community Participants

Stanley Tom, Tribal Administrator Newtok Traditional Council
David Albert, Newtok IGAP Coordinator
Margaret Nicholson

Steve Oomittuk, Mayor - Point Hope
Christine Amaktoolik, Elim

Enoch Adams, Kivalina – Northwest Arctic Borough
Janet Mitchell, City of Kivalina
Colleen Swan, Tribal Village of Kivalina
Alice Adams
Bobby Schaefer, Northwest Arctic Borough

Frank Myomick, St Michaels–Kawerak Transportation Planner
Robert Iyatunguk
Ester Iyatunguk
Howard Weyiouanna, Sr.- Member of SERC, member of the City of Shishmaref and the Native Village of Shishmaref
Brice Eningowuk, Shishmaref Kawerak Transportation Planner
Curtis Nayokpuk
Karla Nayokpuk
Fred Eningowuk
Stanley Taktoo

Cindy Pilot, Tribal Administrator Koyukuk

John Alvis, Kawerak Transportation Engineer
Jeanette Pomrenke, Kawerak
Sterling Gologergen, Kawerak
Steve Ivanoff, Unalakleet - Kawerak Transportation Planner

Roberta Chavez (Alaska Village Council of Presidents)
Erin Harman, Tanana Chiefs Conference

Michael Sookiayak, Shaktoolik

Toby Anungazuk, Jr., Golovin
Jack Fagerstrom, Golovin

Public and Agency Participants

Karen Rehfield (Alaska OMB/Denali Commission)
Rhonda McBride (State of Alaska)

Tara Jollie (DCCED/DCRA Director)
Sally Russell Cox (DCCED/DCRA)
Erik O'Brien (DCCED/DCRA)
Athena Logan (DCCED/DCRA)
Taunnie Boothby (DCCED/DCRA)

Carl Borash (USACE)
Bruce Sexauer (USACE)
Melanie Harrop (USACE)
Guy McConnell (USACE)

David Kang (DHS&EM)
Andy Jones (DHS&EM)

Krag Johnsen (Denali Commission)
Jamilia George (Executive Branch Representative to Denali Commission)

Barbara Sheinberg (Sheinberg & Associates)
Indra Arriaga (Info-Insights)
Randy Freed (ICF)

Facilitator

Margaret (Meg) King (MJ King & Associates)

IAWG Meeting Schedule and Topics: 2008-09	
August 27, 2008	Review IAWG Mission
	Agency Updates including Flood Protection and Planning
	Potential Budget Needs
	National Commission on Energy
October 28, 2008	Framing the IAWG's 2008-09 efforts
	Strategy, timeline and topics
	Policy, funding and other suggestions to effectively meet IAWG's mission
	Detailed discussion notes
November 10, 2008	GAO Draft Report Overview
	EM – 30 Year Hazards Report Overview
	Advance IAWG Policy #2 Data Needs and ANTHC input for RNWG Guidance
	Identify: Budget/OMB Submission Dates /Subcabinet Meeting Dates/Approval on IAWG Policy Recommendations
	Revisit IAWG Membership
	Budget Placeholder Templates for State CIP and Ops Budgets and process/responsibility for getting placeholder in
	Determine how to prioritize other communities for IAWG's efforts: e.g. are others involved, e.g. Regional-health, Native/Village Corps; How vulnerable is a community? (take away homework)
November 24, 2008	Revise and Update Community Projects and Goals for Initial 6 Communities
	Complete Prioritization/Criteria for other communities (11/10 homework)
	Identify Projects and Goals for New Communities
	Mini-Grants – Identify system that transitions mini-grant projects into Program
	Identify New Funding and/or coordination of funding
December 5, 2008	Identify means to advance Policies 1 & 2 from 4/17/08 Report
	Augment Policies 1 & 2 and determine if additional policy recommendations are needed/what can be agreed upon.
	NOAA Opportunities – How to integrates State's needs into NOAA projects
	Review/Refine Projects and Goals for 6 initial and new communities and identify who can provide budget/cost projections
	Create Table of Contents for Draft Report

December 22, 2008	Homework – Identify Community Projects in next 12 – 18 months
	Homework - Identify new priority Communities in peril (beyond the 6)
	CIAP Presentation (S. Kreel – DNR/D. Johnston - MMS)
	Follow – up: Policies 1&2 from 2008 and new potential policies
	NOAA request for additional IAWG input (Lidar)
	First Draft of Recommendations Report – Continue to refine items from previous meetings
January 6, 2009	New Policy on Strategy for addressing/preventing emergencies/IA
	Detailing 2008 Policies 1&2 and identify other potential new policies
	Other states have an Emergency Preparedness Fund – discussion if IAWG wants to make a recommendation
	Characterizing (new) communities and projects not already identified in 4/17/08 – actions in next 12 – 18 months
	CIAP Proposals – Next Steps
	Discussion on Recommendations Report
January 27, 2009	Report Discussion– Recommended projects, budgets, coordination and policies to Subcabinet
	Discussion – Alaska Forum on the Environment – Coordinating IAWG Presentations
	ADOT – Coastal Erosion Efforts and Techniques
	Depicting Strategy Recommendations
	O&M Policy Recommendations
	IAWG Presentation at Subcabinet
February 23, 2009	Review Final Draft IAWG Recommendation Report

Research Needs Work Group

Recommendations on Research Needs Necessary to Implement an Alaska Climate Change Strategy

Submitted to the Alaska Climate Change Sub-Cabinet

June 2009

Technical Work Group Reports ..... Appendix A

Letter to Governor's Sub-Cabinet on Climate Change ..... Appendix B

1 Executive Summary

The Challenge

Native and long-time Alaskan residents describe dramatic changes in Alaska's climate and the chronic and catastrophic effects these changes are having on their lifestyles and cultures. Knowledgeable scientists, engineers, leaders, and decision-makers acknowledge that climatic changes are occurring in Alaska and have great potential, in consort with other factors, to adversely impact the natural, social, economic, and infrastructure systems that Alaskans rely upon for their way of life. Nearly everyone, however, unanimously laments the paucity of data, analyses, information infrastructure, and decision-support and sharing tools necessary for effective assessment and response to such changes.

While many of the impacts are potentially negative, others may be beneficial. For example, reduced Arctic sea ice may open new shipping opportunities. A warming climate may increase growing seasons, thereby increasing agricultural opportunities. New fishing opportunities may become available in the Arctic. Each of these will require assessment and monitoring.

There is no single agency, organization, or collaborative association within Alaska that is tasked with systematically coordinating the identification, collection, compilation, analysis, and publishing of climate change data and research. This important task is required to ensure the quality necessary to effectively support decision-making and evaluate and manage multifaceted risks and threats such as those associated with climate change in Alaska. However, there are many scientific agencies and organizations collecting and interpreting natural and economic data in Alaska that can be used in an overall climate change response strategy. The challenge is to coordinate the many different data sets, identify the information and data gaps for climate related policy and mitigation/adaptation efforts, and make sure sufficient funding is available and distributed to do the work.

One Process

Through Administrative Order 238 Governor Sarah Palin established, a Sub-cabinet on Climate Change to advise her on the preparation and implementation of an Alaska climate change strategy. The Sub-cabinet established four advisory groups. The four groups included the:

- Immediate Action Working Group (IAWG) focusing on near term actions needed in Alaska;
- Mitigation Advisory Group (MAG) to identify and propose measures to mitigate Alaska's greenhouse gas emissions;
- Adaptation Advisory Group (AAG) to identify and propose methods to adapt to the impacts of climate change on Alaska; and
- Research Needs Work Group (RNWG) to recommend research strategies for mitigating greenhouse gases and adapting to the impacts of climate change.

The RNWG was established to assist the Sub-cabinet in identifying needed research to implement mitigation and adaptation strategies identified by the Advisory Groups, and ultimately, the Sub-cabinet. Research needs were broadly defined and included measures to implement or encourage:

- data collection and management;
- monitoring;
- addressing workforce needs;
- scientific research;
- the development of engineering standards, practices and other support tools;
- infrastructure needs and improvements;
- technology development;
- the assembly of traditional knowledge; and,
- modeling.

To develop its recommendations, the RNWG worked with the Technical Working Groups (TWG) of the MAG and AAG to identify research needs that dovetail with the policy recommendations being offered for the climate change strategy. Input was compiled from the policy recommendations from the MAG TWG:

- Cross Cutting (7)
- Energy Supply and Demand (9 recommendations)
- Forestry, Agriculture and Waste Management (3 recommendations)
- Oil and Gas (8 recommendations)
- Transportation and Land Use (10 recommendations)

and from the AAG TWG:

- Economic Activities (5 recommendations)
- Health and Culture (5 recommendations)
- Natural Systems (7 recommendations)

- Public Infrastructure (3 recommendations)

Additional policy recommendations made by the RNWG are also presented in the respective sections.

The Vision

The Research Needs Work Group (RNWG) envisions an integrated research and knowledge management infrastructure supporting multi-disciplinary systematic analyses and decision-making as an integral part of the climate change strategy that will allow Alaska to effectively, economically, and sustainably adapt to and mitigate the consequences of climate change.

The Strategy

The RNWG members recognized that addressing the impacts to Alaska from climate change and the value of efforts to mitigate greenhouse gases will be most effective through a systematic approach. The State of Alaska should pursue this systematic approach by:

- Developing a comprehensive inventory of ecosystems, communities, resources and infrastructure vulnerable to climate change;
- Developing and implementing a robust monitoring system of key climate change indicators;
- Increasing the current acceptance of risk by managing uncertainty with strengthened science-based research and probabilistic scenario analyses;
- Embracing a systematic outcome-focused approach to decision-making that addresses sustainability, economic impact, climate change adaptation needs, and long-range planning;
- Promoting innovation and continuous quality improvement by increasing applied research capacity and incentives for new methods for adapting to impacts and managing mitigation measures; and
- Establishing mechanisms to ensure communication and coordination among State agencies and with federal agencies and with stakeholders to provide research-derived information to address multi-jurisdictional needs in mitigating greenhouse gas emissions and adapting to climate change.

The RNWG encourages the leaders of the Executive Branch, the Legislature, and the University to assume a more proactive and collaborative role in planning, developing, and clarifying a strategic vision, goals, and performance measures for State government in promoting sustainable communities and addressing climate change in Alaska. The strength and effectiveness of this integrated strategic planning will be a function of the specificity of the state's roles, focus on long-term sustainability, and extent of collaboration with stakeholders. The RNWG believes that this strategic planning is necessary for, and will be the most effective way to prioritize the research needs identified herein.

Identified Research Needs

This report identifies both overarching and specific research needs that are necessary to implement policy recommendations being offered by the MAG and AAG TWGs. Included is an evaluation of the completeness of the TWG policy recommendations and the identified research needs necessary to implement the identified recommendations. An assessment of the research required to fully complete the goals of specific suggested policies is included. For each identified needs, a description of the need is provided. In total, 52 overarching and 95 specific research needs are identified.

The Urgency

Impacts to Alaska from climate change have been increasingly recognized over the past decade, with the breadth of impacts well documented since 2004 (ACIA, 2004). Research strategies have been evolving to address the challenges being faced in Alaska. These include advanced models, various climate change scenarios, and research programs aimed at understanding the rate of change and potential risks to state resources. There is a general consensus that a systematic approach within a multi-disciplinary research strategy will provide the best science-based decision making tools for proactive solutions. It takes time, however, to transform research data to useful information. Identifying research today, with particular attention to the cross cutting needs, will support better decisions in a shorter time frame and ensure that Alaska leads the nation in successfully adapting to the impacts of climate change, while mitigating the greenhouse gas emissions as part of our national role.

2 Introduction

The Arctic is a unique and dynamic ecosystem. Many natural and anthropogenic factors influence this system. Of these, a changing climate has become a dominant driver of change in the Arctic. Native and long-time Alaskan residents describe dramatic changes in Alaska's climate and the chronic and catastrophic effects these changes are having on their lifestyles and cultures. Knowledgeable scientists, engineers, leaders, and decision-makers acknowledge that climatic changes are occurring in Alaska and have great potential, in consort with other factors, to adversely impact the natural, social, economic, and infrastructure systems that Alaskans rely upon for their way of life. While many of the impacts are potentially negative, others are potentially beneficial. For example, reduced Arctic sea ice may open new shipping opportunities. A warming climate may increase growing seasons, thereby increasing agricultural opportunities. New fishing opportunities may become available in the Arctic.

Nearly everyone unanimously laments the paucity of data, analyses, information infrastructure, and decision-support and sharing tools. This leads to significant uncertainty in our ability to predict the effects of climate change and to develop responses to such changes. Despite this, there is an urgent need to develop proactive mitigation and adaptation strategies to climate change.

There is no single agency, organization, or collaborative association within Alaska that is tasked with systematically coordinating the identification, collection, compilation, analysis, and publishing of climate change data and research. This important task is required to ensure the quality necessary to effectively support decision-making and evaluate and manage multifaceted risks and threats such as those associated with climate change in Alaska. However, there are many scientific agencies and organizations collecting and interpreting natural and economic data in Alaska that can be used in an overall climate change response strategy. The challenge is to coordinate the many different data sets, identify the information and data gaps for climate related policy and mitigation/adaptation efforts, and make sure sufficient funding is available and distributed to do the work.

There is a general consensus that a systematic approach within a multi-disciplinary research strategy will provide the best science-based decision making tools for proactive solutions. It takes time, however, to transform research data to useful information. Identifying research today, with particular attention to the cross cutting needs, will support better decisions in a shorter time frame and ensure that Alaska leads the nation in successfully adapting to the

impacts of climate change, while mitigating the greenhouse gas emissions as part of our national role.

It is in this frame that Governor Sarah Palin issued Administrative Order 238. This order established a Sub-cabinet on Climate Change to advise her on the preparation and implementation of an Alaska climate change strategy. The Sub-cabinet established four advisory groups. The four groups included the:

- Immediate Action Working Group (IAWG) focusing on near term actions needed in Alaska;
- Mitigation Advisory Group (MAG) to identify and propose measures to mitigate Alaska's greenhouse gas emissions;
- Adaptation Advisory Group (AAG) to identify and propose methods to adapt to the impacts of climate change on Alaska; and
- Research Needs Work Group (RNWG) to recommend research strategies for mitigating greenhouse gases and adapting to the impacts of climate change.

The RNWG was established to assist the Sub-cabinet in identifying needed research to implement mitigation and adaptation strategies identified by the Advisory Groups, and ultimately, the Sub-cabinet. Research needs were broadly defined and included measures to implement or encourage data collection and management; monitoring; addressing workforce needs; scientific research; the development of engineering standards, practices and other support tools; infrastructure needs and improvements; technology development; the assembly of traditional knowledge; and, modeling.

To develop its recommendations, the RNWG worked with the Technical Working Groups (TWG) of the MAG and AAG to identify research needs that dovetail with the policy recommendations being offered for the climate change strategy. Input was compiled from the policy recommendations from the MAG TWG:

- Cross Cutting (7)
- Energy Supply and Demand (9 recommendations)
- Forestry, Agriculture and Waste Management (3 recommendations)
- Oil and Gas (8 recommendations)
- Transportation and Land Use (10 recommendations)

and from the AAG TWG:

- Economic Activities (5 recommendations)
- Health and Culture (5 recommendations)
- Natural Systems (7 recommendations)
- Public Infrastructure (3 recommendations)

Additional policy recommendations made by the RNWG are also presented in the respective sections.

3 Overarching Needs Summary

The overarching needs identified by the RNWG are:

- **Improved downscaled (local) climate models:** The ability to effectively implement policy recommendations is largely dependent upon being able to act at local levels. This necessitates being able to predict the impacts of a changing climate locally. Programs like Scenario Network for Alaska Planning need to be expanded to include more variables and greater specificity, as well as the variety of Alaska ecosystems (ocean, coastal, terrestrial) and the needs of natural system services (e.g. wildlife, fisheries, subsistence, economic, etc.).
- **Need for baseline environmental research and monitoring:** The success and accuracy of downscaled models is largely dependent upon the quantity and quality of data available. There is an urgent need to collect baseline environmental research and monitoring data. This includes developing a robust baseline monitoring program of a variety of physical, chemical, biological and socio-economic variables that take into account seasonal, annual, and decade-long variability. It also includes implementing a well-developed research program that includes process studies and applications.
- **Improved research infrastructure:** Our ability to collect data is largely dependent upon our ability to improve our research infrastructure (e.g. computers, radars, ships, satellites, personnel, etc). This includes research as well as baseline data collection and monitoring.
- **Improved data integration and sharing:** To assure there is not duplication of efforts it is imperative to coordinate data integration and sharing between agencies. This will ensure the success of various inter-disciplinary efforts that will be needed to address climate change issues. Other key elements include data management, interoperability, access and archiving.
- **Multiple level decision-making tools:** Many of the identified policy recommendations will need to be implemented at the local level. There is an urgent need for expanding the availability of appropriate decision-making tools for local and state officials.
- **Adaptable legal and policy frameworks:** Many laws, regulations and policies on the federal, state, and local levels were developed for a static environment where climate change was not recognized. The challenge for government leaders and businesses will be to adapt to a future made less certain due to a more rapidly changing climate. This will necessitate an evaluation of existing laws, regulations and policies and possible changes to institutional, legal and policy frameworks in an adaptive manner
- **Improved baseline mapping:** The ability to predict landscape level changes due to climate change is dependent upon being able to define the status quo. Unfortunately,

few baseline maps of key environmental variables are available for Alaska. Improved baseline mapping and associated data collection is a critical need.

- **Education and Outreach:** Our ability to implement policy changes is largely affected by public perception and understanding. There is a critical need to develop and implement an education and outreach program aimed at improving public understanding of climate change and its affects, as well as the need to address them.

4 Recommendations: Mitigation

Mitigation Technical Workgroups

The Mitigation Advisory Group (MAG) was tasked with identifying policy recommendations that could be implemented to reduce Alaska GHG emissions and carbon footprint. Five technical workgroups (TWGs) were formed as a part of the MAG:

- Cross Cutting
- Energy Supply and Demand
- Forestry, Agriculture and Waste Management
- Oil and Gas
- Transportation and Land Use

4.1 Cross Cutting (CC) TWG

TWG Recommendations

CC-1. Establish an Alaska Greenhouse Gas Emission Reporting Program

CC-2. Establish Goals for Statewide GHG Emission Reduction

CC-3. Identify and Implement State Government Mitigation Actions

CC-4. Integrate Alaska's Climate Change Mitigation Strategy with the Alaska Energy Plan

CC-5. Explore Various Market-Based Systems to Manage GHG Emissions

CC-6. Create an Alaska Climate Change Program that Coordinates State Efforts for Addressing Climate Change

RNWG Recommendations

CC-7. Assess the long-term economic impact of GHG emissions reporting and reduction programs on the Alaskan economy at statewide and local levels.

Specific Research Needs

The RNWG did not identify specific research needs for this TWG. It is the opinion of the RNWG that research needs identified for other TWGs, in combination, will be sufficient to implement the identified policy recommendations.

4.2 Energy Supply and Demand (ESD) TWG

The Energy Supply and Demand (ESD) TWG was charged with evaluating climate change mitigation policy options related to energy. The ESD TWG prepared a suite of draft policy options, some of which contained elements of research and development, and one of which was specifically about research and development (see TWG Recommendations). As such, three of the policy options, ESD 7, 8 and 9 were lumped into one and it was from there forward referred to as the R&D policy option. A subgroup of TWG members generated the R&D Policy Option. In addition, a second subgroup was assembled to discuss the specifics about energy research that related to minimizing or managing carbon. These were then detailed and are included as research needs under unique identifiers.

The TWG did two things. First, it created a policy option for research (ES&D 7, 8 and 9). Only one "Policy Option" was drawn up for ESD 7, 8 and 9 and it is hereafter referred to as a single, group option. Second, a subcommittee generated a list of specific research needs on behalf of the TWG. The list of specific research needs was generated to address needs for the ESD policy options 1-6.

