ABSTRACT: The Kenai River drainage supports the largest recreational fishery in Alaska and is a major contributor to the Cook Inlet commercial sockeye salmon fishery. In 1992, for example, the Kenai River recreational and commercial fisheries contributed over \$70 million to the state economy. The nearshore waters of the Kenai River mainstem provide critical rearing habitat for over 90 percent of the Kenai River chinook salmon population. These nearshore waters and associated shorelands habitats have been substantially altered by commercial, residential, and recreation uses and activities. The public and agencies are concerned with the cumulative effects of past and future uses and activities on fish habitat. The State of Alaska initiated a study in July 1992 under the Section 309 Program as a Project of Special Merit to assess and control these impacts. By June 1994, the following will be completed: 1) a cumulative impact assessment methodology, 2) an initial impact assessment and evaluation of the assessment methodology, 3) a summary of potential non-regulatory mechanisms to control these impacts, and 4) an analysis of the socioeconomic importance of commercial and recreational fisheries to the local economy. The local coastal district will also initiate efforts to develop draft enforceable policies.

The qualitative analysis and resulting model to evaluate the effects of structures (i.e., river and riparian habitat alterations) requires substantial information on the effects of such structures on natural physical processes (e.g., erosion, sedimentation, deposition) and important habitat parameters (e.g., water velocity, substrate, cover). A comprehensive literature review by the Fish and Wildlife Service (FWS) revealed little information on the effects of structures on physical processes and habitat parameters important to fish. In the absence of this data, the Alaska Department of Fish and Game (ADF&G) cannot complete the qualitative impact assessment. This information is necessary to win public support of the specific enforceable policies necessary to effectively control cumulative impacts. In State Fiscal Year 1995 (SFY95) -- the third year of the project -- the ADF&G proposes to address this information gap and complete the qualitative assessment (Task 1). Information on the effects on physical processes and habitat parameters will be used to develop models and complete the qualitative assessment of the effects of structures on fish habitat. A joint hydrologist/biologist team will conduct the evaluation. ADF&G will make appropriate revisions to the Geographic Information System (GIS) and develop models used in the assessment.

The ADF&G, in coordination with local government, will also design an integrated approach for the continued assessment and management of cumulative impacts (Task 2). ADF&G will design and recommend an integrated approach to evaluate and improve the Kenai River cumulative impact problem statements, data, analytical tools, management approaches, and models. The project will identify authorities governing uses and activities that effect fish habitat; identify problems, needs, and priorities for future assessment and management of cumulative impacts; evaluate the applicability of ADF&G's Kenai River GIS to the integrated management approach; and identify potential funding sources for the ongoing assessment and management approach.

The primary focus of Alaska's Revised Section 309 Strategy is a proactive approach to assess, plan for, and minimize the impacts of activities on coastal resources and uses. The Kenai River is identified in the Strategy as a possible model for other coastal districts. This project should enhance other Section 309 projects related to cumulative impact issues in Alaska. The use of GIS in cumulative impact assessment, and revisions to ACMP regulations to more effectively assess and manage cumulative impacts will benefit from this SFY95 proposal.

PROJECT NARRATIVE

INTRODUCTION

The Kenai River drainage supports the largest recreational fishery in Alaska and is a major contributor to the Cook Inlet commercial sockeye salmon fishery (2.5 to 9.0 million fish annually). In 1992, the Kenai River commercial and recreational fisheries contributed an estimated \$70 million to Alaska's economy. The river provides critical habitat for several species of salmon. Over two thirds of the 50 miles of the shorelands adjoining the Kenai River mainstem below Skilak Lake are privately owned (see Attachment 1 for study area map). Much of the river and adjacent shorelands on both private and public lands are developed, or will be subject to future recreational, commercial, and residential developments or uses. Biologists, land managers, and many users of the Kenai River are concerned about the cumulative impacts of past and future development and other uses on salmon rearing habitat. Rearing habitat is the primary limiting factor in the production of chinook salmon in the Kenai River system. Over 90 percent of the chinook salmon population in Kenai River drainage rear within six feet of the shoreline of the Kenai River mainstem: an estimated 67 acres of suitable habitat.

Alaska's Section 309 Assessment and Strategy emphasizes the proactive assessment and management of cumulative impacts through planning, and identifies the Kenai River as an area of concern. A comprehensive approach to an assessment and management planning process, as described by Williamson¹, involves: (1) a *scoping phase* to define the problems and select a strategy for each program; (2) an *analysis phase* to assess the problems and their causes; (3) an *interpretation phase* to develop and document options, estimate changes with models, and develop a plan and implementation approach (both regulatory and non-regulatory mechanisms); and (4) a *direction phase* to implement and incrementally approve a management plan and systematically evaluate and improve the problem statements, data, analytical tools, and models.

In SFY93, the ADF&G received Project of Special Merit (PSM) funding under Section 309 for a study to assess and control the cumulative impacts² of uses and activities on Kenai River fish habitat. In the first year of the project, ADF&G completed the scoping phase (defined the problem, identified the study area, and developed an assessment methodology), initiated the analysis phase (assessment of cumulative impacts), and summarized available non-regulatory mechanisms for controlling individual and cumulative impacts. Now in the second year (SFY94) of the project, ADF&G will complete the initial cumulative impact analysis based on available information, evaluate the assessment methodology and develop project approvals for activities which maintain or enhance fish habitat. The local coastal district -- the Kenai Peninsula Borough (KPB) -- will complete a socioeconomic analysis of the importance Kenai River chinook and sockeye salmon fisheries to the KPB economy and start the interpretation phase (initiate revisions to the enforceable policies of the local coastal management plan).

¹ Williamson, S.C. 1993. Cumulative Impacts Assessment and Management Planning: Lessons Learned to Date. in *Environmental Analysis: The NEPA Experience*. Lewis Publishers, Ann Arbor, pp. 391-407

² The concept of cumulative impacts embodies a number of related but different kinds of effects: direct, indirect, secondary, additive, and synergistic (see: Riser, A. 1987. Managing the Cumulative Effects of Coastal Land Development: Can Maine Law Meet the Challenge? *Maine Law Review*, 39(2): 321-389). Due to funding and practical constraints, the assessment methodology will not address all these effects. The cumulative impact assessment report in SFY94 will describe the focus of the assessment methodology.

In SFY95, the state is proposing to complete efforts on the interpretation phase and design an approach for the direction phase. Through Section 306 funding, the KPB will continue efforts to review and revise the enforceable policies of the KPB Coastal Management Program (CMP) to more effectively control cumulative impacts. In the third year through Section 309 funding, the project will complete two main tasks listed below:

Task 1:

- Evaluate the effects, both upstream and downstream, of selected structures on physical processes and fish habitat parameters.
- Develop habitat evaluation models to evaluate the habitat effects of past actions, support the development of specific enforceable policies, and evaluate the effects of future actions.

Task 2:

- Design and recommend a multi-agency, integrated approach to evaluate and improve Kenai River cumulative impact problem statements, data, analytical tools, management approaches, and models.

A comprehensive management and implementation approach will require use of regulatory and non-regulatory/cooperative implementation mechanisms. Given available funding and the focus of the Section 309 program towards "program changes," the Kenai River Section 309 project has and will continue to focus on the technical cumulative impact assessment and management through regulatory means. Program changes that will result from the SFY95 project (with previous year efforts) include revisions to KPB CMP enforceable policies and additional or revised B-list projects³. This project will lay the foundation for the development of Memoranda of Agreement (MOAs) or Understanding (MOUs) among participating local, state, and federal governmental agencies in outyears.

Non-regulatory or cooperative conservation approaches that can be used to control cumulative impacts will be addressed under other sources of funding. In SFY94, through Environmental Protection Agency (EPA) funding, the department will 1) identify wetlands and uplands important for maintaining the health of the Kenai River watershed, 2) assess public attitudes towards Kenai River watershed protection, and 3) develop recommendations for a full range of cooperative conservation strategies for the identified uplands. ADF&G is also seeking funding from EPA in SFY95 to 1) identify additional sources of financial and human resources support to develop cooperative conservation efforts and 2) design and hold a watershed conservation conference for public education and consensus-building of cooperative watershed conservation strategies. The Section 309 assessment/policy development efforts and the EPA non-regulatory efforts are complementary. As the lead on both projects, ADF&G will ensure that projects are coordinated.

³ ACMP regulations provide for classification of permits and approvals based upon the potential for impact on coastal resources and uses. A "B-List" project is a type of project that includes routine activities that can be made consistent with the ACMP by imposing standard stipulations on applicable permits. In this project, we will develop project descriptions and standard conditions for permitted uses and activities that protect, restore, or enhance fish habitat.