The R&D Policy Option (ESD 7,8,9) was directed to establishing programmatic incentives for participation and support of public and private investment in fundamental research, demonstration, and deployment of carbon-emission reduction and energy production technologies that hold promise for implementation throughout Alaska.

- Advanced technologies in electric power generation, both small-scale and large-scale, in fossil generation, nuclear generation, and renewables will provide greater efficiency in power supply for utility and industrial purposes.
- A statewide emphasis on enhanced utilization of new and emerging technologies that provide the end-use benefits of electric energy with greater efficiency will provide economic and environmental benefits throughout Alaska.
- The policy will provide incentives and reduce barriers to implementation of advanced generation technologies using the variety of energy sources available to Alaska.
- While emphasis may be provided on cold-climate applicability (e.g., combined heat and power) or other regional characteristics (e.g., geothermal availability) the emphasis will be on cost-effective supply and net environmental impacts.
- In addition to R&D on reducing CO_2 production, policy should encourage R&D on carbon capture and management. Such examples could include food production in greenhouses or other novel value-added carbon capture as well sequestration.

TWG Recommendations

ESD-1. Transmission System Optimization and Expansion

ESD-2. Energy Efficiency for Residential and Commercial Customers

ESD-3. Implementation of Renewable Energy

ESD-4. Building Standards/Incentives

ESD-5. Efficiency Improvements for Generators

ESD-6. Energy Efficiency for Industrial Installations
ESD-7. Implementation of Small-Scale Nuclear Power
ESD-8. Research and Development for Cold-Climate Renewable Technologies
ESD-9. Implementation of Advanced Supply-Side Technologies

RNWG Recommendations

No additional recommendations.

Specific Research Needs

The list of specific research needs centered around two themes: managing carbon, and minimizing carbon. Both of these themes were limited to the aspects related to energy supply and demand.

4.2.1 Carbon Capture, Sequestration and Management

4.2.1.1 Carbon sequestration research is needed to better understand the state's options for storing carbon in geologic formations. This research involves field investigation of likely sites. (Responds to Policy Option ES&D 7-9)

Alaska has a major coal resource. New coal power plants or coal to liquids processes will likely either require carbon sequestration or be negatively impacted by carbon caps or taxes. To prepare the state for both managing the carbon dioxide it produces currently and for permitting of new carbon dioxide producing facilities, sequestration options must be available. ***Action Type: Modeling, Data Management, Monitoring. Cross-Cutting Topics:*** Oil and Gas

4.2.1.2 Research is needed on value added carbon capture technologies such as carbon capture and use in greenhouses for food and energy production, carbon incorporation into high-tech products, such as carbon fiber or H_2 storage, enhanced oil recovery, and carbon addition to H_2 for fuels production. Many other options may also be available. Research is needed to determine which opportunities hold the greatest promise for Alaska. (Responds to Policy Option ES&D 7-9)

To comply with future carbon caps, trading, taxation, and carbon dioxide reduction for mitigation purposes, the state needs to identify options for carbon dioxide management. Beneficial use makes the most sense if reasonable options are available. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Oil and Gas***

4.2.1.3 Research is needed to improve generation efficiency from improved control and operation practices of existing generation capacity (e.g., diesel). This includes the management of hybrid systems which typically are very complicated from a management and control standpoint. (Responds to Policy Option ES&D 5,6)

Carbon emissions can be reduced by increasing the efficiency of carbon producing processes such as diesel power generation and hybrid power systems. The goal is not to improve the efficiency of the diesel engine itself, but to introduce control strategies that would reduce the net carbon emissions from the diesel power plant without a reduction in supply. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.1.4 Research is need on the best application and best management of a coal-to-liquids technology as well as carbon capture and beneficial use. (Responds to Policy Option ES&D 7-9)

Research on the use of coal in Alaska is needed to most effectively develop an abundant energy rich resource while achieving goals for mitigating climate change. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.2 Geothermal Research

4.2.2.1 A site-specific geothermal resource assessment is needed. In addition, research and testing of low temperature power generation designs for power and heat, mineral recovery from geothermal brines, and ground source heat pumps is needed. Additionally, research into uses for power at or close to geothermal prospects should be conducted. Such uses could include value added mineral refining, timber processing, or greenhouse food/energy production. (Responds to Policy Option ES&D 3, 7-9. This potentially could be coupled with the Natural Systems, Policy Option 2B.)

A general understanding of the state's geothermal potential is available. However, little site-specific information is available to assess feasibility of implementation. Without this information there is little chance that developers will be willing to invest in a geothermal prospect. Exploration often accounts for ¼ to ½ of the cost of a geothermal power development project. ***Action Type: Modeling, Products, Monitoring. Cross-Cutting Topics: NA***

4.2.3 Hydropower and Hydrokinetic Research

4.2.3.1 To make hydropower an effective and efficient power alternative, research is needed into technologies for fuel switching (e.g., from gas to electric heat), pumped storage and integration, reducing adverse intake icing conditions, and integration schemes for incorporating small-scale

hydro power in village settings where other generating technologies are being used. (Responds to Policy Option ES&D 3, 7-9)

Hydropower has many different forms and has many issues that determine its ultimate effectiveness as a source of power. In this need hydropower is limited to water retention and passage through power generating turbines. In-river, tidal, and wave power is discussed in a subsequent need referred to as hydrokinetic power.

Research is needed on propeller and crossflow turbine runners to reduce manufacturing costs and advanced materials such as composite blades and other blade types not requiring extensive metal casting, and use of heat recovery for heat load dumps used to regulate hydropower frequency fluctuation. Testing is needed on intake screens for cold weather hydro applications, and water conservation schemes for preservation of reservoir storage during frequency regulation. To reduce the cost of hydropower programs, standardized plans for small hydro applications are needed with details on intakes, powerhouse, induction plants, tailraces, etc., Alaska needs friendly fish passage designs for in and out of a lake/reservoir, as well as research into how best to provide for flushing flows and sediments to replenish spawning gravels in fish streams, optimal winter instream flow releases for traditional hydropower projects, and improved methods to predict snow-melt and runoff for modeling reservoir operations. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.3.2 There is a need for hydrokinetic resource assessment, including a baseline inventory of possible development sites. Research is needed on the impacts of hydro on fish populations, hydrokinetic device testing, and optimization of hydrokinetic devices for the Alaskan environment (issues such as deployment, anchoring, ice effects, tidal energy capture, etc). Another area of research needed is the application of high pressure water in non-electrical generating applications such as mechanical grinding and processing. (Responds to Policy Option ES&D 3, 7-9)

Many of Alaska communities are on rivers or along coastlines where hydrokinetic devices could augment power provided by diesel or another source. Unfortunately without some research into the likelihood of success and environmental impact of hydrokinetic devices, very little funding will be dedicated to such prospects. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.4 Wind Energy Research

4.2.4.1 There remain significant issues with wind field modeling, grid integration, power storage, foundations, and de/anti-icing options for wind turbine

blades in Alaska that require additional research. (Responds to Policy Option ES&D 3, 7-9)

Wind systems are being installed around Alaska. While they are producing power, many are not reducing the use of diesel as much as they could. This is largely a controls, grid integration, and power storage issue. The issue of foundations and de-icing are practical problems that increase the cost of wind projects. These issues could be resolved with some applied research and development. Other issues relate to wind field modeling. Wind field models can provide information about variability in power production and are needed before a windfarm can be adequately sited. ***Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: NA***

4.2.5 Biomass Technologies

4.2.5.1 Research is needed to find suitable biomass technologies for generating power in the smaller communities that could simultaneously provide space heating. (Responds to Policy Option ES&D 3, 7-9. This option could also overlap with options in the Forestry and Agricultural Waste Management technical working group.)

Biomass produced heat could be coupled with greenhouse production of food and energy crops. Algae, for example, could be grown in concentrated masses in greenhouses and converted to biofuels. Heat, light and CO2 from biomass burning could fuel the greenhouse operation. Little has been done in this area to prove the economics or other benefits of such an operation thereby limiting investment. A field-scale demonstration site would encourage the development of biomass generated heat and power (incl. food and energy) in Alaska.

There is also a need to optimize biomass development opportunities for rural heat and power as well as investigating the opportunities to cultivate biomass. For example, if willows can be cultivated and harvested for use in heat and power generation, the land area required for biomass production would be significantly reduced compared to harvesting of native biomass stands. ***Action Type: Products, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.6 Nuclear Technologies

4.2.6.1 There are currently no commercial nuclear power plants operating in Alaska. As part of a diversified energy portfolio, nuclear power should be investigated. (Responds to Policy Option ES&D 7-9)

There is a need to better understand the technologies and opportunities for nuclear power in Alaska. Potential matches between technologies and potential sites needs to be identified and studied. ***Action Type: Products, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.7 Transmission Technologies

4.2.7.1 The Denali Commission has just finished a study into transmission potential for the state of Alaska. In particular, the potential for hub and spoke solutions to rural transmission were evaluated further. Research is needed into the vulnerabilities and efficiencies of small rural grids. In particular, as many rural communities invest in renewable technologies, small grids could be looking at very high renewable penetration rates. The stability and efficiency of these grids in not known. Applied research and monitoring for high renewable penetration grids could develop new control strategies that would make these grids more stable and able to meet customer needs. **(Responds to Policy Option ES&D 1)** ***Action Type: Products, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.2.7.2 Assess Advanced Coal Technologies and their applicability in Alaska. (Responds to Policy Option ES&D 7-9)

Alaska has a major coal resource. New coal power plants or coal to liquids processes advances into clean coal processing or technologies such as in situ or on-site gasification. Much is unknown about clean coal technologies with respect to Alaskan Coal. In most cases, pilot studies for new technologies should be conducted. A testbed for clean coal technologies would help ensure success when technologies are finally implemented. *Action Type: Modeling, Data Management, Monitoring.*

4.3 Forestry, Agriculture and Waste Management (FAW) TWG

The Forestry, Agriculture and Waste Management (FAW) TWG reviewed and evaluated a number of policy options and narrowed the focus to three recommendations. The group did consider several ideas for agricultural projects, but the scope and scale of agriculture is fairly small in the state and thus the impact from a CO2 mitigation standpoint was low. The group focused their attention on the Forestry and Waste Management opportunities.

TWG Recommendations

The TWG forwarded the following mitigation policy options for further consideration by the Mitigation Advisory Group (MAG) and the Climate Change Sub-Cabinet:

FAW-1. Forest Management Strategies for Carbon Sequestration

FAW-2. Expanded Use of Biomass Feedstocks for Energy Production

FAW-3. Advanced Waste Reduction and Recycling

RNWG Recommendations

No additional recommendations.

4.3.1 Overarching Research Needs

4.3.1.1 Develop a protocol for determining carbon baselines, carbon sequestration rates, additionality permanence and leakage of carbon for silvicultural treatments in boreal and coastal forests.

Carbon trading under a cap and trade system requires verification of carbon additionality above a baseline reference. This "additional" carbon can be sold as part of a mitigation strategy for a carbon producer that needs to exceed their cap. Silvicultural treatments need rigorous third party review to ensure they meet the needs of the market. ***Action Type: Modeling, Data Management, Monitoring. Cross-Cutting Topics: Overarching, Natural Systems***.

4.3.1.2 Refine global climate models for better understanding of regional variations within Alaska. Provide means to disseminate these data.

Improved monitoring and modeling data will allow for development and dissemination of environmental information and design criteria for use in adapting to climate change. ***Action Type: Modeling, Products. Cross-Cutting Topics: Overarching.***

4.3.1.3 Study expected carbon losses during permafrost melt and addition of emissions to the Alaska GHG Inventory and Forecast (I&F).

Better understanding of the GHG impacts of melting permafrost and appropriate representation in Alaska's GHG Inventory and Firecast There is a potential for large impact to the Inventory and Forecast report if these areas are considered to be anthropogenic. ***Action Type: Modeling. Cross-Cutting Topics: Overarching***

4.3.1.4 Review IPCC materials on the definition of managed or unmanaged forests. Confer with in-state forestry experts to assess the proper classification of the Boreal Forest based on past and future management.

There is a potential for a large impact on the overall GHG emissions of the state if the Boreal Forest is considered a managed forest, and hence, an anthropogenic source of emissions. Determination of coverage of carbon fluxes in the boreal forest as part of the Alaska GHG Inventory and Forecast. ***Action Type: Education/Outreach. Cross-Cutting Topics: Overarching.***

Specific Research Needs

Specific research needs are discussed in more detail in the appendix.

4.3.2 EPA Compliance/Public Health

4.3.2.1 In an arctic climate wood burning appliances need testing for particulate matter (PM), nitrogen oxides (NOx) and carbon monoxide (CO) to ensure

public health is not negatively impacted. Demonstrate that in arctic weather conditions, modern wood combustion appliances, such as wood pellet stoves, boilers and larger scale wood chip or co-fire facilities meet Environmental Protection Agency (EPA) particulate matter (PM-2.5) and other pollutant standards. This is very important for the communities of Fairbanks and Juneau which have been in violation of the new PM-2.5 standard and may have wood burning closures to help deal with the issue.

Like other combustion systems wood boilers emit a variety of pollutants, including particulate matter, nitrogen oxides, carbon monoxide, volatile organic compounds (VOC), sulfur dioxide (SO2), carbon dioxide (CO2) and other pollutants. Wood boilers emit PM, NOx, and CO in much greater quantities than the other pollutants. For this reason, these are the three pollutants to track and carefully monitor to determine potential impacts. Wood systems also emit greater quantities of CO2, however unlike fossil fuels; woody biomass is considered carbon neutral. ***Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Natural Systems***.

4.3.3 Carbon Cycle

4.3.3.1 Develop a protocol that assigns a carbon life to different types of wood products, including durable wood products.

In most models that portray carbon flux between sinks and sources there is currently no allocation made for carbon storage as a tree moves from a log to a forest product. When the tree is harvested from the forest, it is treated as an emission. This is a simplification that is not accurate in the real world use of wood. Products substitution (using wood instead of steel, concrete or other building products) can have much higher carbon footprint then wood. Life cycle assessment studies have conclusively shown marked differences in energy requirements associated with different building materials and structures made from them, yet current carbon trading protocols don't make allowances for this type of sequestration or reduction of GHG emissions. ***Action Type: Modeling, Data Management. Cross-Cutting Topics: Natural Systems***.

4.3.3.2 Determine if woody biomass used in energy production is a carbon-neutral fuel source. Scientifically demonstrate that woody biomass used as a fuel for energy is a carbon-neutral fuel.

Currently woody biomass is considered a carbon neutral fuel when compared to fossil fuels, such as coal, oil or natural gas. The combustion of all fuels produces CO2, but trees that are harvested for this purpose are replaced by new trees that sequester carbon from the atmosphere. Over time, the CO2 released by the combustion process will be captured again by the new tree crop. This concept is important because in the carbon trading market place, an offset credit can be

generated by using a biomass fuel for a fossil fuel. It is a straight forward calculation to determine how much C is in a gallon of fuel oil or ton of coal and when you "offset" this fuel type with biomass you generate a credit that can be sold. ***Action Type: Modeling, Data Management. Cross-Cutting Topics: NA***.

4.4 Oil and Gas (OG) TWG

The Oil and Gas Technical Work Group was tasked with developing recommendations for policies and actions to reduce GHG emissions related to the oil and gas industry in Alaska. Of the 52 MMT gross CO_2/yr emissions in Alaska, the oil and gas industry produces 15 MMT, 12 MMT of which are from the North Slope, the majority from Prudhoe Bay. Recognizing that although most of the recommendations focus on the North Slope and Prudhoe Bay, many of the principles can also be applied to the Cook Inlet and other oil and gas operations. Additionally, this TWG was tasked to address Carbon Capture and Sequestration (CCS) research needs both within and outside oil and gas facilities.

TWG Recommendations

The TWG's principal working mitigation options being worked at this time are:

OG-1. Evaluate reductions in GHG that can be related to overall conservation activities, i.e. reducing liquid fuel consumption, minimal venting, and other best practices.

OG-2. Reduce fugitive methane emissions (emissions due to leaks.)

OG-3. Electrification of Oil and Gas Operations, with Centralized Power Production and Distribution

OG-4. Improved Efficiency Upgrades for Oil and Gas Fuel burning Equipment

OG-5. Use of Renewable Energy Sources in Oil and Gas Operations

OG-6. Carbon capture and sequestration from high CO2 fuel gas. Use of CO2 for enhanced oil recovery.

OG-7. Carbon capture and sequestration from exhaust gas at Prudhoe Bay. Use of CO2 for enhanced oil recovery.

OG-8. Carbon capture and sequestration from exhaust gases away from existing oil and gas fields.

RNWG Recommendations

To these policy options the following additions are recommended:

Identify critical infrastructure risks associated with:

OG-9. Changes in permafrost

OG-10. Changes in surface and subsurface hydrology

OG-11. Sea level changes

OG-12. Changes in habitat and wetlands

OG-13. Changes in length of operational season

OG-14. Coastal erosion from reduced sea ice during storm season

OG-15. Changes in shipping scenarios

OG-16. Data sets, maps, and digital information needed for long term monitoring and forecasting of environmental change

OG-17. Engineering change needed in operations, i.e., platform design

Economic

OG-18. Short and long term value of carbon

OG-19. Short and long term value of natural gas

OG-20. Impact of various incentives to major capital improvement investment

OG-21. Potential impact of carbon mitigation efforts on royalty revenue stream coming to the State of Alaska from oil and gas production

General infrastructure and baseline data needs

OG-22. Bathymetry and detailed Digital Elevation Model (DEM) information

OG-23. Regionally appropriate baseline physical mapping and imagery including bathymetry

OG-24. Regionally appropriate baseline mapping and monitoring of surface and subsurface (groundwater) hydrology

Research Needs

There are some significant research topics that should be pursued, and they are segregated between the reactionary and proactive realms. On the reactionary front, there must be analysis of how various policies will affect the ultimate recovery of the state's resource given some economic threshold. Secondly, analysis must be done on a "bang for the buck" scale that at least addresses an economic prioritization of research topics. Ultimately, it is critical that much of the available time and capital be spent pursuing 'low hanging fruit', and only minimal effort be expended on those projects that will produce minimal reductions.

On the proactive front, there should be vigorous research on new energy technologies and efficiencies, and incorporating long-term renewable energies into the huge energy sink of producing oil. This only makes sense from the standpoint of maximizing the sale of the transportable energy by exploiting local renewables that cannot be easily exported.

Finally, small advances in technology can have the greatest affect on aged developments, especially if those assets have experienced minimal modernization and upgrade during their history. Focusing a reasonable portion of research on new innovations to old equipment and methods has the capability of reaping the strongest benefit.

4.4.1 Overarching Research Needs

Overarching research needs for the Oil and Gas TWG activities include:

4.4.1.1 Economic: Investigate impact of various incentives to major capital improvement investments.

This is an issue because incentives will drive a significant amount of private sector investment to reduce overall emissions and improve energy efficiency. ***Action Type: Modeling. Cross-Cutting Topics: Energy supply and demand***

4.4.1.2 Economic: Assess short and long term value of carbon and determine whether the state may benefit from proactive carbon policies.

Understanding the value of carbon will be critical in developing reasonable and effective policy for all CO2 mitigation activity. These values will also be used to assess the economic impact of CO2 mitigation on the state's economic future. Many states are now developing local policy in the forefront of federal regulation. Alaska should evaluate this option carefully and determine whether some level of control can be attained by proactive policy measures. ***Action Type: Modeling. Cross-Cutting Topics: Overarching***

4.4.1.3 Economic: Determine potential impact of carbon mitigation efforts on royalty revenue stream coming to the State of Alaska from oil and gas production.