Loving A River To Death

Habitat Changes On The Kenai River

By Terry Bendock and Jon Lyman

©Russ Dixon/ADF&G

The survival of the Kenai River's world famous king salmon depends upon water flows of less than one foot per second. Although the adult fish have little trouble swimming against swift flows, the young require the reduced velocity and cover provided by naturally vegetated banks to survive. Each spring, young chinook and coho salmon migrate from upriver areas where they were hatched to the rich feeding grounds along the mainstem. Each fall they return to

Paid for by Division of Sport Fish
Produced by Public Communications Section

Users Impact on Fish Habitat

Private and commercial developments eliminate riparian vegetation. This weakens the streambank and reduces cover and food for juvenile salmon.

Land clearing increases subsurface drainage rates and streambank erosion.

Structures along the shoreline alter water velocity and decrease useable habitat for juvenile salmon.

Draining wetlands reduces subsurface flow and nutrients for juvenile salmon.

Boat wakes increase erosion along banks where the vegetation has been damaged.

Foot trails damage vegetation and root systems increasing the risk of erosion.

Removing log jams and woody debris eliminates important rearing habitat for young salmon.

Parking riverboats along the shoreline often results in damaged vegetation and increased erosion.

Steep banks and water-saturated soils are subject to erosion and are easily damaged by **foot traffic**.

Unfiltered runoff from city and state highways and parking lots is discharged directly into the Kenai River-- lowering water quality.

You only hurt the one you love

Flooding on Kenai, Bing's Landing, August 1984.

overwinter in Skilak, Kenai, and other lakes. The role of streambank vegetation in modulating flow speed and providing cover is essential to the successful upriver journey of the young fish.

The Alaska Department of Fish and Game has long focused on managing the Kenai River's returning populations of adult salmon to ensure adequate numbers of spawners to reproduce the runs. Given good returns from the Pacific Ocean, management plans and modern technology assure us that sufficient salmon will survive to spawn. This, however, is only part of the picture. We must also be concerned with the young fish rearing in the river and the continuing degradation of their habitat.

Natural vegetation that overhangs the banks or trails in the water provides food for aquatic organisms which juvenile salmon eat. Natural vegetation also stabilizes banks and helps prevent erosion.

Cover is the woody vegetation along the shoreline, irregular and undercut banks, aquatic vegetation, log jams, large woody debris, rootwads, sweepers, large rocks or boulders, and the turbidity of the glacier water itself. Cover slows the speed of the river along the streambanks, creating ideal flows for young fish. Over 80 percent of the young salmon in the Kenai River can be found within 6 feet of the bank.

The one you shouldn't hurt at all

Bankbank erosion at King's Landing, July 1992.

Anglers cannot influence most of the forces that affect the return of salmon to the Kenai River. High seas interruption, harvests in inland sock commercial fisheries, the use or misuse of private and public property along the river, natural mortality due to forces we do not understand—all have a great impact on the numbers of returning salmon. The one place where anglers can have the greatest long term impact on these fish is on the banks of the river.

Anglers and landowners need to participate in local land use planning efforts to develop public solutions to the continued degradation of river habitat. The key to maintaining the long term health of the Kenai River is the development of land use

Anglers Can Reduce Impacts

Use developed trails, ladders, and boardwalks, when available, to access the river.

Always launch and retrieve boats at a developed launch site.

Select either an exposed or protected site when beaching your boat to avoid eroding bank vegetation.

Minimize damage from boat wakes whenever possible by lowering speed and traveling in mid-channel.

Fuel your boat at a site that does not discharge into the river should an accident occur.

Avoid trampling and damaging vegetation along the waters edge.

Move away from the waters edge when walking up and downstream.

Use hip boots or chest waders to avoid standing on the bank while fishing.

Avoid steep banks and water-saturated soils when bank fishing.

Remember that fish habitat and bank stability are often determined by the amount and quality of streamside vegetation.

Participate in local discussions on land use regulations and the need to protect fish habitat.

Tell friends and visitors of the importance of minimizing shorebank.

Be a role model!

regulations to control incompatible uses along the river. While the Division of Parks and the city of Soldotna are attempting to regulate bank use on their lands, other landowners, public and private, have yet to take action to protect the habitat necessary for fish. By working with the following organizations, individuals can begin to shape the future of the river and its salmon resources. (See list of on the next page.)

Kenai River Special Management Area Advisory Board
c/o Chris Titus, Division of Parks and Recreation
Department of Natural Resources
PO, Box 1247
Soldotna, AK 99669

In 1984 the Legislature recognized the importance of the Kenai River to all Alaskans and created the Kenai River Special Management Area. An advisory board was formed to help the Division of Parks and Recreation implement a management plan for the river. The board members represent user groups, property owners, municipalities, state and federal agencies, and other interested groups. The board continues to serve in its advisory capacity and holds monthly meetings except during the summer months.

City of Soldotna
177 North Birch
Soldotna, AK 99669

The city of Soldotna has zoned the banks of the Kenai within the city limits and has the authority to regulate land use to protect the river. The city has begun work on a Kenai River erosion control and habitat restoration demonstration project. Funded with grants from the Alaska Science and Technology Foundation and the Coastal America Program, the city is attempting to apply bioremediation technology to damaged river habitat at two city parks along the Kenai River. These sites have seen intense bank fishing which has degraded vegetation and accelerated bank erosion. The project is intended to demonstrate ways to control riverbank erosion and enhance fish habitat while continuing to allow anglers access to the river.

Kenai River Sportfishing, Inc.
c/o Ben Ellis, Executive Director
PO, Box 1228
Soldotna, AK 99669

Kenai River Sportfishing, Inc. (KRSI) is a non-profit association dedicated to protecting the greatest salmon sport fishing in the world. The organization represents the thousands of sport anglers who fish the Kenai each year. KRSI members have long been involved with conservation measures on the river. This group launched the Kenai River Habitat Protection Program during the past year. The program awards certificates to private property owners who protect or restore fish habitat. It also works to educate the public and encourage other property owners to protect and restore river habitat.

Department of Natural Resources
Division of Parks and Outdoor Recreation
PO, Box 1247
Soldotna, AK 99669

The Kenai River became a unit of the state parks system in 1984. The Division of Parks and Outdoor Recreation has the

responsibility for providing for the public's recreation as well as for protecting and preserving the river's fish and wildlife habitats. Serious riverbank degradation has occurred as a result of intensive bank fishing at most of the public access areas along the river. Many areas are devoid of vegetation, their banks trampled into mud. The challenge is to protect the fragile riparian habitat and rehabilitate the existing sites, yet continue to provide public access.

Soil Conservation Service
PO, Box 409
Homer, AK 99603

The U.S. Department of Agriculture Soil and Conservation Service has published the Kenai River Landowner's Guide. This reference guide is written to help Kenai River landowners understand and manage plants, soils, and riverbanks and to protect the Kenai River's resources. The SCS collects resource information and provides technical assistance to help both public and private land managers conserve, improve, and sustain natural resources.

Kenai River King Salmon Fund

Habitat Division
333 Raspberry Rd.
Anchorage, AK 99508

The Alaska Department of Fish and Game has a statutory mandate to protect fisheries habitat in the Kenai River. Any persons or agency wishing to construct a project below ordinary high water must submit plans and specifications to the department and obtain a permit before proceeding.

The Alaska Department of Fish and Game collects all programs and activities free from discrimination on the basis of sex, color, race, religion, national origin, age, marital status, pregnancy, parenthood, or disability. For information on alternative formats available for this and other department publications, please contact the Department ADA Coordinator at (voice) 907-467-6126, (TDD) 1-800-478-3048 or (fax) 907-596-6206. Any person who believes s/he has been discriminated against should write to: 4310465, 465 Box 20526, Homer, AK 99602-0526 or 6440, U.S. Department of the Interior, Washington, DC 20340.

The Alaska Department of Fish and Game encourages public interest and involvement in local land use planning efforts. We all need to help find solutions to allow for development that will not degrade Alaska's rivers for fish.