Carbon mitigation costs will have a detrimental effect on the ultimate recovery of oil and gas in the state because of the impact on production costs and reduction of economically recoverable oil and gas. This impact is potentially quite large for some of the depleted fields. ***Action Type: Modeling. Cross-Cutting Topics: Overarching***

4.4.1.4 Technical: Develop regionally appropriate baseline mapping and monitoring of surface and subsurface (groundwater) hydrology.

Most areas of the state do not have adequate data on hydrology and what the affects development might have on requirements and impacts of surface and subsurface water resources. ***Action Type: Modeling, Education/Outreach, Monitoring. Cross-Cutting Topics: Overarching***

4.4.1.5 Technical: Develop regionally appropriate baseline physical mapping and imagery including bathymetry.

Nearly all modern research efforts must be based on a solid foundation of baseline topographic and attribute mapping in order to achieve the level of resolution needed. It is difficult to perform modern analyses without up-to-date DEMs, orthoimagry, and detailed geologic mapping. Unfortunately, Alaska is woefully lacking in much of this most basic information, and when compared to all other states, and most other countries, Alaska is literally in the "dark ages" when it comes to baseline data. ***Action Type: Products, Data Management, Monitoring. Cross-Cutting Topics: NA***

4.4.1.6 CO2 storage: Evaluate capacity of geologic and biologic sequestration in different regions of the State of Alaska.

Depending on what type of reductions mandates are adopted, understanding the capacity and location of viable storage sites is critical. It is equally important that regulations and legal liabilities are developed and identified prior to the planning and implementation of long-term storage activities. ***Action Type: Modeling, Education/Outreach. Cross-Cutting Topics: Overarching, Energy supply and demand***.

Specific Research Needs

Specific research needs are discussed in more detail in the appendix.

4.4.2 Economic

4.4.2.1 Assess short and long term value of natural gas. Understanding the value of natural gas will allow a comparison of other forms of power generation at operations and will drive investment decisions on energy source.

Action Type: Modeling. Cross-Cutting Topics: Energy supply and demand

4.4.3 CO2 Storage

4.4.3.1 Evaluate enhanced hydrocarbon recovery options using CO2 flooding and pressure support.

Enhanced Hydrocarbon recovery is one of the only CCS methods that derives economic benefit from the activity and increases ultimate recovery of a resource for the State. ***Action Type: Modeling. Cross-Cutting Topics:*** NA

4.4.3.2 Evaluate the feasibility of saline reservoir sequestration in non-marine basins prevalent throughout Alaska.

CO2 storage in saline reservoirs may become an issue in Alaska after conventional reservoirs are saturated or in areas where no convention reservoirs exist (e.g., interior Alaska). ***Action Type: Modeling, Monitoring. Cross-Cutting Topics: NA***

4.4.4 Technical

4.4.4.1 Evaluate the feasibility of various entrained and exhaust CO2 capture technologies for North Slope and Cook Inlet.

Capturing CO2 from various exhaust systems will be a challenging effort and will need many new technologies. ***Action Type: Products. Cross-Cutting Topics: Energy supply and demand***.

4.4.4.2 Study where renewable energy sources co-exist with oil and gas operations.

Renewables may be able to play a significant role in the portfolio of supplying energy for operations. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: Energy supply and demand***.

4.5 Transportation and Land Use (TLU) TWG

The Transportation and Land Use TWG assessed to potential areas in transportation and land use where GHG emissions can be reduced. Actions by the state are identified that include education, planning, and regulations.

TWG Recommendations

The TWG forwarded the following adaptation policy options for consideration by the Climate Change Sub-Cabinet:

TLU-1. Transit, Ridesharing, and Commuter Choice Programs
TLU-2. Vehicle Idling Regulations and/or Alternatives
TLU-3. Transportation System Management
TLU-4. Promote Efficient Development Patterns (Smart Growth)
TLU-5. Promotion of Alternative Fuel Vehicles
TLU-6. Vehicle Mile Travelled and Greenhouse Gas Reduction Goals in Planning
TLU-7. On-Road Diesel Engine Efficiency Improvement
TLU-8. Marine Vessel Efficiency Improvements
TLU-9. Aviation Emissions Reductions
TLU-10. Alternative Fuel Research and Development

RNWG Recommendations

To these policy options the following addition is recommended:

TLU-11. Systematically identify and address economic barriers to implementing climate change planning efforts.

Research Needs

4.5.1 Overarching Research Needs

Overarching research needs for Transportation and Land Use TWG activities include:

4.5.1.1 Develop statewide tools for planning.

Need statewide planning tools to systematically evaluate GHG emissions on future scenarios. Priority: High. Urgency: Planning tools can provide the most benefit if

they are immediately available. Activity type: Modeling, Products. Cross-Cutting Topics: NA

Specific Research Needs

4.5.2 Fuels

4.5.2.1 **An essential research need is to understand carbon cycle from cradle to grave to see if reducing tail pipe emissions is worthwhile.**

The carbon-cost of creating fuel needs to be included in the evaluation. Decision makers need complete information to make valid data driven decisions. If only part of the carbon cycle is considered, the economics of decisions may not be realistic. ***Activity type: Modeling, Products. Cross-Cutting Topics: NA***

4.5.2.2 There is a need to analyze the life-cycle GHG impacts of various alternative fuels in the Alaska context. The life-cycle GHG impacts of alternative fuels depend heavily on emissions from fuel production and transport. Nearly all research to date has focused on the lower 48. GHG impacts in Alaska could be quite different. Need to understand which alternative fuels have GHG benefits in AK. ***Activity type: Modeling. Cross-Cutting Topics: NA***

4.5.3 Transportation Planning

4.5.3.1 Develop methods or tools to accurately estimate GHG impacts of transportation plans in Alaska.

Transportation agencies will soon be required to quantify GHG impacts of transportation plans. Tools and methods are being developed for lower 48. But arctic climate in AK might affect the GHG emissions from motor vehicles and necessitate tools or methods that are adapted to AK. ***Activity type: Modeling, Products. Cross-Cutting Topics: NA***

4.5.3.2 Investigate potential to reduce fuel use and GHG emissions by coordinating transportation networks and commercial fishery openings.

Excess fuel use and GHG emissions occur because of poor coordination of fishery openings. Priority: ***Activity type: Modeling, Monitoring. Cross-Cutting Topics: NA***

4.5.4 Marine Vessels

4.5.4.1 Determine GHG impacts of replacing older marine vessel engines with newer engines.

Newer marine engine have lower particulate matter emissions due to federal standards. But their effect on GHGs is uncertain. ***Activity type: Modeling. Cross-Cutting Topics: NA***

4.5.5 Aviation

4.5.5.1 Evaluate the actual reduction of GHG from a pilot study of continuous descent approaches to Ted Stevens International Airport.

Aviation in Alaska has a disproportionate impact on GHG emissions compared to other forms of transportation. Focusing on aviation reductions may be an area where large reductions can be realized. ***Activity type: Modeling, Monitoring. Cross-Cutting Topics: NA***

4.5.6 Public Transportation

4.5.6.1 Conduct analysis to determine what is required to increase citizen use of public transportation and increase conservation efforts.

Need to understand what actions by the government result in greater use of public transportation and greater conservation efforts. ***Activity type: Education/Outreach. Cross-Cutting Topics: NA***

5 Recommendations: Adaptation

Adaptation Technical Workgroups

The Adaptation Advisory Groups (AAG) was tasked with identifying policy recommendations that could be implemented to help Alaska adapt to a changing environment resulting from climate change impacts. Four technical workgroups (TWGs) were formed as part of the AAG:

- Economic Activities
- Health and Culture
- Natural Systems
- Public Infrastructure

5.1 Economic Activities (EA) TWG

The Economic Activities TWG evaluated the effects of climate change on a wide range of economic activities across Alaska. They focused on oil and gas, renewable energy, mining, ocean transportation, rural non-road transportation, transportation and recreation, boundaries and ownership, energy demand, evolving jobs and economy, information collection and dissemination, and other economic sectors.

TWG Recommendations

The TWG forwarded the following adaptation policy options for consideration by the Climate Change Sub-Cabinet:

EA-1. Evaluate potential needs for expanded ocean oversight and regulatory activities
EA-2. Explore economic activity opportunities offered by climate change
EA-3. Develop scenarios for the Alaska economy affected by climate change
EA-4. Establish a center for knowledge sharing on Arctic issues
EA-5. Improve availability of mapping, surveying, charting, and imagery data

RWNG Recommendations

To these policy options the following addition is recommended:

EA-6. Systematically identify and address economic barriers to implementing climate change planning efforts

EA-7. Evaluate full-cycle economic impact of mitigation and adaptation proposals in relation to ultimate cost of energy, state revenue income stream, required state and federal subsidies, and local economic impact to businesses reliant on existing infrastructure.

Research Needs

5.1.1 Overarching Research Needs

Successful implementation of these policy options will require baseline data collection, scenario modeling, monitoring and assessment. Many of these research needs overlap those identified by other TWG, in that economic factors form a common thread. Overarching research needs for economic activities include:

5.1.1.1 Develop higher resolution climate modeling and monitoring data and improve its accessibility and utility.

This need is common among nearly all the TWG. To assess and plan for changing economic conditions as a result of a changing climate will require higher resolution climate modeling and monitoring information at more local levels. Additionally, there is a need to increase the accessibility and utility of these data to government officials and businesses. Finally, there is a need to tailor these data to the needs of government officials and businesses. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: All**

5.1.1.2 Assess statutory, regulatory, and policy frameworks and barriers to implementing climate change policy recommendations.

Many laws, regulations and policies on the federal, state, and local levels were developed before the signs of more rapid climate change were recognized. For example, resource managers in Alaska may need to revise Alaska policies relative to wildland fire management in light of the effects of climate change. Another example is the need to modify water quality standards that call for maintenance of water temperatures in cold water systems in light of warming temperature. The challenge for government leaders and businesses will be to adapt to a future made less certain due to a more rapidly changing climate. This will necessitate an evaluation of existing laws, regulations and policies and possible changes to institutional, legal and policy frameworks in an adaptive manner. **Action Type: Products, Education/Outreach. Cross-Cutting Topics: All**

5.1.1.3 Assess economic impacts of market-based approaches (e.g., cap and trade) to manage greenhouse gas (GHG) emissions and their impacts on the Alaskan economy.

Market-based approaches to manage GHG emissions can have a significant impact on many aspects of the Alaskan economy. It will be imperative to track these approaches as they develop and to proactively formulate strategies to adopt state approaches and, if necessary, adapt to adopted approaches. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: All**

5.1.1.4 Systematically identify and address economic barriers to implementing climate change planning efforts.

Uncertainty associated with climate change may result in barriers to implement identified climate change strategies/options and planning efforts. It is important to identify these barriers and strategies for addressing them. The uncertainty and risk of the current predictions should be well understood and incorporated in the decision process. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: All**

5.1.1.5 Assess data and information (economic indicators) needed to develop or adapt short and long term planning tools to assess impacts of climate change on economic activities.

There is a lack of baseline economic information and data needed to develop or adapt both short and long term planning tools to implement identified climate change strategies and options. It is critical to identify and collect the needed economic indicators. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: All**

5.1.1.6 Implement adaptive (scenario-based) planning tools that integrate economic indicators to improve climate change mitigation and adaptation decision-making and implementation.

Successful implementation of climate change strategies/options will require development and implementation of adaptive planning tools. These tools need to be probabilistic and scenario-based and integrate economic indicators. **Action Type: Products, Education/Outreach, Monitoring. Cross-Cutting Topics: All**

5.1.1.7 Catalog and assess new or expanded economic opportunities that may become available with climate change.

While some existing economic activities may be deleteriously affected by a changing climate, others may be benefited while still others may become established. For example, a warming climate may open new economic opportunities in the Arctic basin, including commercial fishing and transpolar shipping. A necessary first step towards developing these opportunities is to catalog and assess them. **Action Type: Products, Education/Outreach. Cross-Cutting Topics: All**

Specific Research Needs

Specific research needs by economic activity research area are presented below by sector. They are discussed in more detail in the appendix.

5.1.2 Oil and Gas

5.1.2.1 Develop economic analysis of potential rise or decline of oil and gas development on state revenues.

Oil and gas production provides significant revenues to Alaska. As such, any changes to oil and gas production can be expected to have significant impacts to the Alaskan economy. Climate change and resultant efforts to mitigate for it, or adapt to it, is expected to have impacts to oil and gas production. For example, development of cap and trade programs could have significant impacts on oil and gas production. Given the likelihood of such impacts it is imperative to develop economic analysis of potential rise or decline of oil and gas development on state revenues. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Oil and Gas**

5.1.2.2 Consider how potential rise or decline of oil and gas operation and maintenance may affect state revenues.

Climate change is expected to have impacts on oil and gas operations and maintenance. Under current tax structures, operation and maintenance costs can influence the amount of revenue the state receives from production. For this reason, it is important to determine how potential rise or decline of oil and gas operation and maintenance may affect state revenues. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Oil and Gas**

5.1.2.3 Model coastal vulnerability to establish criteria for pipeline coastal transition set-backs and burial depths.

Climate change is expected to impact coastal zones through erosion and coastal inundation. This will require an assessment of the current permitting and oversight of pipelines and other operations in the coastal zone. This assessment will require a modeling of coastal vulnerability to establish criteria for pipeline coastal transition set-backs and burial depths. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Public Infrastructure and Oil and Gas**

5.1.2.4 Expand research on ice road and pad construction techniques and in-season monitoring to maximize seasonal use and minimize impacts.

Climate change is impacting the length of time ice roads and pads can be used on the North Slope of Alaska. Expanded research on ice road and pad construction techniques and in-season monitoring is needed to maximize seasonal use and minimize impacts. **Action Type: Modeling, Products, Education/Outreach, Data**

Management, Monitoring. Cross-Cutting Topics: Public Infrastructure and Oil and Gas

5.1.2.5 Expand research on climate change impacts on permafrost engineering design.

Permafrost is being impacted by climate change. These impacts are affecting existing and planned structures. Design standards are inadequate to address these impacts. Expanded research on climate change impacts on permafrost engineering design is needed. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Public Infrastructure and Oil and Gas**

5.1.2.6 Develop new techniques to clean up oil spills in icy waters.

There is an interest in developing offshore oil and gas in Arctic areas. This increases the potential for oil spills in offshore areas that are being impacted by changing ice conditions associated with climate change. There is a need to develop new techniques to plan for and clean up oil spills in icy waters. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Oil and Gas**

5.1.3 Renewable Energy

5.1.3.1 Assess economic potential for developing carbon-neutral energy sources.

Federal legislation may likely call for a larger proportion of energy production to come from carbon-neutral sources (definition, e.g. including forest materials). In Alaska, little is known about the economic potential for developing carbon-neutral energy sources. Given this, it is imperative to assess the potential for developing carbon-neutral energy sources. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Energy Supply and Demand**

5.1.3.2 Identify potential economies of scale and return on investments in developing renewable energy sources.

Little is known about the long-term economics associated with renewable energies. As there is an increased call for shifting energy production to renewable energy sources it is important to identify potential economies of scale and return on investments in developing renewable energy sources. This will allow better decision tools to be developed to inform the economic impacts of renewable energy sources. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Energy Supply and Demand**

5.1.4 Mining

5.1.4.1 Research cost-effective techniques for construction, operation, and reclamation that will be responsive and useful in changed environmental conditions.

Energy conservation and renewable energy alternatives require metals and metal alloys. As renewable energies increase, this will increase the demand for metals. Since Alaska has world class metal resources, it can be expected that there may be increased interest in mining. It will be important to research cost-effective techniques for construction, operation, and reclamation that will be responsive and useful in changed environmental conditions. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Public Infrastructure, Natural Systems, Energy Supply and Demand.**

5.1.4.2 Assess engineering standards for tailings storage in Arctic/Subarctic climates.

Energy conservation and renewable energy alternatives require metals and metal alloys. As renewable energies increase, this will increase the demand for metals. Since Alaska has world class metal resources, it can be expected that they will be increased interest in mining. As new mines are developed it will be important to assess engineering standards for tailings storage in Arctic/Subarctic climates. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Public Infrastructure, Natural Systems, Energy Supply and Demand**

5.1.4.3 Develop economic analyses of potential rise or decline of mining and impact on state revenues.

Energy conservation and renewable energy alternatives require metals and metal alloys. As renewable energies increase, this will increase the demand for metals. Since Alaska has world class metal resources, it can be expected that they will be increased interest in mining. As this demand increases it will be important to develop economic analyses of potential rise or decline of mining and impact on state revenues. **Action Type: Modeling, Education/Outreach, Monitoring. Cross-Cutting Topics: Public Infrastructure, Natural Systems, Energy Supply and Demand**

5.1.5 Ocean Transportation

5.1.5.1 Model sea ice and its effect on ocean transportation.

Climate change is reducing sea ice in the Arctic at varying rates. It is important to model sea ice and its effect on ocean transportation. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Natural Systems, Public Infrastructure**

5.1.5.2 Develop economic analysis of potential rise or decline of shipping and impact on state revenues.

Climate change is reducing sea ice in the Arctic, creating economic opportunities and localized costs. It is important to assess the impacts of increased shipping to Alaska and its economy. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Natural Systems, Public Infrastructure**

5.1.5.3 Identify trends that may influence impacts of shipping on the environment, hunting, fishing and communities.

Climate change is reducing sea ice in the Arctic and allowing for increased shipping. This will potentially influence the environment, hunting, fishing and coastal communities. As such it is necessary to identify trends that may influence impacts of shipping on the environment, hunting, fishing and communities. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Natural Systems, Public Infrastructure**

5.1.5.4 Increase ice-breaking capabilities in the Arctic.

Climate change is impacting the formation and breakup of sea ice in the Arctic. To increase the duration of shipping and provide for assistance in sea ice conditions, ice-breaking will be required. For these reasons it is imperative to Increase ice-breaking capabilities in the Arctic. **Action Type: Modeling, Products, Monitoring. Cross-Cutting Topics: Public Infrastructure**

5.1.5.5 Research innovative approaches and building techniques for supporting arctic shipping and developing sustainable ports.

Climate change is changing sea ice formation and breakup in the Arctic, which will change how ports are developed and shipping routes maintained. This will require research into innovative approaches and building techniques for supporting arctic shipping and developing sustainable ports. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Public Infrastructure**

5.1.6 Rural Non-Road Transportation

5.1.6.1 Assess the impact of climate change on existing rural transportation networks.

Much of Alaska's rural transportation network is non-road based, depending on frozen tundra and unfrozen river and lake routes for surface transportation. As a result, climate change can potentially significantly affect these networks. For these reasons, it is imperative to assess the impact of climate change on existing rural transportation networks. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Public Infrastructure and Health and Culture**

5.1.6.2 Develop economic analysis of potential costs associated with expected impacts to rural transportation networks.

Much of Alaska's rural transportation network is non-road based. As a result, climate change can potentially significantly affect these networks. With increases to costs of transportation, it is important to develop economic analysis of potential costs associated with expected impacts to rural transportation networks. **Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Public Infrastructure and Health and Culture**

5.1.7 Other Economic Sectors

5.1.7.1 Develop economic analysis of potential rise or decline of recreational, subsistence and commercial fishing.

Climate change will impact fish and their habitats to varying degrees. Some fisheries will benefit while others will be negatively impacted. Research into fisheries should support economic analysis of the potential rise or decline of recreational, subsistence and commercial fishing. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Natural Systems, Health and Culture**

5.1.7.2 Assess and model increased insurance costs.

Climate change is recognized as causing increased risks to private and government infrastructure. Insurance premiums are based on environmental conditions and projected risks. It will be important to assess and model insurance costs associated with risks perceived from climate change influences. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Public Infrastructure and Health and Culture**

5.1.8 Transportation and Recreation

5.1.8.1 Develop economic analysis of potential rise or decline of tourism and impact on state revenues.

Tourism is an increasing contributor to the Alaskan economy. It is unknown how a changing climate may impact tourism. It is important to develop economic analysis of potential rise or decline of tourism and impact on state revenues related to climate change. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Natural resources, Public Infrastructure, Health and Culture**

5.1.8.2 Develop economic (scenario) analysis of potential national and international changes in patterns of people and freight movements.