EXECUTIVE SUMMARY

AN ASSESSMENT OF THE CUMULATIVE IMPACTS OF DEVELOPMENT AND HUMAN USES ON FISH HABITAT IN THE KENAI RIVER

Technical Report No. 94-6

Prepared by:

**Gary S. Liepitz
Habitat Biologist**

**Alaska Department of Fish and Game
Habitat and Restoration Division
333 Raspberry Road
Anchorage, AK
99518-1599**

July 1994

EXECUTIVE SUMMARY

The Kenai River Cumulative Impacts Assessment of Development Impacts on Fish Habitat, was funded in part by the Alaska Coastal Management Program's (ACMP) Section 309 Enhancement Grant Program. This study was designed to identify and evaluate the cumulative impacts of development actions including public and private land use impacts on Kenai River fish habitat. The Alaska Department of Fish and Game (ADF&G) established a Technical Advisory Group (TAG) to help define the issues and identify an acceptable methodology to be used for the assessment. The TAG was composed of representatives from all state and federal resource agencies with regulatory and management responsibilities on the Kenai River. The TAG was provided a summary of the results of the ADF&G's literature search of cumulative impact methodologies. The ADF&G also recommended the TAG consider the use of the U.S. Fish and Wildlife Service's (FWS) developed Habitat Evaluation Procedures (HEP) as the process to be used for the impacts analysis portion of this study. The group concurred with this recommendation. They concurred with the ADF&G recommendation for the development of a habitat classification process for the Kenai River's fish habitats that incorporates a combination of assessment techniques including aerial photograph assessment, field inventory, and the use of a Geographic Information System (GIS) for data compilation and analysis.

Existing mapped and/or digitized data for land ownership, soils and vegetation types were obtained through the Soil Conservation Service (SCS) and the Kenai Peninsula Borough (KPB). This information was edited and stored for use in our assessment efforts on the GIS at the ADF&G's regional office in Anchorage. Information from this data set was edited and provided to the SCS for inclusion in their technical report.

Field data compilation and ground truthing of aerial photograph interpretation data was initiated during the fall 1992 low water period and was completed during the summer and fall of 1993. The field survey resulted in an inventory of existing bank and fish habitat conditions occurring along the entire 67 miles of Kenai River mainstem from the outlet of Kenai Lake to the Skilak Lake inlet and from Skilak Lake's outlet downstream to its confluence with Upper Cook Inlet near the City of Kenai. All natural and disturbed bank habitat conditions were inventoried using a field data inventory form and color photo documentation. Data collected included vegetation type and coverage at both the river's ordinary high water (OHW) mark and the top of bank, nearshore substrate composition, fish cover characteristics, and documentation (description and measurement) of all structures and bank alterations observed. Positions were confirmed using Global Position Satellite (GPS) receivers that were differentially corrected to a resolution of 10.0 feet.

The diverse habitat types occurring along the river's 67 mile length (approximately 166 miles of water frontage) provide a varying degree of habitat value to juvenile salmon. The nearshore waters of the Kenai River provide critical early life stage rearing habitat for juvenile chinook salmon during that period of the year when these fish are using this important part of the river

(this included the late spring, summer and early fall period). Mainstem rearing habitat within the Kenai River, which occurs primarily in a very narrow (6.0 foot wide) corridor adjacent to the river's banks, has been described in previous studies by the ADF&G and FWS. ADF&G surveys of fish rearing habitat indicates that over 80 percent of all rearing juvenile chinook are found within this corridor. The total area within this narrow corridor including both the river's upland and island shorelines amounts to a mere 121 acres. It should be noted, however, that much of this 121 acres does not constitute preferred juvenile chinook salmon rearing habitat because: a) it is a tidally influenced reach with brackish water conditions and no cover habitat or lacks an adequate food source; b) it is naturally unsuitable to rearing juvenile salmon due to high water velocities and/or a lack of cover habitat; c) alteration of natural conditions by man associated with river access have led to vegetation loss and/or bank erosion; or d) the nearshore fish habitat has been degraded as a result of bank stabilization and property protection efforts.

The field inventory and fish habitat classification analysis completed in this study has documented that 11.1 percent to 12.4 percent (18.4 to 20.6 miles) of the river's 134 miles of upland and 32 miles of island shoreline and nearshore habitats have been impacted by bank trampling, vegetation denuding, and structural development along the river's banks. The two different lengths or percentages cited above relate to the habitat impacts measured at either the OHW line or at the top of the bank. Optimum fish rearing conditions (i.e., water velocities less than 1.0 foot per second, undercut banks with overhanging vegetation, and gravel/cobble substrates) occur on only 80,440 feet (15.2 miles or 9.2 percent) of this important fish rearing corridor along the entire river length. Study results indicate that 63,299.0 feet (12.0 miles) of this corridor is currently in the developed/impacted category, amounting to approximately 8.7 acres of the total 121 acres of available juvenile rearing habitat. The sum of the impacted or altered habitats (8.7 acres) plus the lower quality habitat for rearing fish (which includes all of the Kenai River 309 Study's Reach 1 or lower 10 miles of river nearshore habitat)(15.7 acres) and the heavily trampled/denuded areas documented on the river (5.1 acres) equals 29.5 acres or 24.4 percent of the river's total nearshore habitat. This leaves a total of 91.5 acres (75.6 percent) of mainstem nearshore rearing habitat for juvenile fish of which only 11.0 acres (9.2 percent) provide their ideal rearing conditions.