Climate change is impacting natural systems throughout the Arctic, both in the terrestrial and ocean areas. The impact to these natural systems will likely change the patterns of movement of people and freight. It is important to develop

economic (scenario) analysis of potential national and international changes in patterns of people and freight movements. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Natural resources, Public Infrastructure, Health and Culture**

5.1.8.3 Assess opportunities for development/enhancement of recreation due to climate change.

Climate change is impacting natural systems throughout the Arctic with changes to seasonal recreation. It is imperative to assess opportunities for development/enhancement of recreation due to climate change. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Natural resources, Public Infrastructure, Health and Culture**

5.1.9 Boundaries and Ownership

5.1.9.1 Improve mapping and surveying to accurately and efficiently establish boundaries, address boundary disputes as needed and aid charting for safe navigation.

As climate changes, boundaries that are dependent upon physical features may be impacted. It is necessary to improve surveying and mapping to accurately display the land and land/water interface. This will support establishing boundaries and provide data to address boundary disputes. Improved charting for safe navigation and mapping for overland travel will be an ancillary product. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Natural resources, Public Infrastructure**

5.1.10 Energy Demand

5.1.10.1 Assess how climate change will impact application of federal, state, and local laws, regulations and policies on energy demand and use.

Climate change legislation will impact application of federal, state, and local laws, regulations and policies on energy demand and use. For example, increased pressure to reduce GHG will have impacts on laws, regulations, and policies related to natural resources. For this reason it is imperative to assess how climate change will impact application of federal, state, and local laws, regulations and policies on energy demand and use. **Action Type: Products, Education/Outreach. Cross-Cutting Topics: All**

5.1.11 Evolving Alaska's Jobs and Economy

5.1.11.1 Assess how climate change will impact application of federal, state, and local laws, regulations and policies on economic development activities.

Climate change legislation will impact application of federal, state, and local laws, regulations and policies on economic development activities. For example,

increased Arctic shipping and resource development will have impacts on laws, regulations, and policies related to natural resources and indigenous people. For this reason it is imperative to assess how climate change will impact application of federal, state, and local laws, regulations and policies on economic development activities. **Action Type: Products, Education/Outreach. Cross-Cutting Topics: All**

5.1.12 Information Collection and Dissemination

5.1.12.1 Continue to refine the "Cost of Climate Change" study recently completed by the UAA ISER.

The University of Alaska Institute of Social and Economic research is conducting a study to assess the costs of climate change to Alaska. This is an overarching economic analysis of the climate related impacts. This study should be completed. **Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: All**

5.1.12.2 Identify climate trends and downscale models leading to establishing environmental information, analysis tools, and design criteria for use in adapting to climate change.

This need is common among nearly all the TWG. To assess and plan for changing economic conditions as a result of a changing climate will require higher resolution climate modeling and monitoring information at more local levels. Additionally, there is a need to increase the accessibility of these data to government officials and businesses. Finally, there is a need to tailor these data to the needs of government officials and businesses. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: All**

5.1.12.3 Provide resources for good Digital Elevation Model (DEM) and GIS data, and current and high resolution imagery to establish a more robust information infrastructure to plan and adapt.

There is a need for improved Digital Elevation Model (DEM) and GIS data, and current and high resolution imagery to establish a more robust information infrastructure to plan and adapt. This information is needed to develop down-scaled models and to assess potential economic impacts. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: All**

5.1.12.4 Invest in monitoring and data dissemination programs to enhance information available for safe and efficient resource development.

Much data is currently available but for a variety of reasons is unavailable to researchers or decision-makers. There is an urgent need to invest in monitoring and data dissemination programs to enhance information available for safe and efficient resource development. **Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: All**

5.2 Health and Culture Research Needs (HC) TWG

Health and Culture can be divided into two research focuses, i.e. health which researches the risks associated with a changing climate and communities and culture which researches the risk to losing that which has endured and evolved with the people, their traditions and knowledge.

TWG Recommendations

The TWG forwarded the following adaptation policy options for consideration by the Climate Change Sub-Cabinet:

HC-1. Identify a central agency, as well as responsible individuals, to support rural communities in dealing with complex issues requiring coordination among multiple state and federal agencies, local governments, NGOs, and others.

HC-2. Augment surveillance and control programs for vector-, water-, and foodborne diseases likely to become greater threats because of climate change. Develop educational programs for the public, health care providers, environmental staff, and others on approaches to reduce emerging disease threats.

HC-3. Initiate a community health impacts evaluation mechanism to evaluate recommended adaptation and mitigation options to determine whether they could results in adverse health impacts and, if so, to recommend approaches to reduce these risks.

HC-4. Assess risks to rural sanitation and solid waste management from flooding, thawing permafrost, and other risks, or that is otherwise subject to changed conditions that significantly reduce performance in environmental health protection. Consider the modification, rebuilding, or relocation of sanitation infrastructure to protect human and environmental health.

HC-5. Assess archeological, historical, and cemetery sites at risk from climate change. In cooperation with appropriate local, regional, and statewide entities, assess archaeological sites at risk from accelerated coastal and river erosion; convene archaeologists, anthropologists, Alaska Native elders, and others to discuss how best to address and prioritize sites at risk; and develop a plan for the protection or recovery of important at-risk sites. Complete a statewide assessment of the gravesites most at risk; assist in identifying and opening new gravesites; convene a respectful discussion about gravesites and explore best practices; provide assistance for the relocation of existing at-risk gravesites.

RNWG Recommendations

To these policy options the following addition is recommended:

HC-6. Research mechanisms to insure that traditional knowledge and wisdom is integrated into research programs and research results are corroborated in understanding the climate change impacts to and opportunities for indigenous people and their culture.

Background for health research needs

Sentinel events and indicators will show risks to public health and indigenous people and fauna in areas where the climate is changing at an accelerated rate. The research must help to understand the exposure-response relationship associated with the indicator and the potential duration and extent of the event. This research will help to understand the link between the change happening and the potential risks beyond the sentinel event so that health models can be developed and risks estimated.

Health models will need to be refined to propose response to the sentinel events and account for risks to the health of the residents and the flora and fauna in the adjoining ecosystem. The models should provide a scientific methodology for conducting surveillance and establishing control in response to a "sentinel event". The models must be clear enough to enable local collection of health information that will fit into the scientific methodology and yet allow flexibility to researchers to adapt the research strategy and health models to accurately portray and understand the sentinel event and its link to changes in climate and environment.

Health impact assessments will be an essential research tool to adjusting the models to the indicators of sentinel events and the changes to health that are associated with changing climates and escalation of health risks with the sentinel event. How this happens and what happens over the duration of the event will need a monitoring protocol that is consistent with the scientific methodology yet designed for collection by the local health community members. Meeting this research component will allow the databases to be expanded on a community by community basis and refine the health impact assessments to address specific community needs.

The research matrix required in understanding the health risks associated with climate change must assess the factors causing the sentinel event. This should include, but not be limited to whether it is a water, food, insect or vermin borne vector. The matrix should recognize whether the event is part of range extension, as may be shown with icthyophonous or paralytic shellfish poisoning in fish and shellfish, wasting disease in the fauna, or tumors, asthma or infection in the people. This information will portray impacts on the physical and mental health of the people. It is at this point where health and culture research come together in a research matrix approach, as the health is directly linked to the subsistence culture and social well being of a traditional lifestyle.

Background for culture research needs

Research protocols that document the social impacts to community life of climate change are essential in addressing the questions of adaptation. Through the use of community social and health services, a research protocol can be implemented that meets the scientific needs while recognizing the communities' capabilities and insight. This includes the

integration of traditional knowledge and wisdom into the research questions so as to insure that what is seen is consistent with what is measured.

A standardized social network approach to research is recommended. This will allow consistency with research in other socio-cultural programs while allowing the research to adapt to the uniqueness of changes within the last generation. The social network will provide the data needed to identify communities at risk and the risks that are affecting the communities in the short and long term.

Modeling local economies from the standardized social network data will help in addressing the social and cultural impacts of climate change and link back to health risks. This will focus on the people and the community. Additional research will be needed to model the potential for a sentinel event or the probability of a failure in the solid waste and sanitation.

Monitoring will remain an essential part of the cultural research as it pertains to changes in cultural activities, accuracy and applicability of traditional knowledge, risks from failure of community sanitation, and occurrence and trends in vector borne illnesses. Such monitoring will provide the data to refine the models that can predict the sustainability of the communities and survivability of the traditional ways.

Research protocols must be designed to document and preserve the culture, including cultural and historic artifacts. This research should focus on preserving community identity while protecting the importance to the people and confidentiality allowed by law. Efforts should be included to continue to preserve the historic stories and catalog language as a means to insure that future researchers can understand the cultures of Alaska before technology and loss to climate change.

Correlation and verification of western science with traditional knowledge and wisdom and traditional ecological knowledge will be an integral part of the research protocols and outcomes. Specifically, this correlation and verification will focus on documenting the impacts of climate change on the cultures through loss of sea ice, change in subsistence living, and deterioration of subsistence foods. While western science can document the change, this research must link to that observed by the people in their communities and how today under climate change is different than that learned from their elders.

Research should also build upon long term research as collected by state and federal agencies, e.g. ADF&G Harvest Surveys. Continuing and expanding the analyses of this and comparable other data sets can provide the western science needed to understand how the changes are observed by the people and integrated into the culture.

Socio-economic research, like the ADF&G Harvest Surveys but across the other state and federal agencies, is an integral part of the research strategy that will deliver the reports upon which the impacts of climate change can be assessed. A statewide socio-economic research plan should be developed that encompasses the breadth of climate change on Alaska's culture and the local economies. This should include a structured dialog that

strengthens the understanding of the elders in providing traditional knowledge with the data collection and research protocols of modern science.

Within the questions of socio-economic research is the impacts of public policy on community sustainability. Research questions transcend the impacts of climate change to the issue of if public policy allowing action to protect the communities, allow subsistence lifestyles to continue, and allow timely adaptation to climate related events. Research into whether barriers to adaptation exist due to present laws and/or public sentiment. Assessing whether the regulatory framework for the harvest of flora and fauna, adapting infrastructure to protect in place or relocate, and insuring community health and sustainability is adequate or counter-productive will need information based on accurate research. An interagency research team may prove an effective tool for addressing such questions.

Research needs for health and culture also cross-cut to many of the other research needs, as assessing health risks and sustaining culture depend on having the same information as other research disciplines in adapting to climate change. Cross-cutting research needs can be characterized as:

Researchers need improved cross-agency coordination. Research to address climate change impacts on health and culture will benefit from research conducted to address questions in other disciplines. Methods to improve cross agency coordination and data sharing are identified in every discussion of research needs in adapting Alaska communities to climate change. Methods often used are seminars, research meetings, web-posting, and inter-agency working groups. Cross-discipline scientific review panels can expand the dialog in finding multiple applications in understanding changes and developing adaptation strategies. Together, this can expand the breadth of research, lead to applications in other disciplines and develop response strategies for adaptation.

Research plans, projects and results need to be made available to the communities to support understanding of impacts from and options in adapting to climate change. Addressing this research need requires internet tools for distributing the information as well as improving the feedback on the value of the research project and results. Culturally tailored materials are need to reflect on traditional knowledge and wisdom (better term?) and explain how the research plan, project, and/or results will build upon the local knowledge. This will foster dialog and improve community acceptance of the results and enable adaptive planning.

Research needs include developing an education component that supports observations of indicators and monitoring of changes that may provide a basis for understanding climate impacts. Education materials are needed to support workforce development and encourage interest in local students to be involved in the science and research that is being conducted to understand climate change. This includes vocational technical training curriculum, secondary education materials, and teacher training.

Health and Culture research needs recognize the importance of having accurate materials to plan future research. This includes downscaling models to the community level for various parameters. These include ultraviolet radiation for exposure risk assessments; weather patterns and water transport for contaminants and toxin transport; and exposure to dust and methane. Health and Culture research also recognize that environmental change needs to be accurately modeled for the impacts to communities from flooding and coastal inundation and permafrost thaw, slumping and erosion. These points are clearly outside the research needs of health and culture, yet are essential in understanding the impacts of climate on health and culture.

5.2.1 Overarching Research Needs

Overarching research needs for Health and Culture TWG activities include:

5.2.1.1 Develop regional economic models to quantify climate change impacts on communities and provide input to the NEPA process.

Communities cannot adapt to the impacts of climate change without state and federal assistance, which requires compliance with the NEPA process and recommended alternatives. Climate change is raising significant economic questions with investment in communities and sustainability. ***Action Type: Modeling, Products. Cross-Cutting Topics: Public Infrastructure and Economics***

5.2.1.2 Revise Flood Risk Maps.

Use projections for increased precipitation, loss of sea ice and the accompanied increase in storm activity over previously ice covered waters for the next 100 years to develop revised flood risk maps that will help guide communities and state agencies in making future planning and infrastructure development decisions. Allow for continual update of these maps to incorporate the expected ongoing refinement in climate projections over time. Communities cannot obtain flood insurance. Securing funding for improving and maintaining community will be difficult as lack of information and accurate data will require conservative attitudes towards investment and economic development. This will hinder economic development for the community. ***Action Type: Products. Cross-Cutting Topics: Public Infrastructure and Economics and Natural Systems***

5.2.1.3 Develop sea level rise projection maps for coastal areas throughout Alaska, accounting for local isostatic rebound in conjunction with global sea level rise predictions.

Work with coastal communities and the State of Alaska to incorporate this information into community and state planning efforts to better guide future development decisions. Allow for continual update of these maps to incorporate the expected ongoing refinement in climate projections over time. Communities are unable to accurately plan for economic development and assess risks from erosion or inundation. Public is developing inaccurate perception of sea level rise

and coastal inundation because of lack of accurate information and heavy press coverage. ***Action Type: Modeling. Products. Cross-Cutting Topics: Public Infrastructure and Economics and Natural Systems***

5.2.1.4 Downscale climate modeling projections to the local or regional level to aid communities in planning.

Alaska's communities will have significant challenges in adapting if climate modeling projections downscaled to the local or regional level are not available on which to base decisions. They will also have little incentive to adapt. Currently, Alaska Center for Climate Assessment and Policy (ACCP) has identified global circulation models (GCM) best suited to northern latitudes, and can downscale the model results to every community in the state. Disseminating this information to communities is a first step toward helping them to plan and tailor adaptation to their own specific needs and impacts. However, data gaps remain. Information on projected changes to permafrost and sea level at the local and regional levels is still lacking. Development of a statewide research grant fund could be used to focus the scientific community on filling data gaps critical to community adaptation. Develop Downscaled Climate Modeling for Municipalities. Communities are coping with changes as seen over time while decision makers are looking for more accurate information to plan and predict actions that will be required. Research that will downscale models is identified as one solution. ***Action Type: Modeling, Products, Education/Outreach, Data Management. Cross-Cutting Topics: Public Infrastructure and Economics***

5.2.1.5 Conduct a comprehensive inventory of the wide range of data collection, monitoring efforts, and research projects underway or planned in relation to the impacts of climate change on the environment.

The benefit to federal, state and municipal entities of having this information accessible in some form of centralized information portal, gateway, or web-based clearinghouse would be significant, most notably in terms of improved ability to make adaptation decisions intelligently and effectively. In turn, duplication of monitoring efforts could be avoided and government entities could provide feedback on specific data gaps, serving to drive future research objectives. Conduct a Comprehensive Inventory of Current Research, Monitoring and Data Collection Efforts. Overall perception that the communities and decision makers do not have adequate information on the research projects ongoing to make plans to adapt to changing climate. There is limited understanding of the timeline by which the research will conducted, analyzed and developed into applied research and information. With the days of Internet and modern communication technology, impacted Alaska communities need access to up to date information and the ability to help guide research projects. ***Action Type Data Management, Monitoring. Cross-Cutting Topics: Mitigation All***

5.2.1.6 Provide communities with social research on the cultural impediments and history of government.

This research need is being addressed in the Public Infrastructure Working Group. Providing this information to communities may provide insight into how to sustain communities and maintain community infrastructure to different cultural standards, while recognizing the challenges of weather and seasons. Community-based reporting and protocols can insure longevity in public and private investment while fostering agreement to maintain systems to higher standards. Costs and sources of funding are major issues in this area. ***Action Type: Modeling, Products. Cross-Cutting Topics: Public Infrastructure***

5.2.1.7 Conduct social and education research to develop culturally appropriate curriculums for maintaining public infrastructure and community property.

Develop economic forecast models that show the cost savings by not deferring maintenance or in determining where deferred maintenance goes from cost savings to higher costs. This is a continuation of the research needs associated with the public infrastructure TWG. ***Action Type: Education/Outreach. Cross-Cutting Topics: Public Infrastructure***.

5.2.1.8 Perform standardized social network research in select communities to understand potential impacts of relocation on social, sharing, economic and subsistence networks.

Standardized sampling methods for social networks, as being applied in different locations and for different cultures, can provide a tool by which the challenges facing Alaska communities can be better understood. ***Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Economic Activities and Natural Systems***

5.2.1.9 Use the SPOT satellite data system or others to track changes in permafrost extent and work to develop projection maps for changes in extent over the next 100 years, based on climate change projections.

Satellite data and permafrost extent mapping and modeling would serve to guide communities and state agencies in construction planning decisions, both for determining the location and means of construction of new projects as well as identifying those existing projects which may be at risk from thawing permafrost in the future. Satellite data will allow for continual update of these maps to incorporate the expected ongoing refinement in climate projections over time. Communities need accurate data to understand changes to their community and surrounding environment. This will support the traditional ways of life with modern mapping products. ***Action Type: Data Management, Monitoring. Cross-Cutting Topics: Public Infrastructure, Agriculture, and Economics***

5.2.1.10 Refine global climate models for better understanding of regional variations within Alaska.

Modeling will provide a better understanding of the effects of climate change. Improved monitoring and modeling data will allow for development and dissemination of environmental information and design criteria for use in adapting to climate change. ***Action Type: NA. Cross-Cutting Topics: NA***

5.2.1.11 Assess the degree and rate of thawing submarine permafrost deposits in coastal areas due to warming sea temperatures.

Study of the climate-driven instability of coastal permafrost is needed to evaluate the risk of subsidence and erosion and the consequent impact on human developments and ecosystems. Newtok relocated because of the thawing of subterranean and submarine permafrost. Other coastal communities in western, northwest and northern Alaska have comparable risk with retreat of sea ice and exposure of permafrost to wind induced waves. Research to identify susceptible communities and assess the rate of permafrost loss is needed. ***Action Type: Modeling, Monitoring. Cross-Cutting Topics: Public Infrastructure and Natural Systems***

5.2.1.12 Consider developing a series of television segments for Alaska Weather that provides climate change projection information and data on issues of specific importance to Alaska's rural communities.

Rural Alaska and the indigenous people have important stories to tell on how the changing climate is impacting the traditional ways of life. Developing a series of television segments would foster better understanding of how changes in future climate, both gradual and sudden, can impact communities and individual lives. This can become a catalyst for change in individual behavior. Research into these stories and observations will improve the sharing of traditional knowledge and wisdom while increasing the publics' understanding of climate change and the impacts to the health and culture of rural residents. *Priority: NA. Urgency:* Low as covered by other networks. Distribution to rural Alaska may be a different unmet need. ***Action Type: Education/Outreach. Cross-Cutting Topics: All***

5.2.1.13 Research and develop culturally appropriate curriculums and materials for traditional knowledge and local observations with accuracy of observations

Cross-cultural understanding of the impacts of climate change will benefit when prepared in culturally appropriate curriculum that recognizes the complimentary role and value of observations and scientific measurements with traditional knowledge. Developing this cross-cultural curriculum may be supported with social scientists who understand the scientific method and native leaders that are seeing the impacts of climate change on their traditional knowledge. Research conducted in developing this material will have a greater likelihood of community

buy-in, cultural acceptance and to be implemented. ***Action Type: Education/Outreach. Cross-Cutting Topics:*** **All**

5.2.1.14 Improve communications between federal scientists and state government agencies (such as the Alaska Departments of Fish and Game, Environmental Conservation, and Natural Resources) on climate science, the potential impacts, and data needs for those agencies concerning climate change.

State and Federal Science and Resource Agencies and stakeholders have concern that the information is not accurate or all inclusive. This leads to questions on whether decision makers do not make decisions or communities have insufficient information to make an informed decision. Regardless, with the number of working groups that have collaborated for decades there are still challenges in applying research results to public policy and social and cultural impacts. The Governor's sub-cabinet and working groups are an example of an effective method to address this issue. ***Action Type: Education/Outreach, Data Management. Cross-Cutting Topics: All***

Specific Research Needs

Specific research needs identified by the Health & Culture TWG are presented below. They are discussed in more detail in the appendix.

5.2.2 Subsistence Research

5.2.2.1 Decline and migratory shifts of major subsistence species and vegetation can significantly affect a wide range of cultural, community, and economic conditions. The effects of events must be assessed after an assessment is made of existing climate related socio-economic studies.

Assess socio-economic impacts of existing and emergent climate change events on culture, community wellness, subsistence, and overall economics. Assess socio-economic impacts of existing and emergent climate change events on culture, community wellness, subsistence, and overall economics.

The enculturation process of young hunters and gatherers through experienced adults can be severely disrupted with loss or disappearance of important subsistence species. Migration of wildlife may require extended subsistence trips, increasing costs and risks as well as substitution of expensive store bought foods. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: NA***

5.2.2.2 Standardized ADF&G Harvest Surveys.

This includes considerable social, demographic and economic information in addition to household harvest per species. Harvest surveys need to be accomplished in each of the villages designated with emergency status.

Action Type: Monitoring, Products, Education/Outreach, Data Management. Cross-Cutting Topics: Health and Culture, Economic Activities, and Transportation and Land Use

5.2.3 Social Impact Assessment

5.2.3.1 Regional assessments of existing social service infrastructure, staffing, budgets and delivery need to be accomplished at regional level as baseline to plan for increased demand.

Services are changing with the stress on rural communities that are increasing because of many factors, including climate change. Stressors include health, behavioral health, and culture with sustainability. Having accurate assessments based on research results and predictive models will allow decision makers to make plans for meeting these future needs. ***Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics:*** **NA**

5.2.3.2 Social Impact Assessments need to be conducted at regional and community level to provide information for Section III of the NEPA process, description of the affected environment.

Gathering social impact assessment information will be needed to complete impact assessments and provide preferred alternatives. By assessing the cultural impacts in an analytical manner, thorough documentation of the questions, responses and recommendations will be available to support the preferred alternatives. ***Action Type: Modeling, Products. Cross-Cutting Topics: NA***

5.2.3.3 Detailed interviews and oral histories need to be conducted to provide narrative information needed to assess the impacts of climate change and the potential impacts of different forms of relocation.

As stressors associated with climate change impact health and culture of rural communities and indigenous people, risks to cultures and oral histories exist. Insuring comprehensive collection and archiving will preserve heritage. This is critical as heritage is being lost with aging and passing of elders. These interviews and oral histories need to be placed in a comprehensive library and archive. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: NA***

5.2.4 Bio-Environmental Impact Assessment

5.2.4.1 Assess ADEC watershed contamination protection laws and source water protection program. Assess effectiveness of current monitoring and surveillance programs to identify and control new pathogens or increased contaminant infiltration/runoff from.

Increased temperatures, changing precipitation patterns, flooding, melting permafrost, and other climate change-related risks could alter the geographic range and incidence of a wide range of infectious diseases and can result in

contamination of food and water sources. A research program that assesses the effectiveness of current monitoring and surveillance programs, while identifying improvements given the uniqueness of changing climate and geographic ranges, is needed. ***Action Type: NA. Cross-Cutting Topics: NA***

5.2.4.2 Assess sanitation and solid waste disposal infrastructure and practices at risk from flooding, melting permafrost, and other risks, or that is otherwise subject to changed conditions that significantly reduce performance in environmental health protection.

Increased temperatures, changing precipitation patterns, flooding, melting permafrost, and other climate change-related risks could compromise sanitation and solid waste disposal infrastructure and render current practices ineffective. Research is needed in assessing the risk to existing facilities and identifying options for adapting the facility in the face of risks. Modeling of potential loss to erosion or flooding and associated risks to environmental health is needed. ***Action Type: NA. Cross-Cutting Topics: NA***

5.2.4.3 Work to quantify the climate warming impact from the potential release of methane hydrates in the Arctic due to warmer sea temperatures.

Study climate warming and methane hydrate deposits. ***Action Type: NA. Cross-Cutting Topics: NA***

5.2.4.4 Study the potential increase in bioavailability of persistent organic and transboundary pollutants, including pesticides, mercury, perfluorochemicals and flame retardants, which may be released from melting ice and snow and thawing soil as a result of climate warming in the arctic.

Transport of pollutants and toxins with changes in atmospheric flows and oceanographic currents are impacting Alaska. Evaluate the potential health impacts on humans, ecosystems from toxins, persistent organic chemicals and other pollutants, including their behavior in the food web. Develop projections as to whether these impacts and release rates can be expected to increase and to what degree in the future. Conduct the research in determining the extent and risk to health in the Arctic. ***Action Type: Monitoring. Cross-Cutting Topics: NA***

5.2.4.5 Study the interaction of increased UV exposure in the arctic on humans, animals and vegetation in conjunction with projected climate changes.

Climate change can change UV exposure that may affect human health and change plant and animal distribution. Research to study climate warming and Ultra-violet radiation, including monitoring plans will help to document the risks associated with the increased UV exposure. Research should include understanding the impact on people, flora and fauna, and traditional ways of life and culture. ***Action Type: NA. Cross-Cutting Topics: NA***

5.2.5 Cultural Resources Impacts

5.2.5.1 1) In cooperation with appropriate entities, complete an assessment of archaeological sites most at risk, and develop a plan for their protection or recovery. 2) Complete a statewide assessment of and response to the gravesites most at risk.

Research to improve the understanding of the potential cultural impacts of climate change on indigenous people must consider archeological sites. Increased temperatures, changing precipitation patterns, flooding, melting permafrost, and other climate change-related risks will affect the stability of archeological sites and gravesites, requiring plans for protection or recovery. The magnitude of the problem will depend on a complete statewide assessment and a mitigation plan to reduce the loss and allow relocation. Developing a confidential but interactive data base should stem from this research. ***Action Type: NA. Cross-Cutting Topics: NA***

5.2.6 Community Capacity Assessment

5.2.6.1 1) Identify effective cooperative mechanisms to support rural communities in dealing with multiple rules and requirements. 2) In partnership with local communities, conduct an assessment of the capacity of communities to design and implement programs.

Increased temperatures, changing precipitation patterns, flooding, melting permafrost, and other climate change-related risks will present a wide range of challenges to rural communities that will require them to deal with multiple state and federal agencies, with overlapping and sometimes conflicting rules and regulations. Researching socio-economic and socio-cultural methods to equip rural communities in gaining assistance in designing and implementing programs that adapt a community is needed. ***Action Type: NA. Cross-Cutting Topics: NA***

5.3 Natural Systems (NS) TWG

The Natural Systems Technical Working Group (TWG) has developed a catalog of adaptation options related to the expected effects of climate change on Alaska's natural systems. This section presents research needs associated with the work group's recommendations on the relevant actions the State of Alaska could take to adapt to changes in Alaska's natural systems due to climate change. The research needs work group looked at adaptation options in the following areas: Fisheries, Wildland Fire, Freshwater Resources, Invasive Species and Disease, Fish and Wildlife Management, Forestry and Wood Biomass, Sustainable Agriculture, and Natural Hazards.

TWG Recommendations

The TWG forwarded the following adaptation policy options for consideration by the Climate Change Sub-Cabinet:

NS-1. Incorporate climate change into **fisheries** management and assist fishing communities and users in adaptation.

NS-2. Review and modify Alaska's **wildland fire** policy and programs.

NS-3. Address the effects of climate change on **Alaska's freshwater resources** through adaptive management, supported by improved hydrologic data.

NS-4. Reduce introduction and spread of **invasive species** in the context of climate change.

NS-5. Prepare for **adaptive management of fish and wildlife.**

NS-6. Develop capacity in new **forestry and wood biomass** opportunities.

NS-7. Support **local sustainable agriculture** in Alaska.

RNWG Recommendations

The RNWG recommended the following additional policy option relative to Natural Systems:

NS-8. Reduce risks to health, safety and property from **natural hazards** resulting from climate change.

Research Needs

5.3.1 Overarching Research Needs

Overarching research needs for Natural Systems TWG activities include:

5.3.1.1 Develop better hydrology data and models statewide.

Trend data and global climate models indicate a warmer and sometimes wetter climate for Alaska in the future. Planning for river navigation, flood hazard estimation, and cost-efficient engineering of public roads, culverts, bridges, water, and wastewater systems require accurate estimation of water flow volume and seasonality. Historic data and existing statewide coverage are inadequate for present and future needs. ***Action Type: Data Management, Modeling, Monitoring. Cross-Cutting Topics: Overarching***

5.3.1.2 Identify permafrost thaw hazards and incorporate into engineering guidelines.

Many of the scenario models used in IPPC reports suggest that widespread permafrost thaw will occur across the Northern Hemisphere in this century. Cracking roads and subsiding building foundations are common in some areas where permafrost thaw is occurring. Landslides and mudflows are also occurring on thawing wet hill slopes, sometimes blocking roads, rivers, and degrading fish habitats. Engineers, builders, and planners need accurate maps and forecasts for

planning. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Overarching***

5.3.1.3 Identify and research laws, policies, and regulations that could be modified to better support adaptation.

Many of the laws, policies, and regulations that direct management of public and private lands and waters are premised on stable climates, or at least on the ability to envision future conditions (e.g., ANILCA, ESA, CFR, CZMA). What will be the standard of successful resource management in a changing future? Can state and federal agencies preserve the unique and special values that are identified in legislation in the face of climate change? How will they develop adaptation strategies for fish, animals and plants when their natural climate zones move beyond management units, state and national borders? How can access to subsistence resources be ensured in light of changing resource availability, sedentary human settlement patterns, and the mix of agency rules and regulations? ***Action Type: Products. Cross-Cutting Topics: Overarching***

5.3.1.4 Implement local climate change scenario planning workshops in communities across Alaska (coastal, arctic, interior, etc.).

Alaskan's are receiving conflicting, sometimes sensational and frightening information about climate change from many sources. While environmental change has taken place in Alaska for a long time, much of the state's permanent development occurred before future climate change was given serious consideration. Recent trends and forecasts have made it increasingly apparent that future climate change needs to be factored into community planning. However, few communities really understand what additional changes to expect in their area, or how fast to expect them. As heard at the ACTEM climate change session, communities need updated mapping, photographs, and projections of environmental changes to be able to effectively plan for their adaptation to climate change. ***Action Type: Modeling, Products, Education/Outreach, Data Management. Cross-Cutting Topics: Overarching***

5.3.1.5 Identify and assess health and safety hazards resulting from climate change

Research is needed to identify risks and opportunities for early warning, avoidance, and hazard mitigation. Rapid climate change affects fire regimes and forest fuel hazards, physical hazards (glacial outbursts and river flooding, surging glaciers, avalanches, landslides, ground failures, solifluction, erosion, inundation, subsidence), invasive species (plants, animals, pests and diseases), species habitat loss and fragmentation, and vulnerabilities to spread of contaminants resulting from persistent organic pollutants (POPS) and permafrost thaw. ***Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: Overarching***

5.3.1.6 Coordinate data integration.

Decisions are being made without benefit of available data and redundant research activities are started for lack of access to existing data. Better access to existing data would be a cost-effective measure to provide more information for better decision making. ***Action Type: Data Management. Cross-Cutting Topics: Overarching***

5.3.1.7 Research changes to vital ecosystem services.

The cascading effects of large scale environmental change can affect critically important natural services and economic resources, such as water supply, air quality, ocean fisheries, etc. For example, large scale changes to boreal forest are expected, with uncertain effects to other factors. Information about potential "tipping points" could help to avoid situations where vital ecosystem services are no longer being provided (e.g. wildlife and fisheries population crashes). ***Action Type: Modeling. Cross-Cutting Topics: Overarching***

5.3.1.8 Fill gaps in geospatial data coverage, aerial photography, digital elevation models (DEM), and remote sensing data that are needed to assess and forecast climate change impacts.

There are highly important specific early needs to facilitate other data gathering efforts. For example, accurately represented coastal land elevations are needed for modeling how sea level rise will affect low lying coastal areas. ***Action Type: Products, Data Management. Cross-Cutting Topics: Overarching***

5.3.1.9 Conduct coastal mapping and shoreline characterization.

Baseline data is needed to enable coastal impact forecasting, scenario planning for sea level rise and coastal erosion, monitoring, trend analysis, and spill response following shipping accidents, which are expected to increase as sea ice diminishes in the Northwest Passage. ***Action Type: Products, Data Management. Cross-Cutting Topics: Overarching***

5.3.1.10 Assess, model, and monitor coastal impacts of changes to sea level and ice.

Coastal erosion is increasing with reduced sea ice cover and thawing permafrost. Rapid erosion is exposing buried infrastructure, undercutting road and building foundations, and destroying natural and cultural resources. ***Action Type: Modeling, Products, Data Management, Monitoring. Cross-Cutting Topics: Overarching***

5.3.1.11 Develop and refine down-scaled climate models.

Global Climate Model data is too coarse to inform communities and local resource managers about probable changes at local levels. ***Action Type: Modeling, Products, Education/Outreach, Data Management. Cross-Cutting Topics: Overarching***

5.3.1.12 Coordinate climate and ecosystem monitoring programs among agencies, organizations, and institutions.

Long-term datasets with reliable indicators and across large geographic areas (regional and continental scale) are essential to determine climate and resource condition trends. ***Long-term. Action Type: Products, Data Management, Monitoring. Cross-Cutting Topics: Overarching***

5.3.1.13 Work with communities to determine appropriate indicators of climate change and community impacts. Improve monitoring of key climate change indicators & effects, with emphasis on effects having large societal impacts. Monitor climate change indicators and their societal impacts.

Improved monitoring of key climate change indicators relevant to Alaska will allow for tracking of climate change effects and will contribute data to modeling and assessments. Monitoring of locally-appropriate indicators and development of thresholds is needed to determine when change is occurring to rapidly for communities to adapt to impacts related to climate change. This information is needed to inform assessments of societal impacts and support planning and adaptation. ***Action Type: Modeling, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Overarching***

5.3.1.14 Conduct research on protecting community water supplies and instream flows.

Freshwater runoff from snow and ice melt is a major source of drinking water for communities. Adequacy of future supplies cannot be assumed with climate change. ***Action Type: Modeling, Products. Cross-Cutting Topics: Overarching.***

5.3.1.15 Expand research and monitoring of contaminants deposition and bioavailability under changing climate.

Contaminants can affect health and survival of fish, wildlife, and people. Results from WACAP and other studies indicate higher than expected levels of contaminants even in remote areas. ***Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Overarching***

5.3.1.16 Acquire or produce vegetation maps that are usually compiled from satellite imagery. Ortho rectified imagery would show human improvements and vegetation. A base map is needed for the state.

Understanding changes in landcover types are critical to assessments related to fire, forestry, wildlife, fisheries, etc. GIS and maps are basic tools needed for many analyses. ***Action Type: Products, Data Management. Cross-Cutting Topics: Overarching***

5.3.1.17 Assess communications strategies for climate change information.

Poorly communicated information about climate change can cause more harm than good. ***Action Type: Education/Outreach. Cross-Cutting Topics: Overarching***

Specific Research Needs

Specific research needs are discussed in more detail in the appendix.

5.3.2 Fisheries

5.3.2.1 Synthesize current information about climate change impacts on fisheries and assess its reliability and degree of uncertainty.

Conduct fisheries ecological modeling. ***Action Type: Modeling, Products, Data Management. Cross-Cutting Topics: NA***

5.3.2.2 Conduct Arctic Ocean fisheries assessments.

Fisheries population shifts are occurring due to ecological change, and ship access is increasing with reduced sea ice. Commercial fishing in new areas would have uncertain effects to previously unaffected populations. ***Action Type: Modeling, Products, Monitoring. Cross-Cutting Topics: NA***

5.3.2.3 Increase real-time monitoring and forecasts of physical ocean conditions (winds, waves, sea ice, currents, temperature, salinity, pH, etc.).

Improved monitoring and forecasting of changing ocean conditions will inform modeling and forecasting of related biotic changes, as well as inform marine-based human uses. Physical data is needed to predict and explain biological responses. Information is needed about impacts of freshwater from glacial melt on marine ecosystems, to improve understanding of effects of climate change on marine ecosystems. Water temperature increases are correlated with oceanic regime changes and with locally reduced salmon returns and increased fish disease (e.g., *Ichthyophonus* in Yukon River salmon). Ocean acidification of the magnitude that has been occurring is expected to have significant impacts to food webs, and certain species (e.g. corals, shellfish). ***Action Type: Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

5.3.2.4 Research fisheries policy considerations.

Research what other countries, U.S. federal agencies and other states are doing to incorporate climate change considerations into commercial fishing policies, management, and other adaptations. Assess what is appropriate to Alaska conditions. ***Action Type: Products. Cross-Cutting Topics: NA***

5.3.2.5 Conduct physical, biological, and socioeconomic monitoring consistently over time to understand environmental change, distribution and abundance of freshwater, marine and anadromous species, and societal impacts.

Broad scale changes in fisheries species abundance and distribution are expected. Changing stream and lake biochemistry may drive freshwater ecosystem change and change the abundance and distribution of species of commercial or subsistence importance (as well as other effects.) Monitoring is essential to inform policy, management, and users' decisions. Data will support modeling and forecasting. The Anadromous Waters Catalog is the key tool for documenting freshwaters that are important to anadromous fish and to provide protection for these habitats. ***Action Type: Monitoring. Cross-Cutting Topics: NA***

5.3.2.6 Consider need for protected fish conservation areas.

Evaluate tools for fish species conservation. Expanding fisheries pressure can deplete target and by-catch populations and degrade habitats. Reduced sea ice increases the likelihood of increased fishing pressure in Arctic waters. ***Action Type: Products. Cross-Cutting Topics: NA***

5.3.3 Wildland Fire

5.3.3.1 Expand modeling of wildland fire, fuel, and smoke.

Fire hazards are expected to increase with rising air temperature, longer growing seasons, and increased soil dryness. Dense and long-lasting smoke from wildland fires can result in severe acute and chronic health impacts in affected communities. ***Action Type: Modeling. Cross-Cutting Topics: NA***

5.3.3.2 Review and coordinate wildland fire policies with Canadian counterparts.

Determine efficacy and ecological effects of different fire management policies. Current wildland fire policy is not Full Suppression. Research would inform policy makers about potential positive and negative effects to wildlife habitat of allowing wildland fires to burn. ***Action Type: Modeling, Products. Cross-Cutting Topics: NA***

5.3.3.3 Research Tundra fire effects and develop measures to reduce impacts.

Tundra fires are expected to increase as shrubs move into tundra and as soils dry from climate warming. Remote communities have limited fire fighting capacity. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: Health and Culture***

5.3.4 Invasive Species

5.3.4.1 Identify and develop methods to assess and control invasive and irruptive plant, animal, and diseases that are likely to become established, expand

their range, or be intentionally introduced in Alaska due to climate change.