The field inventory data was entered into the GIS database for tabulation and graphical analysis. The tabulated data was then used to complete a Habitat Evaluation Procedure (HEP) analysis. HEP converts both the natural and developed habitat areas into a relative value for fish habitat. HEP was developed as a tool to document the quantity and quality of available habitat for a selected fish and/or wildlife species in a given area and uses a species/habitat relationship approach to impact assessment. HEP identifies key habitat components for a species of interest (e.g., an indicator species) which are used for a comparison of existing or future habitat conditions to the optimum habitat conditions for that species.

The HEP assessment approach is based on the fundamental assumption that certain specified habitat parameters can be described numerically and ranked. This ranking allows for the comparative analysis of habitat change over time resulting from individual or multiple development projects or other habitat altering activities (e.g., public and private access, recreational uses, etc.). Comparative analysis determines the overall impact of habitat change

within a system in terms of net gain or loss of habitat units (HU's) associated with these activities.

HEP characterizes habitat quality using a Habitat Suitability Index (HSI) value. HSI's are derived from established or project-developed Suitability Indices (SI) or Curves. The HSI is a numerical value ranging from 0.0 to 1.0 and is generated from an analysis of the ability of key habitat components to supply the life requisites of the indicator species. HSI's assign a value to a species' key habitat component(s) or variables. This value represents that habitat component's relative importance to the evaluation species and is based upon what is considered optimum habitat for that species.

Overall habitat impact can be assessed by calculating the gain or loss of Habitat Units (HU's) associated with a land use or development action affecting fish habitat. Mean HSI values (the sum of all the suitability index values identified for a species' individual habitat components divided by the total number of habitat component SI's defined) are used to calculate the HU's available for the species of concern. The mean HSI values, which are calculated for the habitat conditions occurring as a result of a project or use that has changed the naturally occurring habitat characteristics, are multiplied by the area affected by the habitat altering activity. The product of this calculation defines the HU's available to the indicator species as a result of the activity. The HU's can be used for comparative analysis or an assessment of the amount of habitat gained or lost to the overall system resulting from an action or group of actions which has or will likely affect the system.

Study results indicate that there are 1,482,790 HU's currently available to juvenile chinook salmon in the Kenai River mainstem (see Table 14). These units are distributed throughout six different undeveloped shoreline habitat categories and another six developed shoreline or structures categories. These fish habitat classification categories include: ideal rearing habitat, vegetated undeveloped habitat, vegetated slightly degraded habitat, heavily degraded habitat, non-eroding gravel banks, and erosional gravel banks. The developed categories include: boat launches and access; docks, decks, and other structures; bank protection measures; bulkheads; jetties and groins; and "other development".

Of the total 877,070 feet (166.1 miles) of waterfront on the river, 813,775 feet (154.1 miles) is in a natural state and provides 1,416,783 HU's for rearing chinook salmon. There is currently another 63,299.0 feet (12.0 miles) of water frontage in some form of developed status which, while providing less favorable conditions for rearing fish than that of the natural bank, comprises another 73,189 HU's for these fish. Together they amount to 1,489,972 HU's in the Kenai River currently available for rearing juvenile chinook salmon.

By defining the area of habitat within the river's 6.0 foot corridor along the banks that is either currently developed or altered by man-made structures or that which has been severely impacted by access resulting in heavy trampling, vegetation loss, and bank instability, we have estimated that prior to the presence of these impacts, there was originally 1,523,144 HU's available to rearing juvenile chinook salmon in the Kenai River mainstem (see Table 15). The difference between this figure and the 1,489,972 HU's which currently exist is the amount of habitat lost or gained (lost in this case) to rearing fish. This amounts to 33,172 HU's or 2.2 percent of the

total Habitat Units originally available to rearing juvenile chinook salmon prior to any man induced alteration of the river's shoreline habitat.

A Development Trends Analysis was completed to provide important insight into the rate at which this habitat loss has been occurring on the Kenai River. This analysis used aerial photograph interpretation of development conditions that existed within and adjacent to the river in 1963/64 and compares those conditions to the documented development scenario observed during the 1993 Kenai River 309 field surveys. Such an analysis can be used not only to determine how much development has taken place over the last 30 years, but can also be used as an interpretive tool to extrapolate future development scenarios and estimate the level of additional impact and habitat change (loss or gain) that can be anticipated in the future.

Using the GIS system, the ADF&G developed mylar overlays of the property ownership land use patterns that correlated to the varying scales of the 1963 and 1964 aerial photo coverage of the Kenai River mainstem. This allowed for a direct visual comparison of the amount of development affecting the river shoreline and nearshore habitat over a 30 year time period. The ADF&G, with assistance from the FWS used stereo scopes to interpret the photos which allowed for a resolution of up to two feet. All manmade alterations observed through the scopes were identified and measured.

The final results indicate that over 76 percent of the modified banks and structures that were observed in the field surveys in 1993 and 94 have been introduced since 1963/64. The vast majority of these changes include the large increase in bank stabilization efforts and the construction of boat docks and groins or jetties.

All future development projects, maintenance projects, and land uses that affect the river and its shoreline will have to consider the limits of available habitat within this system, which is critical to the continued production of the Kenai's world class chinook salmon population. If we are to continue to be afforded the opportunity to harvest these fish either commercially, recreationally, or for personal use, we must avoid the continued cumulative loss of their nursery habitat.

The results of this analysis are intended to provide a basic understanding of the current condition of the nearshore fish habitat occurring on the Kenai River mainstem. This information is intended to help educate the general public of the effects of development and access-related habitat impacts that potentially affect the river's ability to continue to produce healthy runs of chinook salmon. The data will provide a basis for the ADF&G to draft Alaska Coastal Management Program project descriptions that result in the approval of sound development projects while promoting efficiency in the application of the coastal review process.

One of the primary objectives for the use of the Kenai River 309 project results has been to assist the local coastal district (KPB) in the review of their existing coastal management plan's policies. The study results are intended to be used as a tool in the district's effort to develop revised or new enforceable policies that can be implemented by the KPB as well as the existing state and federal regulatory agencies charged with Kenai River management responsibilities.

The developed database and analysis process will be used by the ADF&G and hopefully other management agencies to evaluate all future development actions using a cumulative impacts assessment approach which considers the entire Kenai River watershed rather than just the individual project and its immediate and/or local effects.

The application of the type of cumulative impact analysis completed during this study not only allows for the natural resource managers to make a decision to approve or deny an activity based upon the level of impact that would occur as a result of action, it would also allow for a comparison evaluation of alternatives to the proposed action and for the identification of mitigative measures necessary to offset or compensate for the unavoidable losses associated with the activity.

An important strength of this type of impact analysis is the ability for non-technical persons to better grasp the big picture of what an individual project or activity can do to the river system as a whole. By comparing HU changes that result from a proposed project, the degree of habitat impact can be defined. This should be a significant aid in helping individuals that proposing a certain project or activity to understand why that activity is denied or modified during the permitting process. It will also help explain to project proponents how to avoid or minimize project related impacts with a project redesign or the use of an alternative that reduces the identified impact. This assessment process can also be used as a tool to define those actions that improve the habitat quality or availability.

The Kenai River Cumulative Impact Assessment process can be readily used by inexperienced personnel with a minimum of training in the application of the HEP procedures and the existing software systems developed by the FWS.

With regard to the application of this cumulative impact assessment process to other similar riverine systems, it is extremely applicable. Other drainages would likely be less time consuming to evaluate in as much as the development pressure in these drainages is much less than that which has already occurred in the Kenai River and they have not been subdivided into as many small (100 foot) parcels as the Kenai River's riparian areas. Even so, the ability of aerial photograph and videography resolution can allow for detailed habitat classification of these small parcel sizes.