Established terrestrial, aquatic, and marine species are shifting north into Alaska, while other species are also arriving from other seas and continents. Some new arrivals will compete with current species or carry parasites and diseases previously not present in Alaska. ***Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Forestry, Agriculture & Waste, Health & Culture***

5.3.4.2 Provide effective monitoring, forecasting and response to marine invasive species.

The number and distribution of invasive species is expanding in Alaska. Invasive species frequently out-compete valued native species and cause severe economic and ecological damage. Invasive marine species can arrive in ballast water, ship hulls and gear, through aquaculture/mariculture releases, and as a result of changing ocean conditions and migration patterns. ***Action Type: Education/Outreach, Data Management, Modeling, Monitoring. Cross-Cutting Topics: NA***

5.3.5 Fish and Wildlife

5.3.5.1 Improve wildlife and fisheries populations and harvest rate data and access.

Alaska's terrestrial, aquatic and marine ecosystems are changing, as are the natural habitats required by wildlife and fishery species. Scientists expect rapid change in some areas as trees and shrubs expand into tundra, as fires reduce the size and extent of coniferous forests, and as permafrost thawing and thermokarst formation change the distribution and size of wetlands. Alaska's rural population, tourism industry, and many businesses depend on healthy wildlife and fish populations for food and income. Accurate monitoring data and forecasts are needed to inform decision makers about resource management needs and options, including changes to laws, policies, and regulations. ***Action Type: Modeling, Data Management, Monitoring. Cross-Cutting Topics: Health & Culture, Economic Activities***

5.3.5.2 Develop projections of future changes to potential wildlife habitat that are likely to result from climate-driven changes to landscape, landcover (vegetation), wildfire frequency and intensity, permafrost thaw/thermokarst, and fragmented migratory corridors.

Climate change will have cascading effects on multiple physical, biological, social, and cultural resources. However, the scope and scale of those effects is largely undetermined. ***Action Type: Modeling, Products. Cross-Cutting Topics: NA***

5.3.5.3 Evaluate and improve methods for caribou population enumeration.

Subsistence communities need accurate information to adjust harvest patterns to changing wildlife abundance. Some herds are in decline and others may be. The accuracy and timeliness of caribou monitoring programs has been questioned by stakeholders and cooperators. ***Action Type: Modeling, Products, Data Management, Monitoring. Cross-Cutting Topics: NA***

5.3.5.4 Assess disjuncts between calendar dates for legal harvest, and actual biological behavior of species.

For example, moose hunters are concerned that legal harvest dates don't always correspond with available harvest opportunities. Managers are concerned that shifting a hunt into the rut period (when bulls are preoccupied with breeding) can increase hunting success, which could be problematic for low-density populations or those with a low bull: cow ratio. Improved methods for moose population enumeration are needed. ***Action Type: Products, Monitoring. Cross-Cutting Topics: NA***

5.3.5.5 Identify how "sentinel" ecosystems are changing.

Continued monitoring in those areas where there are already long-term records could provide valuable trend information. ***Action Type: Monitoring. Cross-Cutting Topics: NA***

5.3.6 Forestry and Wood Biomass

5.3.6.1 Research and monitor forest response after disturbance.

Research ecological "tipping points." Trees are moving into higher altitudes and higher latitudes as climate warms. Many common species are experiencing severe and recurring pest outbreaks (e.g., bark beetles, budworms, leaf miners) related to climate change (increased temperatures and transpiration, reduced soil moisture). Fire effects are increasing as flammable shrubs and trees expand into tundra, and as fire frequency increases in boreal forests. However, the full scope and trends has not been determined. ***Action Type: Modeling, Products, Data Management, Monitoring. Cross-Cutting Topics: NA***

5.3.6.2 Assess efficacy, economics, and ecological effects of salvage logging to produce timber and wood biomass fuels from fire- and insect-killed trees.

Climate change-related warming and drying is likely to result in more insect and fire-killed timber and biomass. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: NA***

5.3.6.3 Test various wood burning appliances and their air quality emissions in an arctic environment.

Increased use of wood and woody biomass as a "carbon neutral" heating fuel has potential to affect local air quality and resident health. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: Health and Culture***

5.3.6.4 Research net contributions of Alaska's natural areas to GHG release and sequestration.

Recent climate change is largely driven by greenhouse gas (GHG) levels. The effectiveness of cap and trade measures will also be affected by natural carbon sequestration and emissions. Understanding the relative contribution of sources of GHG compared to other human and natural sources is essential. Accurate modeling is critical for effective mitigation of atmospheric greenhouse gas emissions. Carbon emissions cap and trade systems are now being implemented to reduce global emissions of greenhouse gases. These systems are based on models of gas emissions and gas sinks. Current models cannot accurately determine whether Alaska's wild lands will sequester more carbon in vegetation than they release through wildland fires, oxidation of thawed organic permafrost, methane hydrates, etc. ***Action Type: Modeling, Products. Cross-Cutting Topics: Mitigation***

5.3.7 Sustainable Agriculture

5.3.7.1 Research agricultural products and practices suitable for changing conditions.

Research new agricultural product opportunities, technologies and best practices, including locally produced fertilizer and waste nutrient utilization (e.g., fish carcasses/processing waste), in order to prepare to capitalize on opportunities to expand sustainable agriculture in Alaska. Climate change may provide new opportunities in sustainable agriculture that may be of increased importance to food security as access to other food sources changes due to lost fish and wildlife harvest opportunities or increased costs for shipped foods. ***Action Type: Modeling, Products, Education/Outreach. Cross-Cutting Topics: NA***

5.3.8 Natural Hazards

5.3.8.1 Assess effects of climate on safe access for hunting, fishing and other subsistence activities.

Access to subsistence hunting and fishing on land and water is critical for survival in many areas. Accurate forecasting is important to enhance safety of travel in road-less areas. Changes in freeze-up and thaw timing and conditions continue to affect subsistence harvest opportunities and uses through inaccessibility and/or increased access hazards. Low river water may also preclude access. Changes in

safe access may require consideration of alternative access means, changes in season timing, or other adaptation. Access by traditional means may also damage resources when conditions change (e.g. ORVs or snow machines on wet thawed ground). ***Action Type: Modeling, Products, Education/Outreach, Monitoring. Cross-Cutting Topics: Health and Culture***

5.3.8.2 Update the Environmental Atlas of Alaska and Alaska Engineering Design Information System (AEDIS).

Engineers are sometimes using out-of-date environmental information in designing new facilities in Alaska, which may result in premature obsolescence or failure. ***Action Type: Products. Cross-Cutting Topics: Transportation and Land Use, Public Infrastructure***

5.4 Public Infrastructure (PI) TWG

The Public Infrastructure TWG identified and evaluated options and opportunities for the State of Alaska to enhance the resiliency and adaptive capacity of Alaska's public infrastructure to the current and potential future effects of climate change. They defined public infrastructure as the essential facilities and utilities under public, cooperative, or private ownership that deliver goods and services to Alaska's communities.

TWG Recommendations

The Public Infrastructure TWG recommends that State government adopt a systems-based vision for sustainable infrastructure that supports communities in an uncertain environment. This systems approach means shifting infrastructure planning and investment decision-making from a competitive and disconnected project-based orientation to a holistic, long-term, common outcome-based orientation. The TWG policy recommendations are:

PI-1. Create a statewide system for key data collection, analysis, monitoring, and access.

PI-2. Promote "No Regrets" Improvements

PI-3. Build to last. Build resiliency into Alaska's public infrastructure.

RNWG Recommendations

To these policy options the following additions are recommended:

PI-4. Include funding for long-term monitoring of infrastructure in operating budget.

PI-5. Develop and incorporate best practices for energy use reduction and greenhouse gas reduction into state agency policies and procedures.

Research Needs

5.4.1 Overarching Research Needs

Overarching research needs for Public Infrastructure TWG activities include:

5.4.1.1 Collect climate data and develop methodologies and capacity to enhance and increase the resolution of climate forecasting models.

Downscaled climate forecasts are needed so that Federal, state, and community planners & decision makers can establish: 1) time horizons within which they will need to address infrastructure fortification or relocation; 2) locations and designs of new infrastructure that accommodate these conditions; and 3) location-specific conditions that new infrastructure must be designed to accommodate. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

5.4.1.2 Develop and deploy effective mechanism(s) to increase the availability and maximize the exchange of authoritative, defensible, and timely information to support analysis and decision-making on issues of climate change adaptation & mitigation, sustainability, and resiliency.

Climate analysis information delivery and availability is decentralized and uncoordinated, creating inefficiency, duplication of effort, wasted money, and difficulty in locating information of consistent and acceptable quality for a variety of purposes. ***Action Type: Products, Education/Outreach, Data Management. Cross-Cutting Topics: NA***

5.4.1.3 Develop a mechanism to systematically identify, collect, and analyze the data that it needs to economically plan, develop, and manage its public infrastructure in a sustainable manner.

The state's current project-based focus on infrastructure development discourages investment in the systematic collection and evaluation of long-term post-construction performance data after construction. Infrastructure performance monitoring and modeling is necessary to effectively evaluate if and how infrastructure might be developed more sustainably in Alaska. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: NA***

5.4.2 Specific Research Needs

5.4.2.1 Analyze, develop, and update existing engineering and building codes and construction techniques for new infrastructure and structures in vulnerable areas.

Current designs likely do not incorporate the real risks and variability associated with climate change in Alaska. Consequently infrastructure may fail prematurely or require unnecessary expense to build and maintain, resulting in uneconomical and unacceptable risks to Alaskan communities. ***Action Type: Modeling, Products, Education/Outreach, Data Management, Monitoring. Cross-Cutting Topics: Energy Supply and Demand, Transportation & Land Use***

5.4.2.2 Establish an integrated baseline inventory on the location and condition of public infrastructure. Collect, assess and monitor data needed to develop sustainable solutions to adapt public infrastructure to the effects of a changing climate.

A complete inventory of public infrastructure (that is either now, or likely to be, at risk from the effects & hazards due to climate change) is needed in order to systematically identify public infrastructure vulnerability. Data that does exist is owned by several agencies and not effectively integrated and shared amongst. Inefficient duplication of effort is likely given the functionally separate organization and operations of State agencies. ***Action Type: Data Management, Monitoring. Cross-Cutting Topics: Energy Supply and Demand, Transportation & Land Use***

5.4.2.3 Identify, analyze, and use national and international research results and products as a basis for developing solutions and expanding best management practices in AK.

Employees of Alaska State agencies are not consistently clear about the role their agencies play in developing and supporting sustainable and resilient infrastructure. Performance measures of state agencies do not consistently recognize a systems approach and the value of sustainability and resiliency for state investments. State leaders have a tendency to manage public infrastructure funding decisions as expenses rather than investments. ***Action Type: Products, Education/Outreach. Cross-Cutting Topics: Energy Supply and Demand, Transportation & Land Use***

6 Glossary of Terms

ACCAP	Alaska Center for Climate Assessment & Policy
ACCS	Alaska Climate Change Strategy

8 Acknowledgements

The Co-chairs wish to thank and acknowledge the other members of the RNWG for their efforts in producing this report. Each of these members had other full-time jobs, yet found time in their busy schedules to develop this report. The Co-chairs also wish to thank the liaisons of the various Technical Work Groups for their assistance in communicating with the Technical Work Groups. The Co-chairs also express our gratitude to Brenda Holden and Indra Arriaga of Information Insights for their assistance in coordinating and facilitating discussions and preparation of the report. Without their assistance, this report would have been nearly impossible to complete. We would also like to thank Commissioner Hartig for providing the funds for the contract with Information Insights.

Appendix A

Technical Work Group Reports

Full, detailed recommendation reports by RNWG ordered by TWG.

TWG: Energy Supply and Demand

4.2.1.1

Carbon sequestration research is needed to better understand the state's options for storing carbon in geologic formations. This research involves field investigation of likely sites as well as laboratory testing of formations that have the potential to fix the carbon (e.g., in carbonates).

Unique Identifier: 66

☐ Overarching Need

Why is this an issue?

Alaska has a major coal resource. New coal power plants or coal to liquids processes will likely either require carbon sequestration or be negatively impacted by carbon caps or taxes. In order to prepare the state for both managing the carbon dioxide it produces currently and for permitting of new carbon dioxide producing facilities, sequestration options must be available.

Describe the scope of the research need:

The scope involves field investigations of suitable sites, mapping, and equilibrium/reservoir of good candidates for sequestration. This likely covers the entire state, though areas of opportunity would be co-located with carbon producing units.

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.
Recommended action: Direct and fund state agencies (e.g., UA, ADNR) to investigate the potential for CO2 sequestration in geologic formations.

What research is being done/known?

No field research has been conducted in Alaska with the exception of the EOR, which is only one form of geologic sequestration.

What are the gaps in research?

Aside from spent oil and gas reservoirs, we have major gaps in our understanding of the potential sequestration formations, the long term viability of the formations, chemical reactions in the reservoir, and the costs associated with use of the formations.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Oil and Gas

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

ADNR, UA

TWG: Energy Supply and Demand

4.2.1.2

Unique Identifier: 65

☐ Overarching Need

Research should be conducted into value added carbon capture technologies such as carbon capture and use in greenhouses for food and energy production, carbon incorporation into high-tech products, such as carbon fiber or H2 storage, enhanced oil recovery, and carbon addition to H2 for fuels production. Many other options many be available. Research is needed to determine which opportunities hold the greatest promise for Alaska.

Why is this an issue?

In order to comply with future carbon caps, trading, taxation, and carbon dioxide reduction for mitigation purposes, the state needs options for carbon dioxide management. Beneficial use makes the most sense if reasonable options are available.

Describe the scope of the research need:

The research need ranges from basic research (e.g., carbon fibers), to testing and demonstration of greenhouse applications (e.g., algae for biofuels). Some of the opportunities, such as carbon capture in greenhouses might require applied research in year-round, low energy applications (e.g., LEDs).

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.
Recommended action: Direct and fund state agencies (e.g., UA, ADNR, Dept of Commerce) to investigate the potential for CO2 capture and management value-added products and technologies.

What research is being done/known?

Some research is presently being conducted in Alaska, though this research does not presently focus on fuels production. Much of what is being done is done through the University of Alaska or smaller private greenhouses such as that at the Chena Hot Springs Resort. The Office of Electronic Miniaturization at the University of Alaska is currently doing work on carbon fibers.
The Alaska Center for Energy and Power is working with the Fairbanks North Star Borough to develop a Food and Energy Research Station. This effort will include carbon capture in greenhouses producing both fuels and food for the region.

What are the gaps in research?

Gaps are different for the breadth of beneficial uses. It is not known how much carbon could be captured in greenhouses designed for high CO2 processing.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Oil and Gas

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

The University of Alaska (particularly the Alaska Center for Energy and Power, the Institute for Social and Economic Research, and the Agriculture and Forestry Experiment Station), private industry, state agencies

TWG: Energy Supply and Demand

4.2.1.3

Research is needed to improve efficiency from improved control and operation practices of existing generation capacity (e.g., diesel). This includes the management of hybrid systems which typically are very complicated from a management and control standpoint.

Unique Identifier: 64

☐ Overarching Need

Why is this an issue?

Carbon emissions can be reduced by increasing the efficiency of carbon producing processes such as diesel power generation and hybrid power systems. Here the goal is not to improve the efficiency of the diesel engine itself, but to introduce control strategies that would reduce the net carbon emissions from the diesel power plant without a reduction in supply.

Describe the scope of the research need:

Research into diesel and disel/hybrid systems could be accomplished in a diesel efficiency test bed. In the testbed, technologies and control strategies could be tested with the aim of more efficient operation, saving money and carbon.

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.
Recommended action: Direct and fund state agencies (e.g., UA, ADNR, Dept of Commerce) to establish a diesel test-bed.

What research is being done/known?

A collaboration to establish a diesel efficiency testbed has been proposed by the Alaska Center for Energy Power at the University of Alaska and the Alaska Energy Authority as part of the University's FY 10 capital budget.
A good deal of basic and applied research has been done on components to diesel power systems, such as the engine itself, but very little has been done to manage the complex hybrid systems so that they truly lead to efficiencies.

What are the gaps in research?

There is presently not test bed in existence for testing alternatives relevant to Alaska.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

UA (Alaska Center for Energy and Power), Controls companies (e.g., Siemens), other private industry, AEA

TWG: Energy Supply and Demand

4.2.1.4

Research into the best application and best management of a coal-to-liquids technology as well as carbon capture and beneficial use.

Unique Identifier: 192

☐ Overarching Need

Why is this an issue?

Research on the use of coal in the state of Alaska is needed to most effectively develop an abundant energy rich resource while achieving goals for mitigating climate change.

Describe the scope of the research need:

The scope ranges from laboratory testing to testing of field demonstrations.

Policy option or recommendation:

The state should support research, development and testing into alternatives for coal use coupled with carbon management.

What research is being done/known?

Research is being conducted in a variety of areas with Coal, but there is very little funding currently available.

What are the gaps in research?

The major research gap is how best to use the coal resource while still mitigating climate change.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Energy Supply and Demand

4.2.2.1

A resource assessment as needed, in addition to research and testing of low temperature power generation designs for power and heat, mineral recovery from geothermal brines, and ground source heat pumps. Additionally, research into uses for power at or close to geothermal prospects should be conducted. Such uses could include value added mineral refining, timber processing, or greenhouse food/energy production.

Unique Identifier: 63

☐ Overarching Need

Why is this an issue?

Many locations in the state could be good candidates for inexpensive geothermal power. The areal distribution and depth of the geothermal resource is unknown for Alaska except a few isolated locations. Without a basic understanding of the geothermal potential, there is little chance that developers will be willing to invest in a geothermal prospect. Exploration often accounts for ¼ to ½ of the cost of a geothermal power development project.

Describe the scope of the research need:

A statewide geothermal drilling program is needed. This program can start at known areas of high heat flow in Alaska. Coupled with the drilling program, applied research should be conducted on the extraction of minerals from brines and the extraction of heat and power from low temperature geothermal discoveries.

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.
The state should fund a geothermal resource assessment that could be conducted through a partnership of state agencies, industry and the University.

What research is being done/known?

There are a few private companies or individuals who are exploring or exploiting isolated geothermal prospects. Aside from the known developments, little information exists as to the state's geothermal potential outside of hot water surface expressions.

What are the gaps in research?

The geothermal potential of the state is unknown. It is also not known to what extent low temperature prospects can be used to provide heat or power.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☐ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

ADNR, USGS, AEA, UA (Alaska Center for Energy and Power, Institute for Social and Economic Research, Geophysical Institute).

TWG: Energy Supply and Demand

4.2.3.1

Unique Identifier: 61

☐ Overarching Need

To make hydropower an effective and efficient power alternative, research is needed into technologies for fuel switching (e.g., from gas to electric heat), pumped storage and integration, reducing adverse intake icing conditions, and integration schemes for incorporating small-scale hydro power in village settings where other generating technologies are being used.

Why is this an issue?

Hydropower has many different forms and has many issues that determine its ultimate effectiveness as a source of power. If some of these issues were resolved, more hydropower may be accepted in Alaska. Hydropower would be a critical element of the Governor's plan to reach 50% renewable power. In this section hydropower is limited to a water retention and passage through power generating turbines. In-river, tidal, and wave power is discussed in a subsequent section and is referred to as hydrokinetic power.

Describe the scope of the research need:

The scope is documented above. There is a range of applied research and testing needs from laboratory and field research to modeling.

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.
The state should fund a hydropower development fund that could support research and testing to support hydropower projects in Alaska.

What research is being done/known?

Some research is being done at UA but relatively little, and what is being done would benefit from integration with activities at state and federal agencies.

What are the gaps in research?