One of the benefits to the impact assessment approach used in this study is that it is a habitat based assessment which evaluates the actual or potential end result of an action as it affects the pre-existing habitat condition(s) which can occur as the result of the initial or primary activity or a spin-off effect such as a secondary impact affect. It can also effectively quantify the cumulative impact of multiple actions affecting a specific system. For example, this methodology can be used to quantify the effects of the construction of a boat launch at a given site based upon pre-project conditions. It can also quantify the effects of secondary uses such as habitat alterations in the vicinity of the project associated with the other uses that may occur as result of the initial project or action such as bank trampling associated with fisherman access provided by the launch installation. It can also assess habitat change related to bank scour or erosion (or lack thereof) associated with mooring boats either temporarily or long term and

depending on the measures taken to either protect or not protect the bank associated with the launch and the effects of accessing the moored boats.

The HEP analysis, which is a substantial part of this cumulative impact assessment methodology, has been developed with a variety of species specific suitability curves including avian, mammal and fish species, that can be used to quantify habitat loss related, not only to aquatic habitats but to wetland habitats as well. The Kenai River Cumulative Impact Assessment approach would certainly be applicable to evaluating the effects of cumulative impacts on wetland habitats within and outside of Alaska.

In reviewing the development and application of this impact assessment methodology, I would recommend that, for large scale drainage basin applications at least, a joint agency approach be used especially to accomplish the field survey and ground-truthing portion of this assessment process. This can help reduce costs to any one agency or group completing the assessment and lends credibility to the overall study results through the benefits of interagency cooperation and the sharing of technical and local biological expertise.

APPENDIX B

FIGURES

FIG. 5 WATER FRONTAGES ON THE KENAI RIVER
LENGTHS/PERCENTAGES OF WATER FRONTAGE BY REACH

TOTAL = 877,074.2 ft

% = PERCENTAGE OF TOTAL WATER FRONTAGE FOR THE ENTIRE RIVER MAINSTEM

**FIG. 6 KENAI RIVER OWNERSHIP BY PARCEL
PARCELS/PERCENTAGE OF WATER FRONTAGE BY REACH**

TOTAL PARCELS = 1,810
TOTAL WATER FRONTAGE = 877,074.2 ft

% = PERCENTAGE OF TOTAL WATER FRONTAGE FOR THE ENTIRE RIVER MAINSTEM

FIG. 7 KENAI RIVER OWNERSHIP CATEGORIES REACHES 1-4 COMBINED

WATER FRONTAGE (ft)

NUMBERS ABOVE BARS REFLECT % OF TOTAL MAINSTEM WATER FRONTAGE

ADF&G 309, 1994

FIG. 8 KENAI RIVER OWNERSHIP CATEGORIES REACH 5

WATER FRONTAGE (ft)

NUMBERS ABOVE BARS REFLECT % OF TOTAL MAINSTEM WATER FRONTAGE

ADF&G 309, 1994

FIG. 9 KENAI RIVER OWNERSHIP CATEGORIES **ALL REACHES COMBINED**

NUMBERS ABOVE BARS REFLECT % OF TOTAL MAINSTEM WATER FRONTAGE

FIG. 10 STRUCTURES ON THE KENAI RIVER
NUMBERS/PERCENTAGES OF ALL STRUCTURES BY REACH

TOTAL = 1869 STRUCTURES ON 639 PARCELS

% = PERCENTAGE OF TOTAL NUMBER OF STRUCTURES FOR THE ENTIRE RIVER MAINSTEM

ADFG 309, 1994

**FIG. 11 STRUCTURES ON THE KENAI RIVER
LENGTHS/PERCENTAGES OF ALL STRUCTURES BY REACH**

% = PERCENTAGE OF TOTAL STRUCTURE LENGTHS FOR THE ENTIRE RIVER MAINSTEM

ALFAC 0815, 1984

**FIG. 12 STRUCTURES ON THE KENAI RIVER
AREAS/PERCENTAGES OF ALL STRUCTURES BY REACH**

**TOTAL AREA AFFECTED BY STRUCTURES = 1,805,540 sq ft
= 24.2% OF TOTAL STUDY AREA**

% = PERCENTAGE OF TOTAL STRUCTURE AREA FOR THE ENTIRE WATERSHED

ALFRED S. 08/92, 11/2004

FIG. 13 SUMMARY OF KENAI RIVER WATERFRONT LENGTHS AND STRUCTURES

**NUMBERS OF STRUCTURES
TOTAL = 1,063**

**LENGTHS OF STRUCTURES
TOTAL = 63,200 R**

**AREAS OF STRUCTURES
TOTAL = 1,005,540 R**

**WATERFRONTAGE PER REACH
TOTAL = 877,074.2 R**