The main gaps in research on hydropower center around the application of technologies to different environments and different conditions as well as the performance and control.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

ADNR, ADFG, UA (ACEP, others), AEA, NOAA, USGS

TWG: Energy Supply and Demand

4.2.3.2

There is a need for resource assessment, research on the impacts of hydro on fish populations, hydrokinetic device testing, and optimization of hydrokinetic devices for the Alaskan environment (issues such as deployment, anchoring, ice effects, tidal energy capture, etc). Another area of research needed is the application of high pressure water in non-electrical generating applications such as mechanical grinding and processing.

Unique Identifier: 59

☑ Overarching Need

Why is this an issue?

Many of Alaska communities are on rivers or along coastlines where hydrokinetic devices could augment power provided by diesel or another source. Unfortunately without some research into the likelihood of success of hydrokinetic devices, very little funding will be dedicated to such prospects.

Describe the scope of the research need:

There is a range of applied research and testing needed from laboratory and field testing to modeling. In most cases, the research needs are very applied.

Policy option or recommendation:

It is recommended that the state support a hydrokinetic energy test center to serve as a facilities in which state agencies, industries, and citizens can get information on options for hydrokinetic energy production in Alaska.

What research is being done/known?

UA-ACEP has formed a hydrokinetic energy test center in Nenana, Alaska. This is coupled integrated with a complementary testing effort led by UAA in Girdwood, Alaska.

What are the gaps in research?

The main issues center around the application of the technologies to different environments and different conditions.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

ADNR, ADFG, UA (ACEP, others), AEA

TWG: Energy Supply and Demand

4.2.4.1

There remain significant issues with wind field modeling, grid integration, power storage, foundations, and de/anti-icing options for wind turbine blades in Alaska that require additional research.

Unique Identifier: 60

☐ Overarching Need

Why is this an issue?

Wind systems are being installed around Alaska. While they are producing power, many are not reducing the use of diesel as much as they could. This is largely a controls, grid integration, and power storage issue. The issue of foundations and de-icing are practical problems increase the cost of wind projects. These issues could be resolved with some applied research and development. Other issues relate to wind field modeling. Wind field models can provide information about variability in power production and are needed before a windfarm can be adequately sited.

Describe the scope of the research need:

The need here is for a test center that can test and demonstrate controls and storage technologies or designs before they are implemented in the field.

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.
The state should fund a wind-diesel test center that could serve as a partnership of state agencies, industry and the University.

What research is being done/known?

UA-ACEP has formed a Wind-diesel test center to address this. The center is presently building partners in industry and state agencies.

What are the gaps in research?

Gaps principally lie in the applied research, development and testing of technologies in Alaska for Alaska situations. Basic research on wind turbines is done elsewhere.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

UA (ACEP, GI, IARC), AVEC, AEA, REAP

TWG: Energy Supply and Demand

4.2.5.1

Unique Identifier: 62

☐ Overarching Need

On-going research is needed to find suitable biomass technologies for generating power in the smaller communities that could simultaneously provide space heating. The biomass produced heat could be coupled with greenhouse production of food and energy crops. Algae, for example, could be grown in concentrated masses in greenhouses and converted to biofuels. Heat, light and CO2 from biomass burning could fuel the greenhouse operation. Little has been done in this area to prove the economics or other benefits of such an operation thereby limiting investment. A field-scale demonstration site would encourage the development of biomass generated heat and power (incl. food and energy) in Alaska.

Why is this an issue?

There is a need to optimize biomass development opportunities for rural heat and power as well as investigating the opportunities to cultivate biomass. For example, if willows can be cultivated and harvested for use in heat and power generation, the land area required for biomass production would be significantly reduced compared to harvesting of native biomass stands.

Describe the scope of the research need:

A field scale demonstration site is needed to conduct research into biomass cultivation and combustion. The demonstration site should offer opportunities for the public, small communities and cooperatives to learn about biomass production as well as conversion to energy and beneficial use of the excess heat, power, and CO2.

Policy option or recommendation:

This falls under the combined ESD Policy Options 7,8,9.The state should provide funding support for a feed and energy research station.

What research is being done/known?

There is presently work in agriculture that could help support a food and energy research station. The FNSB is in the process of leasing land to the Fairbanks Economic Development Corporation to start such a test site. The Food and Energy Research Station would be located in the Fairbanks area and would serve the state as a demonstration site for biomass cultivation and conversion to heat and power.

What are the gaps in research?

No work has been done to field test cultivation of crops for energy nor the beneficial use of excess heat, power and CO2 for greenhouse production of food and fuel crops.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

Fairbanks North Star Borough, USDA, DCCED, UAF, AEA, Fairbanks Economic Development Corporation

TWG: Forestry, Agriculture and Waste Management 4.3.1.1

To develop a protocol for determining carbon sequestration rates, additionality for silvicultural treatments in boreal and coastal forests.

Unique Identifier: 116

☑ Overarching Need

Why is this an issue?

Carbon trading under a cap and trade system requires verification of carbon additionality above a baseline reference. This "additional" C can be sold as part of a mitigation strategy for a C producer that needs to exceed their cap. Silvicultural treatments need rigorous third party review to ensure they meet the needs of the market.

Describe the scope of the research need:

-Coastal and boreal forests need work completed on this topic -Should look at both above ground biomass and soil biomass and C pools

Policy option or recommendation:

FAW-1, Establish acarbon accounting system for forestry practices

What research is being done/known?

There is both policy development and research being done in this arena, but not specifically related to silviculture treatments in these ecosystems. Modeling will play a keyrole, but protocols for developing a baseline and C accounting over time need more attention. A good paper to review on this topic is "Managed Forests in Climate Change Policy: Program Design Elements

What are the gaps in research?

Soil dynamics are not well understood, especially in permafrost rich soils

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Natural Systems

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

There are several parties that should be include: state and federal forest management agencies and private land owners that undertake active forest management practices, native corporations, University of Alaska (U.A.) land trust, mental health trust. In addition, there are third party organizations that currently certify forest management practices on private and public lands that are exploring the concept of C certification. The Forest Stewardship Council (FSC) and Sustainable Forestry Initiative (SFI) are two potential participants in implementation discussions. Carbon exchanges, such at the Chicago Climate Exchange (CCX) and other trading and broker organizations should also be consulted in this multi stakeholder effort.

TWG: Forestry, Agriculture and Waste Management 4.3.1.2

Refine global climate models for better understanding of regional variations within Alaska. Provide means to disseminate these data.

Unique Identifier: 189

☑ Overarching Need

Why is this an issue?

Better understanding of the effects of climate change. Improved monitoring and modeling data will allow for development and dissemination of environmental information and design criteria for use in adapting to climate change.

Describe the scope of the research need:

Refine global climate models for better understanding of regional variations within Alaska. Provide means to disseminate these data. Develop more detailed regional estimates of potential climate changes for Alaska using site specific estimates of temperature, precipitation, topography, etc. Establish means to effectively distribute details on varying climate changes statewide.

Policy option or recommendation:

None, but a research need identified by the FAW TWG

What research is being done/known?

Scenarios Network for Alaska Planning (SNAP) at the University of Alaska is working on refinement of various climate change models as they pertain to Alaska and some of the unique issues that need addressed.

What are the gaps in research?

Variables not assessed as part of SNAP and their current research effort.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

Alaska state agencies, UA research centers such as the Center for Knowledge Sharing on Climate Change and Arctic Issues, EPA, and other federal agencies.

TWG: Forestry, Agriculture and Waste Management 4.3.1.3

Assess contributions of CO2 & CH4 from melting permafrost to AK's GHG Emissions. Study of expected carbon losses during permafrost melt and addition of emissions to the AK GHG I&F.

Unique Identifier: 191

☑ Overarching Need

Why is this an issue?

Better understanding of the CO2e impacts of melting permafrost and appropriate representation in AK's GHG I&F. Potential for large impact to the I&F report if these areas are considered to be anthropogenic.

Describe the scope of the research need:

Review of existing modeling, if available, addition of results to the GHG I&F appendix for Forestry and Land Use. New modeling, if needed.

Policy option or recommendation:

None, but a research need identified by the FAW TWG

What research is being done/known?

Unknown

What are the gaps in research?

Unknown

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

University of Alaska research centers.

TWG: Forestry, Agriculture and Waste Management 4.3.1.4

Assess whether the Boreal forest should be considered managed or unmanaged and hence either considered either an anthropogenic or natural source (current consideration is as a natural source)

Unique Identifier: 190

☐ Overarching Need

Why is this an issue?

Determination of Coverage of carbon fluxes in the Boreal Forest as part of the Alaska GHG Inventory & Forecast. There is a potential for a large impact on the overall GHG emissions of the state if the Boreal Forest is considered a managed forest, and hence, an anthropogenic source of emissions.

Describe the scope of the research need:

Review IPCC materials on the definition of managed or unmanaged forests. Confer with in-state forestry experts to assess the proper classification of the Boreal Forest based on past and future management.

Policy option or recommendation:

None, but a research need identified by the FAW TWG

What research is being done/known?

None on this specific topic.

What are the gaps in research?

See scope of research need for discussion on this point.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☐ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

UA Research Centers, State Foresters, USFS

TWG: Forestry, Agriculture and Waste Management 4.3.2.1

Unique Identifier: 119

☐ Overarching Need

Demonstrate that in arctic weather conditions, modern wood combustion appliances, such as wood pellet stoves, boilers and larger scale wood chip or co-fire facilities meet Environmental Protection Agency (EPA) particulate matter (PM-2.5) and other pollutant standards. This is very important for the communities of Fairbanks and Juneau which have been in violation of the new PM-2.5 standard and may have wood burning closures to help deal with the issue.

Why is this an issue?

In an arctic climate wood burning appliances need testing for particulate matter (PM), nitrogen oxides (NOx) and carbon monoxide (CO) to ensure public health is not negatively impacted. Like other combustion systems wood boilers emit a variety of pollutants, including particulate matter, nitrogen oxides, carbon monoxide, volatile organic compounds (VOC), sulfur dioxide (SO2), carbon dioxide (CO2) and other pollutants. Wood boilers emit PM, NOx, and CO in much greater quantities than the other pollutants. For this reason, these are the three pollutants to track and carefully monitor to determine potential impacts. Wood systems also emit greater quantities of CO2, however unlike fossil fuels; woody biomass is considered carbon neutral. (See 118 for a more detailed discussion on this concept).

Describe the scope of the research need:

There are several different scales to address, from individual home appliances, to mid-size boilers for larger public facilities, such as schools. There may also be a need to look at co-firing uses, such as electric utilities where coal and wood chips are combusted together.

Policy option or recommendation:

FAW-2, Allay concerns that wood burning has detrimental health impacts

What research is being done/known?

Cold Climate Housing Research Center (CCHRC) in Fairbanks is doing some testing in conjunction with the Fairbanks North Star Borough (FNSB). The military did some emission tests on co-firing with wood chips and coal at Fort Wainwright in the 1980's. The Western Forestry Leadership Coalition has published an issue brief that provides a good summary on this topic.

What are the gaps in research?

Unregulated wood burning appliances, such as outdoor wood boilers, and EPA approved devices in arctic conditions.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Natural Systems

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

Department of Environmental Conservation (DEC), EPA, local governments and the legislature could all have roles in the implementation of this option. Joint effort by private and public sector such as: stove manufacturers, wood fuel manufactures, Cold Climate Housing Research Center (CCHRC), retailers of wood combustions devices and the Cooperative Extension Service.

TWG: Forestry, Agriculture and Waste Management 4.3.3.1

Development of a protocol that assigns a carbon life to different types of wood products, including durable wood products.

Unique Identifier: 117

☐ Overarching Need

Why is this an issue?

Currently in most models that portray carbon flux between sinks and sources there is no allocation made for C storage as a tree moves from a log to a forest product. When the tree is harvested from the forest, it is treated as an emission. This is a simplification that is not accurate in the real world use of wood.
Products substitution; using wood instead of steel, concrete or other building products that have much higher C footprint then wood. Life cycle assessment studies have conclusively shown marked differences in energy requirements associated with different building materials and structures made from them, yet current carbon trading protocols don't make allowances for this type of sequestration or reduction of GHG emissions.

Describe the scope of the research need:

A national or international standard needs developed so that the C market has the ability to certify and verify amounts of C stored by wood products
Carbon budgets need developed for different types of building materials to accurately portray the gain or loss of C based on the type of product used as compared to wood products

Policy option or recommendation:

FAW-1

What research is being done/known?

There are several papers that discuss this topic and the issues surrounding the concept. Dovetail Partners, Inc. have published a report entitled: Wood Products and Carbon Protocols Carbon Storage and Low Energy Intensity Should Be Considered and in Chapter 3 of the Society of American Foresters publication: Forest Management Solutions for Mitigating Climate Change in the United States there are also several good discussions on these topics.

What are the gaps in research?

Complete literature review to identify gaps, may be mostly policy gaps.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☑ Data Management ☐ Monitoring

Parties involved in implementation:

Wood product manufacturing businesses, state and federal forest management agencies and private land owners. Alaska Forest Association, other. National or state level review of issue

TWG: Forestry, Agriculture and Waste Management 4.3.3.2

Determine if woody biomass used in energy production is a carbon neutral fuel source, Scientifically demonstrate that woody biomass used as a fuel for energy is a carbon neutral fuel

Unique Identifier: 118

☐ Overarching Need

Why is this an issue?

Currently woody biomass is considered a carbon neutral fuel when compared to fossil fuels, such as coal, oil or natural gas. The combustion of all fuels produces CO2, but trees that are harvested for this purpose are replaced by new trees that sequester C from the atmosphere. Over time, the CO2 released by the combustion process will be captured again by the new tree crop. This concept is important because in the carbon trading market place, an offset credit can be generated by using a biomass fuel for a fossil fuel. It is a straight forward calculation to determine how much C is in a gallon of fuel oil or ton of coal and when you "offset" this fuel type with biomass you generate a credit that can be sold.

Describe the scope of the research need:

Scope is pretty narrow, need to demonstrate that this concept is valid or if not fully neutral by what percentage is it a Carbon neutral fuel?

Policy option or recommendation:

FAW-2

What research is being done/known?

Unknown, would benefit from a literature review

What are the gaps in research?

Not sure, it seems like a pretty straight forward problem that could be answered with current inventory and data. Needs re-worked from a Carbon perspective.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Natural Systems

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☑ Data Management ☐ Monitoring

Parties involved in implementation:

Any biomass project would benefit so long as they are offsetting the use of a fossil fuel. Community governments, school districts, utilities, state or private institutions are all potential beneficiaries of this policy option. The research can be conducted at the University of Alaska , perhaps at the Center for Knowledge Sharing on Climate Change and Arctic Issues with assistance from staff at state and federal agencies.

TWG: Oil and Gas

4.4.1.1

Economic: Impact of various incentives to major capital improvement investment

Unique Identifier: 130

☑ Overarching Need

Why is this an issue?

This is an issue because incentives will drive a significant amount of private sector investment to reduce overall emissions and improve energy efficiency.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

There is no current research on this topic in Alaska

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy supply and demand

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

University, State Government; DNR, DOR

TWG: Oil and Gas

4.4.1.2

Economic:Short and long term value of carbon

Unique Identifier: 128

☑ Overarching Need

Why is this an issue?

Understanding the value of carbon will be critical in developing reasonable and affective policy for all CO2 mitigation activity. It will also be used to assess the economic impact of mitigation to the state.

Describe the scope of the research need:

The value of carbon on the local and global scale must be assessed for business models to have validity.

Policy option or recommendation:

The value of carbon must be determined to understand the impacts policy will have on commerce and state revenue. It will also be critical in order to design affective policy.

What research is being done/known?

Much research is being done on a national scale, yet understanding what the federal government will require is critical to the equation.

What are the gaps in research?

Pending regulation will have a huge affect on carbon values.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Oil and Gas

4.4.1.3

Economic: Potential impact of carbon mitigation efforts on royalty revenue stream coming to the State of Alaska from O&G production

Unique Identifier: 131

☑ Overarching Need

Why is this an issue?

Carbon mitigation costs will have a detrimental affect on the ultimate recovery of oil and gas in the state because of the, potentially large, impact on production costs and reduction of economically recoverable oil and gas.

Describe the scope of the research need:

Because the costs associated with carbon mitigation will be widely variant and dependant upon many factors, a broad scope of work must be accomplished.

Policy option or recommendation:

It is critical to understand the impacts of policy, if reasonable and non-damaging policy is to be developed

What research is being done/known?

A fair amount of national research is being done, but the impacts are very site specific.

What are the gaps in research?

Local variability and unique issue that will affect costs.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Oil and Gas

4.4.1.4

Technical: Regionally appropriate baseline mapping an monitoring of surface and subsurface (groundwater) hydrology

Unique Identifier: 127

☑ Overarching Need

Why is this an issue?

Most areas of the state do not have adequate data on hydrology and what the affects development might have on requirements and impacts of surface and subsurface water resources.

Describe the scope of the research need:

The need for hydrologic baseline research is ubiquitous across the state and includes water quality and quantity and is necessary for any type development, including renewable energy or sequestration.

Policy option or recommendation:

Affects on and availability of water resources must be considered in any policy development or recommendation.

What research is being done/known?

Relatively small areas of the state are now being mapped and analyzed, but are limited in extend.

What are the gaps in research?

Energy supply and demand, and any other associated with development.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

State and federal regulatory and research agencies and the University

TWG: Oil and Gas

4.4.1.5

Technical: Regionally appropriate baseline physical mapping and imagery including bathymetry

Unique Identifier: 126

☑ Overarching Need

Why is this an issue?

So much of the current research is based on a solid foundation of baseline topographic and basic mapping and remote sensing that it is difficult to perform modern analyses without up to date DEMs, orthoimagry, and detailed geologic mapping. Unfortunately, Alaska is woefully lacking in much of this most basic information, and when compared to all other states, and most other countries, Alaska is literally in the 'dark ages" when it comes to baseline data.

Describe the scope of the research need:

Numerous baseline data sets are needed

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☐ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Oil and Gas

4.4.1.6

CO2 storage: Evaluate capacity of geologic and biologic sequestration in different regions of the State of Alaska

Unique Identifier: 132

☑ Overarching Need

Why is this an issue?

Depending on what type of reductions mandates are adopted, understanding the capacity and location of viable sites, and the liabilities associated with those sites is critical.

Describe the scope of the research need:

The scope is limited to a few sequestration opportunities.

Policy option or recommendation:

Sequestration will be a limited option in many instances and should be carefully implemented. Government cannot mandate the existence of capacity

What research is being done/known?

The State DNR and federal DOE are enguaged in a statewide preliminary analysis.

What are the gaps in research?

Detailed subsurface information is lacking in most areas of the state that need capacity information once the federal and state mandates are set out.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy Supply and Demand

Research category/type:

☑ Modeling ☐ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Oil and Gas

4.4.2.1

Economic: Short and long term value of natural gas

Unique Identifier: 129

☐ Overarching Need

Why is this an issue?

Understanding the value of natural gas will allow a comparison of other forms of power generation at operations and will drive investment decisions on energy source.

Describe the scope of the research need:

The scope of this need is focused on oil and gas operations.

Policy option or recommendation:

What research is being done/known?

Research on this topic is likely being done within the industry and will have different parameters depending on company and location.

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy Supply and Demand

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

Industry and regulatory agencies

TWG: Oil and Gas

4.4.3.1

CO2 Storage: Evaluate enhanced hydrocarbon recovery options using CO2 flooding and pressure support

Unique Identifier: 134

☐ Overarching Need

Why is this an issue?

Enhanced Hydrocarbon recovery is one of the only CCS methods that derives economic benefit from the activity and increases ultimate recovery of a resource for the State.

Describe the scope of the research need:

The research on enhanced oil (EOR) and enhanced gas recovery (EGR) will be basin specific, and in many cases field specific.

Policy option or recommendation:

EOR and EGR feasibilities will help design incentive and regulatory programs

What research is being done/known?

Significant research in Nation, as well as within Alaska industry players.

What are the gaps in research?

How technologies can be applied to broader spectrum of fields, and specifically EGR.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

Industry, University, State Agencies, Federal Agencies

TWG: Oil and Gas

4.4.3.2

CO2 Storage: Evaluate the feasibility of saline reservoir sequestration in non-marine basins prevalent throughout Alaska

Unique Identifier: 133

☐ Overarching Need

Why is this an issue?

CO2 storage in saline reservoirs may become an issue in Alaska after conventional reservoirs are saturated, or in areas where no convention reservoirs exist (e.g., interior Alaska)

Describe the scope of the research need:

Saline reservoir sequestration research in Alaska must include long-term viability, EPA groundwater standards, liability issues, and existence of reservoir.

Policy option or recommendation:

It is important to understand the capacities of storages areas across the state for development planning purposes.

What research is being done/known?

A significant amount of research on this topic is underway nationally, but given the limited applicability in Alaska very little has been done.

What are the gaps in research?

Failure liability and technical feasibility are the greatest gaps in this research.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Oil and Gas

4.4.4.1

Technical: Feasibility of various entrained and exhaust CO2 capture technologies for North Slope and Cook Inlet

Unique Identifier: 121

☐ Overarching Need

Why is this an issue?

Capturing CO2 from various exhaust systems will be a challenging effort and will need many new technologies.

Describe the scope of the research need:

Very broad and semi specific to source type.

Policy option or recommendation:

What research is being done/known?

A significant amount of research is on-going for specific applications, but will not transverse all needs.

What are the gaps in research?

Different applications will require different parameters and it will be very difficult to capture all scenarios.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy Supply and Demand

Research category/type:

☐ Modeling ☑ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Oil and Gas

4.4.4.2

Technical: Study where renewable energy sources co-exist with Oil and Gas operations

Unique Identifier: 122

☐ Overarching Need

Why is this an issue?

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Transportation and Land Use

4.5.1.1

Development of statewide tools for planning

Unique Identifier: 166

☐ Overarching Need

Why is this an issue?

Need statewide planning tools to systematically evaluate GHG emissions on future scenarios

Describe the scope of the research need:

Develop tools that support scenario evaluation for planning options.

Policy option or recommendation:

NA

What research is being done/known?

Unknown

What are the gaps in research?

Scenarios need to be developed that are specific to the Alaskan environment. National level models don't work in Alaska. Alaska is a very diverse state geographically and we need models that can be applied to specific projects.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Transportation and Land Use

4.5.2.1

Understand carbon cycle from cradle to grave to see if reducing tail pipe emissions is worthwhile. The carbon-cost of creating fuel needs to be included in the evaluation.

Unique Identifier: 140

☐ Overarching Need

Why is this an issue?

Decision makers need complete information to make valid data driven decisions. If only part of the carbon cycle is considered, the economics of decisions may not be realistic.

Describe the scope of the research need:

For each type of fuel, assess the total carbon cycle, including carbon outputs in the Alaskan environment to ensure the reduction in tailpipe outputs of carbon are not negated by the cost of producing or transporting the alternative fuel.

Policy option or recommendation:

T-5. Promotion of Alternative Fuel Vehicles
T-10. Alternative Fuels Research and Develpment

What research is being done/known?

No known research is being done on Alaska specific conditions.

What are the gaps in research?

How does the Alaskan environment impact the benefits of using alternative fuel vehicles? Do the transportation requirements for getting alternative fuels to Alaska significantly diminish the benefits of using alternative fuel vehicles?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Transportation and Land Use

4.5.2.2

Analyze the life-cycle GHG impacts of various alternative fuels in the Alaska context. Better understanding of the life-cycle GHG benefits of alternative fuels in Alaska

Unique Identifier: 34

☐ Overarching Need

Why is this an issue?

The life-cycle GHG impacts of alternative fuels depend heavily on emissions from fuel production and transport. Nearly all research to date has focused on the lower 48. GHG impacts in Alaska could be quite different. Need to understand which alternative fuels have GHG benefits in AK.

Describe the scope of the research need:

At a minimum, analysis should be done for:
- natural gas
- biodiesel
- ethanol

Policy option or recommendation:

What research is being done/known?

Modeling for US is being by Argonne National Labs, but is not specific to AK. Some states (such as CA) have done state-specific modeling.

What are the gaps in research?

life-cycle GHGH impacts specific to AK.

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

Alaska state agencies, UA research centers, EPA, DOE

TWG: Transportation and Land Use

4.5.3.1

Development of methods or tools to accurately estimate GHG impacts of transportation plans in AK.

Unique Identifier: 36

☐ Overarching Need

Why is this an issue?

Transportation agencies will soon be required to quantify GHG impacts of transportation plans. Tools and methods are being developed for lower 48. But arctic climate in AK might affect the GHG emissions from motor vehicles and necessitate tools or methods that are adapted to AK.

Describe the scope of the research need:

Develop tools similar to those being developed for the lower 48 with a focus on Alaska and the arctic. This should include the differences in how Alaskan's use vehicles. Many Alaskan communities are accessible only via aircraft. While the high energy prices are driving rural citizens to migrate to urban areas, the GHG emissions associated with additional VMT may offset the GHG emissions from aircraft. Therefore, the variety of transportation modes used in different parts of Alaska must be built in to the models.

Policy option or recommendation:

T-6. VMT and GHG Reduction Goals in Planning

What research is being done/known?

National research being done for U.S. EPA, TRB, FHWA.

What are the gaps in research?

No Alaska or arctic specific research

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

Alaska DOT&PF, AMATS and FMATS

TWG: Transportation and Land Use

4.5.3.2

Investigate potential to reduce fuel use and GHG emissions by coordinating transportation networks and commercial fishery openings.

Unique Identifier: 35

☐ Overarching Need

Why is this an issue?

Excess fuel use and GHG emissions occur because of poor coordination of fishery openings.

Describe the scope of the research need:

Better understanding of the potential to reduce GHG emissions by coordinating transportation networks and commercial fishery openings.

Policy option or recommendation:

What research is being done/known?

None

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

Alaska Department of Energy; Alaska Board of Fisheries (BOF); Alaska DOT&PF

TWG: Transportation and Land Use 4.5.4.1

Determine GHG impacts of replacing older marine vessel engines with newer engines.

Unique Identifier: 37

☐ Overarching Need

Why is this an issue?

Newer marine engine have lower particulate matter emissions due to federal standards. But their effect on GHGs is uncertain.

Describe the scope of the research need:

Develop tools for better understanding of GHG impacts of modernizing marine vessel engines. Analyze the potential trade-off of reducing particulate pollution with GHG outputs.

Policy option or recommendation:

What research is being done/known?

May be recent or ongoing research by US EPA.

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

AK DEC; Alaska Board of Fisheries (BOF)

TWG: Transportation and Land Use 4.5.5.1

Evaluate the actual reduction of GHG from a pilot study of continuous descent approaches to Ted Stevens International Airport.

Unique Identifier: 139

☐ Overarching Need

Why is this an issue?

Aviation in Alaska has a disproportionate impact on GHG emissions compared to other forms of transportation. Focusing on aviation reductions may be an area where large reductions can be realized.

Describe the scope of the research need:

Real time activities are underway to enhance safety and reduce fuel usage on arrivals to Ted Stevens International Airport. Assessment of these activities should be undertaken to evaluate the impact to GHG emissions.

Policy option or recommendation:

T-9. Aviation Emissions Reduction

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☐ Products ☐ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Transportation and Land Use

4.5.6.1

Analysis to determine what is required to increase citizen use of public transportation and increase conservation efforts.

Unique Identifier: 167

☐ Overarching Need

Why is this an issue?

Need to understand what actions by the government result in greater use of public transportation and greater conservation efforts.

Describe the scope of the research need:

Policy option or recommendation:

T-1. Transit, Ridesharing, and Commuter Choice Programs

What research is being done/known?

Unknown

What are the gaps in research?

Unknown

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☐ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.1

Develop higher resolution climate modeling and monitoring data and improve its accessibility and utility.

Unique Identifier: 88

☑ Overarching Need

Why is this an issue?

This need is common among nearly all the TWG. To assess and plan for changing economic conditions as a result of a changing climate will require higher resolution climate modeling and monitoring information at more local levels. Additionally, there is a need to increase the accessibility and utility of these data to government officials and businesses. Finally, there is a need to tailor these data to the needs of government officials and businesses.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.2

Assess statutory, regulatory, and policy frameworks and barriers to implementing climate change policy recommendations.

Unique Identifier: 89

☑ Overarching Need

Why is this an issue?

Many laws, regulations and policies on the federal, state, and local levels were developed before the signs of more rapid climate change were recognized. For example, resource managers in Alaska may need to revise Alaska policies relative to wildland fire management in light of the effects of climate change. Another example is the need to modify water quality standards that call for maintenance of water temperatures in cold water systems in light of warming temperature. The challenge for government leaders and businesses will be to adapt to a future made less certain due to a more rapidly changing climate. This will necessitate an evaluation of existing laws, regulations and policies and possible changes to institutional, legal and policy frameworks in an adaptive manner.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.3

Assess economic impacts of market-based approaches (e.g., cap and trade) to manage greenhouse gas (GHG) emissions and their impacts on the Alaskan economy.

Unique Identifier: 90

☑ Overarching Need

Why is this an issue?

Market-based approaches to manage GHG emissions can have a significant impact on many aspects of the Alaskan economy. It will be imperative to track these approaches as they develop and to proactively formulate strategies to adopt state approaches and, if necessary, adapt to adopted approaches.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.4

Systematically identify and address economic barriers to implementing climate change planning efforts

Unique Identifier: 91

☑ Overarching Need

Why is this an issue?

Uncertainty associated with climate change may result in barriers to implement identified climate change strategies/options and planning efforts. It is important to identify these barriers and strategies for addressing them. The uncertainty and risk of the current predictions should be well understood and incorporated in the decision process.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.5

Assess data and information (economic indicators) needed to develop or adapt short and long term planning tools to assess impacts of climate change on economic activities.

Unique Identifier: 92

☑ Overarching Need

Why is this an issue?

There is a lack of baseline economic information and data needed to develop or adapt both short and long term planning tools to implement identified climate change strategies and options. It is critical to identify and collect the needed economic indicators.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.6

Implement adaptive (scenario-based) planning tools that integrate economic indicators to improve climate change mitigation and adaptation decision-making and implementation.

Unique Identifier: 93

☑ Overarching Need

Why is this an issue?

Successful implementation of climate change strategies/options will require development and implementation of adaptive planning tools. These tools need to be probabilistic and scenario-based and integrate economic indicators.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.1.7

Catalog and assess new or expanded economic opportunities that may become available with climate change.

Unique Identifier: 94

☑ Overarching Need

Why is this an issue?

While some existing economic activities may be deleteriously affected by a changing climate, others may be benefited while still others may become established. For example, a warming climate may open new economic opportunities in the Arctic basin, including commercial fishing and transpolar shipping. A necessary first step towards developing these opportunities is to catalog and assess them.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.10.1

Assess how climate change will impact application of federal, state, and local laws, regulations and policies on energy demand and use.

Unique Identifier: 172

☐ Overarching Need

Why is this an issue?

Climate change legislation will impact application of federal, state, and local laws, regulations and policies on energy demand and use. For example, increased pressure to reduce GHG will have impacts on laws, regulations, and policies related to natural resources. For this reason it is imperative to assess how climate change will impact application of federal, state, and local laws, regulations and policies on energy demand and use.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.11.1

Assess how climate change will impact application of federal, state, and local laws, regulations and policies on economic development activities.

Unique Identifier: 173

☐ Overarching Need

Why is this an issue?

Climate change legislation will impact application of federal, state, and local laws, regulations and policies on economic development activities. For example, increased Arctic shipping and resource development will have impacts on laws, regulations, and policies related to natural resources and indigenous people. For this reason it is imperative to assess how climate change will impact application of federal, state, and local laws, regulations and policies on economic development activities.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.12.1

Continue to refine the "Cost of Climate Change" study recently completed by the UAA ISER.

Unique Identifier: 174

☐ Overarching Need

Why is this an issue?

The University of Alaska Institute of Social and Economic research is conducting a study to assess the costs of climate change to Alaska. This is an overarching economic analysis of the climate related impacts. This study should be completed.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.12.2

Identify climate trends and downscale models leading to establishing environmental information, analysis tools, and design criteria for use in adapting to climate change.

Unique Identifier: 175

☐ Overarching Need

Why is this an issue?

This need is common among nearly all the TWG. To assess and plan for changing economic conditions as a result of a changing climate will require higher resolution climate modeling and monitoring information at more local levels. Additionally, there is a need to increase the accessibility of these data to government officials and businesses. Finally, there is a need to tailor these data to the needs of government officials and businesses.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.12.3

Provide resources for good Digital Elevation Model (DEM) and GIS data, and current and high resolution imagery to establish a more robust information infrastructure to plan and adapt.

Unique Identifier: 176

☐ Overarching Need

Why is this an issue?

There is a need for improved Digital Elevation Model (DEM) and GIS data, and current and high resolution imagery to establish a more robust information infrastructure to plan and adapt. This information is needed to develop down-scaled models and to assess potential economic impacts.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.12.4

Invest in monitoring and data dissemination programs to enhance information available for safe and efficient resource development.

Unique Identifier: 177

☐ Overarching Need

Why is this an issue?

Much data is currently available but for a variety of reasons is unavailable to researchers or decision-makers. There is an urgent need to invest in monitoring and data dissemination programs to enhance information available for safe and efficient resource development.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.2.1

Develop economic analysis of potential rise or decline of oil and gas development on state revenues.

Unique Identifier: 95

☐ Overarching Need

Why is this an issue?

Oil and gas production provides significant revenues to Alaska. As such, any changes to oil and gas production can be expected to have significant impacts to the Alaskan economy. Climate change and resultant efforts to mitigate for it, or adapt to it, is expected to have impacts to oil and gas production. For example, development of cap and trade programs could have significant impacts on oil and gas production. Given the likelihood of such impacts it is imperative to develop economic analysis of potential rise or decline of oil and gas development on state revenues.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy Supply and Demand

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.2.2

Consider how potential rise or decline of oil and gas operation and maintenance may affect state revenues.

Unique Identifier: 96

☐ Overarching Need

Why is this an issue?

Climate change is expected to have impacts on oil and gas operations and maintenance. Under current tax structures, operation and maintenance costs can influence the amount of revenue the state receives from production. For this reason, it is important to determine how potential rise or decline of oil and gas operation and maintenance may affect state revenues.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Oil and Gas

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.2.3

Model coastal vulnerability to establish criteria for pipeline coastal transition set-backs and burial depths.

Unique Identifier: 97

☐ Overarching Need

Why is this an issue?

Climate change is expected to impact coastal zones through erosion and coastal inundation. This will require an assessment of the current permitting and oversight of pipelines and other operations in the coastal zone. This assessment will require a modeling of coastal vulnerability to establish criteria for pipeline coastal transition set-backs and burial depths.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Public Infrastructure and Oil and Gas

Research category/type:

☐ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.2.4

Expand research on ice road and pad construction techniques and in-season monitoring to maximize seasonal use and minimize impacts.

Unique Identifier: 98

☐ Overarching Need

Why is this an issue?

Climate change is impacting the length of time ice roads and pads can be used on the North Slope of Alaska. Expanded research on ice road and pad construction techniques and in-season monitoring is needed to maximize seasonal use and minimize impacts.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Public Infrastructure and Oil and Gas

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.2.5

Expand research on climate change impacts on permafrost engineering design.

Unique Identifier: 99

☐ Overarching Need

Why is this an issue?

Permafrost is being impacted by climate change. These impacts are affecting existing and planned structures. Design standards are inadequate to address these impacts. Expanded research on climate change impacts on permafrost engineering design is needed.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Public Infrastructure and Oil and Gas

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.2.6

Develop new techniques to clean up oil spills in icy waters.

Unique Identifier: 100

☐ Overarching Need

Why is this an issue?

There is an interest in developing offshore oil and gas in Arctic areas. This increases the potential for oil spills in offshore areas that are being impacted by changing ice conditions associated with climate change. There is a need to develop new techniques to plan for and clean up oil spills in icy waters.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Oil and Gas

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.3.1

Assess economic potential for developing carbon-neutral energy sources

Unique Identifier: 101

☐ Overarching Need

Why is this an issue?

Federal legislation may likely call for a larger proportion of energy production to come from carbon-neutral sources (definition, e.g. including forest materials). In Alaska, little is known about the economic potential for developing carbon-neutral energy sources. Given this, it is imperative to assess the potential for developing carbon-neutral energy sources.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy Supply and Demand

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.3.2

Identify potential economies of scale and return on investments in developing renewable energy sources.

Unique Identifier: 102

☐ Overarching Need

Why is this an issue?

Little is known about the long-term economics associated with renewable energies. As there is an increased call for shifting energy production to renewable energy sources it is important to identify potential economies of scale and return on investments in developing renewable energy sources. This will allow better decision tools to be developed to inform the economic impacts of renewable energy sources.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Energy Supply and Demand

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.4.1

Research cost-effective techniques for construction, operation, and reclamation that will be responsive and useful in changed environmental conditions.

Unique Identifier: 103

☐ Overarching Need

Why is this an issue?

Energy conservation and renewable energy alternatives require metals and metal alloys. As renewable energies increase, this will increase the demand for metals. Since Alaska has world class metal resources, it can be expected that there may be increased interest in mining. It will be important to research cost-effective techniques for construction, operation, and reclamation that will be responsive and useful in changed environmental conditions.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Public Infrastructure, Natural Systems, Energy Supply and Demand.

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.4.2

Assess engineering standards for tailings storage in Arctic/Subarctic climates.

Unique Identifier: 104

☐ Overarching Need

Why is this an issue?

Energy conservation and renewable energy alternatives require metals and metal alloys. As renewable energies increase, this will increase the demand for metals. Since Alaska has world class metal resources, it can be expected that they will be increased interest in mining. As new mines are developed it will be important to assess engineering standards for tailings storage in Arctic/Subarctic climates.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Public Infrastructure, Natural Systems, Energy Supply and Demand

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☐ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.4.3

Develop economic analyses of potential rise or decline of mining and impact on state revenues.

Unique Identifier: 105

☐ Overarching Need

Why is this an issue?

Energy conservation and renewable energy alternatives require metals and metal alloys. As renewable energies increase, this will increase the demand for metals. Since Alaska has world class metal resources, it can be expected that they will be increased interest in mining. As this demand increases it will be important to develop economic analyses of potential rise or decline of mining and impact on state revenues.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Public Infrastructure, Natural Systems, Energy Supply and Demand

Research category/type:

☑ Modeling ☐ Products ☑ Education/Outreach ☐ Data Management ☐ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.5.1

Model sea ice and its effect on ocean transportation.

Unique Identifier: 106

☐ Overarching Need

Why is this an issue?

Climate change is reducing sea ice in the Arctic at varying rates. It is important to model sea ice and its effect on ocean transportation.

Describe the scope of the research need:

Policy option or recommendation:

What research is being done/known?

What are the gaps in research?

If this is a Cross-Cutting issue, what other topics (TWGs) does it apply to?

Natural Systems, Public Infrastructure

Research category/type:

☑ Modeling ☑ Products ☑ Education/Outreach ☑ Data Management ☑ Monitoring

Parties involved in implementation:

TWG: Economic Activities

5.1.5.2

Develop economic analysis of potential rise or decline of shipping and impact on state revenues.

Unique Identifier: 107

☐ Overarching Need

Why is this an issue?

Climate change is reducing sea ice in the Arctic, creating economic opportunities and localized costs. It is important to assess the impacts of increased shipping to Alaska and its economy.
